INDEX I.1

Editorial Board

[Updated March 2007]

SECTION EDITORS

Vickie S. Baselski

Department of Pathology, University of Tennessee at Memphis, 930 Madison Ave., Room 510, Memphis, TN 38163

Kathleen G. Beavis

Stroger Hospital of Cook County, 1901 W. Harrison Street, LL-926, Chicago, IL 60612

Michael Bell

Special Pathogens Branch, DVRD, National Center for Infectious Diseases, Centers for Disease Control and Prevention, 1600 Clifton Rd. N.E., Mailstop A-26, Atlanta, GA 30333

Gregory L. Blakey

Department of Pathology, University of Oklahoma Health Sciences Center, Director of Microbiology, OU Medical Center, P.O. Box 26901, BMSB 451, Oklahoma City, OK 73190

Lorraine Clarke

Laboratory Response Network, New York State Department of Health, Wadsworth Center, P.O. Box 22002, Albany, NY 12201-2002

Deirdre Church

Microbiology, Calgary Laboratory Services, 9-3535 Research Rd., N.W., Calgary, Alberta T2L 2K8, Canada

Judy Daly

Primary Children's Medical Center, University of Utah, 100 N. Medical Dr., Salt Lake City, UT 84113-1100

Thomas N. Denny

Duke Human Vaccine Institute and Center for HIV/AIDS Vaccine Immunology, Duke University Medical Center, 106 Research Drive, MSRBII Building, Box 103020 DUMC, Durham, NC 27710

Gerald A. Denys

Clarian Pathology Laboratory, 350 West 11th St., Room 6027B, Indianapolis, IN 46202-4108

Steven D. Douglas

The Children's Hospital of Philadelphia, Abramson Bldg., Room 1208, 34th Street and Civic Center Blvd., Philadelphia, PA 19104-4318

Larry D. Gray

TriHealth Laboratories and Department of Molecular Genetics, Biochemistry, and Microbiology, University of Cincinnati College of Medicine, 619 Oak St., Cincinnati, OH 45206

Gerri S. Hall

Clinical Microbiology, Cleveland Clinic, 9500 Euclid Ave., Cleveland, OH 44195

Kevin C. Hazen

Department of Pathology, University of Virginia Health System, P.O. Box 800255, Charlottesville, VA 22908

Janet Fick Hindler

Clinical Microbiology (171315), Department of Pathology and Laboratory Medicine, UCLA Medical Center, 10833 LeConte Ave., Los Angeles, CA 90095-1713

Susan A. Howell

Mycology, St. John's Institute of Dermatology, St. Thomas' Hospital, Lambeth Palace Road, London SE1 7EH, United Kingdom

Andrea J. Linscott

Clinical Microbiology, LSU Health Sciences Center—Shreveport, 1501 Kings Highway, Shreveport, LA 71103

J. Michael Miller

National Center for Zoonotic, Vector-Borne, and Enteric Diseases, Bldg. 16, Room 4135, MS D-76, Centers for Disease Control and Prevention, Atlanta, GA 30333

Michele Paessler

Clinical Immunology Laboratory, The Children's Hospital of Philadelphia, Abramson Bldg., 7th Floor, 34th Street and Civic Center Boulevard, Philadelphia, PA 19104-4318

Robyn Y. Shimizu

Department of Pathology and Laboratory Medicine, Clinical Microbiology (171315), UCLA Health System, 10833 LeConte Ave., Los Angeles, CA 90095-1713

James W. Snyder

Department of Pathology, Division of Laboratory Medicine, University of Louisville School of Medicine and Hospital, 530 S. Jackson St., Louisville, KY 40202

Alice S. Weissfeld

Microbiology Specialists Inc., 8911 Interchange Dr., Houston, TX 77054-2507

Gail Woods

Department of Pathology and Laboratory Services, University of Arkansas for Medical Sciences, Mail Slot 502, 4301 West Markham St., Little Rock, AR 72205

ASSOCIATE SECTION EDITORS**Susan Munro**

Clinical Microbiology Laboratory, Room H1537-J, Stanford Hospitals and Clinics, 300 Pasteur Dr., Stanford, CA 94305

Kirsten St. George

Clinical Virology Program, Wadsworth Center—Griffin Laboratory, New York State Department of Health, 5668 State Farm Rd. (Route 155), Slingerlands, NY 12159

Contributors

[Updated March 2007]

Maria E. Aguero-Rosenfeld

Department of Pathology, New York Medical College, and Westchester Medical Center, Valhalla, NY 10595

Matthew Arduino

Centers for Disease Control and Prevention, Mail Stop C-16, 1600 Clifton Rd. N.E., Atlanta, GA 30333

H. Ruth Ashbee

Mycology Reference Centre, Department of Microbiology, Leeds General Infirmary, Leeds LS1 3EX, United Kingdom

Elia M. Ayoub

Department of Pediatrics, University of Florida Medical School, Gainesville, FL 32610-0296

Martha Bale

ARUP Laboratories, 500 Chipeta Way, Salt Lake City, UT 84108

Steve Barriere

Gilead Pharmaceuticals, 333 Lakeside Dr., Foster City, CA 94404

Marilyn S. Bartlett

Indiana University School of Medicine, Medical Sciences Bldg., A 128, 635 Barnhill Dr., Indianapolis, IN 46202-5120

Richard C. Barton

Mycology Reference Centre, Department of Microbiology, Leeds General Infirmary, Leeds LS1 3EX, United Kingdom

Vickie Baselski

Department of Pathology, University of Tennessee at Memphis, 930 Madison Ave., Room 510, Memphis, TN 38163

Michael Bell

Special Pathogens Branch, DVRD, National Center for Infectious Diseases, Centers for Disease Control and Prevention, Mail Stop A-26, 1600 Clifton Rd. N.E., Atlanta, GA 30333

Kathryn Bernard

National Microbiology Laboratory Health Canada, 1015 Arlington St., Room H5040, Winnipeg, Manitoba R3E 3R2, Canada

Cindy D. Bethel

Clinical Microbiology, University of Chicago Medical Center, 5841 Maryland Ave., Chicago, IL 60637

Gregory L. Blakey*

Department of Pathology, University of Oklahoma Health Sciences Center, OU Medical Center, P.O. Box 26901, BMSB 451, Oklahoma City, OK 73190

Walter Bond

3366 Station Ct., Lawrenceville, GA 30044

Subhit Boonlayangoor

Clinical Microbiology, University of Chicago Medical Center, 5841 Maryland Ave., Chicago, IL 60637

Philip G. Bowler

Bristol-Myers Squibb, ConvaTec GDC, First Avenue, Deeside Industrial Park, Deeside, Flintshire CH5 2NU, United Kingdom

Joanne J. Bradna*

Hardy Diagnostics, 1430 West McCoy Ln., Santa Maria, CA 93455

June M. Brown

Meningitis and Special Pathogens Branch, Division of Bacterial and Mycotic Diseases, Centers for Disease Control and Prevention, Bldg. 17, Room 2207, Mail Stop G-34, Atlanta, GA 30333

David A. Bruckner

Clinical Microbiology (171315), UCLA Medical Center, Los Angeles, CA 90024

Sandra Bullock-Iacullo

Public Health Practice Program Office, Division of Laboratory Services, Centers for Disease Control and Prevention, Mail Stop A-16, Atlanta, GA 30333

Linda Byrd

Microbiology Department, Parkland Health and Hospital, Dallas, TX 75235

*Contributor to the 2007 update.

Angela M. Caliendo

Emory University Hospital and Department of Pathology and Laboratory Medicine, Emory University School of Medicine, Atlanta, GA 30322

Joseph Campos

Department of Laboratory Medicine, Children's National Medical Center, 111 Michigan Ave., N.W., Washington, DC 20010

Karen C. Carroll

Microbiology Division, Department of Pathology, The Johns Hopkins Hospital, Meyer B1-193, 600 N. Wolfe St., Baltimore, MD 21287

Marilyn J. Carroll

J A Turner Diagnostic Parasitology Lab, 519 W. Carson St., Suite 104, Carson, CA 90745

Deirdre Church*

Microbiology, Calgary Laboratory Services, 9-3535 Research Rd., N.W., Calgary, Alberta T2L 2K8, Canada

Lorraine Clarke

Laboratory Response Network, New York State Department of Health, Wadsworth Center, P.O. Box 22002, Albany, NY 12201-2002

Jill Clarridge III

Veterans Administration Medical Center, University of Washington, 1660 S. Columbian Way, Seattle, WA 98108

Judith H. Cook-White

Harbor-UCLA Medical Center, 1000 W. Carson St., Torrance, CA 90509

Paul Crede

Microbiology Unit, State Public Health Laboratory, 307 W. McCarty St., Jefferson City, MO 65101 (retired)

Phyllis Della-Latta

Columbia-Presbyterian Medical Center, Clinical Microbiology Service, CHONY 3S, 622 W. 168th St., New York, NY 10032

Gerald A. Denys

Clarian Pathology Laboratory, 350 West 11th St., Room 6027B, Indianapolis, IN 46202-4108

Steven D. Douglas

The Children's Hospital of Philadelphia, Abramson Bldg., Room 1208, 34th Street and Civic Center Blvd., Philadelphia, PA 19104-4318

Lynn B. Duffy

Diagnostic Mycoplasma Laboratory BBRB 609, University of Alabama at Birmingham, 845 19th St. S., Birmingham, AL 35294

J. Stephen Dumler

Division of Medical Microbiology, Department of Pathology, The Johns Hopkins Medical Institutions, Meyer B1-193, 600 N. Wolfe St., Baltimore, MD 21287

W. Michael Dunne, Jr.

Department of Pathology and Immunology, Division of Laboratory Medicine, Washington University School of Medicine, 660 S. Euclid, Box 8118, St. Louis, MO 63110

Paul H. Edelstein

Department of Pathology and Laboratory Medicine, University of Pennsylvania Medical Center, 3400 Spruce St., Philadelphia, PA 19104-4283

Carolyne B. Ellis

VA Medical Center, 3200 Vine St., Cincinnati, OH 45220

Glyn V. Evans

Welsh Mycology Reference Laboratory, Department of Medical Microbiology and PHLS, University of Wales College of Medicine, Heath Park, Cardiff CF14 4XN, United Kingdom (deceased)

Daniel H. Farkas*

Center for Molecular Medicine, 301 Michigan St., N.E., Suite 580, Grand Rapids, MI 49503

Sheila M. Farnham

bioMérieux Vitek, Inc., 595 Anglum Dr., Hazelwood, MO 63042

Patricia I. Fields

Foodborne and Diarrheal Diseases Branch, Centers for Disease Control and Prevention, Atlanta, GA 30333

Thomas R. Fritsche

JMI Laboratories, 345 Beaver Kreek Centre, Suite A, North Liberty, IA 52317-7110

Ambrosia Garcia

Department of Pediatrics, New Jersey Medical School, 185 S. Orange Ave., MSB F519, Newark, NJ 07103

Lynne S. Garcia

LSG & Associates, 512-12th St., Santa Monica, CA 90402

Zenaida Garcia

Department of Pediatrics, New Jersey Medical School, 185 S. Orange Ave., MSB F519, Newark, NJ 07103

Cheryl Gedris

Westchester Medical Center, Grasslands Road, Valhalla, NY 10595

Mahmoud A. Ghannoum

Center for Medical Mycology, University Hospitals of Cleveland, and Case Western Reserve University, 11100 Euclid Ave., LKS 5028, Cleveland, OH 44106-5028

Mary J. R. Gilchrist

University Hygienic Laboratory, University of Iowa, Iowa City, IA 52242

Peter Gilligan

Clinical Microbiology-Immunology Laboratories, University of North Carolina Hospitals, UNC Hospitals CB 7600, Chapel Hill, NC 27514

Steven Glenn

Public Health Practice Program Office, Centers for Disease Control and Prevention, Mail Stop A-16, Atlanta, GA 30333

Judith G. Gordon

Gordon Recourses Consultants, Inc., Reston, Va. (retired)

Eileen Gorss

Bacteriology Laboratory, Children's Hospital, 300 Longwood Ave., Boston, MA 02115

Jane Griffin

4605 TVC Infectious Diseases, Vanderbilt University Medical Center, Nashville, TN 37232

Beatrice Grinius

bioMérieux Vitek, Inc., 595 Anglum Dr., Hazelwood, MO 63042

Gerri Hall

Clinical Microbiology, Cleveland Clinic, 9500 Euclid Ave., Cleveland, OH 44195

Nancy H. Hall

Oakdall Hall, University Hygienic Laboratory, Iowa City, IA 52242

Jay Hardy

Hardy Diagnostics, 1430 W. McCoy Ln., Santa Maria, CA 93455

Kevin C. Hazen

Department of Pathology, University of Virginia Health System, P.O. Box 800255, Charlottesville, VA 22908-0168

Mary Henry

Clinical Laboratories, University of California Medical Center, Box 0100, Room L515, San Francisco, CA 94143

Sharon L. Hillier

Department of Obstetrics, Gynecology, and Reproductive Sciences, Magee-Womens Hospital of the University of Pittsburgh Medical Center, 300 Halket St., Pittsburgh, PA 15213

Janet Fick Hindler

Clinical Microbiology (171315), Department of Pathology and Laboratory Medicine, UCLA Medical Center, 10833 LeConte Ave., Los Angeles, CA 90095-1713

Lisa Hochstein

Division of Microbiology, Catholic Medical Center of Brooklyn and Queens, 88-25 153rd St., Jamaica, NY 11432

Richard L. Hodinka

Clinical Virology Laboratory, Department of Pathology, The Children's Hospital of Philadelphia, and Department of Pediatrics, University of Pennsylvania, Philadelphia, PA 19104

Judy Holden

Microbiology Laboratory, Massachusetts General Hospital, Gray 526, 55 Fruit St., Boston, MA 02114

Harvey Holmes

Centers for Disease Control and Prevention, Mail Stop C-16, 1600 Clifton Rd. N.E., Atlanta, GA 30333

Anne Howell

1200 N. Veitch St., #1238, Arlington, VA 22201

Susan A. Howell

Mycology, St. John's Institute of Dermatology, St. Thomas' Hospital, Lambeth Palace Road, London SE1 7EH, United Kingdom

Henry D. Isenberg

Long Island Jewish Medical Center, 270-05 76th Ave., New Hyde Park, NY 11040 (deceased)

Nancy Isham

Center for Medical Mycology, University Hospitals of Cleveland, and Case Western Reserve University, 11100 Euclid Ave., LKS 5028, Cleveland, OH 44106-5028

Robert Jacobson

Bureau of Laboratories, Michigan State Department of Health, 3350 N. Martin Luther King Jr. Blvd., P.O. Box 3005, Lansing, MI 48909-0035

William M. Janda

Department of Pathology, University of Illinois Medical Center at Chicago, Chicago, IL 60612

Stephen G. Jenkins

Department of Pathology, Carolinas Medical Center, 1000 Blythe Blvd., Charlotte, NC 28203-5812

Robert C. Jerris

DeKalb Medical Center, 2701 N. Decatur Rd., Decatur, GA 30033

Cheryl A. Jordan

Clinical Microbiology, University of Wisconsin Hospital and Clinics, A4/204 Clinical Science Center, 600 Highland Ave., Madison, WI 53792

Raymond L. Kaplan

Quest Diagnostics, 1777 Montreal Cir., Tucker, GA 30084

Gary Keck

1610 E. Cherry Ln., Bloomington, IN 47401

John L. Kempf

University of Iowa Hygienic Laboratory, Oakdale Research Campus, Iowa City, IA 52242

Timothy E. Kiehn

Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021

Cynthia Knapp

Trek Diagnostic Systems, 982 Keynote Cir., Suite 6, Cleveland, OH 44131

Karen Krisher

The Clinical Microbiology Institute, 9725 S.W. Commerce Cir., Suite A-1, Wilsonville, OR 97070

Patricia M. Kruczak-Filipov*

Microbiology Service, Clinical Pathology Department, Warren G. Magnuson Clinical Center, National Institutes of Health, Bethesda, MD 20892

Vincent LaBombardi

Microbiology, St. Vincent's Hospital and Medical Center, 153 W. 11th St., New York, NY 10011

Mark LaRocco

St. Luke's Episcopal Hospital, 6720 Bertner Ave., P.O. Box 20269, MC 4-265, Houston, TX 77030-2697

Lillian V. Lee

BioThreat Response Laboratory, The City of New York Department of Health and Mental Hygiene, 455 First Ave., New York, NY 10016

Andrea J. Linscott*

Clinical Microbiology, LSU Health Sciences Center—Shreveport, 1501 Kings Highway, Shreveport, LA 71103

Raul Louzao

Department of Pediatrics, New Jersey Medical School, 185 S. Orange Ave., MSB F519, Newark, NJ 07103

Dyan Luper

Christus Spohn Health System, 6845 Fawn Ridge Dr., Corpus Christi, TX 78413-4830

Paula J. Malloy*

Microbiology Laboratory, University of Illinois Hospital, Chicago, IL 60612

James I. Mangels

Sutter Medical Center of Santa Rosa, 3325 Chanate Rd., Santa Rosa, CA 95404

David McDevitt

University of Pittsburgh Medical Center, 200 Lothrop St., Room A-807, Pittsburgh, PA 15213

Karin L. McGowan

The Children's Hospital of Philadelphia, University of Pennsylvania School of Medicine, Room 5060A Main Bldg., 3400 Civic Center Boulevard, Philadelphia, PA 19104

Michael M. McNeil

Epidemiology and Surveillance Division, National Immunization Program, Centers for Disease Control and Prevention, Mail Stop E-61, 1600 Clifton Rd., Atlanta, GA 30333

J. Michael Miller

National Center for Zoonotic, Vector-Borne, and Enteric Diseases, Bldg. 16, Room 4135, MS D-76, Centers for Disease Control and Prevention, Atlanta, GA 30333

Julia Moody

Infection Control and Microbiology, Lakeland Regional Medical Center, 1324 Lakeland Hills Blvd., Lakeland, FL 33804

Arlene Morton

Clinical Microbiology Laboratory, Stanford University Hospital, 300 Pasteur Dr., Stanford, CA 94305 (retired)

Ross M. Mulder

bioMérieux Vitek, Inc., 595 Anglum Dr., Hazelwood, MO 63042

Susan Munro

Clinical Microbiology Laboratory, Room H1537-J, Stanford Hospital and Clinics, 300 Pasteur Dr., Stanford, CA 94305

Ron Neimeister

Continuing Education and Technology Evaluation Section, Division of Laboratory Improvement, Pennsylvania Department of Health, P.O. Box 500, Exton, PA 19341 (deceased)

Mabel Ann Nicholson

Foodborne and Diarrheal Diseases Branch, Centers for Disease Control and Prevention, Atlanta, GA 30333

Susan Novak

Clinical Microbiology, Kaiser Regional Laboratories, 11668 Sherman Way, N. Hollywood, CA 91605

Sandra L. Novick

ViroMed Laboratories, Minnetonka, MN 55343

Michele Paessler*

Clinical Immunology Laboratory, The Children's Hospital of Philadelphia, Abramson Bldg., 7th Floor, 34th Street and Civic Center Blvd., Philadelphia, PA 19104-4318

A. William Pasculle

University of Pittsburgh Medical Center, Room A-807, 200 Lothrop St., Pittsburgh, PA 15213

Ellena Peterson

Department of Pathology, Medical Science Bldg., Room D-440, University of California Irvine, Irvine, CA 92697-4800

Marie Pezzlo

Medical Microbiology Division, University of California Irvine Medical Center, 101 The City Dr. S., Orange, CA 92868

Michael A. Pfaller

Department of Pathology, University of Iowa College of Medicine, Iowa City, IA 52242

Perkins B. Poon

Microbiology Laboratory, Department of Laboratory Medicine, Huntington Memorial Hospital, 100 W. California Blvd., Pasadena, CA 91106 (deceased)

Victoria Pope

Division of AIDS, STD, and TB Laboratory Research, National Center for Infectious Diseases, Centers for Disease Control and Prevention, Mail Stop D-13, 1600 Clifton Rd. N.E., Atlanta, GA 30333

Nancy E. Raftery

Department of Immunologic and Infectious Diseases, The Children's Hospital of Philadelphia, 34th Street and Civic Center Boulevard, Philadelphia, PA 19104

Barbara Robinson-Dunn

Clinical Microbiology Laboratory, William Beaumont Hospital, 3811 W. Thirteen Mile Rd., Royal Oak, MI 48073-6769

Patricia Rodrigues-Wong

Clinical Laboratories, University of California Medical Center, Box 0100, Room L515, San Francisco, CA 94143

Darcie Roe-Carpenter

DadeBehring MicroScan 4008 P2, 1584 Enterprise Blvd., W. Sacramento, CA 95691

Kathryn L. Ruoff

Dartmouth Hitchcock Medical Center, One Medical Center Dr., Lebanon, NH 03756

Maria Saragias

TB Laboratory, Columbia-Presbyterian Medical Center, Clinical Microbiology Service, CHONY 3S, 622 W. 168th St., New York, NY 10032

Ron B. Schiffman

Diagnostics, Southern Arizona VA Healthcare System, Tucson, AZ 85723

Paul C. Schreckenberger

Clinical Microbiology Laboratory, University of Illinois Medical Center at Chicago, 840 S. Wood St., Room 238 CSB, MC 750, Chicago, IL 60612

Stephanie B. Schwartz

Respiratory Diseases Branch, Centers for Disease Control and Prevention, Atlanta, GA 30333

Frank I. Scott IV

Department of Immunologic and Infectious Diseases, The Children's Hospital of Philadelphia, 34th Street and Civic Center Boulevard, Philadelphia, PA 19104

Lynne Schulster

Centers for Disease Control and Prevention, Mail Stop A-35, 1600 Clifton Rd. N.E., Atlanta, GA 30333

David L. Sewell

Pathology and Laboratory Medicine Service, Veterans Affairs Medical Center, and Department of Pathology, Oregon Health and Sciences University, Portland, OR 97239

Sandip Shah

Bureau of Laboratories, Michigan State Department of Health, 3350 N. Martin Luther King Jr. Blvd., P.O. Box 3005, Lansing, MI 48909-0035

Gillian S. Shankland

Mycology Laboratory, Robertson Building 56, Dumbarton Rd., Glasgow G11 6NU, Scotland

Susan E. Sharp

Microbiology, Kaiser Permanente Airport Way Regional Laboratory, 13705 N.E. Airport Way, Suite C, Portland, OR 97230

Ribhi Shawar

14732 S.E. 66th St., Bellevue, WA 98006

Yvonne R. Shea

Microbiology Service, Department of Laboratory Medicine, Warren G. Magnuson Clinical Center, National Institutes of Health, Bldg. 10, Room 2C385, 10 Center Dr., MSC 1508, Bethesda, MD 20892-1508

Susan L. Shiflett

How To Use This Handbook

[Updated March 2007]

General Format

The 2007 update of the second edition of this handbook has been divided into three volumes containing the front matter, 16 sections (composed of “procedures”), and an index. Volume 1 contains the front matter of the handbook plus sections 1 through 4. Volume 2 contains sections 5 through 9. Volume 3 contains sections 9 through 16 and the index.

Included at the front of each volume is a short table of contents listing the items contained in the front and back matter and the 16 sections of the handbook. In addition to the table of contents for the entire handbook, each section is immediately preceded by a detailed table of contents for that section, giving the section editors’ names, the procedure titles included in that section, and the authors’ names for each procedure.

Sections

The content of the handbook has been organized into 16 sections as follows:

Section 1: Procedure Coding, Reimbursement, and Billing Compliance

Section 2: Specimen Collection, Transport, and Acceptability

Section 3: Aerobic Bacteriology

Section 4: Anaerobic Bacteriology

Section 5: Antimicrobial Susceptibility Testing

Section 6: Aerobic Actinomycetes

Section 7: Mycobacteriology and Antimycobacterial Susceptibility Testing

Section 8: Mycology and Antifungal Susceptibility Testing

Section 9: Parasitology

Section 10: Viruses and Chlamydiae

Section 11: Immunology

Section 12: Molecular Diagnostics

Section 13: Epidemiologic and Infection Control Microbiology

Section 14: Quality Assurance, Quality Control, Laboratory Records, and Water Quality

Section 15: Biohazards and Safety

Section 16: Bioterrorism

Procedures

Each section listed above consists of procedures. The procedures have been numbered and are referred to by number in cross-references in the text. The procedure number consists of the section number plus the number of the procedure (plus the number of a subprocedure if applicable). For example, “procedure 5.6” is the sixth procedure in section 5; “procedure 7.4.2” is the second subprocedure of the fourth procedure in section 7.

Page Numbers

The page number within a procedure is the procedure number followed by the number of the page within the procedure. Thus, from the examples given above, “page 5.6.10” is the 10th page within procedure 5.6, and “page 7.4.2.3” is the 3rd page within procedure 7.4.2. In all cases, the last number is the page number within a procedure.

The index is numbered beginning with an “I” followed by the number of the page within the index. For example, “page I.3” is the third page in the index.

Abbreviations

[Updated March 2007]

Abbreviations

In this handbook, most abbreviations have been introduced in parentheses after the terms they abbreviate on their first occurrence, e.g., “a central nervous system (CNS) specimen.” Some exceptions to this rule are explained below and given in Tables 1 to 4.

Because of their frequent use in this handbook and/or their familiarity to readers, the terms listed in Table 1 have been abbreviated in the procedures; i.e., they have not been spelled out or introduced. Based on the editorial style for books and journals published by the American Society for Microbiology (ASM), the abbreviations listed in Table 2 have also been used without introduction in this handbook. Table 3 lists abbreviations that have been used without introduction in the bodies of tables. Abbreviations for commonly accepted units of measurement have been used without definition if they appeared with numerical values. Table 4 lists some common units of measurement appearing in this handbook. These last two items are also based on ASM style.

As readers use the various procedures in this handbook and see unfamiliar abbreviations that are not defined in the procedures themselves, they should refer to these tables for definitions.

Table 1 Common abbreviations used without introduction in this handbook

Abbreviation	Definition
ATCC	American Type Culture Collection
BAP (<i>not</i> SBA)	5% Sheep blood agar plate
BHI	Brain heart infusion
BSL	Biosafety level
CAP	College of American Pathologists
CDC	Centers for Disease Control and Prevention
CHOC	Chocolate agar
CLSI	Clinical and Laboratory Standards Institute (formerly NCCLS)
CMPH	<i>Clinical Microbiology Procedures Handbook</i> (first edition)
CSF	Cerebrospinal fluid
EIA	Enzyme immunoassay
ELISA	Enzyme-linked immunosorbent assay
EMB	Eosin-methylene blue
EPCM	<i>Essential Procedures for Clinical Microbiology</i>
GLC	Gas-liquid chromatography
JCAHO	Joint Commission on Accreditation of Healthcare Organizations
MAC	MacConkey agar
MSDS	Material safety data sheet

(continued)

Table 1 Common abbreviations used without introduction in this handbook (*continued*)

Abbreviation	Definition
N.A.	Numerical aperture
NBS	National Bureau of Standards (pertaining to a special calibrated thermometer)
NCCLS	National Committee for Clinical Laboratory Standards
NIH	National Institutes of Health
OSHA	Occupational Safety and Health Administration
PMNs	Polymorphonuclear leukocytes
PPE	Personal protective equipment
QA	Quality assurance
QC	Quality control
RBCs	Red blood cells <i>or</i> erythrocytes
TCBS	Thiosulfate citrate bile salt sucrose agar
THIO	Thioglycolate broth
TSA	Trypticase soy agar <i>or</i> tryptic soy agar
TSB	Trypticase soy broth <i>or</i> tryptic soy broth
WBCs	White blood cells <i>or</i> leukocytes

Table 2 Additional abbreviations used without introduction (according to ASM style)

Abbreviation	Definition
AIDS	Acquired immunodeficiency syndrome
AMP, ADP, ATP, GTP, dCMP, ddGTP, etc.	Adenosine 5'-monophosphate, adenosine 5'-diphosphate, adenosine 5'-triphosphate, guanosine 5'-triphosphate, deoxycytidine 5'-monophosphate, dideoxyguanosine triphosphate, etc.
ATPase, dGTPase, etc.	Adenosine triphosphatase, deoxyguanosine triphosphatase, etc.
cDNA	Complementary deoxyribonucleic acid
CFU	Colony-forming unit(s)
cRNA	Complementary ribonucleic acid
DEAE	Diethylaminoethyl
DNA	Deoxyribonucleic acid
DNase	Deoxyribonuclease
EDTA	Ethylenediaminetetraacetate, ethylenediaminetetraacetic acid
EGTA	Ethylene glycol-bis(β -aminoethyl ethyl)- <i>N,N,N',N'</i> -tetraacetic acid
HEPES	<i>N</i> -2-hydroxyethylpiperazine- <i>N'</i> -2-ethanesulfonic acid
MIC	Minimal inhibitory concentration
mRNA	Messenger ribonucleic acid
NAD	Nicotinamide adenine dinucleotide
NAD ⁺	Oxidized nicotinamide adenine dinucleotide
NADH	Reduced nicotinamide adenine dinucleotide
NADP	Nicotinamide adenine dinucleotide phosphate
NADPH	Reduced nicotinamide adenine dinucleotide phosphate
oligo(dT), etc.	Oligodeoxythymidylic acid, etc.
PCR	Polymerase chain reaction
PFU	Plaque-forming unit(s)
poly(A), poly(dT), etc.	Polyadenylic acid, polydeoxythymidylic acid, etc.
RNA	Ribonucleic acid
RNase	Ribonuclease
rRNA	Ribosomal ribonucleic acid
Tris	Tris(hydroxymethyl)aminomethane
tRNA	Transfer ribonucleic acid
UV	Ultraviolet

Table 3 Abbreviations used without introduction in the bodies of tables

Abbreviation	Definition	Abbreviation	Definition
amt	Amount	SD	Standard deviation
approx	Approximately	SE	Standard error
avg	Average	SEM	Standard error of the mean
concn	Concentration	sp act	Specific activity
diam	Diameter	sp gr	Specific gravity
expt	Experiment	temp	Temperature
exptl	Experimental	tr	Trace
ht	Height	vol	Volume
mo	Month	vs	Versus
mol wt	Molecular weight	wk	Week
no.	Number(s)	wt	Weight
prepn	Preparation	yr	Year

Table 4 Some common units of measurement used in this handbook

Abbreviation	Definition
°C	Degree Celsius
h	Hour
µg	Microgram
mg	Milligram
min	Minute
ml	Milliliter
mm	Millimeter
mM	Millimolar
s	Second

Icons

The three icons listed below are used throughout this handbook. The icons direct the readers to follow important directions as they carry out the procedures. As a reminder, an explanation of the icon appears next to it at each appearance in the text.

It is imperative that these cultures be handled in a biosafety hood.

Include QC information on reagent container and in QC records.

Observe standard precautions.

Preface

[Updated March 2007]

The 2007 update of the second edition of the *Clinical Microbiology Procedures Handbook* (CMPH) was based on the value and user requirements following the first and second editions of CMPH and its companion volume *Essential Procedures for Clinical Microbiology*.

In response to the changes regarding the sixteen sections of the second edition of CMPH, most of these sections have been updated, some totally and some with the addition and deletion of certain protocols. Those sections that were not updated this time will be scheduled for updating during the next cycle of changes.

The purpose of the CMPH 2007 update remains constant. That is to provide everyone engaged in the microbiological analysis of clinical specimens with procedures that will enable them to correctly perform the appropriate tasks. CMPH remains a cookbook that provides step-by-step descriptions of the numerous procedures used by workers at the bench.

As with the second edition of CMPH, there is increased emphasis on molecular approaches, bioterrorism, infection control in medical facilities, and the host's immunological responses to microbial challenges. Also, continued emphasis is placed on the need to respond to governmental regulations and fiscal constraints. Highly experienced workers with many years working at the bench have written these procedures, and the format adheres to CLSI document GP2-A.

As was true of the original and second editions, all procedures included have been reviewed extensively by section editors, the editor in chief, and the ASM Press editors. We continue to encourage the users of these documents to bring new methods of universal relevance to our attention so they can be incorporated into the next update and shared with the clinical microbiology community.

Readers are reminded that naming any specific product in CMPH is not intended as an endorsement of that specific product or a suggestion to exclude other equally acceptable products. CMPH is for laboratory use only by qualified, experienced individuals or by personnel under the direct supervision of qualified, experienced individuals. Every effort has been made to ensure that the contents of this update are comprehensive, accurate, reliable, and reproducible.

Certainly not all existing microbiological protocols are included; however, the editors and authors are familiar with all commonly used protocols.

The 2007 updates are available on-line, with possible additions and revisions of the print and CD-ROM versions. While the print versions may be the preferred format for many users, the on-line version represents the most effective approach for incorporating changing and new protocols rapidly. This approach also provided maximum flexibility for future changes.

Lynne S. Garcia

Acknowledgments

[Updated March 2007]

I thank each of the section editors and authors for their tremendous efforts in planning and completing the 2007 update of the second edition of CMPH. Everyone who participated in the original version, the second edition, and the 2007 update of the second edition deserves our thanks for their comprehensive contributions in updating these diagnostic procedures for all microbiologists. Our very special thanks and acknowledgments will still be insufficient to thank the late Dr. Henry D. Isenberg for his outstanding guidance and leadership during the development and updating of CMPH. We owe him a tremendous debt of gratitude; he will always be known as the “father of CMPH” and its greatest supporter.

All editors and authors join me in extending our thanks to the officers of ASM, the Publications Board, and, especially, ASM Press. As editor in chief, I particularly want to acknowledge Susan Birch, John Bell, Cathy Balogh, and Jeff Holtmeier of ASM Press for their efforts in supporting the two CMPH print editions and this first series of updated procedures.

It has been a great privilege to work with this current group of editors and authors, and I sincerely hope that Dr. Isenberg would be pleased with our efforts—he is always in our thoughts.

Lynne S. Garcia

Reader Response Form

Dear Reader:

We solicit your help in improving the *Clinical Microbiology Procedures Handbook* (CMPH). Updates will be published periodically to keep CMPH current, accurate, and reliable. Your guidance will play an important role in achieving our objective of making CMPH the most useful laboratory procedures guide available. *Please copy this page for your continued use.*

1. Have you found any errors? Please list the section, procedure, and page number; describe the error.

2. Please list procedures that you deem to be outdated, confusing, or inadequately presented. List the section, procedure, and page number; explain.

3. Indicate the topics that you would like to see added. Please list your reasons for the selection.

4. Additional comments.

Thank you for your help. We are certain that future users will be grateful for your helpful suggestions. Please use extra sheets as needed.

Disclaimer

[Updated March 2007]

Microbiological analysis of clinical specimens is a constantly changing discipline; new methods and technologies emerge. The contributors to this 2007 update of the second edition of CMPH believe that the procedures and guidelines suggested here are from reliable sources and in line with the practices accepted at the time of publishing. Readers are reminded that the naming of any specific product is not intended as an endorsement of that specific product by ASM Press or any other agency, nor is it a suggestion to exclude other equally acceptable products. CMPH is for laboratory use only by qualified, experienced individuals or by personnel under the direct supervision of qualified, experienced individuals. Every effort has been made to ensure that the contents of this update are comprehensive, accurate, reliable, and reproducible.

SECTION 1

Procedure Coding, Reimbursement, and Billing Compliance

SECTION EDITOR: *Alice S. Weissfeld*

ASSOCIATE SECTION EDITOR: *Vickie S. Baselski*

1.1. Introduction	
<i>Alice S. Weissfeld and Vickie S. Baselski</i>	1.1.1
1.2. Procedure Coding, Reimbursement, and Billing Compliance	
<i>Alice S. Weissfeld and Vickie S. Baselski</i>	1.2.1

When the last edition of this handbook was published, regulatory billing compliance for laboratory tests was not a major laboratory issue. Most hospital laboratories generally performed services for their own inpatients (and occasionally affiliated outpatients), and tests were billed according to a formula established by the business office. In the setting of prospective payment (e.g., diagnosis-related groups), payment credit was allocated based on a different formula. Today, however, microbiologists must be aware not only of the scientific basis of infectious-disease diagnostics, but the costing, coding, billing, and reimbursement for individual tests for patients seen in a broad spectrum of health care settings with coverage by an enormous number of health care plans. Jargon previously unknown in the clinical laboratory, such as reflex testing, upcoding, downcoding, LMRP, and NCD, is now so extensive that a glossary of common terminology has been included in this section (see Appendix 1.1–1). The goal is to be reimbursed adequately for all appropriate work performed and in a manner that is in compliance with all regulations.

The issues discussed in this section are complex. In keeping with the mission of this handbook, a model compliance procedure has been written. As with any procedure, we expect some customization to occur. The model procedure deals primarily with some of the more important regulatory principles. It should *not*, in any situation, take the place of guidance established by your own compliance committee or of legal advice from your own institution's legal counsel. It simply represents a starting point for review of salient issues.

A brief historical overview of the economic challenges faced by clinical microbiology laboratories is provided for back-

ground. This may be reviewed in detail in the Institute of Medicine's report, *Medicare Laboratory Payment Policy, Now and in the Future* (1). The history of reimbursement and compliance begins with Title XVIII, commonly known as the Social Security Act. This act outlines the principles of the Medicare program, specifying broad benefit categories, including physician and hospital services. In accordance with section 1862 (a)(1)(A), the Medicare program provides payment *only* for diagnostic laboratory tests "that are reasonable and necessary for the diagnosis or treatment of illness or injury." It does *not*, however, authorize payment for screening diagnostic services. Over the 35 years since Title XVIII became law, the interpretive determination of whether a test meets the criteria of being reasonable and necessary to justify payment by Medicare has become known as "medical necessity." Most other third-party payers have established similar payment guidelines with which the laboratory must be familiar. It is notable that both Medicare and other payers may make specific exceptions to allow payment for screening services (e.g., coverage of Pap smears or PSA [prostate-specific antigen] testing).

The Social Security Act is known as a statute, i.e., a piece of legislation voted into law by Congress and signed by the president. Statutes form the basis for subsequent regulations, which are rules established by a federal agency in response to its interpretation of a statute that it is their duty to enforce. A number of federal agencies are directly or indirectly involved with laboratory reimbursement and compliance. The CDC is responsible for the scientific and quality aspects of laboratory testing under the Clinical Laboratory Improvement Act (CLIA '67) and Clinical Laboratory Improvement Amend-

ment (CLIA '88). The CDC is advised in this process by the Clinical Laboratory Improvement Advisory Committee (CLIAC). The Food and Drug Administration (FDA) is responsible for new-product clearance. Medicare regulators have historically interpreted tests that are subject to FDA approval or clearance but that have not obtained it as "not reasonable or necessary" for payment purposes. The FDA is assisted by its Microbiology Medical Device Advisory Committee. The Centers for Medicare and Medicaid Services (CMS), previously known as the Health Care Financing Administration (HCFA), administers the Medicare program and determines test categorization under CLIA. CMS interprets statutes and regulations, as well as other official documents (e.g., program memoranda and transmittals), to define reimbursement criteria and to establish national limitation amounts (NLAs) and national coverage decisions (NCDs). CMS also contracts with independent insurers, known generically as contractors and specifically as carriers (for Medicare part B outpatient services) and fiscal intermediaries (FIs) (for Medicare part A inpatient services or part B services through part A providers), to administer claims to reimburse physicians or laboratories. CMS is advised in developing coverage policies by the Medicare Carrier Advisory Committee (MCAC). Individual carriers and FIs may also set payment policies, known as local medical review policies (LMRPs), for their own geographic regions. Examples of LMRPs in infectious-disease diagnostics include syphilis testing, blood cultures, antimicrobial susceptibility testing, TORCH (*Toxoplasma*, rubella, cytomegalovirus, and herpes simplex virus) testing, and HPV (human papilloma virus) testing. Any information on institutional billing and re-

imbursement should start with a search for LMRPs specific to infectious-disease diagnostic testing. A specific website for this exists at <http://www.lmrp.net> (see Appendix 1.1–2). Medicare prefers that laboratories submit billings electronically but also accepts hand-written bills on HCFA form 1500 for Part B and HCFA form UB92 for Part A; both are universal insurance billing forms. Payment denials may be appealed through a formal process and are ultimately referred to an administrative law judge. As a result of deliberations by a Negotiated Rulemaking Committee on clinical laboratory diagnostic tests mandated by the Balanced Budget Act of 1997, 23 NCDs have been developed which take precedence over any existing LMRPs for the same tests. The implementation date for these NCDs was late 2002. Three policies were developed in infectious-disease diagnostics by a committee cochaired by the American Society for Microbiology: urine culture, human immunodeficiency virus (HIV) diagnosis, and HIV monitoring and prognosis.

Again, billings to other payers may require submission of other specific forms, but these are often modeled after Medicare billing guidelines.

Coding is the process of assigning a Current Procedural Terminology, version 4 (CPT-4) or International Classification of Diseases, Clinical Modification (ICD-9-CM) code to a laboratory test or clinical condition, respectively. CPT-4 codes are the property of the American Medical Association but have been designated the official CMS procedure coding system. CPT-4 codes are updated annually by a lengthy, systematic process. Most codes are category I and represent generally accepted procedures, but category III codes for emerging technologies were also introduced in 2002. Category III codes are generally not reimbursable. In some cases, newer emerging technologies may also be assigned an interim Health Care Financing Administration Common Procedure Coding System (HCPCS) code. The ICD-9-CM system is a public-domain consensus document developed by the World Health

Organization. It includes specific diagnoses, as well as signs and symptoms that represent the physician's reason for ordering a test. It also has a series of preventive-medicine screening codes (V codes) that, in general, do not support medical necessity. Correct coding is the cornerstone of reimbursement and compliance.

Finally, in 1997, in response to a major anti-fraud and abuse campaign in the Medicare program (Operation Restore Trust), the Office of the Inspector General (OIG) published a series of compliance documents, including one for clinical laboratories. The final document, the Office of the Inspector General's Compliance Program Guidance for Clinical Laboratories, published in August 1998, contains an outline for the design of individual institutional compliance plans to ensure correct coding, appropriate billing, and honest and ethical laboratory business practice (2). This document forms the basis for the model compliance plan presented in this section.

ADDENDUM IN PROOF: 2003 UPDATE

Subsequent to the development of this section, 23 NCDs were implemented effective 25 November 2002. Also implemented were a number of specific administrative policies developed during the Negotiated Rulemaking meetings on clinical laboratory diagnostic tests. These policies became effective beginning 5 March 2002. The NCDs as well as quarterly

technical updates and relevant program memoranda may be accessed at <http://www.cms.hhs.gov/ncd/labindexlist.asp>.

Also revised were the program memorandum pertaining to the use of a laboratory-test-specific advance beneficiary notice (ABN-L) and specific modifiers to indicate ABN status on claims filed. In-

structions and ABN form CMS-R-131-L may be accessed at http://www.cms.hhs.gov/pm_trans/AB02168.pdf.

The 2003 clinical laboratory fee schedule program memorandum is transmittal AB-02-163 (8 November 2002) and may be accessed at http://www.cms.hhs.gov/pm_trans/AB02-163.pdf.

APPENDIX 1.1–1

Glossary of Reimbursement and Compliance Terminology and Acronyms

Terminology

Terminology	Definition
Abuse	Systematically accepting improper payment without knowledge of illegality (<i>see</i> Fraud)
Add on	A test added after the original date of service
Bundling	Placing codes together in a panel
Carrier	CMS contractor for Medicare part B claims
Carve out	Exclude from a capitated contract and bill fee-for-service
Code jamming	Inserting ICD-9-CM codes which will pass claims review
Code steering	Encouraging ICD-9-CM code use to satisfy medical necessity
Contractor	Generic term for Medicare claims administrator
Composite	Use of two codes simultaneously in accordance with standard of care where the codes are not otherwise described as a panel
Covered lives	Population insured by a managed-care contract
Crosswalked	Deemed equivalent
Custom panel	User-defined composite of test codes performed simultaneously which is not a standard of care
Downcoding	Using a lower-paying code to encourage utilization
E-codes	Codes for external sources of injury
Fair market value	A reasonable payment amount for a specified service
Fraud	Knowingly or willingly accepting improper payments with knowledge of illegality (<i>see</i> Abuse)
Frequency limits	Number of times a service may be reimbursed
Gap fill	Temporary assignment of reimbursement
Mapped	Deemed comparable
Inducement	Service or item with monetary value given to encourage utilization by a purchaser of laboratory services
Kickback	Acceptance of an inducement
Medical necessity	Determination of ICD-9-CM codes for which a CPT-4 code will be reimbursed as reasonable and necessary
Neg Reg	Negotiated Rulemaking Committee on diagnostic clinical laboratory tests
Not medically necessary	Determination that an ICD-9-CM does not justify payment
Panel	CMS-approved test composite encompassed in a single CPT-4 code
Program integrity	Process by which CMS monitors for fraud and abuse
Reasonable charge methodology	Based on inherent reasonableness, authority to arbitrarily increase or decrease payment
Reflex	Second, related test automatically performed when an initial test result is positive or abnormal
Sink testing	Fraudulently reporting results for tests not performed
Standing orders	Preapproved set of test codes performed on a regular defined basis
Unbundling	Coding individual tests rather than an approved CMS panel
Upcoding	Using a higher-paying code to maximize reimbursement
V-codes	Generally, health-screening codes
Zero tolerance	Absolute institutional policy that no fraudulent practice will be allowed

APPENDIX 1.1–1 (continued)

Acronyms	
Acronym	Definition
ABN	Advance beneficiary notice
ALJ	Administrative law judge
AMA	American Medical Association
APC	Ambulatory payment classification
ASR	Analyte-specific rule
BBA	Balanced Budget Act of 1997
CAC	Carrier Advisory Committee
CAP	College of American Pathologists
CCI	Correct Coding Initiative also known as the National Correct Coding Initiative, NCCI
CDC	Centers for Disease Control and Prevention
CLIA '67	Clinical Laboratory Improvement Act of 1967
CLIA '88	Clinical Laboratory Improvement Amendments of 1988
CLIAC	Clinical Laboratory Improvement Advisory Committee
CMD	Contractor medical director
CMS	Centers for Medicare and Medicaid Services
CO50	Medical necessity denial code
CPT-4	Current Procedural Terminology, version 4
DRG	Diagnosis-related group
EOB	Explanation of benefits (<i>see</i> EOMB)
EOMB	Explanation of medical benefits (<i>see</i> EOB)
ESRD	End stage renal disease (dialysis center)
FBI	Federal Bureau of Investigation
FDA	Food and Drug Administration
FI	Fiscal intermediary
FTE	Full-time equivalent
HCFA	Health Care Financing Administration (now CMS)
HCPAC	Health Care Professionals Advisory Committee
HCPCS	HCFA Common Procedure Coding System
HIPAA	Health Insurance Portability and Accountability Act
ICD-9-CM	International Classification of Diseases, 9th ed., Clinical Modification
IDE	Investigational device exemption
IOM	Institute of Medicine
LCD	Local coverage decision
LMIP	Laboratory Management Index Program
LMRP	Local Medical Review Policy
MedPAC	Medicare Payment Advisory Council
NCD	National coverage decision (also known as NCP)
NCP	National coverage policy
NLA	National limitation amount
OCE	Outpatient code editor (for OPPTS)
OIG	Office of the Inspector General
OPPS	Outpatient Prospective Payment System
PPAC	Practicing Physician Advisory Council
SBT	Standardized Billable Test
SNF	Skilled-nursing facility (nursing home)

I. PURPOSE

The Office of the Inspector General (OIG) of the U.S. Department of Health and Human Services (HHS) issued compliance program guidance for clinical laboratories in August 1998 (2). This anti-fraud and abuse document addresses Medicare and Medicaid program integrity with emphasis on issues such as coding and billing, medical necessity, sales and marketing, ar-

rangements with outside providers, suppliers and vendors, and auditing and monitoring. Every clinical laboratory should be committed to doing business with any client, governmental or private, in an honest and trustworthy manner. While this document covers principles laid out in the federal compliance program guidance, the issues of integrity and the

prevention of wrongdoing must be customized for each clinical laboratory to be compatible with the overall institutional compliance program. Specific details pertaining to elements of the Medicare program are detailed in *Medicare Laboratory Payment Policy* from the Institute of Medicine (1).

II. ELEMENTS OF A COMPREHENSIVE COMPLIANCE PROGRAM

A. The seven essential elements

At a minimum, a comprehensive compliance program for a clinical laboratory should include seven key elements.

1. Development of written standards of conduct (detailed in item IIIA below)
2. Designation of a CCO and a Compliance Committee
A committee composed of the laboratory director, the laboratory manager, clinical consultants, the materials manager, the business office manager, and the technical supervisors of each laboratory section will assist the chief executive officer (CEO) and the chief compliance officer (CCO) in the surveillance of the institutional compliance program. Each committee member will be responsible for day-to-day observation that no fraudulent activities are occurring. However, all employees are responsible for reporting any problems to the CCO immediately. A zero tolerance policy should be adopted for dealing with any individual demonstrated to have engaged in fraudulent activity.
3. Development of regular, effective training and education programs (detailed in item V below)
4. Development of a process to receive complaints
A dedicated hotline should be established for the reporting of potentially fraudulent activities. Anonymity should be absolutely assured. No employee should ever be disciplined for reporting a problem, even if the miscreant is part of upper management.
5. Development of a system to respond to allegations of potentially fraudulent activities
A systematic investigation of all reports to the CCO should occur, and a report should be made to the Compliance Committee.
6. Establishment of an ongoing system of audits and monitors for compliance (detailed in item VIII below)

II. ELEMENTS OF A COMPREHENSIVE COMPLIANCE PROGRAM *(continued)*

7. Development of a system for investigation and remediation of systemic problems and for dealing with business associates who are sanctioned
It is the responsibility of the employer to assure that problems have been corrected, repayments have been made, and all employees and business associates have not been sanctioned by the Medicare program for previous illegal activities.

B. Written procedures and policies

All procedures and policies should be developed under the direction of the CCO with formal review by the Compliance Committee. All documents should be in written form and readily available to employees to whom the policies apply. Additions and revisions should be clearly indicated and expeditiously communicated to employees, with documentation maintained.

III. WRITTEN PROCEDURES AND POLICIES APPLICABLE TO MICROBIOLOGY**A. Standards of conduct**

All laboratory employees are expected to be honest in all their endeavors and in compliance with all applicable regulatory requirements. Practices such as sink testing (sending out results but not performing the work), issuing results when controls are out of range (in conflict with the Clinical Laboratory Improvement Amendment [CLIA '88]), or billing for work which is not ordered or necessary are major areas of inappropriate practice which should not be tolerated. In addition, no laboratory professional may influence anyone to send laboratory work by offering kickbacks or inducements of any kind. This includes practices such as the provision of free work to clients or their families or friends. No laboratory employee may induce any client to order a more expensive test if a less expensive one will suffice to make the clinical diagnosis, nor may they encourage anyone to order a reflex test(s) if it is not medically necessary. No employee may suggest Current Procedural Terminology, version 4 (CPT-4), coding that systematically results in higher reimbursement or International Classification of Diseases (ICD-9) coding that will guarantee reimbursement if it is not medically appropriate. In general, if any employee has to reflect on whether some action is legal or ethical, it is probably best not to undertake that action. Referral of questionable issues to the CCO or Compliance Committee is encouraged. It should be emphasized that a dishonest or unethical practice renders an individual subject to immediate sanctions. Sanctions may include oral or written warning, disciplinary probation, suspension, demotion, dismissal from employment, or revocation of medical staff privileges.

B. Medical necessity issues

Medical necessity as defined by the Centers for Medicare and Medicaid Services (CMS) is an assessment of whether the clinician's reason for ordering a test is covered (i.e., reimbursable) for the diagnosis or treatment of a specific illness or injury. Examinations or diagnostic procedures performed in the absence of signs or symptoms (often performed based on a patient's age and/or family history) are considered screening tests by CMS and, with a few statutory exceptions, are not reimbursed. The physician must provide a narrative diagnosis or diagnosis code ICD-9, Clinical Modification (ICD-9-CM) so that Medicare or Medicaid and other contractors can assess the claim for medical necessity as defined by national coverage decisions (NCDs), local medical review policies (LMRPs), or other published policies. Any ICD-9-CM code beginning with a "V" designates a screening procedure, which will generally not be reimbursed.

1. Requisition design

- a.** The requisition should have orderable tests indicated by descriptor or mnemonic consistent with the menu described in the current laboratory service manual. The orderable tests should be only CMS defined (i.e.,

III. WRITTEN PROCEDURES AND POLICIES APPLICABLE TO MICROBIOLOGY *(continued)*

- CPT-4 codeable) specific individual tests or CMS-approved panels unless one of the conditions described below applies. The provision of CPT-4 codes on the requisition is optional if they are readily available elsewhere.
- b. The requisition should ensure that the physician has the ability to make an independent decision with regard to each billed test, e.g., the physician must be able to order a culture with or without a susceptibility test or direct stain.
 - c. The requisition should identify reflex situations and offer the option not to reflex. A reflex test is a second related test performed automatically when initial results are positive or abnormal, e.g., a quantitative titer on a cryptococcal antigen if the qualitative screen is positive. A list of some microbiology reflex tests is provided in Appendix 1.2–1.
 - d. The requisition should identify situations in which the standard of care is to provide services which are a composite of two or more CPT-4 codes and offer the opportunity to order individual tests. A list of common composites is provided in Appendix 1.2–1.
 - e. The requisition should require an ICD-9-CM code (preferably) or narrative diagnosis.
 - f. The requisition should indicate noncovered services (screening tests).
 - g. The requisition should identify “limited-coverage” tests (i.e., those having NCDs or LMRPs).
 - h. The requisition should include or allow for an advance beneficiary notice (ABN). An ABN is typically obtained at the time of specimen collection for a test which the provider believes will be denied as not medically necessary. It constitutes a waiver of financial liability, in which a Medicare or Medicaid beneficiary acknowledges he or she will pay for the service, since it does not fulfill the criteria for medical necessity.
 - i. The date of service on the requisition is the date of specimen collection.
 - j. All test requests must be in writing, including requests for reflex, composite, or add-on procedures. An add-on procedure is defined as a test requested on an existing specimen. However, the date of service is the date of retrieval rather than collection.
 - k. The requisition should meet all other requirements of licensure (e.g., by CLIA), voluntary accreditation (e.g., by the College of American Pathologists), or other regulations (e.g., the Health Insurance Portability and Accountability Act).
 - l. The requisition should be accompanied by or supplemented with thorough instructions for accurate completion.
2. Notices to physician clients
- Annual notices to physician clients should include all of the following.
- a. Each institution should determine if there are any active infectious disease LMRPs or NCDs. These policies indicate the ICD-9-CM codes which justify the medical necessity of specific CPT-4 codes. These limited-coverage policies should be shared with clients if they are not altered in any manner which might encourage inappropriate utilization or coding.
 - b. Reflex test protocols and composite test groups should be clearly defined.
 - (1) For noninstitutional clients, a letter should be sent which clearly identifies laboratory policies.
 - (2) For institutional clients, annual medical staff approval will suffice for documentation.
 - c. Only CMS-approved panels should be offered unless a composite has been established as a recognized standard of care.

III. WRITTEN PROCEDURES AND POLICIES APPLICABLE TO MICROBIOLOGY (continued)

- d. Physician-requested custom panels not meeting the condition in item 2.e below require a signed physician acknowledgement of the financial and compliance implications of routinely ordering the custom panel.
 - e. The Medicare fee schedule should be provided along with a statement that the Medicaid fee schedule will be equal to or less than the Medicare amounts. Fee schedules should include applicable CPT codes for each test.
 - f. The name of the individual who serves as the CLIA Clinical Consultant in the specialty of microbiology should be publicized, and a phone number should be provided.
 - g. A list of standing orders for applicable clients should be reviewed and renewed at least annually.
3. Physician acknowledgements
- a. Specific written acknowledgement of receipt of an annual notice is not required. However, the laboratory should maintain records of the documentation and the date sent.
 - b. Specific written acknowledgement of special request protocols (custom panels, reflexes, and standing orders) must be obtained and renewed on a regular basis.
4. Use of ABNs
- a. ABNs will be used whenever there is a likelihood that an ordered test will not be covered. Only the format and language currently recommended by CMS will be used.
 - b. The laboratory should identify tests which require Food and Drug Administration (FDA) clearance or approval but which do not have it. These tests are generally considered not reasonable and necessary by Medicare and require an ABN. "Home brew" tests using analyte specific reagents as defined by the FDA may be covered unless excluded by a specific coverage policy. Coverage conditions for other payers must be determined on a case-by-case basis.
 - c. ABNs must specify the specific test and the specific date of service, as well as the anticipated reason for denial.
 - d. Because microbiology specimens are usually collected at a location remote from the laboratory by nonlaboratory personnel, it is essential to verify that an appropriate ABN has been obtained.
 - e. If an ABN has not been obtained, the ordering provider should be contacted to obtain one. It is essential to educate physicians regarding the importance of this process.
 - f. Modifiers should be added to claims to indicate the status of the ABN (i.e., whether on file or not).
5. Test utilization monitoring
- a. The laboratory should monitor yearly the utilization rates for the top 30 tests performed annually. In microbiology, these may include urine cultures, bacterial identification or susceptibility tests, and tests for *Neisseria gonorrhoeae* or *Chlamydia trachomatis*.
 - b. Any increase of >10% should be evaluated to ascertain the cause and rule out inappropriate utilization.
 - c. Any other aberrancy noted by the laboratory which might be related to inappropriate utilization should be similarly investigated.
- C. Coding and billing issues
1. CPT-4 selection
- a. The laboratory should have access to the American Medical Association annual updates of the CPT-4 code book. Medicare and Medicaid payment is based on assigning the most correct code(s) for the work actually per-

III. WRITTEN PROCEDURES AND POLICIES APPLICABLE TO MICROBIOLOGY *(continued)*

- b. Reflex tests must be clearly described as such on the requisition and in other laboratory test information resources. The client must have a means by which the reflex test may or may not be performed.
- c. Reflex protocols must be reviewed and approved by the Compliance Committee annually and included in the annual physician notice.
- d. Composites (a grouping of two or more codes in accordance with standard-of-care and accreditation or licensure requirements) and confirmations (a second test done to validate an initial positive result) should be dealt with in a manner similar to that for reflex testing.

D. Standing orders

1. Standing orders are acceptable in connection with situations involving extended treatment, but they must have a fixed term of validity and be renewed in writing with the ordering provider at term. The term should be no more than 1 year.
2. Environments in which standing orders may be applicable include nursing homes and end stage renal disease (ESRD) centers. However, microbiology testing is generally performed in cases of specific signs or symptoms of an infection and is not commonly a component of standing orders.

E. Compliance with fraud alerts

1. Through the CCO, the laboratory should have access to review of all applicable OIG- and CMS-published documents outlining fraud risk areas.
2. If it is applicable to microbiology practice, the laboratory should review the alert and take steps to alter any current practices that are relevant. A full report of the review and the corrective action plan should be given to the Compliance Committee.

F. Marketing

1. Any marketing information provided for microbiology testing should adhere to the same principles of clear, correct, nondeceptive, and fully informative guidance affecting any other section.
2. No free services should be marketed which may be construed as inducement for the submission of Medicare work. For example, antibiograms that are provided to external clients (e.g., nursing homes) must be billed at a fair market rate.

G. Prices charged to physicians and other providers

1. Laboratories should establish fair market value fee schedules that will not be viewed as inducement for referral of federally reimbursed laboratory work.
2. In general, a federal charge substantially in excess of a charge to any other third-party payer cannot be established. Although only the contractor fee schedule amount for Medicare will be reimbursed, these charges are used in the calculation of the NLA.
3. Laboratories should review and justify charges if 50% or more of non-Medicare work is heavily discounted.
4. Discounts below costs, particularly if done to match competitor pricing, may be viewed as inducement.
5. The laboratory should review test cost information on at least an annual basis to ensure the conditions listed above are met.

H. Retention of records

All records should be maintained as required by applicable statutes or regulations for use if needed in the investigation of possible fraud. There may also be additional requirements based on voluntary accreditation standards. Federal statutes include the following.

III. WRITTEN PROCEDURES AND POLICIES APPLICABLE TO MICROBIOLOGY *(continued)*

1. 42 CFR 482.24(b)(1)
Conditions of participation for hospitals; standard form and retention of records; specifies 5 years.
2. 42 CFR 488.5(a)
Discussion of accreditation standards deemed to meet Medicare conditions of participation; variable times, but at least 5 years.
3. 42 CFR 493.1105
CLIA '88; 2 years for test requisitions.
4. 42 CFR 493.1107
CLIA '88; 2 years for test records.
5. 42 CFR 493.1107 and 1109
CLIA '88; transfusion medicine records; minimum of 5 years.
6. 42 CFR 493.1257(g)
CLIA '88; cytology slides; 5 years.
7. 42 CFR 1003.132
Related to civil actions (False Claims Act); may be initiated up to 6 years after the date of claim presentation.

I. Compliance as an element of a performance plan

Compliance training (initial and annual retraining) should be incorporated into an employee's annual performance evaluation and competency assessment. Any policies specific to microbiology should also be discussed in detail with employees and incorporated into the competency assessment.

IV. THE CCO AND COMPLIANCE COMMITTEE

- A. The CCO should be known to all members of the laboratory. Any issues specific to microbiology should be brought to the attention of the CCO or the supervisor or reported through the hotline.
- B. The Compliance Committee for the laboratory should have representation from all areas of the laboratory, including microbiology. The microbiologist will have responsibility for providing expertise in the evaluation of any protocols, audits and monitors, or issues pertaining to the diagnosis of infectious diseases.

V. EDUCATION AND TRAINING

Compliance training should be conducted during orientation and at least annually thereafter. Training should emphasize those areas that each individual will deal with under normal circumstances, e.g., microbiology personnel should receive training in assisting clients in proper microbiology test ordering. CMS and Medicare contractor fraud alerts, compliance newsletters, minutes of Compliance Committee meetings, and results of audits and monitors of relevance to microbiology should be used for continuing education at monthly laboratory meetings.

VI. EFFECTIVE LINES OF COMMUNICATION

- A. Lines of communication for discussion and reporting of potential compliance issues among employees, the CCO, and other administrative staff should be open, convenient, and anonymous. Microbiology personnel must be made aware of the routes of communication. In no case should any person reporting a violation be ignored or ostracized. Anonymity should be protected, and there should be no retaliation for coming forward.
- B. Communication routes should include an anonymous hotline which is posted in the laboratory and the inclusion of compliance topics in regular departmental meeting agendas.

VII. ENFORCING STANDARDS THROUGH DISCIPLINARY GUIDELINES

- A. Zero tolerance for error applies to all aspects of adherence to compliance policies.
- B. Disciplinary action against an employee found committing fraud should be commensurate with the violation. Employees who make an honest mistake should be counseled and retrained. Employees who show a consistent pattern of unsavory practices should be terminated. All violations must be investigated by the Compliance Committee, who should make a recommendation as to the appropriate disposition of each incident.
- C. Hiring of new employees must include a background check to ensure that the individuals have not previously been restricted from providing service in a federal health care program.

VIII. AUDITING AND MONITORING

- A. Audits should be conducted on a regular basis whenever necessary to address specific issues brought forward by in-house individuals or by knowledgeable individuals from outside laboratories and/or consulting firms to ensure adherence to all written compliance policies. The results should be reviewed by the Compliance Committee and reported to all relevant laboratory sections.
- B. Examples of audits applicable to microbiology
 - 1. List the top 30 codes in the laboratory annually and evaluate any microbiology codes with >10% increase.
 - **NOTE:** The laboratory may also choose to list the top codes in microbiology only and look for trends.
 - 2. Select requisitions and review the entire test process for accuracy through ordering, testing, determining test results, and billing. Requisitions may be pulled randomly or in a targeted fashion, but ensure that microbiology CPT-4 codes are evaluated in the process.
 - 3. Establish a method for systematic review of denials for microbiology testing and for evaluation of the root cause(s) of the denials.
 - 4. Establish a tracking system for microbiology supplies, and ensure that specimens are received on an acceptable percentage basis.
- C. Establish an action plan for responding to any discrepancies noted in audits, and ensure that the audit results and plans are reviewed by the Compliance Committee.

IX. RESPONDING TO COMPLIANCE ISSUES

- A. Be familiar with the laboratory plan for investigating and reporting any finding representing overpayment or possible violation.
- B. Take every issue regarding microbiology practice seriously, and respond in accordance with the overall institutional policies.

**X. SUMMARY OF AREAS
REQUIRING COMPLIANCE
POLICY DEVELOPMENT**

- A. ABN
- B. Ambiguous test orders
- C. Anonymity and nonretribution
- D. Billing for calculations
- E. Claim submission; postsubmission review of explanation of medical benefits
- F. Claim submission; presubmission review
- G. CLIA regulations
 - 1. Client contracts
 - 2. Provision and monitoring of client supplies
- H. Confidentiality of medical information
- I. Contracts with third-party billing companies
- J. Cost reporting; laboratory component
- K. Courier service
- L. CPT coding
- M. Custom panels and physician acknowledgement
- N. Data summaries as a free service
- O. Diagnosis information; translating to ICD-9-CM codes
- P. Discounts and special prices
- Q. Education and training for customers as inducement
- R. Employees; phlebotomists in client offices
- S. ESRD arrangements
- T. Excused charges and adjustments
- U. Fraud alerts; review and compliance
- V. Gifts, contributions, and entertainment
- W. Health fairs as inducement
- X. Home Health Service client arrangements
- Y. ICD-9-CM codes; obtaining and using
- Z. Indigent care
- AA. Medical necessity guidelines
- BB. Monitoring utilization of laboratory services by clients
- CC. Nonemployment of sanctioned individuals
- DD. Notices to physicians
- EE. Nursing home client arrangements
- FF. OSHA regulations
- GG. Placement of equipment or products in client offices
- HH. Professional courtesy
 - II. Record retention
- JJ. Reflex testing
- KK. Release of test results by phone, fax, and/or other nonroutine methods
- LL. Removal of hazardous waste for clients as inducement
- MM. Rental or lease of space from health care providers
- NN. Reporting compliance issues and open-door policy
- OO. Requisition design
- PP. Sales and marketing
- QQ. Sales proposals
- RR. Standing orders
- SS. Test not ordered and/or not performed
- TT. Test ordering by authorized individuals
- UU. Test orders, requisitions, and electronic order review
- VV. Verbal and add-on test orders

APPENDIX 1.2–1

Reflex and Composite Scenarios in Microbiology

- I. BACTERIOLOGY
Culture (separate charges for Gram stain, definitive identification, and antimicrobial susceptibility added if appropriate for source or a pathogen is recovered)
 - A. Gram stain not desired
 - B. Identification not desired
 - C. Susceptibility not desired
- II. MYCOLOGY
Culture (separate charges for calcofluor white or modified Giemsa stain and for identification added if appropriate for source or a pathogen is recovered)
 - A. Calcofluor white or modified Giemsa stain not desired
 - B. Identification not desired
- III. CRYPTOCOCCUS ANTIGEN
(Includes additional charge for quantitation if qualitative screen is positive)
Quantitation not desired
- IV. MYCOBACTERIOLOGY
Culture (separate charges for auramine-rhodamine or Ziehl-Neelsen stain identification and antimicrobial susceptibility added if appropriate for source or a pathogen is recovered)
 - A. Auramine-rhodamine or Ziehl-Neelsen stain not desired
 - B. Identification not desired
- V. VIROLOGY
Culture by tube and shell vial reflex to specific identification, or molecular detection reflex to typing (separate charges for each component)
 - A. Herpes simplex virus types 1 and 2 typing not desired
 - B. Hepatitis C virus load reflex to genotyping not desired

Specimen Collection, Transport, and Acceptability

2.1

Collection, Transport, and Manipulation of Clinical Specimens and Initial Laboratory Concerns

The tables in this section address the initial events that lead to the accurate, rapid identification of microorganisms and viruses. Remember that results can be only as good as the original specimens. All the long-established precautions must be observed, keeping in mind that many specimens are obtained from anatomic sites that encourage specimen contamination with indigenous microbiota. Laboratorians in clinical microbiology laboratories must be aware of these quasiautochthonous organisms and evaluate their results accordingly (7).

Table 2.1–1 summarizes the microorganisms, including viruses, involved in disease production at various anatomic sites. The term “clinical impression” is used to indicate the most likely diagnosis for the patient conditions listed. The corresponding organisms are those most frequently isolated and that demonstrate some involvement with the disease manifestations in the patient (6). This table should be useful in counseling individuals preparing to collect specimens and in alerting laboratory personnel to choose the most appropriate means to ensure the isolation of the most likely etiological agents.

Table 2.1–2 summarizes instructions for the collection of specimens for transport to the laboratory and for bacteriological analyses. These instructions are intended to help health care personnel charged with the responsibility of collecting specimens and laboratory personnel in their effort to ensure that only specimens properly obtained, placed into appropriate containers, and of adequate volume are analyzed. In this time of cost containment efforts, specimens that do not meet all requirements cannot be examined cost-effectively (see Table 2.1–6). The excuse most often proffered for inadequate or mishandled specimens is the inability to secure a correct specimen for repeat examination. Decisions about proceeding with analyses under these circumstances are the laboratory directors’ responsibility

and should be referred to these individuals whenever possible. A policy reflecting the laboratory director’s opinion on such claims and the consequent action to be taken should be made part of the instruction manual of the laboratory and that provided to the clinical staff. In Table 2.1–2, the column headed “Helpful clinical information” is intended to heighten the awareness of all personnel involved that pertinent clinical information and the patient’s history are indispensable in the interpretation of microbiological results. Similarly, the “Comments” column provides additional information and caveats where needed.

Table 2.1–3 provides guidelines for the collection of fungal specimens. Pityriasis versicolor usually is not cultured—microscopic demonstration in scrapings suffices; therefore, scrapings are best submitted in sterile tubes or small sterile containers for direct examination in the laboratory.

Table 2.1–4 lists the requirements for collecting and transporting clinical specimens for parasite examinations. Blood smears for the detection of plasmodia are frequently submitted to the Hematology Division. Arrangements between the two laboratories are advisable, enabling both to provide input concerning the presence and identity of these protozoa. For blood parasites other than the etiological agents of malaria and babesiosis, note Table 2.1–4 footnote *b* and the appropriate references provided.

A great variety of skin preparations for obtaining blood, CSF, and other specimens have been advocated. Remember, the purpose of such preparations is the elimination of contaminants capable of obfuscating your analyses and confusing the clinician.

Table 2.1–5 is an abbreviated listing of commercially available transport media that should be used to ensure the integrity of the specimen from patient to laboratory. Most of these preparations do not require

refrigeration if the specimens can be delivered to the laboratory within 24 h (or, in some cases, 48 h). Plastic meshes (polyurethane), rather than cotton, on collection swabs provide an effective and nontoxic means for adsorbing, rather than absorbing, microorganisms from clinical material and can be used for the isolation of anaerobic bacteria in casual specimens. For sinus tracts, biopsy specimens, deep surgical or traumatic wounds, and body fluids, a variety of excellent transport media are available. Microbiologists who still manufacture their own transport media can consult appropriate sections of this edition of the handbook for details. While this reference also addresses the requirements for transporting parasites and ova, even more detailed advice is provided by Garcia and Bruckner (5). Detailed instructions concerning the transport of viral specimens and the requirements for shipping specimens to reference laboratories can be found in this edition of the handbook and in the virology section of EPCM.

Once a specimen arrives in the microbiology laboratory, personnel must ascertain that all pertinent information has been provided, that the specimen has been collected in the proper transport device, and that all other conditions for an acceptable specimen have been met. The previously mentioned need for a policy of rejecting specimens that do not meet these requirements is expanded in Table 2.1–6 in an effort to provide a sample policy that should be modified by each individual laboratory to address its particular problems. Footnote *b* is a special reminder to all laboratory personnel to be acutely aware that a record of any and all actions concerning the lack of acceptability of a clinical specimen, including the name and location of the person notified by telephone, must be maintained. Similarly, footnote *c* may seem redundant but is meant to emphasize that only appropriate specimens are suitable for anaerobic cul-

tures. To attempt to use unsuitable specimens for this purpose is a waste of material and labor and will likely provide meaningless results.

Table 2.1–7 outlines an example of how laboratory personnel can proceed to process specimens. Accessioning varies greatly from institution to institution, but the essential steps enumerated in section I of Table 2.1–7 must be met. Note that each specimen receives an identification number reserved for that particular specimen alone. Specimens obtained from the same patient but of different anatomic origins must be designated separately. Table 2.1–7 does not mention that smears should be prepared for many of the specimens. While this step is not needed universally, smears remain one of the best and most cost-effective means of providing important information almost immediately. The smear also serves as a control for culture results and permits an informed guess as to the cellular responses of immunocompetent patients. The suggestions for media to be used are just that: suggestions. Many laboratory workers prefer to use the media they encountered when first introduced to microbiology. It does not matter which particular medium is used as long as the microorganisms presumed to be present as pathogens or members of the normal microbiota can be separated from the clinical specimen.

The procedure for streaking agar plates is intended to make the experienced laboratorian pause to consider whether shortcuts have been introduced into this procedure with time and to guide the neophyte microbiologist to the easiest way to dilute an inoculum to obtain isolated colonies. Urine is singled out, since some quantitation of the microbial bioload is desirable. Laboratories that use dipstick

technology as a prescreen for culture of urine must remember that immunocompromised patients may not meet a microbial challenge with increased segmented neutrophils and thus will not react positively for leukocyte esterase, while many of the microorganisms other than members of the family *Enterobacteriaceae* do not reduce nitrate to nitrite. Microbiologists should keep in mind that a Gram stain of well-mixed, uncentrifuged urine showing two or more bacteria per oil immersion field reflects approximately 100,000 CFU/ml.

Time and again, health care personnel and even an occasional administrator will inquire about “normal values” for microbiology. Confusion and disbelief usually meet the microbiologist’s assertion that “normal” in microbiology can be defined only by the isolation or demonstration of an “abnormal” representation of the microbial world, that is, an organism that should not be found in a particular specimen. However, all clinical microbiology personnel must be aware of the urgent need to report the observations and isolations listed in Table 2.1–8. This list may be expanded, shortened, or modified in accordance with existing conditions and the emergence or reemergence of potentially pathogenic microorganisms. For example, vancomycin-resistant enterococci and penicillin-tolerant and -resistant pneumococci deserve such special attention. In addition, the organisms listed in Table 2.1–9 might be missed unless the laboratory staff is alerted to the clinician’s suspicion. This “alert request” should be part of the manual that provides health care personnel with the requirements of the clinical pathology service.

Table 2.1–10 lists the serodiagnostic tests presently available to be performed

in-house or to be sent to reference laboratories. Unless a laboratory performs a test routinely (at least once a week on several specimens), it is advisable to enlist the services of an established reference laboratory. It is important that the reference laboratory provide not only reports of expeditiously performed tests but also the values obtained with appropriate controls. These reports should be made part of the patient’s record, with clear indications that the test was not performed in the institutional laboratory. Copies of reference laboratory reports should be kept in the microbiology laboratory files. Table 2.1–10 also lists normal values that represent the cutoff points generally accepted for these examinations. However, these interpretations are subject to the instructions on the package insert, the variations reported by the reference laboratory, or the results obtained when the population in a particular geographic locale is studied. Instructions provided by reference laboratories concerning the collection and transport for these examinations must be followed to the letter. For some tests, refrigerated storage space for acute- and convalescent-stage specimens should be available unless the reference laboratory indicates that the acute-stage specimen will be held in its facility. If the tests are performed in-house, it is advisable to store serum rather than clotted blood.

Acknowledgments. The tables in this section have been gleaned from the laboratory manuals used by several of the editors and authors who participated in preparing this volume. I am indebted to each and every one of them for their generosity and assistance.

Table 2.1–1 “Rule-out” clinical impressions and potential etiological agents

Clinical impression	Potential etiological agent
Head and neck infections	
Gingivitis	Spirochetes, <i>Prevotella intermedia</i> , <i>Prevotella oralis</i>
Periodontitis	<i>Prevotella melaninogenica</i> , spirochetes
Juvenile	<i>Actinobacillus actinomycetemcomitans</i>
Early onset	Spirochetes, <i>Porphyromonas gingivalis</i> , <i>Actinobacillus actinomycetemcomitans</i>
Adult	Spirochetes, <i>Prevotella melaninogenica</i> , <i>Actinobacillus actinomycetemcomitans</i>
Progressive	<i>Bacteroides forsythus</i> , <i>Campylobacter rectus</i>
Peritonsillar abscess (Quinsy)	Polymicrobial: <i>Streptococcus pyogenes</i> , aerobic bacteria, plus normal microbiota of the oral cavity
Ludwig’s angina	Viridans streptococci, peptostreptococci, <i>Prevotella melaninogenica</i> , <i>Fusobacterium nucleatum</i>
Pterygopalatine, infratemporal	Anaerobes, aerobic and facultatively anaerobic gram-negative rods
Para- and retropharyngeal abscesses, temporal fossa infections	Polymicrobial with anaerobes, streptococci, staphylococci, <i>Enterobacteriaceae</i>
Septic jugular thrombophlebitis (postanginal sepsis)	Anaerobic streptococci, <i>Prevotella</i> spp., <i>Porphyromonas</i> spp., viridans streptococci, <i>Streptococcus pyogenes</i> , <i>Streptococcus pneumoniae</i> , <i>Eikenella corrodens</i>
Suppurative parotitis	<i>Staphylococcus aureus</i> , anaerobes, <i>Enterobacteriaceae</i> , <i>Pseudomonas aeruginosa</i> , oral microbiota, <i>Eikenella corrodens</i>
Parotitis (viral)	Mumps, coxsackievirus, influenza virus, parainfluenza virus types 1 and 3, lymphocytic choriomeningitis virus, cytomegalovirus
Sinusitis	<i>Streptococcus pneumoniae</i> , <i>Haemophilus influenzae</i> , <i>Prevotella</i> spp., <i>Porphyromonas</i> spp., <i>Fusobacterium</i> spp., <i>Peptostreptococcus</i> spp., <i>Staphylococcus aureus</i> , <i>Veillonella</i> spp., <i>Streptococcus pyogenes</i> , <i>Moraxella catarrhalis</i> , aerobic and facultatively anaerobic gram-negative rods, microsporidia, free-living amoebae, rhinovirus, influenza virus, parainfluenza virus, adenovirus (children)
Cranial epidural abscess	<i>Peptostreptococcus</i> spp., viridans streptococci, <i>Streptococcus milleri</i> group, <i>Bacteroides</i> spp., (<i>Prevotella</i> spp.), <i>Enterobacteriaceae</i> , <i>Pseudomonas aeruginosa</i> , <i>Staphylococcus aureus</i>
Otitis media	<i>Streptococcus pneumoniae</i> , <i>Haemophilus influenzae</i> , <i>Moraxella catarrhalis</i> , <i>Streptococcus pyogenes</i> , <i>Staphylococcus aureus</i> , <i>Pseudomonas aeruginosa</i>
Chronic suppurative	As above plus <i>Staphylococcus epidermidis</i> , <i>Candida</i> spp., <i>Corynebacterium</i> spp., <i>Bacteroides</i> spp., <i>Peptostreptococcus</i> spp.
Pharyngitis	<i>Streptococcus pyogenes</i> , groups C and G β -hemolytic streptococci, (rare— <i>Corynebacterium diphtheriae</i> , <i>Corynebacterium ulcerans</i> , <i>Arcanobacterium haemolyticum</i> , <i>Neisseria gonorrhoeae</i> , mixed anaerobes [Vincent’s angina], <i>Yersinia enterocolitica</i> , <i>Treponema pallidum</i>), rhinovirus, coronavirus, adenovirus, influenza viruses A and B, parainfluenza viruses (less common herpes simplex virus [types 1 and 2], coxsackie A [types 2, 4, 5, 6, 8, and 10], Epstein-Barr virus, cytomegalovirus, human immunodeficiency virus [HIV])
Laryngitis	<i>Moraxella catarrhalis</i> , <i>Bordetella pertussis</i> , <i>Bordetella parapertussis</i> , <i>Haemophilus influenzae</i> (may be secondary invaders), <i>Mycobacterium tuberculosis</i> , <i>Corynebacterium diphtheriae</i> , (rare—also <i>Histoplasma capsulatum</i> , <i>Coccidioides immitis</i> , <i>Blastomyces dermatitidis</i> , <i>Candida</i> spp., <i>Treponema pallidum</i> , herpes simplex virus, varicella virus), influenza virus, parainfluenza virus, rhinovirus, adenovirus
Epiglottitis	<i>Haemophilus influenzae</i> serogroup b, <i>Haemophilus parainfluenzae</i> , <i>Streptococcus pneumoniae</i> , <i>Staphylococcus aureus</i> , <i>Streptococcus</i> spp., non-b <i>Haemophilus influenzae</i> , <i>Pasteurella multocida</i>
Tracheitis	<i>Staphylococcus aureus</i> , <i>Streptococcus pyogenes</i> , <i>Haemophilus influenzae</i> b
Thyroiditis	
Acute suppurative	Oral microbiota, <i>Staphylococcus</i> spp., <i>Streptococcus pneumoniae</i> , anaerobes (needle aspiration); in immunocompromised patients, <i>Pseudoallescheria boydii</i> , <i>Candida</i> spp., <i>Aspergillus</i> spp., <i>Coccidioides immitis</i> , <i>Actinomyces</i> spp.
Subacute granulomatous	Mumps, rubeola virus, influenza virus, adenovirus; Epstein-Barr virus, coxsackievirus; cytomegalovirus, <i>Yersinia</i> spp.
Common cold	>200 different viruses, including different serotypes of adenoviruses, coronaviruses, influenza virus, parainfluenza virus, respiratory syncytial virus, rhinovirus, and enterovirus
Pleuropulmonary infections	
Acute community-acquired pneumonia (adults)	<i>Streptococcus pneumoniae</i> , <i>Haemophilus influenzae</i> , <i>Staphylococcus aureus</i> , <i>Legionella pneumophila</i> , <i>Legionella</i> spp., oral anaerobes (aspiration), <i>Neisseria meningitidis</i> , <i>Moraxella catarrhalis</i> , <i>Mycoplasma pneumoniae</i> , (very rare— <i>Yersinia pestis</i> , <i>Bacillus anthracis</i> , <i>Francisella tularensis</i> , <i>Pseudomonas pseudomallei</i>), <i>Histoplasma capsulatum</i> , <i>Blastomyces dermatitidis</i> , <i>Coccidioides immitis</i> , <i>Actinomyces</i> spp., <i>Cryptococcus neoformans</i> , <i>Chlamydia pneumoniae</i> , <i>Chlamydia psittaci</i> , rubeola virus, varicella virus, influenza virus (A, B, C), adenovirus, <i>Nocardia asteroides</i> , <i>Sporothrix schenckii</i> , <i>Penicillium marneffei</i> , <i>Geotrichum</i> spp., <i>Histoplasma duboisii</i> (rare)

(continued)

Table 2.1–1 “Rule-out” clinical impressions and potential etiological agents (*continued*)

Clinical impression	Potential etiological agent
Pneumonia in immunocompromised host	Members of <i>Enterobacteriaceae</i> , <i>Pseudomonas</i> spp., and related obligately aerobic gram-negative rod-shaped bacteria; <i>Staphylococcus aureus</i> , <i>Streptococcus pneumoniae</i> , <i>Nocardia</i> spp., <i>Legionella</i> spp., <i>Mycobacterium tuberculosis</i> , <i>Mycobacterium avium-intracellulare</i> , <i>Mycobacterium haemophilum</i> , <i>Aspergillus</i> spp., zygomycetes, <i>Cryptococcus neoformans</i> , <i>Curvularia lunata</i> , <i>Fusarium</i> spp., <i>Paecilomyces varioti</i> , <i>Candida</i> spp., <i>Trichosporon</i> spp., <i>Torulopsis glabrata</i> , <i>Pneumocystis carinii</i> , <i>Toxoplasma gondii</i> , <i>Strongyloides stercoralis</i> , <i>Cryptosporidium parvum</i> , microsporidia, cytomegalovirus, varicella-zoster virus, herpes simplex virus
Bronchitis	<i>Haemophilus influenzae</i> , <i>Haemophilus parainfluenzae</i> , <i>Streptococcus pneumoniae</i> , <i>Moraxella catarrhalis</i> , <i>Neisseria</i> spp., <i>Klebsiella</i> spp., <i>Pseudomonas</i> spp., obligately aerobic gram-negative rod-shaped bacteria
Aspiration pneumonia (caused by microorganisms)	<i>Peptostreptococcus</i> spp., <i>Fusobacterium nucleatum</i> , <i>Porphyromonas asaccharolytica</i> , <i>Prevotella melaninogenica</i> , (<i>Enterobacteriaceae</i> , <i>Pseudomonas</i> spp., and related bacteria in nosocomial aspiration pneumonia)
Lung abscess	<i>Peptostreptococcus</i> spp., <i>Fusobacterium nucleatum</i> , <i>Prevotella melaninogenica</i> , <i>Bacteroides fragilis</i> group, <i>Staphylococcus aureus</i> , <i>Escherichia coli</i> , <i>Klebsiella pneumoniae</i> , <i>Pseudomonas aeruginosa</i> , <i>Streptococcus pneumoniae</i>
Granulomas, cavities, etc.	<i>Mycobacterium tuberculosis</i> , <i>Nocardia</i> spp., <i>Burkholderia pseudomallei</i> , <i>Paracoccidioides brasiliensis</i> , <i>Paragonimus</i> spp., <i>Chlamydia trachomatis</i>
Miscellaneous	<i>Dirofilaria immitis</i> , Hantavirus (especially Sin Nombre)
Cardiovascular infections	
Bloodstream infections	<i>Streptococcus pneumoniae</i> , <i>Streptococcus pyogenes</i> , <i>Streptococcus agalactiae</i> , <i>Enterococcus</i> spp. (especially <i>E. faecalis</i> and <i>E. faecium</i>), <i>Streptococcus bovis</i> , <i>Streptococcus</i> serogroup G, viridans streptococci, <i>Staphylococcus aureus</i> , <i>Staphylococcus epidermidis</i> , other <i>Staphylococcus</i> spp., <i>Corynebacterium jeikeium</i> , <i>Listeria monocytogenes</i> , <i>Enterobacteriaceae</i> , <i>Pseudomonas</i> spp., <i>Stenotrophomonas maltophilia</i> , <i>Burkholderia cepacia</i> , <i>Acinetobacter</i> spp., <i>Flavobacterium</i> spp., <i>Haemophilus</i> spp., <i>Neisseria</i> spp., <i>Moraxella catarrhalis</i> , <i>Bacteroides</i> spp., <i>Fusobacterium</i> spp., <i>Prevotella</i> spp., <i>Porphyromonas</i> spp., <i>Peptostreptococcus</i> spp., other anaerobic bacteria, <i>Mycobacterium</i> spp., <i>Candida</i> spp., <i>Hansenula</i> spp., <i>Malassezia furfur</i> and <i>Plasmodium</i> spp., <i>Leptospira</i> spp., <i>Babesia</i> spp., <i>Trypanosoma</i> spp. (rare), <i>Leishmania donovani</i> (rare), <i>Toxoplasma gondii</i> (rare), <i>Wuchereria bancrofti</i> (rare), <i>Brugia malayi</i> (rare), <i>Brugia timori</i> (rare), <i>Loa loa</i> (rare)
Septic shock	<i>Lactococcus</i> spp., <i>Vagococcus</i> spp. (rare), <i>Globicatella sanguis</i> (rare), <i>Leuconostoc</i> spp. (rare), <i>Aerococcus</i> spp. (rare), most gram-negative bacteria, <i>Neisseria meningitidis</i> , <i>Haemophilus influenzae</i> , <i>Salmonella</i> spp., other <i>Enterobacteriaceae</i> , including <i>Yersinia</i> spp., <i>Vibrio</i> spp., <i>Pseudomonas</i> spp., <i>Streptococcus pneumoniae</i> , <i>Mycobacterium</i> spp. (steroids; T-cell abnormalities), zygomycetes (diabetes, neutropenia), <i>Aspergillus</i> spp., <i>Candida</i> spp., <i>Listeria</i> spp. (T-cell abnormality), herpes simplex virus (T-cell abnormalities), cytomegalovirus (T-cell abnormalities), varicella-zoster virus (T-cell abnormalities)
Endocarditis	
Native valve	Viridans streptococci (<i>Streptococcus sanguis</i> , <i>Streptococcus salivarius</i> , <i>Streptococcus mutans</i> , <i>Streptococcus mitior</i> , etc.), <i>Enterococcus faecalis</i> , <i>Enterococcus faecium</i> , <i>Enterococcus durans</i> , <i>Streptococcus bovis</i> (caveat: colon malignancy), <i>Streptococcus equinus</i> , <i>Streptococcus pyogenes</i> , <i>Streptococcus agalactiae</i> , <i>Staphylococcus aureus</i> , coagulase-negative staphylococci, <i>Streptococcus pneumoniae</i> , <i>Neisseria gonorrhoeae</i> , <i>Haemophilus</i> spp., <i>Pseudomonas</i> spp., <i>Listeria</i> spp., <i>Corynebacterium</i> spp., (<i>Candida</i> spp., <i>Torulopsis glabrata</i> , and <i>Aspergillus</i> spp. can produce native valve endocarditis in severe underlying disease, corticosteroid therapy, prolonged antibiotic use, or cytotoxic therapy)
Intravenous drug abuser	<i>Staphylococcus aureus</i> , <i>Streptococcus</i> spp., <i>Enterococcus</i> spp., gram-negative rod-shaped bacteria (mostly <i>Pseudomonas</i> spp. and <i>Serratia</i> spp.), <i>Candida</i> spp., <i>Plasmodium</i> spp., <i>Leishmania</i> spp., anaerobic oral bacteria
Prosthetic valve	
Early	<i>Staphylococcus epidermidis</i> , <i>Staphylococcus aureus</i> , aerobic gram-negative rods, fungi (usually <i>Candida</i> spp. and/or <i>Aspergillus</i> spp.), <i>Streptococcus</i> spp., <i>Enterococcus</i> spp., <i>Corynebacterium</i> spp.
Late	Viridans streptococci, <i>Staphylococcus</i> spp., <i>Enterococcus</i> spp., (staphylococci, gram-negative rods, fungi, and corynebacteria are isolated in earlier infections occurring at <18 months)
Vascular graft infections	<i>Staphylococcus aureus</i> , <i>Staphylococcus epidermidis</i> , <i>Streptococcus</i> spp., <i>Escherichia coli</i> , <i>Proteus mirabilis</i> , <i>Pseudomonas aeruginosa</i> , anaerobic bacteria, <i>Candida</i> spp.

Table 2.1–1 (continued)

Clinical impression	Potential etiological agent
Pericarditis, myocarditis	<i>Staphylococcus aureus</i> , <i>Streptococcus pneumoniae</i> , <i>Streptococcus pyogenes</i> , <i>Escherichia coli</i> , <i>Proteus</i> spp., <i>Pseudomonas aeruginosa</i> , <i>Salmonella</i> spp., <i>Shigella</i> spp., <i>Neisseria meningitidis</i> , <i>Histoplasma capsulatum</i> , <i>Candida</i> spp., <i>Aspergillus</i> spp., <i>Trypanosoma cruzi</i> , <i>Aspergillus</i> spp., coxsackievirus (especially B), echoviruses, <i>Mycobacterium tuberculosis</i> , <i>Echinococcus granulosum</i> , <i>Entamoeba histolytica</i> , <i>Toxoplasma gondii</i> , <i>Trichinella spiralis</i> , <i>Mycoplasma pneumoniae</i>
Fevers (viral)	Lassa virus
Intestinal tract infections	
Diarrhea	<i>Shigella</i> spp., <i>Salmonella</i> spp., <i>Vibrio cholerae</i> , <i>Escherichia coli</i> , <i>Giardia lamblia</i> , <i>Campylobacter</i> spp., <i>Entamoeba histolytica</i> , <i>Dientamoeba fragilis</i> , rotavirus, Norwalk agent, toxins of <i>Clostridium difficile</i> , <i>Staphylococcus aureus</i> , <i>Bacillus cereus</i> , <i>Clostridium perfringens</i> , <i>Yersinia enterocolitica</i> , <i>Plesiomonas shigelloides</i> , <i>Cryptosporidium</i> spp., <i>Isospora belli</i> , <i>Sarcocystis hominis</i> , <i>Cyclospora cayetanensis</i> , <i>Encephalitozoon</i> spp., <i>Nosema</i> spp., <i>Enterocytozoon</i> spp., <i>Pleistophora</i> spp., <i>Microsporidium</i> spp., <i>Balantidium coli</i> , <i>Vibrio parahaemolyticus</i>
Salmonellosis	
Gastroenteritis	<i>Salmonella enteritidis</i> serovar Typhimurium, serovar Newport, serovar Aviatum, other <i>Salmonella</i> serovars
Enteric fever	<i>Salmonella enterica</i> serovars Typhi, Paratyphi A, Schotimuelleri, other <i>Salmonella</i> spp., <i>Burkholderia pseudomallei</i>
Bacteremia	<i>Salmonella</i> , <i>enterica</i> serovars Typhimurium, Cholavasuis, Heidelberg, other <i>Salmonella</i> serovars
Carrier state	<i>Salmonella</i> serovars
<i>Escherichia coli</i> diarrheagenic infections	Enterotoxigenic <i>E. coli</i> , common O serogroups (6, 8, 15, 20, 25, 27, 63, 78, 80, 114, 115, 128ac, 148, 153, 159, 167); enteropathogenic <i>E. coli</i> , common O serogroups (55, 86, 111, 119, 125, 126, 127, 128ab, 142); enteroadherent <i>E. coli</i> , significance not determined; enteroinvasive <i>E. coli</i> , common O serogroups (28ac, 29, 112, 124, 136, 143, 144, 152, 164, 167); enterohemorrhagic <i>E. coli</i> , common O serogroups (157:H7; also implicated, 26:H11, 111:H8, 103:H2, 113:H21, 104:H21); enteroaggregative <i>E. coli</i> , common O serogroups (3:H2, 44:H18) (NOTE: flagellar antigen designation provided only when required for pathogenic manifestation)
Intestinal campylobacteriosis (diarrhea)	<i>Campylobacter jejuni</i> , <i>Campylobacter coli</i> , <i>Campylobacter lari</i> , <i>Campylobacter upsalensis</i> , <i>Campylobacter fetus</i>
Gastric/duodenal ulcers	<i>Helicobacter pylori</i>
Viral gastroenteritis	Rotavirus, Norwalk agent, adenovirus (enteric), astrovirus, calicivirus, Norwalk-like viruses
Food poisoning (food as vehicle and/or contains toxins)	<i>Bacillus cereus</i> , <i>Campylobacter</i> spp., <i>Clostridium perfringens</i> , <i>Salmonella</i> spp., <i>Shigella</i> spp., <i>Staphylococcus aureus</i> , <i>Clostridium botulinum</i> , <i>Escherichia coli</i> , <i>Vibrio parahaemolyticus</i> , <i>Yersinia enterocolitica</i> , <i>Listeria monocytogenes</i> , <i>Giardia lamblia</i> , microsporidia, <i>Entamoeba histolytica</i> , <i>Anisakis</i> spp., (raw saltwater fish), <i>Taenia saginata</i> , <i>Taenia solium</i> , <i>Diphyllobothrium latum</i> , lung and liver trematodes, <i>Trichinella spiralis</i> , hepatitis A virus, Norwalk virus
Intra-abdominal infections	<i>Escherichia coli</i> , <i>Klebsiella</i> spp., <i>Proteus</i> spp., <i>Enterobacter</i> spp., <i>Pseudomonas aeruginosa</i> , <i>Staphylococcus aureus</i> , <i>Enterococcus</i> spp., <i>Bacteroides</i> spp., <i>Fusobacterium</i> spp., <i>Veillonella</i> spp., <i>Peptostreptococcus</i> spp., <i>Propionibacterium</i> spp., <i>Staphylococcus</i> spp.
Intra-abdominal abscess, including appendicitis, diverticulitis	<i>Escherichia coli</i> , <i>Bacteroides fragilis</i> , <i>Enterococcus</i> spp., <i>Peptostreptococcus</i> spp., <i>Clostridium</i> spp., <i>Proteus</i> spp., <i>Fusobacterium</i> spp., <i>Klebsiella</i> spp., <i>Pseudomonas</i> spp., aerobic gram-negative rod-shaped bacteria, <i>Staphylococcus</i> spp., <i>Eubacterium</i> , spp., <i>Streptococcus pyogenes</i> , <i>Streptococcus</i> spp., <i>Angiostrongylus costaricensis</i>
Liver abscess/infections	<i>Streptococcus</i> spp., <i>Escherichia coli</i> , <i>Proteus</i> spp., <i>Peptostreptococcus</i> spp., <i>Fusobacterium</i> spp., <i>Bacteroides</i> spp., <i>Entamoeba histolytica</i> , <i>Leishmania donovani</i> , microsporidia, hepatitis viruses (A–E)
Liver granulomata	<i>Mycobacterium tuberculosis</i> , <i>Mycobacterium</i> spp., <i>Brucella</i> spp., <i>Francisella tularensis</i> , <i>Histoplasma capsulatum</i> , <i>Coccidioides immitis</i> , <i>Coxiella burnetii</i> , <i>Treponema pallidum</i> (secondary syphilis), <i>Echinococcus</i> spp., <i>Schistosoma</i> spp., cytomegalovirus, Epstein-Barr virus
Bile duct infections	<i>Clonorchis sinensis</i> , <i>Opisthorchis felinus</i> , <i>Clostridium</i> spp.
Pancreatic infections	<i>Escherichia coli</i> , <i>Enterococcus</i> spp., <i>Staphylococcus</i> spp., <i>Klebsiella</i> spp., <i>Proteus</i> spp., <i>Candida</i> spp., <i>Pseudomonas</i> spp., <i>Streptococcus</i> spp., <i>Torulopsis glabrata</i> , <i>Haemophilus</i> spp., <i>Corynebacterium</i> spp., <i>Serratia marcescens</i>
Splenic abscess	<i>Staphylococcus</i> spp., <i>Salmonella</i> spp., <i>Escherichia coli</i> , <i>Enterococcus</i> spp., <i>Streptococcus</i> spp., <i>Klebsiella</i> spp., <i>Enterobacter</i> spp., <i>Proteus</i> spp., <i>Pseudomonas</i> spp., <i>Corynebacterium</i> spp., <i>Shigella</i> spp., <i>Bacteroides</i> spp., <i>Propionibacterium</i> spp., <i>Clostridium</i> spp., <i>Fusobacterium</i> spp., <i>Candida</i> spp., <i>Aspergillus</i> spp., <i>Leishmania donovani</i> , microsporidia, <i>Blastomyces dermatitidis</i>

(continued)

Table 2.1-1 “Rule-out” clinical impressions and potential etiological agents (continued)

Clinical impression	Potential etiological agent
Intestinal/abdominal parasites	<i>Enterobius vermicularis</i> , <i>Fasciola hepatica</i> (liver), <i>Fasciola gigantica</i> (liver), <i>Fasciolopsis buski</i> , <i>Necatur americanus</i> , <i>Ancylostoma duodenale</i> , <i>Ancylostoma caninum</i> (rare), <i>Hymenolepis nana</i> , <i>Hymenohepis diminuta</i> , <i>Dypilidium caninum</i>
Genitourinary tract infections	
Urinary tract infections	<i>Escherichia coli</i> , <i>Staphylococcus saprophyticus</i> , <i>Proteus</i> spp., <i>Klebsiella</i> spp., <i>Enterococcus</i> spp., <i>Pseudomonas</i> spp., <i>Candida</i> spp., <i>Staphylococcus</i> spp.
Urethritis	
Male	<i>Neisseria gonorrhoeae</i> , <i>Chlamydia trachomatis</i> , <i>Ureaplasma urealyticum</i>
Female	<i>Escherichia coli</i> , <i>Staphylococcus saprophyticus</i> , <i>Chlamydia trachomatis</i> , <i>Ureaplasma urealyticum</i>
Prostatitis	<i>Escherichia coli</i> , other <i>Enterobacteriaceae</i> , <i>Pseudomonas</i> spp., <i>Staphylococcus aureus</i> , <i>Enterococcus</i> spp., <i>Trichomonas vaginalis</i>
Epididymitis	<i>Chlamydia trachomatis</i> , <i>Neisseria gonorrhoeae</i> , <i>Enterobacteriaceae</i> , <i>Pseudomonas</i> spp.
Renal abscess	
Cortical	<i>Staphylococcus aureus</i>
Corticomedullary	<i>Escherichia coli</i> , <i>Klebsiella</i> spp., <i>Proteus</i> spp.
Perinephric	<i>Staphylococcus aureus</i> , <i>Escherichia coli</i> , <i>Proteus</i> spp., <i>Klebsiella</i> spp., <i>Pseudomonas</i> spp., <i>Streptococcus</i> spp., <i>Enterococcus</i> spp., <i>Mycobacterium</i> spp., <i>Bacteroides</i> spp., <i>Candida</i> spp.
Sexually transmitted diseases (STD)	
Acute pelvic inflammatory disease	<i>Neisseria gonorrhoeae</i> , <i>Chlamydia trachomatis</i> , <i>Mycoplasma hominis</i> , <i>Peptostreptococcus</i> spp., <i>Bacteroides</i> spp., <i>Enterobacteriaceae</i>
Neonatal/perinatal complications of STD	<i>Neisseria gonorrhoeae</i> , <i>Chlamydia trachomatis</i> , cytomegalovirus, herpes simplex virus, <i>Ureaplasma urealyticum</i> , <i>Mycoplasma hominis</i>
Potential factors in neoplasia	Human papillomavirus, hepatitis B virus, human immunodeficiency virus, herpes simplex virus
Mucopurulent cervicitis	<i>Chlamydia trachomatis</i> , <i>Neisseria gonorrhoeae</i> , herpes simplex virus
Vaginitis, vulvovaginitis	<i>Trichomonas vaginalis</i> , <i>Candida</i> spp., <i>Bacteroides</i> spp., <i>Prevotella bivia</i> , <i>Prevotella disiens</i> , <i>Prevotella</i> spp., <i>Actinomyces</i> spp., <i>Peptostreptococcus</i> spp., <i>Eubacterium nodatum</i> , <i>Mobiluncus</i> spp., (<i>Corynebacterium diphtheriae</i> —rare)
Vaginosis	<i>Gardnerella vaginalis</i> , <i>Mycoplasma hominis</i> , <i>Mobiluncus</i> spp.
Genital ulcers with lymphadenopathy	<i>Treponema pallidum</i> , <i>Haemophilus ducreyi</i> , <i>Chlamydia trachomatis</i> (lymphogranuloma venereum strains), <i>Calymmatobacterium granulomatis</i> , herpes simplex virus
Endometritis	<i>Chlamydia trachomatis</i> , <i>Neisseria gonorrhoeae</i> , (<i>Streptococcus agalactiae</i> , <i>Mycoplasma hominis</i> isolated from cervix)
Amniotic fluid infections	<i>Ureaplasma urealyticum</i> , <i>Mycoplasma hominis</i> , <i>Bacteroides</i> spp., <i>Gardnerella vaginalis</i> , <i>Streptococcus agalactiae</i> , <i>Peptostreptococcus</i> spp., <i>Escherichia coli</i> , <i>Enterococcus</i> spp., <i>Fusobacterium</i> spp., <i>Bacteroides</i> spp.
Skin and soft tissue infections	
Impetigo	<i>Streptococcus pyogenes</i> , <i>Staphylococcus aureus</i> , (<i>Corynebacterium diphtheriae</i> —rare)
Echthyma	<i>Streptococcus pyogenes</i> , <i>Staphylococcus aureus</i>
Blistering distal dactylitis	<i>Streptococcus pyogenes</i> , <i>Staphylococcus aureus</i>
Folliculitis	<i>Staphylococcus aureus</i>
Euruncles and carbuncles	<i>Staphylococcus aureus</i>
Erythema migrans	<i>Borrelia burgdorferi</i>
Erysipelas	<i>Streptococcus pyogenes</i> , (serogroup G, C, and B streptococcus—rare)
Cellulitis, acute	<i>Streptococcus pyogenes</i> , <i>Staphylococcus aureus</i> , (<i>Haemophilus influenzae</i> , <i>Enterobacteriaceae</i> , <i>Clostridium</i> spp., <i>Bacillus anthracis</i> , <i>Pasteurella multocida</i> , <i>Erysipelothrix</i> spp., <i>Aeromonas hydrophila</i> , <i>Vibrio vulnificus</i> , <i>Mycobacterium</i> spp.—rare), <i>Vibrio alginolyticus</i> , <i>Vibrio damsela</i> , <i>Helcococcus</i> spp.
Fasciitis, necrotizing	<i>Streptococcus pyogenes</i> or synergistic infection by facultative and anaerobic bacteria, <i>Apophysomyces elegans</i>
Nodules, papules, subcutaneous, tissue involvement and sinus, tracts, other skin manifestations	<i>Mycobacterium leprae</i> , <i>Loa loa</i> , <i>Wuchereria bancrofti</i> , <i>Onchocerca volvulus</i> , <i>Mansonella perstans</i> , <i>Mansonella streptocerca</i> , molluscipox virus, <i>Nocardia brasiliensis</i> , <i>Nocardia asteroides</i> , other <i>Nocardia</i> spp., <i>Actinomadura</i> spp., <i>Nocardiosis dassonvillei</i> , <i>Streptomyces somaliensis</i> , <i>Madurella</i> spp., <i>Pseudoallescheria boydii</i> , other fungi, <i>Treponema carateum</i> , <i>Yersinia pestis</i> , <i>Ancylostoma brasiliensis</i> , <i>Ancylostoma caninum</i> , <i>Gnathostoma spiniserum</i>
Fournier’s gangrene	<i>Escherichia coli</i> , <i>Pseudomonas aeruginosa</i> , <i>Proteus mirabilis</i> , <i>Enterococcus</i> spp., <i>Staphylococcus</i> spp., <i>Peptostreptococcus</i> spp., <i>Bacteroides</i> spp.

Table 2.1–1 (continued)

Clinical impression	Potential etiological agent
Abscess, cutaneous	
Axilla, paronychia, breast, hands, head, neck, and trunk	<i>Staphylococcus aureus</i> , <i>Staphylococcus epidermidis</i> , <i>Propionibacterium</i> spp., <i>Peptostreptococcus</i> spp., <i>Leishmania tropica</i> complex, <i>Leishmania braziliense</i> complex
Perineal, vulvovaginal, scrotal, perianal, and buttocks	<i>Staphylococcus aureus</i> , <i>Staphylococcus epidermidis</i> , <i>Propionibacterium</i> spp., <i>Peptostreptococcus</i> spp., <i>Streptococcus</i> spp.
Myositis	
Bacterial	<i>Staphylococcus aureus</i> , <i>Streptococcus</i> spp., influenza virus, coxsackievirus, Epstein-Barr virus, herpes simplex virus type 2, parainfluenza virus type 3, adenovirus type 21, echovirus type 9
Protozoan	<i>Toxoplasma gondii</i> , <i>Trypanosoma</i> spp., microsporidia
Tinea favosa	<i>Trichophyton schoenleinii</i> , (<i>Trichophyton mentagrophytes</i> , <i>Trichophyton verrucosum</i> , <i>Microsporum canis</i> —rare)
Piedra	
White	<i>Trichosporon beigelii</i> (Indonesia, South America, Far East)
Black	<i>Piedraia hortae</i> (tropical South America, Africa, Pacific Islands, Far East)
Tinea corporis (ringworm)	<i>Trichophyton</i> spp., <i>Microsporum</i> spp., <i>Epidermophyton</i> spp.
Tinea imbricata	<i>Trichophyton rubrum</i> , <i>Trichophyton mentagrophytes</i> , <i>Epidermophyton floccosum</i>
Onychomycosis	
Dermatophytic	<i>Trichophyton rubrum</i> , <i>Trichophyton mentagrophytes</i> , (<i>Epidermophyton</i> spp., <i>Microsporum</i> spp., <i>Scytalidium</i> spp.—rare)
Nondermatophytic	<i>Candida albicans</i> , <i>Geotrichum candidum</i> , <i>Scopulariopsis brevicaulis</i> , <i>Cephalosporium</i> spp., <i>Acremonium</i> spp.
Chromomycosis (dornato-blastomycosis, dermatitis verrucosa)	<i>Phialophora verrucosa</i> , <i>Fonsecaea pedrosii</i> , <i>Fonsecaea computa</i> , <i>Cladiosporium carrionii</i> , <i>Rhinocladiella aquaspersa</i> , <i>Botryomyces caespitosus</i> , <i>Exophiala spinifera</i> , <i>Exophiala jeanselmei</i>
Viral skin infections	Rubeola rubella virus, varicella virus, herpes simplex virus (types 1 and 2), herpes zoster virus, papillomavirus (warts), parvovirus (erythema infectiosum), human herpesvirus 6-B (roseola); enteroviral exanthems—hand-foot-mouth syndrome, coxsackievirus A (select types); other types of rashes—echovirus and coxsackievirus, maculopapular; coxsackievirus and echovirus, petechial (caveat: hard to differentiate from meningococemia rash); (maculopapular rash—Marburg virus, Ebola virus, parapoxviruses [very rare])
Fungal and parasitic soft tissue/skin infections	<i>Dracunculus medinensis</i> , <i>Dirofilaria tenui</i> , <i>Dirofilaria ursi</i> , <i>Dirofilaria repens</i> , <i>Bruggia</i> spp. (lymph nodes), <i>Onchocerca volvulus</i> , <i>Madurella</i> spp., <i>Pseudoallescheria boydii</i> , <i>Scedosporium apiospermum</i> , <i>Exophiala jeanselmei</i> , <i>Acremonium</i> spp., <i>Leptospira senegalensis</i> (rare), <i>Paracoccidioides brasiliensis</i>
Bone and joint infections	
Osteomyelitis	
Hematogenous	<i>Staphylococcus aureus</i> , <i>Staphylococcus</i> spp., <i>Streptococcus agalactiae</i> , <i>Candida</i> spp., <i>Pseudomonas aeruginosa</i> , <i>Salmonella</i> , serovars, <i>Burkholderia pseudomallei</i>
Trauma associated	<i>Streptococcus</i> spp., <i>Propionibacterium</i> spp., <i>Enterobacteriaceae</i> , <i>Pseudomonas</i> spp., <i>Staphylococcus</i> spp., anaerobic bacteria
Vascular insufficiency	<i>Enterobacteriaceae</i> , anaerobic bacteria
Septic arthritis, nongonococcal arthritis	<i>Neisseria gonorrhoeae</i> , <i>Staphylococcus aureus</i> , <i>Streptococcus pyogenes</i> , <i>Streptococcus pneumoniae</i> , <i>Streptococcus</i> spp., <i>Enterococcus</i> spp., <i>Enterobacteriaceae</i> , obligately aerobic gram-negative rod-shaped bacteria
Rare arthritides	<i>Brucella</i> spp., <i>Salmonella</i> spp., rubella virus, mumps virus, coxsackievirus, echovirus (transient), parvovirus B 19, hepatitis B virus (immune response), <i>Mycobacterium</i> spp.
Infections of the eye	
Eyelid	<i>Staphylococcus aureus</i> , herpes simplex virus, varicella virus, papillomavirus, <i>Trichophyton</i> spp., <i>Microsporum</i> spp., <i>Trichosporon</i> spp.
Styes	<i>Staphylococcus aureus</i>
Chalazion	<i>Staphylococcus aureus</i> , <i>Moraxella lacunata</i>
Conjunctivitis	
Purulent	<i>Neisseria gonorrhoeae</i> , <i>Neisseria meningitidis</i> (newborn); <i>Chlamydia trachomatis</i> serovars D to K, <i>Staphylococcus aureus</i> , <i>Streptococcus pyogenes</i> , <i>Streptococcus pneumoniae</i> , <i>Haemophilus influenzae</i> , (<i>Haemophilus aegyptius</i>), <i>Pseudomonas aeruginosa</i> , <i>Escherichia coli</i> , <i>Moraxella</i> spp., <i>Corynebacterium diphtheriae</i> , feline strains of <i>Chlamydia psittaci</i>

(continued)

Table 2.1-1 “Rule-out” clinical impressions and potential etiological agents (continued)

Clinical impression	Potential etiological agent
Chronic	<i>Moraxella lacunata</i> , <i>Staphylococcus</i> spp.
Parinaud’s oculoglandular	<i>Bartonella henselae</i> (or possibly <i>Afipia felis</i> [both possibly agents of cat scratch disease]), <i>Lymphogranuloma venereum</i> , <i>Mycobacterium tuberculosis</i> , <i>Treponema pallidum</i> , <i>Haemophilus ducreyi</i> , <i>Francisella tularensis</i> , Epstein-Barr virus, mumps virus
Viral	Adenovirus type 8, 19, or 37, usually causing keratoconjunctivitis severe disease types 8, 5, 19; serotypes 3, 7, and 4—pharyngoconjunctival fever; herpes simplex viruses, varicella-zoster virus, Epstein-Barr virus, cytomegalovirus, rubeola virus, mumps virus, influenza virus, Newcastle disease virus (paramyxovirus)
Corneal infections	
Bacterial keratitis	<i>Staphylococcus aureus</i> , <i>Staphylococcus</i> spp., <i>Streptococcus pneumoniae</i> , <i>Streptococcus</i> spp., <i>Pseudomonas aeruginosa</i> , <i>Bacillus cereus</i> , <i>Enterobacteriaceae</i> , <i>Neisseria</i> spp., <i>Moraxella lacunata</i> , <i>Mycobacterium fortuitum</i> , <i>Mycobacterium chelonae</i> , anaerobes
Fungal keratitis	<i>Fusarium solani</i> , <i>Candida albicans</i> , <i>Aspergillus fumigatus</i> , <i>Alternaria</i> spp., <i>Curvularia</i> spp., <i>Acremonium</i> spp.
Viral keratitis	Herpes simplex virus, varicella-zoster virus
Protozoan keratitis	<i>Acanthamoeba</i> spp.
Lacrimal system infections	
Dacryoadenitis	<i>Staphylococcus aureus</i> , <i>Streptococcus</i> spp., <i>Neisseria gonorrhoeae</i> , <i>Mycobacterium tuberculosis</i> , <i>Treponema pallidum</i> , mumps virus, Epstein-Barr virus
Canaliculitis	<i>Actinomyces israelii</i> , <i>Streptococcus</i> spp., <i>Candida</i> spp., <i>Aspergillus</i> spp., herpes simplex virus, varicella-zoster virus
Dacryocystitis	<i>Streptococcus pneumoniae</i> , <i>Staphylococcus aureus</i> , <i>Haemophilus influenzae</i> , <i>Pseudomonas aeruginosa</i> , <i>Proteus mirabilis</i> , <i>Candida albicans</i> , <i>Aspergillus</i> spp.
Retina and choroid infections	Cytomegalovirus, <i>Toxoplasma gondii</i>
Endophthalmitis	
Exogenous (surgical or nonsurgical trauma)	<i>Staphylococcus epidermidis</i> , <i>Staphylococcus aureus</i> , <i>Streptococcus</i> spp., <i>Bacillus</i> spp., <i>Pseudomonas</i> spp., <i>Enterobacteriaceae</i> , <i>Haemophilus influenzae</i> , <i>Propionibacterium</i> spp.
Endogenous	<i>Staphylococcus aureus</i> , <i>Neisseria meningitidis</i> , <i>Streptococcus</i> spp., <i>Bacillus cereus</i> , <i>Enterobacteriaceae</i> , <i>Pseudomonas aeruginosa</i> , <i>Nocardia asteroides</i>
Fungal (endogenous)	<i>Candida albicans</i> , <i>Aspergillus fumigatus</i> , <i>Aspergillus flavus</i>
Fungal (exogenous)	<i>Candida</i> spp., <i>Aspergillus</i> spp., <i>Cephalosporium</i> spp., <i>Penicillium</i> spp., <i>Curvularia</i> spp.
Orbital infections	<i>Staphylococcus aureus</i> , <i>Streptococcus</i> spp., <i>Peptostreptococcus</i> spp., <i>Pseudomonas aeruginosa</i> , <i>Haemophilus influenzae</i> , <i>Mycobacterium</i> spp., zygomycetes, <i>Aspergillus</i> spp., <i>Echinococcus</i> spp., <i>Taenia solium</i>
Nervous system infections	
Acute bacterial meningitis	<i>Neisseria meningitidis</i> , <i>Streptococcus pneumoniae</i> , <i>Streptococcus agalactiae</i> , <i>Listeria monocytogenes</i> , <i>Escherichia coli</i> , <i>Enterobacteriaceae</i> , <i>Leptospira</i> spp., <i>Haemophilus influenzae</i> , <i>Staphylococcus aureus</i> ; less commonly, <i>Peptostreptococcus</i> spp., <i>Fusobacterium necrophorum</i> , <i>Prevotella melaninogenica</i> , <i>Bacteroides fragilis</i> , <i>Clostridium perfringens</i> ; rarely (zoonotic), <i>Brucella</i> spp., <i>Francisella tularensis</i> , <i>Streptococcus suis</i> , <i>Yersinia pestis</i>
Acute viral meningitis	Coxsackievirus, echovirus, poliovirus, herpes simplex viruses 1 and 2, varicella-zoster virus, flaviviruses (St. Louis encephalitis), mumps virus, bunyaviruses (California group, La Crosse), rubeola, lymphocytic choriomeningitis virus, adenoviruses
Chronic meningitis	<i>Mycobacterium tuberculosis</i> , <i>Brucella</i> spp., <i>Francisella tularensis</i> , <i>Listeria monocytogenes</i> (rare), <i>Neisseria meningitidis</i> (rare), <i>Tropheryma whippelli</i> (rare), <i>Borrelia burgdorferi</i> , <i>Leptospira</i> spp. (rare), <i>Treponema pallidum</i> , <i>Actinomyces</i> spp., <i>Nocardia</i> spp., <i>Cryptococcus neoformans</i> , <i>Coccidioides immitis</i> (rare), <i>Histoplasma capsulatum</i> (rare), <i>Candida</i> spp., <i>Aspergillus</i> spp. (rare), zygomycetes (rare), <i>Parastrongyloides cantonensis</i> , lymphocytic choriomeningitis virus, mumps virus, herpes simplex virus, varicella-zoster virus, arbovirus, flavivirus, echovirus, parasites (rare)
Brain abscess	<i>Streptococcus</i> spp., <i>Peptostreptococcus</i> spp., <i>Porphyromonas</i> spp., <i>Bacteroides</i> spp., <i>Prevotella</i> spp., <i>Fusobacterium</i> spp., <i>Staphylococcus aureus</i> , <i>Enterobacteriaceae</i> , <i>Burkholderia cepacia</i> , <i>Streptococcus pneumoniae</i> , <i>Neisseria meningitidis</i> , <i>Haemophilus influenzae</i> , <i>Listeria monocytogenes</i> , <i>Haemophilus aphrophilus</i> , <i>Actinomyces</i> spp., <i>Nocardia</i> spp., zygomycetes, <i>Mycobacterium</i> spp., <i>Naegleria</i> spp. (primary meningoencephalitis), <i>Acanthamoeba</i> spp., <i>Balamuthia mandrillaris</i> (granulomatous encephalitis)
Spinal cord, peripheral and cranial nerves	Poliomyelitis virus, herpesvirus simiae, human immunodeficiency virus type 1, human T-lymphotrophic virus type 1; myelitis associated—cytomegalovirus, herpes simplex virus; following infection with rubeola virus, varicella-zoster virus, influenza virus, mumps virus; <i>Borrelia burgdorferi</i> , <i>Borrelia recurrentis</i> , <i>Chlamydia</i> spp.

Table 2.1–1 (continued)

Clinical impression	Potential etiological agent
Epidural abscess	<i>Staphylococcus aureus</i> , <i>Escherichia coli</i> , <i>Pseudomonas aeruginosa</i> , <i>Streptococcus</i> spp., <i>Peptostreptococcus</i> spp., <i>Salmonella</i> servovars, <i>Staphylococcus</i> spp., <i>Nocardia</i> spp., <i>Actinomyces</i> spp., <i>Fusobacterium</i> spp., <i>Mycobacterium</i> spp., <i>Aspergillus</i> spp., <i>Brucella</i> spp., <i>Treponema pallidum</i>
Ear infections	
Otitis externa	<i>Staphylococcus aureus</i> , <i>Propionibacterium acnes</i> , <i>Pseudomonas aeruginosa</i>
Otitis media	<i>Streptococcus pneumoniae</i> , <i>Haemophilus influenzae</i> , <i>Streptococcus pyogenes</i> , <i>Staphylococcus aureus</i> , <i>Moraxella catarrhalis</i> , <i>Pseudomonas aeruginosa</i> , <i>Alloiococcus otitidis</i> , respiratory syncytial virus, influenza virus, enteroviruses, rhinoviruses, <i>Chlamydia trachomatis</i> (infants <6 months old), (<i>Corynebacterium diphtheriae</i> , <i>Mycobacterium tuberculosis</i> , <i>Mycobacterium chelonii</i> , <i>Clostridium tetani</i> , <i>Ascaris lumbricoides</i> —rare)
Encephalitides (4)	
Viral	
Mosquito borne	Japanese encephalitis (JE), western equine encephalitis (WEE), eastern equine encephalitis (EEE), St. Louis encephalitis (SLE), Murray Valley (MV) encephalitis (Australia), La Crosse, California, Rocio encephalitis, Jamestown Canyon, snowshoe hare viruses
Tick borne	Far-Eastern (Russian spring/summer), central European, louping ill, powassan (member of <i>Flaviviridae</i>) viruses EEE and WEE (<i>Togaviridae</i>), JE, Kunjin, MV encephalitis, SLE, and Rocio encephalitis viruses (<i>Flaviviridae</i>), La Crosse, California, Jamestown Canyon, snowshoe hare viruses (<i>Bunyaviridae</i>)
Spongiform	Creutzfeldt-Jakob, Creutzfeldt-Jakob variant bovine spongiform encephalitis—prions; <i>Paramyxoviridae</i> (Hendra and Nipah viruses)
Meningoencephalitis	<i>Naegleria fowleri</i>
Granulomatous encephalitis	<i>Acanthamoeba</i> spp., <i>Balmuthia mandillaris</i>
Infections caused by rather recently recognized etiological agents that may or may not be cultured in routine microbiology laboratories	
Bartonellosis	<i>Bartonella bacilliformis</i>
<i>Chromobacterium</i> bacteremia	<i>Chromobacterium violaceum</i>
Strawberry foot rot (exudative, scabbing dermatitis)	<i>Dermatophilus congolensis</i>
Bacterial vaginosis	<i>Gardnerella vaginalis</i> , <i>Mobiluncus</i> spp., <i>Mycoplasma</i> spp.
Legionellosis and related diseases	<i>Legionella</i> spp.
Chronic nodular skin lesions (joint infections, wound infections)	<i>Prototheca</i> spp.
Occasional endocarditis, dialysis	<i>Stomatococcus mucilaginosus</i>
Rat bite fever (Haverhill fever)	<i>Streptobacillus moniliformis</i>
Rat bite fever (Sodoku)	<i>Spirillum minus</i> (Wright stain/dark field)
Cat scratch fever	<i>Bartonella henselae</i> (<i>Afipia felis</i>)
Rhinosporidiosis	<i>Rhinosporidium seeberi</i> (epithelial cell tissue culture)
Lobomycosis	<i>Loboa lobo</i> (histological diagnosis)
Whipple's disease	<i>Tropheryma whippelii</i>
Erythema infectiosum (fifth disease)	Parvovirus B 19
Hemorrhagic fever	Hantavirus (pulmonary and renal [outside northeast Asia])

Table 2.1–2 Collection of specimens for bacteriological analysis^{a,b}

Specimen	Preparation	No., type, volume	Container	Helpful clinical information	Comments
Anaerobic cultures					
Actinomycosis	Decontaminate skin.	Aspirated pus	Anaerobic TM	History of “lumpy jaw”	Fistulating chronic infection often in the neck, jaw, and upper chest area.
Body fluids Secretions, pus	Decontaminate skin.	>1 ml ^c	Anaerobic TM	Foul-smelling discharge, abdominal surgery, abscess aspirate	Do not refrigerate; immediately transport to laboratory.
Respiratory tract	Transtracheal aspirate, pleural or empyema fluid only	>1 ml	Anaerobic TM	Foul-smelling sputum, history of aspiration	Do not submit sputum.
Tissues	Surgery	1 cm if possible	Anaerobic TM	Clinical impression	Do not add fluid. Larger specimens (>1 cm) tolerate short exposure to air.
Autopsy material					
Blood	Best collected before body is handled too much or opened. Decontaminate skin or sear surface of heart or other organ before inserting needle or cutting out tissue block.	10 ml of right-heart blood	Sterile tube, vacutainer with anticoagulant, lysis centrifugation tube (Isolator)	Clinical diagnosis, postmortem interval, autopsy impression, previous positive cultures, suspected infection	Autopsy cultures are often contaminated with bacteria from the water faucet and with enteric bacteria.
Tissue	Same as above	6 cm ³ (if possible) with one serosal or other surface; this large size is preferred because aseptic collection of smaller fragments is difficult.	Sterile container		A block of spleen tissue may be submitted in lieu of a blood culture. (<i>Note: Coccidiomycosis and tuberculosis are often discovered at autopsy only.</i> ^{d,e,f,g})
Blood					
Peripheral	Skin decontamination with 70% alcohol followed by povidone iodine	10 ml (adults and older child); 1–2 ml (infants); 3 samples per 24 h or 4–6 for FUO	Culture bottle for direct inoculation; vacutainer with SPS; Isolator tube; designated containers for automated instruments		Clinical diagnosis, antimicrobics and chemotherapy, immune status. Inoculate and incubate as soon as possible.
Bone marrow	Same as above	≥1 ml	Same as above		Direct smears should be made. Recommended by many authorities for diagnosis of systemic histoplasmosis and for other fungus infections, also for diagnosis of miliary TB, brucellosis.

Table 2.1–2 (continued)

Specimen	Preparation	No., type, volume	Container	Helpful clinical information	Comments
Body fluids (other than blood, urine, CSF)					
Bile	Surgery or decontaminate skin area before aspiration	Several ml (first ml from post-op drain site often contains contaminants)	Sterile container, TM	Consider viruses, fungi, and parasites for analysis.	Sample may contain gallstones, which should be examined; duodenal aspirates sometimes submitted for special tests.
Hematomas	Skin decontamination	Several ml	Sterile tube, vacutainer, TM	Suspected abscess	May clot; when in doubt, use anticoagulant (SPS).
Joint fluid	Same as above	Several ml	Same as above	History of trauma, previous surgery, or infection; consider GC chlamydia, etc., in analysis.	Often proteinaceous; may clot. Do not add acetic acid or other fluid which may precipitate protein; this makes cell evaluation impossible. Distilled sterile water is acceptable.
Pericardial fluid	Same as above	Several ml	Sterile jar, tube, TM	History of TB or previous surgery	Consider viral etiology, especially coxsackievirus.
Peritoneal fluid	Same as above	Several ml or more	Sterile jar, tube, TM	History of TB, surgery, or cancer	Same as for joint fluids; consider also GC; specimen may be peritoneal dialysis fluid.
Pleural fluid	Same as above	Several ml or more	Sterile tube, jar, TM	Same as above	
Breast milk	Skin decontamination of nipple	Several ml; first few may be contaminated.	Sterile tube, jar, TM	Suspected abscess	Often submitted for presence of <i>Staphylococcus aureus</i> and/or hemolytic streptococci.
Catheter tips					
Foley catheter		Not recommended			Foley catheters or tips should not be cultured except unused, as sterility check.
Vascular cannulae, venous access devices, arterial lines	Skin decontamination; careful aseptic removal mandatory	Segment near skin and tip end should be used; use sterile scissors to cut.	Sterile jar or tube	History of local infection, signs and symptoms	Peripheral blood cultures help with interpretation.
Central nervous system, brain biopsy	Surgery	See tissues (under "Autopsy material" above).	As for aerobic and anaerobic cultures	Suspected abscess, cryptococcosis, toxoplasmosis, etc.	Needs coordination with Pathology. Include viruses in diagnostic analysis.

(continued)

Table 2.1–2 Collection of specimens for bacteriological analysis^{a,b} (continued)

Specimen	Preparation	No., type, volume	Container	Helpful clinical information	Comments
CSF	Skin decontamination	Several ml if possible	Sterile, clean, screw-cap tube	Tentative clinical diagnosis and/or suspicion	Since culture yields more from a larger volume, an alternate method is to aseptically pool all tubes collected (after cell count). The supernatant goes to Chemistry and Serology, with aliquot reserved for antigen detection when indicated. Obtain smears from precipitate.
Eye					
Internal	Surgery	Volume of specimen often sub-optimal	Sterile tube	History of trauma or postoperative infection	Since specimen is usually small and obtained under great difficulty, speed in transport and care in handling are very important.
External	Cleanse skin around eye with mild antiseptic. Gently remove makeup and ointment with sterile cotton and saline.	For most cases, moistened swabs are used. For diagnosis of viral or chlamydial infections and for cytology, conjunctival and/or corneal scrapings are necessary. Make two slides per lesion.	Moist sterile swabs in sterile tubes with a small amount of nutrient broth; alcohol-cleaned glass slides for scrapings; sterile tube for scrapings to be cultured (AFB, fungi)	History and suspected agent, e.g., bacterial, fungal, AFB, inclusion bodies (viral or chlamydial), GC only, allergic	Handle carefully; inoculate at bedside (or office) as culture for <i>Acanthamoeba</i> on special media. Transport to laboratory immediately. Often only a few microorganisms present. Scraping should be done by ophthalmologist. Consult with physician about use of terms or the handling of the specimen (CD-RIGHT EYE, OS-LEFT EYE). Giemsa and Gram stains are frequently requested.
Genital tract—female					
Amniotic fluid		Uncontaminated fluid	Sterile tube	Premature rupture of membranes >24 h	Treat as any other normally sterile body fluid; may contain <i>Neisseria gonorrhoeae</i> .
Cervix (endocervix)	Wipe cervix clean of vaginal secretion and mucus. Use speculum and no lubricant.	Uncontaminated endocervical secretions; take two swabs.	Sterile container with TM; appropriate collection containers for demonstration of specific organisms, such as <i>N. gonorrhoeae</i> , <i>Chlamydia</i> , HSV, etc.	Venereal disease, postpartum infection	Viability of <i>N. gonorrhoeae</i> held in Amies or modified Stuart TM decreases substantially after several h.
Cul de sac (culdocentesis)	Surgical procedure	Fluid, secretions	See “Anaerobic cultures,” STD diagnosis (see Table 2.1–1).	Venereal disease; pelvic inflammatory disease	Pelvic inflammatory disease

Table 2.1–2 (continued)

Specimen	Preparation	No., type, volume	Container	Helpful clinical information	Comments
Endometrium	As for cervix	Curettings or aspiration	Sterile container, anaerobic TM	Postpartum fever, venereal disease	Likelihood of external contamination is high for cultures obtained through the vagina.
Intrauterine device	Surgical	Entire device plus secretion, pus	Sterile container	History of bleeding	Unusual organisms may be isolated, e.g., <i>Actinomyces</i> , <i>Torulopsis</i> , and other yeasts.
Lymph nodes (inguinal)	Skin decontamination	Biopsy or needle aspirate	Sterile container	History of venereal disease	May require sending to reference laboratory.
Products of conception (fetal tissue, placenta, membranes, lochia)	Surgical	Tissue or aspirates	Sterile container		Occasionally, this type of specimen is expelled into toilet and is grossly contaminated.
Urethra	Wipe clean with sterile gauze or swab.	Swab with urethral secretion or free discharge	TM	History of discharge	Discharge may be stimulated by gently stripping and massaging the urethra against pubic symphysis through the vagina.
Tubes, ovaries	Surgical	Tissue, aspirates, or swabs	Sterile container; see "Anaerobic cultures."	Salpingo-oophoritis	Consider venereal, fungal, anaerobic, and AFB infection.
Vagina	Use of speculum without lubricant	Aspirate or swab, Gram stains, and wet mounts	Swab with TM, Transgrow	History of discharge	Ulcerations should be checked for syphilis, soft chancre, or genital herpes. Yeast common. For GC, cervical specimen is preferred. Wet mount is for yeast and <i>Trichomonas</i> , "clue cells," <i>Gardnerella</i> , and organisms of vaginosis.
Vaginal cuff		Aspirate of abscess	See "Anaerobic cultures."	Postsurgery	
Vulva (including labia, Bartholin glands)	Do not use alcohol for mucous membranes. Skin prep for regular skin sites.	Swab or aspirate (Bartholin gland abscess)	Swab with TM. See "Anaerobic cultures" for aspirate.	Discharge	Same as above
Lesion (dark field, for <i>Treponema pallidum</i>)	1- to 2-h soaking with sterile saline on gauze	Several slide preparations or aspirate fluid into capillary tube	Slide and coverslip or capillary tube		Characteristic motility is seen only on warm material. Seal coverslip or capillary tube with lanolin or petrolatum.
Genital tract—male					
Lymph nodes		Same as for female genital tract			
Penile lesion	Skin prep for regular skin sites.			Duration of lesion, pain, discomfort	Special culture/microscopic techniques are required for chancroid and granuloma inguinale.

(continued)

Table 2.1–2 Collection of specimens for bacteriological analysis^{a,b} (continued)

Specimen	Preparation	No., type, volume	Container	Helpful clinical information	Comments
Culture		Swab	Swab with TM if pus		
Dark field (for <i>T. pallidum</i>)			Same as for female genital tract		
Prostatic fluid		Secretion for smear and culture	Sterile tube or swab with TM	History of chronic UTI	Not recommended for GC cultures but helpful in some chronic UTI, <i>Trichomonas</i> spp.
Urethra		Same as for female	Secretion, slide, and/or swab	History and duration of painful discharge	In males, diagnosis of gonorrhea can often be made by microscopic examination of a Gram-stained smear.
Pus/abscess			See “Anaerobic cultures” and “Skin (deep suppurative lesion).”		May be labeled “incision and drainage” (I & D)
Intestinal					
Duodenal contents	Through tube	Several ml	Sterile tube	Travel, food	Examine for bacterial overgrowth, <i>Salmonella enterica</i> , serovar, Typhi and parasites.
Feces		At 1 g, 3 consecutive specimens	Stool preservative, Culturette for bacteria, special transport for parasites and ova	Travel, food suspected etiology	See section 9 (Parasitology) for further information.
Rectal swab		3 consecutive specimens	Swab with TM; GN broth	Same as above	Not useful for the detection of carriers
Gastric aspirate, neonate		Enough for smear and culture	Sterile container	History of ruptured membranes	May visualize and isolate causative agent of septicemia before blood cultures become positive
Respiratory tract					
Throat/pharynx		Swab	Swab with TM; commercial kits for <i>Streptococcus</i>	Agent suspected (e.g., group A streptococci, <i>N. gonorrhoeae</i>)	Do not touch oral mucosa or tongue with swab.
Epiglottis	Swab		TM	Suspected bacteria include <i>Haemophilus influenzae</i>	Do not swab throat in cases of acute epiglottitis unless prepared for tracheostomy.
Nasal sinuses			See “Anaerobic cultures (Body fluids).”		
Nasopharynx		Swab	Thin wire or flexible swab with TM	Agent suspected (e.g., <i>Bordetella pertussis</i>)	Transport to laboratory immediately or inoculate at bedside. Prepare smear for DFA.
Nose			Swab with TM	Mainly for staphylococcal carriers	
Oral cavity					
Mucosal surface of gums or teeth	Rinse mouth.	Scraping, swab	Swab, tongue depressor, or slide in sterile container	Duration, agent suspected	Culture for yeast, smear for yeast or organisms of Vincent’s angina.

Table 2.1–2 (continued)

Specimen	Preparation	No., type, volume	Container	Helpful clinical information	Comments
Dental abscess, root abscess	Rinse mouth; prep with dry sterile gauze.	Exudate	See “Anaerobic cultures.”		Predominant pathogens are anaerobes, including <i>Actinomyces</i> and various streptococci and gram-negative rods.
Bronchoscopy		Brushings, trans-bronchial biopsies, bronchial secretions	Sterile container	Agent(s) suspected on clinical impression	Gram stains may help direct culture effort. Patient’s history important. May require culture for mycobacteria, legionellae in addition to DFA, stains for <i>Pneumocystis</i> , culture for fungi, viruses, and parasites.
Expectorated sputum	May require ultrasonic nebulization, hydration, physiotherapy, or postural drainage	Sputum, not saliva	Sterile container	Pneumonia	Culture processing must be preceded by Gram stain demonstrating >25 PMNs and <10 epithelial cells/lpf. See section 7 on acid-fast organisms if submitted for mycobacteria. May be refrigerated overnight.
Tracheal aspirate		Sputum	Sterile container	Pneumonia	Cellular composition may be misleading due to inflammatory reaction caused by endotracheal tube. May be refrigerated.
Transtracheal aspirate (infra-laryngeal aspirate)	Skin is cleansed, anesthetized, and decontaminated.		Sterile container. See “Anaerobic cultures”	Pneumonia, aspiration, TB	Process immediately. See “Bronchoscopy.”
Skin					
Superficial wound	Clean wound surface with 70% alcohol.	Pus, biopsy	Aspirate or swab with transport medium	Animal bite or trauma, duration, travel	
Extensive burns, ^a decubitus ulcer	Clean wound surface with 70% alcohol.	For quantitative culture, 3- to 4-mm dermal punch	Sterile container		Consider quantitative culture. See section 3. Decubitus ulcers should not be cultured casually; appropriate debridement and punch biopsy are required for quantitative evaluation of decubitus.
Deep suppurative lesion, closed abscess	Clean and decontaminate.	Pus, >1 ml if possible	Syringe or anaerobic container	Duration, location	See “Anaerobic cultures.”
Fistula, sinus tract	Clean surface; decontaminate.	Pus, >1 ml if possible	Syringe or swab with TM	Duration, location	Examine stained smear for guidance on isolation media.
Rash	Clean surface with 70% alcohol.	Pus, fluid	Syringe		

(continued)

Table 2.1–2 Collection of specimens for bacteriological analysis^{a,b} (continued)

Specimen	Preparation	No., type, volume	Container	Helpful clinical information	Comments
Tissue, surgical, or biopsy	Surgical	5 to 10 mm ³ or as-pirate	Sterile container with TM		See “Anaerobic cultures.” Do not discard leftover tissue. Freeze in sterile broth until culture and pathology are completed.

^a NOTE: Standard precautions must be observed at all times. When the “Container” column indicates the specimen may be submitted in a syringe, the caveats of standard precautions must be followed, i.e., the syringe must be capped with a sterile closure; syringes with needles in place are unacceptable. Many specimens may contain important yeasts, moulds, or viruses. Follow the instructions of the director of the laboratory in concert with Infectious Disease Advisory Committee which designate such examinations as routine procedures with select specimens or follow the request of the physician of record based on the patient’s history and clinical impression. Perform smears whenever possible.

^b Abbreviations: TM, transport medium; TB, tuberculosis; SPS, sodium polyanethole sulfonate; GC, gonorrhea; AFB, acid-fast bacillus; STD, sexually transmitted disease; UTI, urinary tract infection; GN, gram negative; DFA, direct fluorescent-antibody assay; Fuo, fever of unknown origin; HSV, herpes simplex virus; lpf, low-power field.

^c If copious amounts are available, fill sterile tube.

^d Preparation of smears for Gram (and other) stains at time of autopsy is helpful.

^e Culture for viruses based on clinical impression; inoculate virus transport vial if intended for reference laboratory.

^f Culture for yeasts and moulds if suspected from clinical history or premortem findings.

^g Cultures for mycobacteria and fungus require special attention. See the appropriate sections.

Table 2.1–3 Laboratory approaches to suspected fungal infections

Disease	Specimen type	Culture medium ^a
Superficial mycoses		
Pityriasis versicolor	Scrapings	Not necessary
Tinea nigra	Skin scrapings	SAB-SPEC
Piedra	Cut hair	SAB
Cutaneous mycoses		
Tinea capitis	Epilated hair	SAB-SPEC, DTM
Tinea corporis	Skin scrapings	SAB-SPEC
Onychomycosis	Nail scrapings	SAB-SPEC C
Candidiasis	Skin, nail scrapings, mucocutaneous scrapings, vaginal swab	SAB-SPEC
Subcutaneous mycoses		
Chromoblastomycoses	Scrapings, crust exudate from lesions	SAB-SPEC
Mycetoma	Pus from draining sinuses, aspirated fluids, biopsy	SAB, BHI, BHIA with blood
Phaeohyphomycosis	Sputum, BW, ^b e.g., body fluids, pus, corneal scrapings	SAB-SPEC C
Sporotrichosis	Pus from lesions, aspirated fluids	SAB-SPEC
Systemic mycoses		
Yeastlike fungi		
Candidiasis	Sputum, BW, biopsy, CSF, urine, stool, blood	SAB-SPEC C, BHIA, blood culture (isolation)
Cryptococcosis	CSF, sputum, blood, bone marrow, urine, scrapings from skin lesions, pus from abscesses and sinus tracts	SAB-SPEC C, birdseed agar
Geotrichosis	Sputum, BW, stools	SAB-SPEC C
Dimorphic fungi		
Blastomycosis	Scrapings from edge of lesions Pus from abscesses and sinus tracts, urine, sputum, BW	SAB-SPEC BHIA, yeast extract phosphate medium
Paracoccidioidomycosis	Scrapings from edges of lesions, mucous membranes, biopsied lymph nodes, sputum, BW	SAB-SPEC, BHIA yeast extract, phosphate agar
Coccidioidomycosis	Sputum, BW, CSF, urine scrapings from lesions, pus from sinuses, abscesses	SAB-SPEC, yeast extract, phosphate agar
Histoplasmosis	Blood, bone marrow, sputum, BW, CSF, pus from sinus tract or ulcer, scrapings from lesion	Yeast extract, phosphate agar, blood agar
Miscellaneous mycoses		
Aspergillosis	Sputum, BW	SAB-SPEC C
Zygomycosis	Sputum, BW, biopsy	SAB-SPEC C
Hyalohyphomycosis	Sputum, BW, nail scrapings, blood, body fluids, pus, wound scrapings	SAB-SPEC C
External otitis	Epithelial scales and detritus	SAB-SPEC C

^a SAB, Sabouraud's agar; SAB-SPEC, Sabouraud's agar with chloramphenicol and cycloheximide; SAB-SPEC C, Sabouraud's agar with chloramphenicol only; DTM, dermatophyte test medium (presumptive); BHIA, BHI agar; blood culture, any approach extant in laboratory is acceptable—however, lysis-centrifugation (Isolator-Wampole) is preferred. All media required are available commercially (see Appendix A at the end of this handbook). For selected commercial suppliers, see the mycology section.

^b BW, bronchial wash.

Table 2.1–4 Collection of specimens to detect parasites^a

Site	Specimen options	Collection method
Blood	Smears of whole blood	A minimum of four each (separate slides) of thick and thin blood films (first choice)
	Anticoagulated blood ^{b,c}	Anticoagulant (second choice) EDTA vacutainer tube (purple top)
Bone marrow	Aspirate ^{b,c}	Sterile tube
Central nervous system	Spinal fluid ^{b,c}	Sterile tube
Cutaneous	Aspirates from below surface	Sterile tube plus air-dried smears
Ulcers	Biopsy	Sterile tube, nonsterile to Histopathology (formalin acceptable)
Eye	Biopsy	Sterile tube (in saline), nonsterile tube to Histopathology
	Scrapings	Sterile tube (in saline)
	Contact lens	Sterile tube (in saline)
	Lens solution	Sterile tube
Intestinal tract	Feces ^d	PVA (polyvinyl alcohol or nonmercury base), 5 or 10% buffered formalin. SAF (sodium acetate, acetic acid, formalin), single-vial collection system (zinc-based, proprietary formulas)
	Sigmoidoscopy	Fresh, PVA, or Schaudinn's smears
	Duodenal contents	Entero-test or aspirates
	Anal impression smear	Cellulose tape (pinworm examination)
	Adult worm/worm segments	Saline, 70% alcohol
Liver, spleen	Aspirates	Sterile tube, collected in four separate aliquots (liver)
	Biopsy	Sterile tube
Lung	Sputum	True sputum (not saliva)
	Induced sputum	No preservative (10% formalin if time delay)
	BAL	Sterile tube (container)
	Transbronchial aspirate ^{b,c}	Air-dried smears
	Tracheobronchial aspirate ^{b,c}	Same as above
	Brush biopsy ^{b,c}	Same as above
	Open lung biopsy ^{b,c}	Same as above
	Aspirate	Sterile
Muscle	Biopsy	Fresh, squash preparation, nonsterile, to Histopathology (formalin acceptable)
Skin	Scrapings	Aseptic, smear or vial
	Skin snip	No preservative
	Biopsy	Sterile (in saline)
Urogenital system	Vaginal discharge	Saline swab, transport swab (no charcoal), culture medium, plastic envelope culture, air-dried smear for FA
	Urethral discharge	Same as above
	Prostatic secretions	Same as above
	Urine	Single unpreserved specimen, 24-h unpreserved specimen, early morning

^a Abbreviations: FA, fluorescent antibody; BAL, bronchoalveolar lavage.

^b Immediate delivery to laboratory desirable; if request is for organisms other than *Plasmodium* spp., request it be indicated on label and on requisition for parasites such as filariae (2,4).

^c Immediate delivery to laboratory desirable; requires prompt processing.

^d Examinations of fresh stool specimens require special attention. Liquid stool specimens for protozoan trophozoites must be examined within 30 min of passage (not 30 min after arriving at laboratory); soft stools should be examined within 1 h of being passed, although protozoan cysts survive and can be detected in firm stools within 24 h of being passed. The preserved stool specimens are suitable for examination for *Cryptosporidium* spp., *Isospora* spp., and related coccidia. NOTE: Stool examinations for ova, parasites, and enteropathogenic bacteria should not be requested if patients have been hospitalized for 3 days or more.

Table 2.1–5 Commercially available transport media^a

Medium	Purpose
Stuart's medium (9)	Most aerobic and facultatively anaerobic bacteria
Amies medium (1)	Same as above
Amies medium with charcoal	Use for transport of gonococci.
Carey-Blair medium (3)	Transport of pathogenic stool bacteria, e.g., <i>Salmonella</i> , <i>Shigella</i> , <i>Vibrio</i> , <i>Campylobacter</i> , <i>Yersinia</i> spp.
Buffered glycerol	Transport of potentially pathogenic stool bacteria
Anaerobic transport medium	Numerous variations are available; objective is to preserve appropriate atmosphere. Use of swabs should be discouraged; aspirates or tissue in proper transport devices is preferable.
Synthetic mesh	Recently made available on plastic shaft in a protective tube; mesh entraps organisms and preserves them without buffer or medium; can be used for recovery of aerobic and most anaerobic organisms. Suitable for smear preparation and/or antigen detection when two shafts are provided.
PVA (5)	For transport of intestinal parasites; suitable for preparation of slides to be stained; specimens may be concentrated.
SAF (5)	Sodium acetate-acetic acid-formaldehyde as PVA substitute
Buffered formalins (4)	Especially for ova and larvae and for concentrations
Viral transport	Contains salt solutions to stabilize viral agents

^a Various commercial suppliers have these transport vials, tubes, and devices available, often packaged with polyester tips and plastic shanks (to avoid toxic effects of cotton and wood). Consult section 9 for names of suppliers. PVA, polyvinyl alcohol.

Table 2.1–6 Rejection criteria for microbiological specimens^{a,b}

Criterion ^c	Procedure
Clerical errors	
Discrepancy between patient identification on requisition and specimen container label	Notify physician or nurse in charge. Request new specimen or have physician or nurse correct error in person in the laboratory.
No identification on container	Notify physician or charge nurse. Proper label must be brought to laboratory and specimen identity verified.
Specimen source or type not noted	Call physician or charge nurse to ascertain missing information.
Test not indicated on requisition	Call physician or charge nurse to ascertain missing information.
General microbiology	
Specimen received in fixative (formalin); exception, stool for parasites and ova	Notify physician or charge nurse and request new specimen; indicate “received in fixative” on requisition and return.
Foley catheter tip	Notify physician or charge nurse that specimen is not suitable for microbiological analysis. Note rejection on requisition and return.
Containers	
Unpreserved urine held in refrigerator for >24 h	Notify physician or nurse in charge and request new specimen. If contact insists specimen be processed, refer to supervisory personnel. Return requisition with appropriate comment.
Improper or nonsterile container	
Leaking container	
Dry swab	Notify physician or charge nurse and request new specimen, properly submitted in appropriate transport device. If physician insists dry swab be cultured, note on laboratory record and report with caveat: “microorganisms recovered may not reflect actual microbiota.”
More than one specimen of urine, stool, sputum, wound, or routine throat specimens submitted on the same day from the same source	Notify physician or charge nurse that as stated in laboratory manual only one specimen will be processed per day.
Only one swab submitted with multiple requests for various organisms (bacteria, AFB, fungi, virus, ureoplasmas, etc.)	Notify physician or charge nurse and request additional material. If additional material cannot be procured, ask physician to prioritize.
Anaerobes	
Specimen for anaerobes not received in appropriate container	Notify physician or charge nurse and request properly handled specimen. If physician insists specimen be processed, refer to supervisory personnel or comment in laboratory record and in report form that inappropriate transport may have influenced recovery of significant anaerobic bacteria.
Anaerobic cultures requested on autopsy material; bronch wash; decubitus ulcer material (not punch biopsy of tissue beneath eschar); drain; drain site; environment; exudate; feces; gastric washing (other than newborn); mid-stream or catheterized urine; mouth, nose, or prostatic secretions; sputum material on swabs from ileostomy or colostomy; fistula or intestinal contents; throat or vaginal secretions	Inform physician or charge nurse that, as detailed in laboratory manual, these specimens are not cultured for anaerobic bacteria, since these anatomic sites harbor anaerobes normally and usually. If physician insists, refer him/her to supervisory personnel.
Aerobic bacteriology	
Gram stain for <i>Neisseria gonorrhoeae</i> on specimens from cervix, vagina, and anal crypts	Notify physician or charge nurse that these smears are not examined for GC, since these anatomic loci may harbor nongonococcal neisseriae.
Specimens for GC and/or <i>Chlamydia</i> culture received in Gen Probe transport medium	Notify physician or charge nurse that the specimens are in a fixative that kills bacteria; only molecular-probe results may be offered with this fixed specimen.
Respiratory culture requested on throat specimens of patients older than 10 yr	Notify physician or charge nurse that a screening culture for group A streptococci only will be performed. Exceptions are transplant, cystic fibrosis, and head and neck clinic patients.
Sputum specimen with <25 WBC, >10 epithelial cells/lpf	Inform physician or charge nurse that specimen is mostly saliva and is not appropriate for culture. Request a repeat specimen.
Sputum with or without WBC and numerous and varying tinctorial bacterial morphotypes for <i>Legionella</i> DFA	Notify physician or charge nurse that specimen is unsuitable for DFA.

Table 2.1–6 (continued)

Criterion ^c	Procedure
Mycobacteriology/mycology	
24-h collection of urine or sputum for AFB or fungus culture	Inform physician or nurse that according to laboratory manual, three separate first morning specimens of sputum or of urine are the best samples for analysis; reject 24-h specimens.
Sputum swabs for AFB or fungi	Notify physician or charge nurse that specimen is inadequate in quantity for the isolation of these microorganisms. Request properly collected specimens.
Parasitology	
Ova and parasites for examination received in only formalin or only PVA	Inform physician or charge nurse that stool in both transport media required for adequate parasitological analysis; request repeat with both transport media used.
Stool for <i>Cryptosporidium</i> and/or <i>Isoospora</i> spp. received in PVA only	Notify physician or charge nurse that both PVA and formalin are required for accurate performance of test; request repeat submission with both transport media.
Excess barium or oil noted in stool submitted for parasitological examination	Notify physician or charge nurse that the barium and/or oil will obscure the examination and that a specimen should be resubmitted in 10 days.
Virology	
Stool specimens received in preservative for viral culture for detection of <i>C. difficile</i> toxins, rotavirus, or adenovirus 40/41	Notify physician or charge nurse to request new proper specimen; record on requisition “specimen unsatisfactory; received in preservative.”
Clotted blood for viral culture (serum acceptable when enterovirus suspected)	Inform physician or charge nurse that blood has clotted; request new specimen and admonish to mix blood well to prevent clotting.

^a Abbreviations: GC, gonococcus; AFB, acid-fast bacillus; lpf, low-power field; DFA, direct fluorescent antibody assay; PVA, polyvinyl alcohol.

^b A record for all rejections or discrepancies must be maintained (book, card file, or computer). Note patient demographic information; physician of record; date and time specimen received; type and source of specimen; examination requested; reason for rejection or discrepancy noted; person contacted by phone; date, time, and manner of contact (phone, computer, or FAX); and final disposition or resolution. Records should be reviewed by supervisory personnel at regular intervals.

^c Specimens unsuitable for routine anaerobic cultures: throat swabs; nasopharyngeal swabs; gingival and other internal mouth surface swabs; expectorated sputum; sputum obtained by nasotracheal or orotracheal suction; bronchial washings or other specimens obtained with bronchoscopy unless procured with a protected double-lumen catheter or by properly executed bronchoalveolar lavage; gastric and small-bowel contents; large-bowel contents except for *Clostridium difficile*, *Clostridium botulinum*, *Anaerobiospirillum succiniciproducens*, and other specific causative agents; ileostomy and colostomy effluents; feces, except for large-bowel contents (as directed above); voided or catheterized urine; vaginal or cervical swabs; female genital tract cultures collected via vagina, except for suction curettings or other specimens collected with a double-lumen catheter; surface swabs from decubitus ulcers, perirectal abscesses, foot ulcers, exposed wounds, eschars, or pilonidal and other sinus tracts; any material adjacent to a mucous membrane that has not been adequately decontaminated.

Table 2.1–7 Procedure for processing clinical specimens in microbiology^a

-
- I. Evaluation of the specimen for adequacy
 - A. The specimen must be properly labeled.
 - B. The transmittal must be submitted with the specimen, and the information on the transmittal must match the information on the specimen label.
 - C. The specimen must be submitted in the proper transport container.
 - D. The specimen volume must be adequate to perform all tests requested.
 - E. The specimen sent must be appropriate for the test ordered.

NOTE: If any of these requirements are not met, refer to list of rejection criteria in Table 2.1–6.
 - II. Medium selection and labeling
 - A. Select appropriate media for the tests ordered.
 - B. Examine all media for expiration date and contamination before the media are inoculated.
 - C. Individually label all media with an accession number and date. Do not obscure the names and expiration dates of the media.
 - D. All media made in Microbiology must be properly labeled with the name of the medium and the expiration date.
 - III. Order of inoculation media. Inoculate the least selective medium first. This prevents any carryover of an inhibitory substance to another medium. Arrange labeled plates in order from least to most selective.
 - A. Routine aerobic culture
 - 1. BAP
 - 2. CHOC
 - 3. MS
 - 4. MAC
 - 5. SEA
 - 6. Nutrient broth
 - B. Genital culture
 - 1. BAP
 - 2. CHOC
 - 3. MS
 - 4. TM
 - 5. MAC or EMB
 - C. Stool culture
 - 1. PEA
 - 2. CAMPY
 - 3. MAC or EMB
 - 4. HE
 - 5. GN broth
 - D. Fungal culture
 - 1. SAB-SEL
 - 2. BHI blood agar with gentamicin and chloramphenicol
 - 3. SAB
 - E. Anaerobe culture
 - 1. BRU
 - 2. PEA
 - 3. BBE/LKV (optional)
 - 4. Chopped-meat broth or THIO
 - F. Urine culture^b
 - 1. BAP
 - 2. MAC or EMB
 - 3. SEA
 - IV. Procedure for streaking plates for primary isolation
 - A. Sterilize the inoculating loop in the incinerator for 5 to 10 s. Allow the loop to cool thoroughly before streaking medium.
 - B. Pass the cooled loop back and forth through the inoculum in the first quadrant several times.
 - C. Do not flame the loop between the quadrants unless necessary.
 - D. Turn the plate a quarter turn, and pass the loop through the edge of the first quadrant approximately four times while streaking into the second quadrant. Continue streaking in the second quadrant without going back to the first quadrant, approximately four times.
-

Table 2.1-7 (continued)

-
- E. Turn the plate another quarter turn, and pass the loop through the edge of the second quadrant approximately four times while streaking into the third quadrant. Continue streaking in the third quadrant without going back into the second quadrant, approximately four times.
 - F. Flame the loop between plates to prevent carrying over a possible contaminant from the previous plate.
 - G. Continue streaking the rest of the culture media in the same manner.
 - H. Inoculate suitable nutrient broth with 1 to 2 loopfuls of specimen or swab.
-

^a Abbreviations: MS, mitis salivarius agar; SEA, selective enterococcus agar; TM, transport medium; PEA, phenyl ethanol agar; CAMPY, campylobacter agar; HE, Hektoen enteric agar; GN, gram-negative; SAB-SEL, Sabouraud's selective agar; BRU, brucella agar; BBE/LKV, bacteroides bile esculin agar/laked blood-kanamycin-vancomycin agar.

^b Special instructions for processing urine specimens:

1. Do not centrifuge urine before culturing.
2. Mix urine well before culturing.
3. Use 0.001-ml calibrated loop for inoculating media for routine urine.
4. Transfer 1 loopful of urine to BAP.
5. Pull the loop down the surface of the agar to form a single streak in the center of the first quadrant.
6. Spread the inoculum over the first quadrant by streaking the loop back and forth.
7. Streak for isolation in the other quadrants.
8. Transfer 1 loopful of urine to MAC or EMB plate. Repeat procedure using SEA or colistin-nalidixic acid (CNA) agar.
9. Pull loop down surface of agar to form a single streak that crosses the center of the plate.
10. Cross streak through the initial inoculum streak by moving the loop back and forth at perpendicular angles to initial streak.
11. To inoculate media for special-collection urines, i.e., suprapubic tap, high and low counts, or nephrostomy, inoculate two sets of plates:
 - a. 0.001 loop: BAP and MAC (EMB) and SEA (CNA) agars.
 - b. 0.01 loop: BAP and MAC (EMB) and SEA (CNA) agars.
 - c. Use the same inoculation procedure outlined above for both the 0.001 loop and the 0.01 loop.
12. If a urine Gram stain is ordered, use a ringed microscope slide.

NOTE: Biplates, commercially available, consisting of MAC and CNA or MAC and SEA may be used instead of single-agar plates of each.

NOTE: bioMérieux-Vitek AMS has urine cards that can be substituted for culture analysis.

Table 2.1–8 Panic values in microbiology^a

Organisms seen in CSF
Organisms seen in joint fluids
Positive cryptococcal antigen detection
Positive CSF antigen detection for pneumococci, <i>Streptococcus agalactiae</i> , <i>Neisseria meningitidis</i> , and <i>Haemophilus influenzae</i> type b (now rare)
Positive AFB smear
Positive blood cultures (not contaminated)
Positive CSF cultures
Positive wound cultures
Isolation of <i>Streptococcus pyogenes</i>
Isolation of <i>Mycobacterium tuberculosis</i>
Isolation of <i>Salmonella</i> spp.
Isolation of <i>Shigella</i> spp.
Isolation of <i>Escherichia coli</i> O157:H7
Isolation of pathogenic neisseriae
Isolation of the reportable etiological agents of any of the following:
Lymphogranuloma venereum
Malaria
Meningitis
Aseptic
<i>Haemophilus</i> spp.
Meningococcal
Other (specify type)
Meningococemia
Mumps
Pertussis
Plague
Poliomyelitis
Psittacosis
Rabies
Rocky Mountain spotted fever
Rubella
Salmonellosis
Shigellosis
Syphilis (specify stage)
Tetanus
Toxic shock syndrome
Trichinosis
Tuberculosis
Tularemia
Typhoid
Typhus
Varicella
Yellow fever
Yersiniosis
Examples of communicable diseases (requiring immediate notification of referring physician and, for some, governmental agencies)
Amebiasis
Anthrax
Babesiosis
Botulism
Brucellosis
Campylobacteriosis
Chancroid
Cholera
Cryptosporidiosis
Diphtheria
Encephalitis
<i>Escherichia coli</i> O157:H7 infections
Giardiasis
Gonococcal infection
Granuloma inguinale
Hemolytic uremic syndrome
<i>Haemophilus influenzae</i> infection (invasive disease)
Hepatitis (A, B, C)
Histoplasmosis
Legionellosis
Leprosy
Leptospirosis
Listeriosis
Lyme disease

^a Panic values in microbiology encompass the detection of clinically important microorganisms and viruses that require notification, immediate action by the physician of record or his/her designate, action by hospital personnel and visitors, and notification of governmental agencies (this may differ from state to state). AFB, acid-fast bacterium.

Table 2.1–9 Alert request

Request all physicians to notify the Microbiology Laboratory if they suspect the following etiological agents in specimens to be sent to the laboratory:	
<i>Bacillus anthracis</i>	<i>Yersinia pestis</i>
<i>Bordetella pertussis</i>	<i>Blastomyces dermatitidis</i>
<i>Brucella</i> spp.	<i>Coccidioides immitis</i>
<i>Francisella tularensis</i>	<i>Histoplasma capsulatum</i>
<i>Pseudomonas pseudomallei</i>	<i>Paracoccidioides brasiliensis</i>

Table 2.1–10 Serodiagnostic tests^a

Test name	Method(s) ^b	Normal value(s)	Specimen requirement(s) ^c
Adenovirus antibody (IgG)	IFA	<1:40	Blood (5 ml)
Amoeba antibody	IHA	<1:64	Blood (5 ml)
Amoeba antibody panel	IHA, ID	<1:64 negative	Blood (5 ml)
Antideoxyribonuclease B	EN	<1:170	Blood (5 ml)
Antihyaluronidase titer	EN	<1:32	Blood (5 ml)
Antistreptolysin-O titer	LPA	<200 Todd units	Blood (5 ml)
Arbovirus antibody panel (western equine encephalitis, eastern equine encephalitis, St. Louis encephalitis, California encephalitis)	IFA	<1:16 (IgG) <1:10 (IgM)	Blood (5 ml) CSF (0.5 ml)
<i>Aspergillus</i> antibody (<i>A. fumigatus</i> , <i>A. flavus</i> , <i>A. niger</i>)	ID	Negative	Blood (5 ml)
Bacterial antigen	LPA	Negative	CSF (2 ml)
Detection panel (group B streptococci, <i>Streptococcus pneumoniae</i> , <i>Neisseria meningitidis</i> , <i>Haemophilus influenzae</i> type b)			
<i>Blastomyces</i> antibody	CF	<1:8 (serum) <1:2 (CSF)	Blood (5 ml)
<i>Blastomyces</i> antibody panel	ID CF	Negative <1:8	Blood (5 ml)
<i>Bordetella pertussis</i> antibody	MAT	<1:2	Blood (5 ml)
<i>Borrelia</i> (relapsing fever)	IFA	<1:16	Blood (5 ml)
<i>Borrelia burgdorferi</i> antibody	(see "Lyme disease antibody")		
<i>Brucella</i> antibody	SA	<1:20	Blood (5 ml)
C-reactive protein	LPA	<6 mg/liter	Blood (5 ml)
California encephalitis antibody	IFA	<1:16 (IgG) <1:10 (IgM)	Blood (5 ml) CSF (0.5 ml)
<i>Candida</i> antibody	ID	Negative	Blood (5 ml)
<i>Candida</i> antigen	LPA	Negative	Blood (5 ml)
Chagas' disease antibody panel (<i>Trypanosoma cruzi</i>)	IFA	<1:16	Blood (5 ml)
<i>Chlamydia</i> antibody (<i>C. psittici</i> , <i>C. pneumoniae</i> , <i>C. trachomatis</i>)	IFA	<1:64	Blood (5 ml)
<i>Coccidioides</i> antibody	CF	<1:2	Blood (5 ml) or CSF (0.5 ml)
<i>Coccidioides</i> antibody panel			
Latex agglutination	LPA (IDTP)	Negative	CSF (0.5 ml)
Immunodiffusion	IDCF	Negative	
Complement fixation	CF	<1:2	
Cold agglutinin titer	TA	<1:4	Blood (5 ml) (Do not refrigerate)
Coxsackie A antibody panel (includes types 7, 9, 10, 21)	CF	<1:8 (serum) <1:2 (CSF)	Blood (5 ml) CSF (0.5 ml)
Coxsackie B antibody panel (includes types 1 through 6)	CF	<1:8 (serum) <1:2 (CSF)	Blood (5 ml) CSF (0.5 ml)
<i>Cryptococcus</i> antigen	LPA	Negative	Blood (5 ml) or CSF (1 ml)
Cysticercosis antibody	EIA	<1:10 (serum) <1:2 (CSF)	Blood (5 ml) CSF (1 ml)
CMV antibody (IgG)	IFA	<1:10	Blood (5 ml)
CMV antibody panel (includes IgG and IgM)	IFA	<1:10 (IgG)	Blood (7 ml)
Diphtheria antitoxin antibody	EIA	>0.01 IU/ml	Blood (5 ml)
Eastern equine encephalitis antibody	IFA	<1:16 (IgG) <1:10 (IgM)	Blood (5 ml) or CSF (0.5 ml)
<i>Echinococcus</i> antibody	IHA	<1:10	Blood (5 ml)
Echovirus antibody panel (includes types 4, 9, 11, 16)	CF	<1:8 (serum) <1:2 (CSF)	Blood (7 ml) CSF (0.5 ml)

(continued)

Table 2.1–10 Serodiagnostic tests^a (continued)

Test name	Method(s) ^b	Normal value(s)	Specimen requirement(s) ^c
Epstein-Barr virus antibody panel			
Viral capsid IgG	IFA	>1:10	Blood (10 ml)
Viral capsid IgM	IFA	<1:10	
EBNA IgG	ACIF	>1:2	
Early antigen IgG	IFA	<1:40	
Febrile agglutinin panel (<i>Salmonella enterica</i> serovar, Typhi, <i>S. enterica</i> , serovar Paratyphi A/B, <i>Brucella</i> , <i>Proteus</i> (OX19))	SA, TA	<1:20	Blood (5 ml)
Fluorescent treponemal antibody absorption	IFA	Nonreactive	Blood (5 ml)
Filariasis antibody	EIA	<1:160	Blood (5 ml)
<i>Francisella tularensis</i> antibody	EIA	<1:20	Blood (5 ml)
Fungal disease antibody panel (<i>Aspergillus</i> , <i>Blastomyces</i> , <i>Coccidioides</i> , <i>Cryptococcus</i> , <i>Histoplasma</i>)	LPA, ID, CF	By report	Blood (10 ml) or CSF (2 ml)
<i>Haemophilus influenzae</i> type b vaccine response (polyribose phosphate antibody)	EIA	By report	Blood (5 ml)
Herpes simplex virus antibody type 1 (IgG)	IFA	>1:10	Blood (5 ml)
Herpes simplex virus antibody (antibody panel includes types 1 and 2, IgG and IgM)	IFA	>1:10 (IgG) <1:10 (IgM)	Blood (7 ml)
Heterophile antibody screen	LPA	Negative	Blood (5 ml)
<i>Histoplasma</i> antibody by CF	CF	<1:8 (serum) <1:2 (CSF)	Blood (5 ml) CSF (0.5 ml)
<i>Histoplasma</i> antibody panel	ID, CF	Negative <1:0 (serum) <1:2 (CSF)	Blood (5 ml) CSF (0.5 ml)
HIV-1 antibody screen	EIA	Negative	Blood (5 ml)
HIV-1 antibody by Western blotting	IB	No bands detected (IB)	Blood (5 ml)
HIV-1 antigen assay	EIA	Negative	Blood (5 ml)
HTLV-1 antibody	EIA	Negative	Blood (5 ml)
Hypersensitivity pneumonitis (antibody panel includes 9 antigens: 5 thermophilic <i>Actinomycetes</i> , 3 <i>Aspergillus</i> , and avian serum proteins)	ID	None detected	Blood (7 ml)
Influenza virus A and B IgG antibody panel	IFA	<1:40	Blood (5 ml)
Influenza virus A and B antibody	IFA	<1:40 (IgG)	Blood (5 ml)
<i>Legionella pneumophila</i> antibody	IFA	<1:64	Blood (5 ml)
Leishmaniasis (visceral) antibody (includes <i>L. donovani</i> , <i>L. mexicana</i> , <i>L. tropica</i> , <i>L. braziliensis</i>)	IFA	<1:16	Blood (5 ml)
<i>Leptospira</i> antibody	IHA	<1:50	Blood (5 ml)
Lyme disease antibody	IFA	<1:16	Blood (5 ml)
Lymphocytic choriomeningitis antibody	CF	<1:8 (serum) <1:2 (CSF)	Blood (5 ml) CSF (0.5 ml)
LGV antibody	IFA	<1:64	Blood (5 ml)
Measles (rubeola) IgG antibody	IFA	>1:10	Blood (5 ml)
Measles (rubeola) IgG and IgM antibody panel	IFA	>1:10 (IgG)	Blood (5 ml)
Melioidosis (<i>Pseudomonas pseudomallei</i>)	IFA	<1:16	Blood (5 ml)
Mumps virus IgG antibody	IFA	>1:10	Blood (5 ml)
Mumps virus IgG and IgM antibody panel	IFA	>1:10 (IgG) <1:10 (IgM)	Blood (5 ml)
<i>Mycoplasma</i> IgG antibody	IFA	<1:40	Blood (5 ml)
<i>Mycoplasma</i> IgG and IgM antibody panel	IFA	<1:40 (IgG) <1:20 (IgM)	Blood (5 ml)
<i>Paragonimus</i> antibody	EIA	None detected	Blood (5 ml)
Parainfluenza virus IgG antibody panel (includes types 1, 2, 3)	IFA	<1:40	Blood (5 ml)
Parainfluenza virus IgG and IgM antibody panel (includes types 1, 2, 3)	IFA	<1:40 (IgG) <1:10 (IgM)	Blood (5 ml)
Poliovirus antibody by neutralization	NT	By report	Blood (5 ml)

Table 2.1–10 (continued)

Test name	Method(s) ^b	Normal value(s)	Specimen requirement(s) ^c
Poliovirus antibody panel (1, 2, 3)	CF	<1:8	Blood (5 ml)
Premarital testing, male	RPR	Nonreactive	Blood (5 ml)
Premarital testing, female			
RPR	RPR	Nonreactive	Blood (5 ml)
Rubella	LPA	Immune	
Psittacosis antibody	IFA	<1:64	Blood (5 ml)
Q fever (<i>Coxiella burnetii</i>) total antibody	IFA	<1:16	Blood (5 ml)
Q fever (<i>Coxiella burnetii</i>) IgG and IgM antibody panel	IFA	<1:16 (IgG) <1:10 (IgM)	Blood (5 ml)
Respiratory virus IgG and IgM antibody panel, adult influenza A and B, mycoplasma	IFA	<1:40 (IgG) <1:10 (IgM)	Blood (7 ml)
Respiratory syncytial virus IgG antibody	IFA	<1:40	Blood (3 ml)
Rickettsial disease total antibody (Rocky Mountain spotted fever, typhus, Q fever)	IFA	<1:16	Blood (5 ml)
Rickettsial disease IgG and IgM antibody panel (Rocky Mountain spotted fever, typhus, Q fever)	IFA	<1:16 (IgG) <1:10 (IgM)	Blood (5 ml)
Rocky Mountain spotted fever total antibody	IFA	<1:10	Blood (5 ml)
Rocky Mountain spotted fever IgG and IgM antibody panel	IFA	<1:16 (IgG) <1:10 (IgM)	Blood (5 ml)
Rotavirus antigen detection	EIA	None detected	Stool (1 g)
Rubella virus IgG antibody	LPA	>1:10	Blood (5 ml)
Rubella virus IgG and IgM antibody panel	LPA, EIA	>1:10 (IgG) Negative (IgM)	Blood (5 ml)
Streptococcal antibody panel			
Antistreptolysin-O	LPA	<1:200	Blood (7 ml), Peds: blood (3 ml)
Antideoxyribonuclease B	EN	<1:170	
Syphilis serology (nontreponemal antibody, RPR)	RPR	Nonreactive	Blood (5 ml)
Syphilis serology (nontreponemal antibody, VDRL on CSF)	VDRL	Nonreactive	CSF (1 ml)
Syphilis serology (treponemal antibody, MHA-TP)	IHA	Nonreactive	Blood (5 ml)
Syphilis serology (fluorescent treponemal antibody absorption)	IFA	Nonreactive	Blood (5 ml)
Tetanus antitoxin antibody (referred to outside lab)	EIA	0.01–0.05 IU/ml	Blood (5 ml)
TORCH IgG antibody panel			
<i>Toxoplasma</i>	IFA	<1:16	Peds: blood (3 ml)
Rubella virus	LPA	<1:10	
CMV	IFA	<1:10	
Herpes simplex virus	IFA	<1:10	
TORCH IgG and IgM antibody panel			
<i>Toxoplasma</i>	IFA	<1:16 (IgG) <1:10 (IgM)	Peds: blood (3 ml)
Rubella virus	LPA, EIA	<1:10 (IgG) Negative (IgM)	
CMV	IFA	<1:10 (IgG) <1:10 (IgM)	
Herpes simplex virus	IFA	<1:10 (IgG) <1:10 (IgM)	
<i>Toxocara</i> antibody	EIA	<1:4	Blood (5 ml)
<i>Toxoplasma</i> total antibody	IFA	<1:16	Blood (5 ml)
<i>Toxoplasma</i> IgG antibody	IFA	<1:16	Blood (5 ml)
<i>Toxoplasma</i> IgG and IgM antibody panel	IFA	<1:16 (IgG) <1:10 (IgM)	Blood (5 ml)
Trichinosis antibody	LPA	<1:5	Blood (5 ml)
Typhus (epidemic, endemic) total antibody	IFA	<1:16	Blood (5 ml)

(continued)

Table 2.1–10 Serodiagnostic tests^a (continued)

Test name	Method(s) ^b	Normal value(s)	Specimen requirement(s) ^c
Typhus (epidemic and endemic) IgG and IgM antibody panel	IFA	<1:16 (IgG) <1:10 (IgM)	Blood (5 ml)
Varicella-zoster virus IgG antibody (immune status)	EIA	Seropositive Index >1.0	Blood (5 ml)
Varicella-zoster virus IgG antibody titer	IFA	>1:10	Blood (5 ml)
Varicella-zoster IgG and IgM antibody panel	IFA	>1:10 (IgG) <1:10 (IgM)	Blood (5 ml)
Western equine encephalitis antibody	IFA	<1:16 (IgG)	Blood (5 ml)
<i>Yersinia</i> antibody	MAT	<1:20	Blood (5 ml)

^a Tests can be performed in the laboratory or sent to a reference laboratory. Abbreviations: IgG, immunoglobulin G; LGV, lymphogranuloma venereum; MHA-TP, microhemagglutination; CMV, cytomegalovirus; HIV-1, human immunodeficiency virus type 1; HTLV-1, human T-cell leukemia virus type 1.

^b ACIF, anticomplement immunofluorescence; CF, complement fixation; DA, direct agglutination; IB, immunoblot; EIA, enzyme immunoassay; EN, enzyme neutralization; ID, immunodiffusion; IFA, indirect fluorescent antibody; IHA, indirect hemagglutination; LPA, latex particle agglutination; MAT, microagglutination titer; MIF, micro-indirect fluorescence; MC, mucin clot technique; NT, neutralization; PHA, passive hemagglutination; RPR, rapid plasma reagin test; SA, slide agglutination; VDRL, venereal disease research laboratory; IDTP, immunodiffusion tube precipitin test; IDCF, immunodiffusion complement-fixing antigen F test; TA, tube agglutinin.

^c Draw blood in red-top tube except when otherwise indicated.

I gratefully acknowledge the following clinical microbiologists for their expertise in providing comments, helpful additions, and review of this section of the handbook: Merrie Bass, Holly d'Souza, Manju Mudambi-best, and Nancy Troup of Stanford Hospitals and Clinics, Stanford, Calif.; Nancy Bennett of Northridge Hospital Medical Center, Northridge, Calif.; Michele Holloway of Glendale Memorial Hospital and Health Center, Glendale, Calif.; Rohan Nadarajah of University of California, San Francisco Hospitals and Clinics, San Francisco; Sharon Abbott of Department of Health Services, Richmond, Calif.; and Caroline I. Mohr of CDC, Atlanta, Ga.

3.1

Introduction to the Section

The Aerobic Bacteriology section of the handbook has been reorganized to place each part of the procedure together, including collection, specimen processing, supplies, QC, and the actual step-by-step testing performed by the microbiologist. This will allow the user to see an overview of the entire procedure together. When several different methods of testing are acceptable, each option is presented. The users should not reproduce the procedural text of this handbook in its entirety but rather should choose among the various options presented to produce practical procedures applicable to their laboratory.

Procedures are first organized by anatomic site. The user may wish to separate each section of these procedures, as recommended in NCCLS document GP2-A4 (6). For example, the information in Specimen Collection can be used to provide a separate nursing manual, the information in Quality Control can be used for QC procedure, the information in Materials can be used for an inventory for reagent preparation and procurement of supplies, and the information in the beginning of each Procedure and many of the tables can be used for a specimen inoculation manual and a teaching manual for new employees, etc. Flowcharts and tables within the Procedure can be used to prepare technical bench manuals. References are provided to allow the reader further information for use in decision making when different options are being considered for test methods. Every attempt was made to provide significant original reviewed articles to support the recommended procedures. For procedures 3.3.1 and 3.3.2, general textbooks are listed, which can be purchased for reference material.

Often the laboratory is requested to examine a specimen for only one micro-

organism. To avoid duplication, when a procedure is presented for a specific organism, the procedure is listed following the general procedure for the most common anatomic site of isolation of the organism. For example, the detection of *Neisseria gonorrhoeae* is listed following the genital culture procedure, although *N. gonorrhoeae* may be sought in throat cultures. The procedure for *Brucella* is found following the general blood culture procedure, yet the organism can be found in a variety of invasively collected specimens, such as joint and spinal fluid specimens.

Following the procedures by anatomic site are procedures for biochemical testing in alphabetical order. The tests that are listed are the generally accepted tests that laboratories should be able to perform to identify the clinically important microorganisms encountered in the laboratory. Smaller laboratories may choose to perform fewer tests and refer cultures when less common microorganisms are found in culture. Procedures for automated methods and multitest kits are not presented because the list is extensive and manufacturers provide updated package inserts with the details for the performance of their products and preparation of laboratory procedure manuals for their kits. However, tables comparing these kits are presented to allow the user to have information for decision making in the purchase of such kits (also see references 5 and 8). The biochemical tests selected for inclusion in this handbook emphasize those that are rapidly performed. Consequently, the X and V factor procedure is not listed, because laboratories are encouraged to perform the more rapid δ -aminolevulinic acid test in combination with growth on CHOC or the satellite test for *Haemophilus influ-*

enxae. If some media or biochemical tests are now thought to be less sensitive than other tests, the less sensitive media or tests are *not* listed. For example, V agar is reported to be less sensitive than human blood Tween bilayer media (procedure 3.9.1) for growth of *Gardnerella vaginalis* and *Burkholderia cepacia* selective agar is more sensitive than *Pseudomonas cepacia* agar for *B. cepacia* (procedure 3.11.3). Thus, V agar and *P. cepacia* agar are not listed as choices in the procedures.

Lastly, flowcharts are listed for common and important organisms. These flowcharts are different from any you will encounter, because they emphasize different levels of identification for different anatomic sites and rely on the reported sensitivities and specificities of each test for decision on the need to confirm the results. They encourage rapid tests and are designed to detect clinically important microorganisms rapidly with very few tests, but not identify to the species level when it is not clinically useful. The tables that follow the flowcharts should help further in the identification of both *common organisms and those that are of great clinical importance*. For more extensive identifications in cases of repeated isolation of organisms that do not usually initiate disease and for information on unusual organisms, the reader is referred to other reference material (1, 2, 3, 4, 5, 7, 9).

I would like to thank the original authors of the first edition for their phenomenal work from which the updated handbook was modeled and often duplicated in this edition. Without their procedures and the expert editor of the first edition, Marie Pezzlo, this edition would not have been possible. I am grateful to the many contributors to the first edition and appreciate their thoughtful presentation of the mate-

rial, especially Frank Citron for the many illustrations and Yvonne Ramsay Shea, Paula J. Malloy (deceased), and Joanne J. Bradna for the extensive information on specimen collection and processing, which is used throughout the procedures. The contribution of Patricia Kruezak-Filipov and Roxanne G. Shively to the Gram stain procedure will be a resource to la-

boratorians for many years. Many of the tables and figures that they developed have been retained in this version of the handbook.

Companies that supply media, reagents, and other products tend to change rapidly. Thus, the products listed from these suppliers may not always be available as they are described. Listing is lim-

ited to companies that sell products that are available in the United States. Rather than repeat the details of these companies, a list of common vendors that supply laboratory media and reagents is presented in Appendix 3.1–1. Other vendors' addresses are listed in the specific procedures when they provide a product used for that procedure alone.

3.2.1

Gram Stain

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The Gram stain is used to classify bacteria on the basis of their forms, sizes, cellular morphologies, and Gram reactions; it is additionally a critical test for the presumptive diagnosis of infectious agents and serves to assess the quality of clinical specimens (12, 16). The test was originally developed by Christian Gram in 1884. The modification currently used for general bacteriology was developed by Hucker in 1921; it provides greater reagent stability and better differentiation of organisms. Other modifications have been specifically developed for staining anaerobes (Kopeloff's modification) and for weakly staining gram-negative organisms (*Legionella* spp., *Campylobacter* spp., *Brucella* spp., etc.) by using a carbol fuchsin or basic

fuchsin counterstain (4, 17). In fact, many laboratories use these counterstains routinely, especially for direct smears of clinical material.

Bacteria stain either gram positive or gram negative on the basis of differences in their cell wall compositions and architectures. Gram-positive species have a thick peptidoglycan layer and large amounts of teichoic acids; they are unaffected by alcohol decolorization and retain the initial stain, appearing deep violet if their cell walls are undamaged by age, antimicrobial agents, or other factors. Gram-negative species have a single peptidoglycan layer attached to an asymmetric lipopolysaccharide-phospholipid bilayer

outer membrane interspersed with protein; the outer membrane is damaged by the alcohol decolorizer, allowing the crystal violet-iodine complex to leak out and be replaced by the counterstain (2, 4).

Interpretation of Gram-stained smears involves consideration of staining characteristics and cell size, shape, and arrangement. These characteristics may be influenced by many factors, including culture age, medium, incubation atmosphere, staining methods (1), and presence of inhibitory substances. Similar considerations apply to the interpretation of smears from clinical specimens, but additional factors include the presence of particular host cell types and phagocytosis.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimens

1. Clinical specimens, generally excluding throat swabs, nasal swabs, sputum from cystic fibrosis patients, fecal material, and prosthetic devices. Direct smears are particularly useful for wounds, eye lesions, body tissues, and certain discharges.
 2. Broth and blood cultures to determine growth, Gram reaction, or morphology of bacteria
 3. Colonies growing on solid medium
- **NOTE:** Young cultures (<24 h old) from noninhibitory media and fresh clinical specimens yield the most favorable results. When morphology is important (e.g., streptococci and gram-positive rods), broth cultures are preferred.

B. Specimen collection

1. Refer to procedures 3.4 to 3.13 for specimen collection by anatomic type.
2. Generally the smear is made in the laboratory; however, when there is a concern that transport will be delayed or that the preservative for culture will alter the specimen, prepare smears and submit slides to the laboratory.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

C. Rejection criteria

1. Gram stains are of little value as direct smears of stool, blood, or throat. They are not helpful for sputum from cystic fibrosis patients.
2. Stains are not part of standard protocols for evaluation of catheter tip specimens (procedure 3.6).

III. MATERIALS

A. Reagents

1. Methanol, absolute
Store in brown bottles or plastic containers.
2. Crystal violet
 - a. Hucker's modification (1, 4, 10)
 - b. Kopeloff's crystal violet
3. Iodine
 - a. Gram's reagent
 - b. Kopeloff's iodine
4. Decolorizers
 - a. Slowest: ethanol, 95%
 - b. Intermediate: acetone-alcohol
 - (1) Mix 50:50.
 - (2) Combine in brown glass bottle, label with 1-year expiration date, and store at room temperature.
 - c. Fastest: acetone (reagent grade)

Caution: Ethanol and acetone are flammable.
5. Counterstain
 - a. Safranin
 - b. Carbol fuchsin
 - c. Basic fuchsin (0.8, 0.1, or 0.2%)
 - d. Kopeloff's safranin
6. Reagents can be purchased or prepared in-house.
 - a. Refer to Appendix 3.2.1-1 for instructions on preparation of reagents.
 - b. Generally prepare large volumes and prepare working solutions as needed (this is efficient and ensures lot uniformity). Decant reagents into smaller bottles for daily use; however, replace the smaller bottles of the crystal violet and counterstain monthly to avoid the formation of precipitate on the slides.

■ Indicate the reagent name, preparation date, "in use" date, lot number, expiration date, and storage conditions on the bottles and in the work record. It is not necessary to label the working bottles with this information other than the name of the reagent, if the "in use" date is clearly on the stock bottles and in the control records.

B. Other supplies

1. Wax pencil
2. Precleaned glass slides (25 by 75 mm), frosted ends desirable. Slides with etched rings are an alternative for liquid specimens.
3. Sterile 0.85% NaCl (saline), water, or broth
4. Sterile Pasteur pipettes, wood applicator sticks, inoculating loops, or needles
5. Supplies for disposal of biological waste, including sharps
6. Sterile tubes with caps
7. Sterile scissors, scalpels, and forceps
8. Immersion oil

C. Equipment, depending on specimen source or laboratory protocol

1. Bacteriometer or flame burner with automatic shutoff
2. Electric slide warmer, 45 to 60°C
3. Cytospin centrifuge
4. Vortex mixer
5. Device for collection of toxic stains for chemical hazard disposal

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A.** Check appearance of reagents daily.
1. If crystal violet has precipitate or crystal sediment, refilter before use.
 2. Change working solutions regularly if not depleted with normal use. Evaporation may alter effectiveness of reagents.
 3. Limit reuse of working stain containers by discarding at least monthly.
- ☑ **NOTE:** Stains can be come contaminated. When contamination is suspected, use a new lot of stain.
- B.** Test laboratory staining procedure prior to use of new lots of each staining and decolorizing reagent and at least weekly thereafter, using a gram-positive and gram-negative microorganism. For laboratory staff that perform Gram stains infrequently, it may be appropriate to have them test a positive and negative control daily or even with each patient specimen tested.
1. Prepare a faintly turbid broth culture of *Escherichia coli* (ATCC 25922) and *Staphylococcus aureus* (ATCC 25923).
 2. Make slides using 2 drops per slide spread in the size of a dime.
 3. Fix in methanol and store at -20°C .
 4. Stain by laboratory Gram stain method.
 5. Expected results
 - a. Gram-negative rods, pink
 - b. Gram-positive cocci, deep violet
 6. Alternatively, with a broken applicator stick or toothpick, procure material from between teeth and apply to the end of slide used for the specimen, separating this area of the slide with a marker. This method provides a built-in control with gram-positive and gram-negative representatives.
- C.** Take corrective action when stained smear preparations show evidence of poor quality, stains are difficult to interpret, or interpretations are inaccurate. Poor staining characteristics (e.g., faintly staining gram-positive organisms, retention of crystal violet by gram-negative organisms, staining only of the edges of a smear, precipitate on slide, etc.) may be due to specimen preparation, reagents, or staining procedure. The following are some common causes of poor Gram stain results.
1. Use of glass slides that have not been precleaned or degreased
 2. Smear preparations that are too thick
 3. Overheating of smears when heat fixation is used
 4. Excessive rinsing during the staining procedure, especially if smear is not properly fixed
 5. Precipitate in reagents
- D.** Additionally, to ensure accuracy of interpretation, establish a system for reviewing Gram stain reports.
1. Review of selected Gram stains by supervisory personnel to determine training needs and aid in correlating relevant clinical information
 2. Compare final culture results with Gram stain reports to check for recovery of morphologies noted in the Gram stain but not recovered in the culture. Similarly, review both the smear and the culture when organisms in 3 to 4+ quantities are recovered in culture but not observed on the Gram stain.
- ☑ **NOTE:** An appreciable number of organisms discerned on a smear can be cultivated. Discrepancies should be investigated for errors in smear evaluation or for indications for further culturing methods (e.g., anaerobic, fungal, or acid-fast bacillus [AFB] culture).
3. Maintain a set of reference slides for competency training.

V. PROCEDURE

Observe standard precautions.

A. Slide preparation**1. General considerations**

- a.** Place frosted-end glass slides in a container of 95% ethanol (change alcohol solution daily).
- b.** Using a forceps, drain excess alcohol and flame slide prior to use.
- c.** Label the frosted ends with the information to identify the specimen or culture.

Wear latex gloves and other protection commensurate with standard precautions when handling clinical specimens. When making preparations from clinical specimens in a biosafety cabinet, observe other BSL 2 recommendations (15).

- 2.** For direct smears, prepare a monolayer of organisms sufficiently dense for easy visualization but sparse enough to reveal characteristic arrangements. As a guideline, newspaper print should be visible through the smear.

■ **NOTE:** Always inoculate culture media before preparing smear when using the same pipette or swab.

a. Body fluids, bronchoalveolar lavage fluid (BAL), and CSF

- (1) Place 5 or 6 drops of sample plus 1 drop of 37% formalin into a cytospin specimen chamber. Follow procedure for operation of centrifuge from manufacturer.

■ **NOTE:** Use of a cytospin slide centrifuge to concentrate body fluids increases the Gram stain sensitivity and decreases time of standard centrifugation and examination, for more rapid results (13).

- (2) As an alternative when the specimen is viscous or cloudy or the quantity is not sufficient for concentration, use a Pasteur pipette to transfer 1 or 2 drops of the specimen directly to the slide, after marking the location with a wax pencil. Allow the drop(s) to form one large drop. Do not spread the fluid. Optionally, add a second drop of fluid to the same area to increase the concentration of fluid for examination (8).

b. Urine specimens

- (1) Place 10 μ l of well-mixed, uncentrifuged urine onto a glass slide marked with a wax pencil to indicate the location of the sample drop. A ring slide may also be used for ease in locating the specimen.
- (2) Air dry without spreading.

c. Specimens received on swabs

- (1) Request a separate swab for adequate smear preparation.

■ **NOTE:** Many culturette systems provide two swabs in the container, eliminating problems with sufficient swabs for each test requested.

- (2) Roll the swab gently across the slide to avoid destruction of cellular elements and disruption of bacterial arrangements.

- (3) Alternatively, when only one swab is received, place the swab in a small amount of saline or culture broth, cap tube, and vortex. Squeeze the swab against the side of the tube, and use swab to prepare smear. Use the remaining suspension to inoculate culture media.

■ **NOTE:** Never mix open tube vigorously. Avoid creation of aerosols.

V. PROCEDURE (continued)

- d. Specimens not received on swabs: aspirates, exudates, sputa, etc.
 - (1) Transfer specimen to the cleaned slide.
 - (a) If the specimen is received in a syringe, first inoculate all culture media and then transfer a small amount to the glass slide.

▣ **NOTE:** To avoid needless exposure, do not accept syringe with needle attached. Establish such a policy and educate medical personnel regarding removal of needles before transport.
 - (b) Select purulent or blood-tinged portions of pus or sputum with a sterile applicator stick, pipette, or wire loop.
 - (c) Spread the sample over a large area of the slide to form a thin film.
 - (2) For extremely thick or purulent specimens
 - (a) Dilute in a drop of saline on the slide for easier smear preparation.
 - (b) Alternately, place the specimen on one slide, cover it with second slide, press the slides together, and pull them apart (Fig. 3.2.1-1). Remove excess material on the side of slides with a disinfectant-soaked paper towel.
- e. Dried material or very small amounts of clinical specimen
 - (1) Emulsify specimen in 0.5 ml of sterile broth. Vortex, if necessary.
 - (2) Use a sterile Pasteur pipette to transfer 1 drop to a slide.
 - (3) Use the pipette tip to spread the drop into an even thin film.
- f. Biopsy specimens and tissue sections
 - (1) Touch preparation (Fig. 3.2.1-2)
 - (a) Place tissue in sterile petri dish, and mince with sterile scissors or surgical scalpel.
 - (b) With sterile forceps to hold pieces, touch the sides of one or more of the minced fragments to a sterile glass slide, grouping the touches together for easier examination.

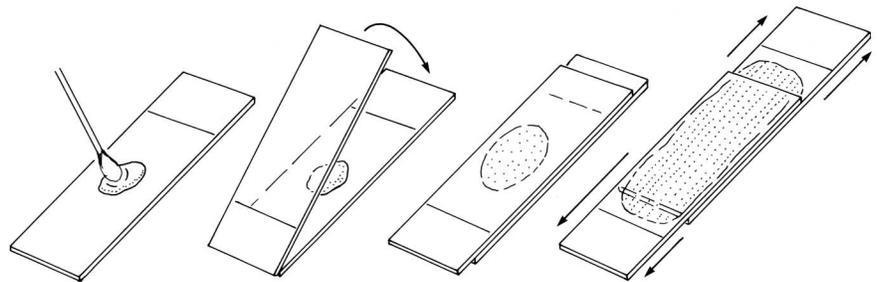

Figure 3.2.1-1 Thin-smear preparation.

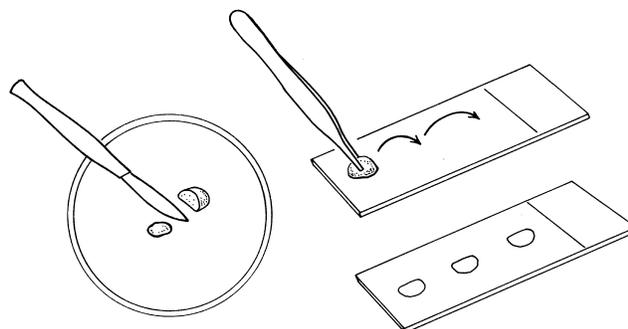

Figure 3.2.1-2 Touch preparation of smear.

V. PROCEDURE (*continued*)

- (2) Thin-smear preparation (Fig. 3.2.1–1)
 - (a) When specimen sample is soft tissue or thick exudate, prepare smear by taking a small portion of tissue, and place it on sterile slide with a swab or sterile forceps.
 - (b) Place second sterile slide over sample, and press slides together.
 - (c) Separate slide by sliding the two away from each other.
 - (3) If there is no other option, use a ground specimen preparation (*see* procedure 3.13.1). Spread 1 drop to the size of a dime.
NOTE: Homogenizing or grinding tissue specimens before preparing the smear will often destroy characteristic cellular entities and bacterial arrangements.
3. Broth cultures
 - a. Prepare one smear per slide to avoid washing off of “dried” liquid from one area to another during staining.
 - b. Use a sterile Pasteur pipette (or a venting needle or syringe adapter for containers with septa, such as blood culture bottles, to avoid manipulating a needle and syringe) to transfer 1 or 2 drops to the slide.
 - c. Spread drop into an even thin film.
 - d. For charcoal-containing medium, prepare blood culture smear as for hematology blood count, using a second slide at a 45° angle to spread a thin layer of cells on first slide.
 4. Colonies from solid media
 - a. Place a drop of sterile saline or water on slide. Distilled water may distort cellular morphology of fragile organisms.
 - b. Transfer a small portion of colony with a sterile applicator stick, wire needle, or loop.
 - c. Gently mix to emulsify. The resulting smear should be slightly cloudy and homogeneous (adjust saline drop size, area of smear, and/or inoculum to achieve optimum results). If swirl lines are evident as the smear dries, the inoculum was too heavy, the drop of saline was too small, and/or the smear was spread over too small an area.
- B. Smear fixation**
1. Air dry slides in a biosafety cabinet or covered on a slide warmer at 60°C until dry.
 2. Heat fixation
 - a. Pass air-dried slides two or three times through a flame, or hold the slide against the front of a microincinerator for 5 to 10 s. To avoid distortions, do not overheat.
 - b. Allow slide to cool before staining.
 3. Alternatively, fix with methanol to prevent the lysis of RBCs, produce a cleaner background, and prevent washing off of liquid specimens (11).
 - a. Place a few drops of methanol on air-dried slide for 1 min, drain off remaining methanol without rinsing, and allow slide to air dry again.
 - b. Do not use heat before staining.
- C. Staining procedures** (*see* Table 3.2.1–1 for comparison of methods)
- NOTE:** Do not apply stains, water, or decolorizer directly to specimen area. Apply drops near the frosted end of the slide, allowing reagent to flow over the remaining surface.
1. Hucker’s modification
NOTE: Hucker’s modification is widely used for routine work. The decolorizer chosen will alter decolorization times. Acetone-alcohol gives consistent results, but 95% ethanol is preferred for students and less experienced personnel. Acetone is a more rapid decolorizer with a shorter range of reproducibility and is recommended for experienced personnel only (1). It is most useful for specimens containing an appreciable number of host cells.

Table 3.2.1–1 Gram stain modifications, recommended reagents, timing, and uses

Stain and use	Hucker's		Carbol fuchsin		Kopeloff's	
	Reagent	Time	Reagent	Time	Reagent	Time
Initial stain	Crystal violet	30 s	Crystal violet	30 s	Alkaline crystal violet: flood with solution A; add 5 drops of solution B	2–3 min
Iodine	Gram's iodine	30 s	Gram's iodine	30 s	Kopeloff's iodine	≥2 min
Decolorizer	Acetone-alcohol	~1–5 s	95% ethanol	~30 s	3:7 acetone-alcohol: rinse immediately after applying	
Counterstain	Safranin ^a	30 s	Carbol fuchsin or 0.8% basic fuchsin	≥1 min	Kopeloff's safranin	10–30 s
Recommended use	General bacteriology		<i>Bacteroides</i> spp. <i>Fusobacterium</i> spp. <i>Legionella</i> spp. <i>Campylobacter</i> spp. <i>Brucella</i> spp. and other faintly staining gram-negative organisms		Anaerobes Diagnosis of bacterial vaginosis (Appendix 3.2.1–3)	

^a Or, preferably, use 0.1 to 0.2% basic fuchsin as a counterstain (7).

V. PROCEDURE (continued)

- a. Flood the fixed smear with the crystal violet solution. Allow the stain to remain for 30 s.
 - b. Decant crystal violet, and rinse slide gently with running tap water.
 - **NOTE:** Excessive rinsing in this step could cause crystal violet to be washed from gram-positive cells. Apply the flow of water to the underside of the angled slide to ensure a gentle flow across the smeared side.
 - c. Rinse off excess water with iodine solution, and then flood the slide with fresh iodine solution. Allow iodine to remain for 30 s.
 - d. Rinse off iodine gently with flowing tap water.
 - e. Decolorize by letting the reagent flow over the smear while the slide is held at an angle. Stop when the runoff becomes clear. Adjust decolorization time to thickness of smear and type of decolorizer used.
 - f. Remove excess decolorizer with gentle flow of tap water.
 - g. Flood the slide with counterstain and allow to remain for at least 30 s and for ≥1 min with fuchsin stains. Use one of the following counterstains.
 - (1) Safranin
 - (2) 0.1 to 0.2% basic fuchsin (7)
 - (3) Carbol fuchsin or 0.1 to 0.8% basic fuchsin counterstain for detecting faintly staining gram-negative organisms (17). See Table 3.2.1–1 for decolorizer options.
 - h. Remove excess counterstain with a gentle flow of tap water.
 - i. Drain slide, and air dry it in an upright position, or use a commercial slide drier.
2. Kopeloff's modification
 - **NOTE:** Kopeloff's modification is recommended for better visualization and differentiation of anaerobes, which may easily overdecolorize and stain faintly with Hucker's modification (4 to 6). It is recommended for vaginal smears to diagnose bacterial vaginosis (see Appendix 3.2.1–3).
 - a. Flood fixed smear with solution A (crystal violet). Add approximately 5 drops of solution B (5% sodium bicarbonate). Blow slide to mix. Then allow the stain to remain for 15 to 30 s or up to 2 min, but do not allow it to dry on the slide.
 - b. Rinse slide gently with Kopeloff's iodine.

V. PROCEDURE (*continued*)

- c. Apply fresh Kopeloff's iodine for at least 2 min.
 - d. Hold the slide in a slanted position, and apply decolorizer. Rinse immediately.
 - e. Counterstain with Kopeloff's safranin for at least 30 s.
 - f. Gently rinse excess counterstain with running tap water. Drain slide, and air dry.
- D.** Examine the direct smear microscopically.
- 1.** Evaluate the general nature of the smear under low power (defined as 10× objective with 10× eyepiece) (9).
 - a.** Observe for stain crystals.
 - (1) If an excess of precipitated stain is observed, decolorize and restain slide.
 - (2) Alternatively, prepare another Gram-stained smear.
 - (3) If precipitate continues, use freshly filtered crystal violet or counterstain in a clean container.
 - b.** Determine if smear has been properly decolorized.
 - (1) Depending on the source of the specimen, the background should be generally clear or gram negative.
 - (2) If WBCs are present, they should appear completely gram negative.
 - (3) If slide is overdecolorized, completely decolorize and restain slide.
 - c.** Determine if thickness of smear is appropriate. For proper interpretation, areas must be no more than one cell thick, with no overlapping of cells. Prepare new slide if unreadable.
 - d.** For smears prepared from clinical specimens, examine several fields (10 for urine, 20 to 40 for other specimens) under low power for evidence of inflammation.
 - (1) Observe distribution of organisms and cells.
 - (2) Determine areas representative of inflammation or purulence and areas of apparent contamination with squamous epithelial cells (SECs). If no purulence is seen, choose areas of apparent necrosis, inflammatory cell debris, and mucus.
 - 2.** If cells are present, determine the average count of WBCs and epithelial cells in 20 to 40 representative fields that contain cells.
 - 3.** In a representative area with a preponderance of inflammation or purulence using the oil immersion lens (defined as 100× objective with 10× eyepiece), examine 20 to 40 fields to observe cell morphology and Gram reaction.
 - a.** If rare or no organisms are seen from a normally sterile-site specimen, but the specimen appears purulent, or the specimen looks suspicious, perform a more extensive review of the slide.
 - b.** Refer to Tables 3.2.1–2, 3.2.1–3, and 3.2.1–4 for characteristic morphologies that may be seen in smears from clinical specimens.
 - 4.** Preservation of direct smear slides
 - a.** Drain or gently blot excess oil from slide and save slides for further evaluation for a minimum of 1 week to allow a confirmatory review, especially if culture or other laboratory test results are inconsistent.
 - b.** Should a slide need to be restained to repeat Gram stain or prepare a special stain to confirm findings suggested by a Gram stain, remove the immersion oil with xylene or a xylene substitute and decolorize smear. Then restain slide.
 - c.** For slide libraries and teaching collections that will be stored for longer periods, remove immersion oil with xylene and overlay smear with a sealer to prevent fading.

Table 3.2.1–2 Gram-positive organisms found in direct smears from some clinical sources

Organism(s)	Gram stain morphology	Frequent sources	Comments and additional tests or media that may be included
<i>Actinomyces</i> spp.	Thin, beaded, branched gram-positive filaments; may be within sulfur granules with peripheral clubs	Cervicofacial, thoracic, abdominal, and pelvic abscesses and drainages; pleural fluid; bronchial washings	Modified acid-fast stain; if sulfur granules present, wash and crush in THIO
<i>Nocardia</i> spp.	Long, thin, branching, beaded, gram-positive or irregularly staining bacilli; in culture smears, may be pleomorphic with branching and coccoid forms	Sputum, bronchial washings, biopsy material, purulent exudates, CSF, blood	Modified acid-fast stain; if mixed microbiota, mycobacterial decontamination procedures may be used; plate incubated at 45°C may enhance recovery; use C _Y E ^α or Thayer-Martin agar.
<i>Mycobacterium</i> spp.	Gram-positive beaded or gram-neutral bacilli; often found inside macrophages; bacilli may be short to long, banded or beaded, and/or slightly curved; some species appear pleomorphic and coccoid	Respiratory tract, urine, blood, biopsy material, CSF	Confirm with acid-fast stain. Add AFB culture.
<i>Corynebacterium</i> spp.	Gram-positive pleomorphic, club shaped, irregularly staining bacilli or coccobacilli with palisading and/or angular arrangements	Blood, tissue aspirates, skin lesions, wounds, indwelling catheters, prosthetic heart valves, upper and lower respiratory tracts	Add selective and differential media for <i>Corynebacterium diphtheriae</i> , if suspected.
<i>C. jeikeium</i>	Often small coccobacilli resembling streptococci		
<i>Propionibacterium</i> spp.	Gram-positive, very pleomorphic “diphtheroid” forms that may branch	Blood, CSF, other body fluids, skin lesions	Common skin contaminant during needle aspiration
<i>Listeria monocytogenes</i>	Gram-positive small to medium coccobacilli that may be pleomorphic; occur in short chains or palisades; may be confused with corynebacteria or enterococci	CSF, blood, amniotic fluid, placental or fetal tissue	Direct wet mount for tumbling motility; if mixed microbiota, cold enrichment may be used
<i>Erysipelothrix rhusiopathiae</i>	In tissue, long, slender, gram-positive bacilli; in blood, small “coryneforms”	Skin lesions, biopsy material, tissue aspirates, blood	Associated with occupational or animal contact
<i>Lactobacillus</i> spp.	Medium, straight, uniform gram-positive bacilli with rounded ends; may form chains or spirals; sometimes short and coccobacillary	Usually involved in mixed infections; rarely from blood, CSF	Recovery may be improved by anaerobic incubation; normal vaginal, mouth, and gastrointestinal tract microbiota
<i>Bacillus</i> spp.	Medium to large square-ended gram-positive bacilli with parallel sides with or without spores; some species have spores that swell sides; may stain gram variable or gram negative with age	May be clinically relevant from any source in compromised patient or intravenous-drug abuser; also intraocular	Frequent culture contaminants; may cause ocular infections

Table 3.2.1–2 (continued)

Organism(s)	Gram stain morphology	Frequent sources	Comments and additional tests or media that may be included
<i>Clostridium perfringens</i>	Gram-positive large “boxcars” with no spores; may stain gram negative	Blood, wounds, intra-abdominal	Add egg yolk agar incubated anaerobically; absence of inflammatory cells may indicate clostridial myonecrosis; normal gastrointestinal tract microbiota
<i>Clostridium</i> spp.	Gram-positive, -variable, or -negative bacilli with or without spores; bacilli may be large, slender and short, or long; sometimes form coils; often smaller than <i>Bacillus</i> spp.	Blood, intra-abdominal, wounds, abscesses	Normal gastrointestinal and genital tract microbiota
<i>S. pneumoniae</i>	Gram-positive cocci in pairs, lancet shapes, short chains	Lower respiratory tract, blood, CSF, sterile fluids	Quellung test may be used on selected clinical specimens.
<i>Enterococcus</i> spp.	Gram-positive cocci in pairs, short chains; may resemble pneumococci	Urine, wounds, blood, intra-abdominal abscesses	Normal gastrointestinal tract microbiota; common cause of superinfections in patients treated with expanded-spectrum cephalosporins
<i>Streptococcus</i> spp.	Round to oval gram-positive cocci, occasionally elongated; in pairs and/or short to long chains; nutritionally variant streptococci often seen as highly pleomorphic, gram-variable to gram-negative coccobacilli with pointed ends and spindle shapes	Blood, CSF, respiratory tract, multiple other sources	May be difficult to distinguish from corynebacteria and lactobacilli
<i>Aerococcus viridans</i>	Gram-positive cocci in pairs, tetrads, clusters	Blood, CSF	
<i>Staphylococcus</i> spp.	Gram-positive cocci in pairs, tetrads, clusters	Abscesses, drainages, wounds, respiratory tract, blood, tissue, sterile fluids, indwelling catheters	Normal microbiota, especially skin, nares
<i>S. aureus</i>	May often be characterized by very uniform, geometric clusters of small cocci, whereas coagulase-negative species are often irregular and more pleomorphic, with greater size variation		
<i>Rothia mucilaginosa</i>	Large gram-positive cocci in pairs, tetrads	Blood in compromised patients, peritoneal dialysates	Normal oral microbiota

^a CYE, charcoal-yeast extract agar.

Table 3.2.1–3 Gram-negative organisms seen in direct smears from some clinical sources

Organism(s)	Gram stain morphology	Frequent sources	Comments
<i>Enterobacteriaceae</i>	Straight thick bacilli; short to medium length with rounded ends; antimicrobial agent-affected organisms may be pleomorphic, filamentous, and/or irregularly staining	Urinary tract, multiple other sources	Includes organisms that cause gastroenteritis and bacterial dysentery; also normal gastrointestinal tract microbiota; nosocomial strains may be multiply resistant to antimicrobial agents
<i>Pseudomonas</i> spp.	Thin bacilli; medium length to long with rounded to pointy ends; often in pairs; antimicrobial agent-affected organisms may appear filamentous, coiled, and/or pleomorphic	Lower respiratory tract, wounds, eyes, multiple sites in compromised patients	Nosocomial strains may be multiply resistant to antimicrobial agents
<i>Haemophilus</i> spp., <i>Pasteurella</i> spp., fastidious gram-negative bacilli	Small coccoid to bacillary forms; pleomorphic; often with filamentous forms; may be faintly staining	Blood, sterile fluid (including CSF), lower respiratory tract, abscesses, wounds, eyes, genital tract	Inoculate CHOC.
<i>Legionella</i> spp.	Pleomorphic slender bacilli of variable lengths that may stain pale; may not take stain in clinical specimens	Lower respiratory tract	Add special growth media; direct fluorescent antibody stains and molecular probes available; acid wash method may be used to enhance recovery from specimens with mixed microbiota
<i>Fusobacterium nucleatum</i> , <i>Capnocytophaga</i> spp.	Long slender bacilli with tapered to pointed ends; “needlelike”; may be in pairs, end to end, or filamentous	Respiratory tract, wounds, blood, abscesses	Endogenous microbiota
<i>Fusobacterium necrophorum</i> , <i>Fusobacterium mortiferum</i> , or <i>Fusobacterium varium</i>	Highly pleomorphic bacilli with rounded to tapered ends; pale and irregularly staining, with bizarre forms and round bodies	Wounds, blood, abscesses	Endogenous microbiota
<i>Bacteroides</i> spp.	Pleomorphic straight bacilli with possible irregular to bipolar staining	Wounds, blood, abscesses	Direct fluorescent antibody stain available; endogenous microbiota
<i>Vibrio</i> spp.	Slightly curved to straight bacilli	Stool, wounds	If mixed microbiota, selective medium (TCBS) recommended
<i>Campylobacter</i> spp. (<i>Helicobacter</i> spp.)	Thin, curved bacilli, including S shapes, gull wings, and long spiral forms	Stool, blood, gastric biopsy samples	Microaerophilic or capnophilic atmosphere required; if mixed microbiota, 42°C incubation recommended for recovery of thermophilic species
<i>Acinetobacter</i> spp.	Medium to large cocci in pairs; occasionally coccoid, bacillary, and filamentous forms; often resistant to decolorization	Urine, lower respiratory tract, blood, sterile fluids, wounds, abscesses, tissues, stool	Multiple sites in compromised patients
<i>Neisseria</i> spp., <i>Moraxella catarrhalis</i>	Medium to large cocci in pairs and tetrads, coffee bean shaped; no bacilli seen	Genital tract, urine, lower respiratory tract, blood, sterile fluids, wounds, abscesses	If mixed microbiota, selective medium may be used to enhance recovery of <i>Neisseria gonorrhoeae</i>
<i>Veillonella</i> spp.	Tiny cocci in sheets or clumps	Wounds, blood	Endogenous microbiota

Table 3.2.1–4 Other organisms seen in direct smears from some clinical sources

Organism(s)	Gram stain morphology	Frequent sources	Comments
<i>Pneumocystis carinii</i>	Gram-negative spherical cysts (5–7 μm) often containing rosette of eight gram-negative intracystic bodies, or cluster of gram-negative cysts surrounded by halos in background of amorphous gram-negative material	Open lung and transtracheal biopsy materials, bronchial washings and lavage specimens, sputum	Confirm with Grocott methenamine-silver, toluidine blue O, Gram-Weigert, or direct or indirect fluorescent antibody stain.
<i>Blastomyces dermatitidis</i>	Gram-variable, broad-based, thick-walled yeast cell with figure-eight appearance	Bronchial washings, sputum, purulent exudates, skin lesions	
Microsporidia	Gram-variable spherical cells (1–4 μm), thicker at one end	Stool, respiratory, cornea, urine	Confirm with chromotrope stain
<i>Cryptococcus neoformans</i>	Partially or completely gram-positive round yeast cell with clear or red-orange halo; yeast cells may appear stippled or gram neutral	CSF, blood, biopsy material, sputum, bronchial washings, cutaneous lesions	Confirm capsule with India ink; direct antigen detection procedures may be used on CSF; inoculate urea slant.
<i>Candida</i> spp.	Gram-positive budding yeast cell with or without pseudohyphae; may also appear stippled or gram neutral	Sputum, urine, blood, biopsy material, vaginal discharge, upper respiratory tract	Endogenous microbiota
<i>Malassezia furfur</i>	Bottle-shaped yeast cells in compact clusters, usually with short hyphal elements	Skin scrapings, blood drawn through catheter lines, hyperalimentation fluids	Inoculate lipid-enriched medium.

V. PROCEDURE (*continued*)**E.** Examination of broth and plate smears

1. Specify Gram stain morphology (e.g., gram-positive cocci in clusters).
2. Specify probable genus or organism group based on Gram stain morphology, colonial morphology, atmospheric requirements (aerobic or anaerobic), and results of any rapid biochemical tests (e.g., probable *Haemophilus* spp. for small pleomorphic aerobic gram-negative bacilli from transparent colonies with a “mousy” odor growing only on CHOC).
3. Refer to Fig. 3.2.1–3 and 3.2.1–4 for typical morphological descriptions of bacterial genera.

- F.** When discarding stained smears, handle as biological waste. Treat slides as sharps, since they may puncture biohazard bags. If cardboard boxes are used, seal with tape prior to discarding.

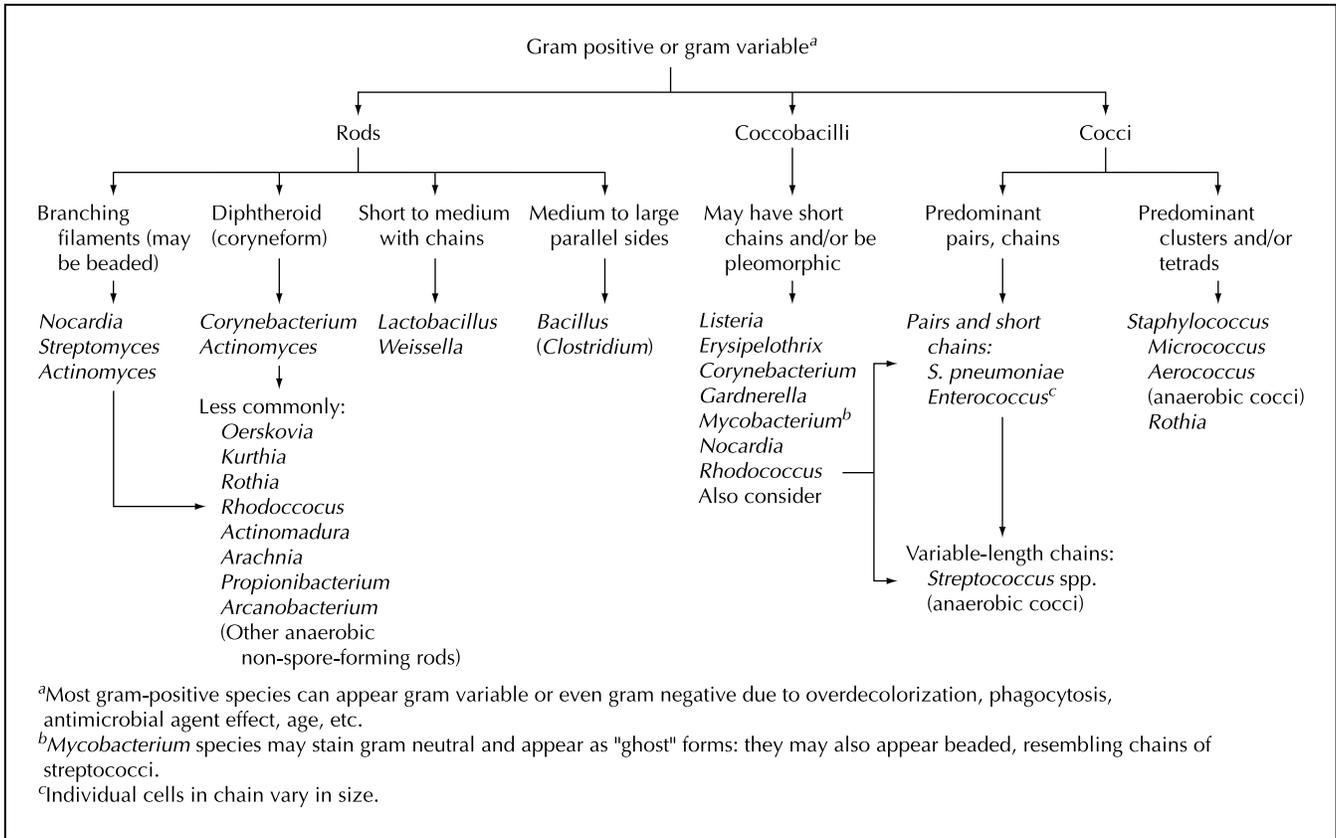

Figure 3.2.1-3 Typical Gram stain morphologies of gram-positive and gram-variable genera.

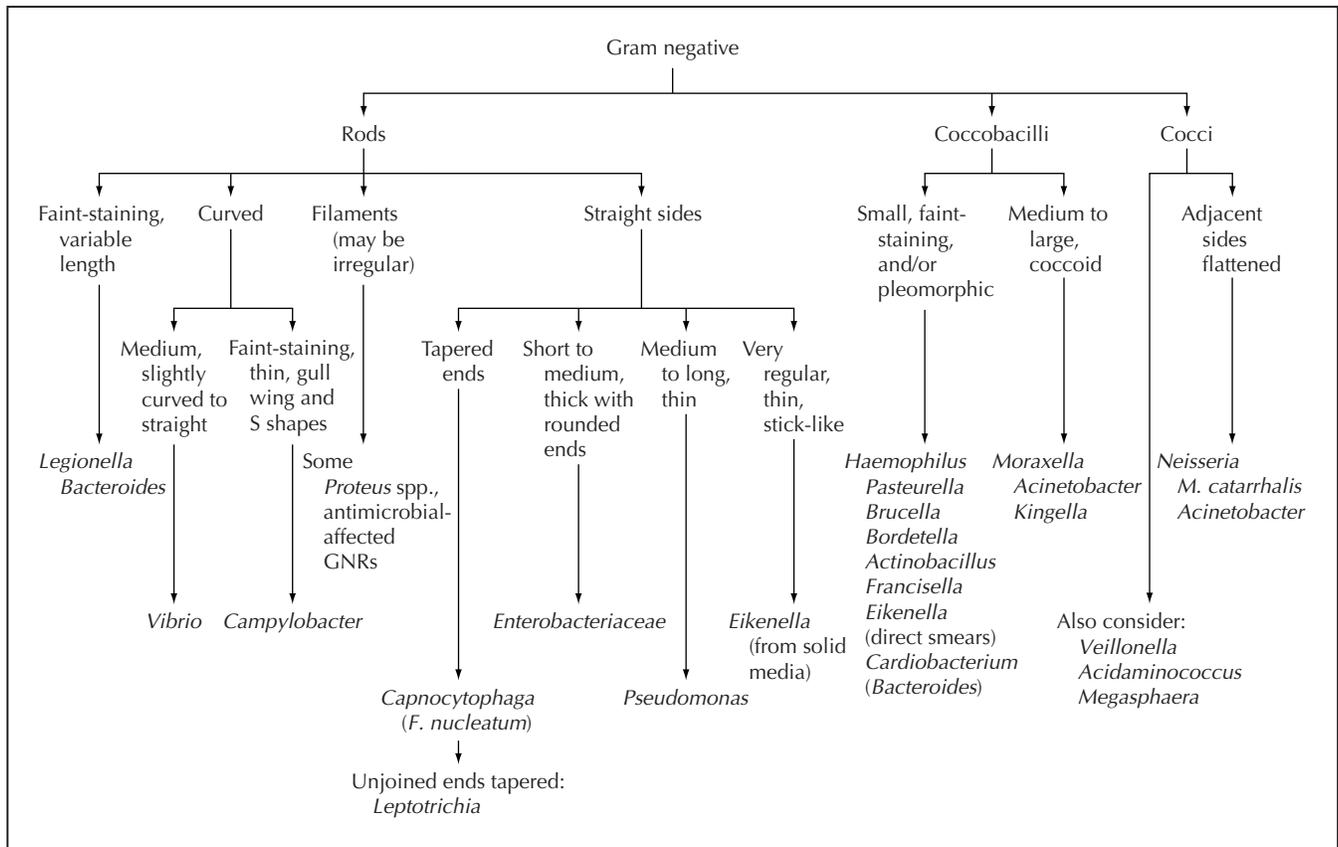

Figure 3.2.1–4 Typical Gram stain morphologies of gram-negative genera.

POSTANALYTICAL CONSIDERATIONS

VI. INTERPRETATION

A. Low-power observations

1. WBCs and RBCs suggest infectious process.

■ **NOTE:** Neutropenic patients may have few WBCs, but they may have necrotic debris and protein in the background.

2. SECs, food debris, etc., suggest an improperly collected specimen (*see* Appendix 3.2.1–2)

3. Certain microorganisms (parasitic forms, branching hyphae, etc.) indicate infectious process.

B. Oil immersion observations

1. Observe microorganisms for characteristic morphology and presentation. See Fig. 3.2.1–3 and 3.2.1–4 for species consistent with each morphology.

2. Gram reaction

a. Gram positive: deep violet

b. Gram negative: pink or red (carbol fuchsin counterstains have a more intense color)

c. Gram variable: both gram-positive and gram-negative cells with the same morphology

■ **NOTE:** This may result from a smear of uneven thickness, incomplete decolorization, overdecolorization, presence of older cells, damage of cell walls, or gram-variable nature of the particular organism.

VI. INTERPRETATION

(continued)

- d. Gram neutral: taking up neither the crystal violet nor the counterstain
 - **NOTE:** These cells appear colorless against a generally gram-negative background and may be intracellular. This reaction has been seen in smears of clinical specimens when fungal elements or *Mycobacterium* spp. are present (3).
- 3. Staining characteristics: even, bipolar, beaded, stippled, barred, or irregular
- 4. Predominant shapes of microorganisms
 - a. Overall shape: round, coccoid, coccobacillary, rod, filament, yeastlike
 - b. Appearance of ends: rounded, pointed, tapered, flattened, clubbed (swollen), concave
 - **NOTE:** Swelling of sides can suggest the presence of spores but can also be due to vacuoles, inclusions, marked pleomorphism, or irregular staining. Phase-contrast microscopy or a spore stain may be helpful in observing bacterial endospores.
 - c. Appearance of sides: parallel, ovoid (bulging), concave, irregular
 - d. Nature of axis: straight, curved, spiral
 - e. Pleomorphism: variation in shape
 - **NOTE:** The descriptive term “diphtheroid” or “coryneform” is used to describe gram-positive bacteria that are pleomorphic, club shaped, or irregularly staining or that have palisading and/or angular arrangements (V and L shapes)
 - f. Branching or cellular extensions
- 5. Relative size
 - **NOTE:** The average size of an RBC is 7 μm , and cytoplasmic granules in neutrophils average 0.2 to 0.3 μm . The size references given here are only guidelines.
 - a. Overall: minute or tiny (<0.3 μm), small (~0.3 to 0.5 μm), medium, or large
 - b. Length: short (~0.5 to 1 μm), medium, long, or filamentous (10 to 30 μm)
 - c. Width: thin, medium, or thick
 - d. Pleomorphic: variation in size
- 6. Characteristic arrangements: singles, pairs, chains, tetrads, clusters, palisades, Chinese letters, packets, angular forms (V and L shapes), etc.
- C. The presence of microorganisms from a normally sterile site is likely to indicate infection with an organism.
- D. For unspun urine, the presence of microorganisms is likely to indicate a bacterial count of $\geq 10^5$ CFU/ml (procedure 3.12).
- E. The presence of large numbers of a single type of microorganism in a noninvasively collected specimen, especially if associated with WBCs, is likely to indicate infection.
- F. Be wary of interpretations made from observing very few organisms (especially in the absence of inflammation or if the organisms are unevenly distributed), because collection tubes, slides, and media may harbor nonviable bacteria. *For critical specimens, where the results will define an infectious process (e.g., CSF smears), prepare a second smear to confirm rare findings of microorganisms.*

VII. REPORTING RESULTS

- A. If no organisms or cells are detected in a smear of a clinical specimen, report “No organisms seen” or “No cells seen,” respectively.
- **NOTE:** While there is no scientific basis for a policy on enumeration of cells and bacteria in stained smears, the following standard is the most applicable to all specimens and will provide consistency in the laboratories. The enumeration of cells is based on the publications documenting the relationship between cells and contaminated respiratory specimens (Appendix 3.2.1–2), and the enumeration of bacteria is based on the publications for counts for female genital specimens (Appendix 3.2.1–3). *Counts should be performed only in areas representative of inflammation or necrosis, if present.*
- B. Determine number of cells and bacteria in 20 to 40 fields of the smear. Skip fields where there are no cells or bacteria, and do not average these fields in the counts if there are fields where cells and/or bacteria are present.
- C. Count cells under low-power objective and report relative numbers accordingly.
- **NOTE:** There is no clinically useful reason to report cells present in amounts less than 10 per 40 fields from a Gram stain, which is not primarily a stain to show host cellular morphology.
1. 1+ (rare or occasional): less than 1 per low-power field (LPF)
 2. 2+ (few): 1 to 9/LPF
 3. 3+ (moderate): 10 to 25/LPF
 4. 4+ (many or numerous): >25/LPF
- D. Count bacteria and yeasts under oil immersion and report relative numbers *from areas associated with cells*.
- **NOTE:** Ignore one or two microorganisms on the entire slide, unless the result can be reproduced on a second smear and only then if it is from an invasively collected specimen.
1. 1+ (rare or occasional): less than 1 per oil immersion field (OIF)
 2. 2+ (few): 1 to 5/OIF
 3. 3+ (moderate): 6 to 30/OIF
 4. 4+ (many or numerous): >30/OIF
- E. Follow cellular enumeration with the description of the type of the cells
1. SECs
 2. WBCs
 3. RBCs
 4. Host cellular material
- F. Follow microorganism enumeration with the description of the morphology of the bacteria, providing as much information as possible. Descriptions which can be used include the following.
1. Gram positive
 - a. Cocci in pairs (and chains)
 - b. Cocci in clusters
 - c. Large bacilli
 - d. Small bacilli
 - e. Branching bacilli
 - f. Coryneform bacilli
 2. Gram negative
 - a. Diplococci
 - b. Bacilli
 - c. Bacilli, filamentous (or pleomorphic)
 3. Gram variable: coccobacilli
 4. Budding yeast cells

VII. REPORTING RESULTS

(continued)

5. Pseudohyphae

☑ **NOTE:** Microbiologists should be encouraged to specify Gram stain morphology and resemblance to organism group consistent with the source if the presentation is classic; however, use caution when in doubt, as other species may mimic the typical presentations listed below:

“gram-positive cocci in pairs, consistent with *Streptococcus pneumoniae*”

“small gram-negative coccobacilli, consistent with *Haemophilus*”

“tiny gram-positive bacilli, consistent with *Listeria*”

“gram-negative diplococci, consistent with *Neisseria*.”

- G. Refer to Appendixes 3.2.1–2 and 3.2.1–3 for special reporting of respiratory specimens and female genital specimens, respectively.
- H. *Notify the caregiver or physician of record, depending on local policy, of any clinically significant findings (any bacteria from a normally sterile site). Document notification, including date and time of notification.*

VIII. LIMITATIONS

- A. The sensitivity of the Gram stain is 10^5 cells/ml or 10^4 /ml if the specimen has been prepared with the cytocentrifuge (13). This is particularly applicable to the smear of a drop of urine, where an average of one bacterial cell per field from an examination of 20 fields corresponds to a count of $\geq 10^5$ CFU/ml.
- B. Gram stain of cytocentrifuged BAL with one or more organisms per OIF correlates with active bacterial pneumonia (14).
- C. Use results of Gram stains in conjunction with other clinical and laboratory findings. Use additional procedures (e.g., special stains, inclusion of selective media, etc.) to confirm findings suggested by Gram-stained smears (3).
- D. Careful adherence to procedure and interpretive criteria is required for accurate results. Accuracy is highly dependent on the training and skill of microscopists (16).
- E. Additional staining procedures, such as acridine orange (procedure 3.2.2), are recommended for purulent clinical specimens in which no organisms are observed by the Gram stain method.
- F. Gram stain-positive, culture-negative specimens may be the result of contamination of reagents and other supplies, presence of antimicrobial agents, or failure of organisms to grow under usual culture conditions (medium, atmosphere, etc.).
- G. False Gram stain results may be related to inadequately collected specimens or delays in transit.

APPENDIX 3.2.1–1

Include QC information on reagent container and in QC records.

Preparation of Gram Stain Reagents

A. Hucker's crystal violet

1. Crystal violet stock solution

crystal violet (90 to 95% dye content) ...40 g
ethanol, 95% 400 ml

Dissolve (may take overnight) and mix in a glass bottle, label with a 1-year expiration date, and store at room temperature.

Caution: Ethanol is flammable.

2. Ammonium oxalate solution (1%)

ammonium oxalate (reagent grade)16 g
distilled water1,600 ml

Dissolve and mix in a brown glass bottle, label with a 1-year expiration date, and store at room temperature.

3. Crystal violet working solution

crystal violet stock solution40 ml
ammonium oxalate solution (1%) 160 ml

Filter crystal violet stock solution into a glass bottle. Allow to filter completely, and then filter ammonium oxalate solution. Label with earliest expiration date of stock solutions.

B. Gram's iodine

1. Stock Lugol's iodine solution

iodine crystals (reagent grade)25 g
potassium iodide (reagent grade)50 g
distilled water 500 ml

Mix or let stand until dissolved in a brown glass bottle, label with a 6-month expiration date, and store at room temperature.

APPENDIX 3.2.1–1 (continued)

2. Sodium bicarbonate, 5% (wt/vol)

sodium bicarbonate (NaHCO ₃), reagent grade	50 g
distilled water	1,000 ml

Dissolve in a glass bottle, label with a 1-year expiration date, and store at room temperature.

3. Gram's iodine

stock Lugol's iodine solution	60 ml
distilled water	220 ml
sodium bicarbonate, 5%	60 ml

Mix in a brown glass bottle, label with a 6-month expiration date, and store at room temperature.

Caution: Iodine and potassium iodide are corrosive. Avoid inhalation, ingestion, and skin contact. Do not store near acids.

C. Counterstains

1. Safranin

a. Safranin stock solution

safranin O (certified)	5.0 g
ethanol, 95%	200 ml

Dissolve in glass bottle, label with a 1-year expiration date, and store at room temperature.

Caution: Ethanol is flammable.

b. Safranin working solution

safranin stock solution	20 ml
distilled water	180 ml

Combine in a glass bottle, label with a 1-year expiration date, and store at room temperature.

2. Basic fuchsin, 0.1, 0.2, or 0.8% (wt/vol)

basic fuchsin (reagent grade)	1, 2, or 8 g
ethyl alcohol	100 ml
distilled water	900 ml

Add basic fuchsin to a brown glass bottle. Slowly add ethyl alcohol and let sit overnight. Filter through Whatman no. 1 filter paper. Add distilled water. Label with a 1-year expiration date, and store at room temperature.

3. Carbol fuchsin counterstain

a. Solution A

basic fuchsin (reagent grade)	3 g
ethanol, 95%	100 ml

b. Solution B

melted phenol crystals	50 ml
distilled water	950 ml

Dissolve basic fuchsin in ethanol in a brown glass bottle (solution A). Add phenol to distilled water in a separate flask (solution B). Add solution B to solution A, label with a 1-year expiration date, and store at room temperature.

Caution: Ethanol is flammable, and phenol is corrosive. Avoid inhalation, ingestion, and skin contact.

D. Kopeloff's modification (for anaerobes)

1. Alkaline crystal violet

a. Solution A

crystal violet (90 to 95% dye content) ...	10 g
distilled water	1,000 ml

Dissolve in a glass bottle, label with a 1-year expiration date, and store in glass-stoppered bottle at room temperature.

APPENDIX 3.2.1–1 (continued)

b. Solution B: sodium bicarbonate, 5% (wt/vol)

sodium bicarbonate (NaHCO ₃), reagent grade	50 g
distilled water	1,000 ml

Dissolve in a glass bottle, label with a 1-year expiration date, and store at room temperature.

2. Iodine (Kopeloff's modification)

sodium hydroxide (NaOH), reagent grade	4 g
distilled water	25 ml
iodine crystals (reagent grade)	20 g
potassium iodide (reagent grade)	1 g
distilled water	975 ml

Dissolve NaOH in 25 ml of distilled water in a brown glass bottle. Add iodine and potassium iodide, and dissolve them well. Gradually add 975 ml of distilled water, mixing well after each addition.

Caution: Iodine and potassium iodide are corrosive. Avoid inhalation, ingestion, and skin contact.

3. Decolorizer: 3:7 acetone-alcohol

ethanol, 95%	700 ml
acetone (reagent grade)	300 ml

Combine and mix in a brown glass bottle, label with a 1-year expiration date, and store at room temperature.

Caution: Ethanol and acetone are flammable.

4. Safranin counterstain (Kopeloff's)

safranin O, certified	20 g
ethanol, 95%	100 ml
distilled water	1,000 ml

In a 1,000-ml glass bottle, add only enough ethanol to the safranin to dissolve it (approximately 50 ml). Add distilled water to safranin solution, label with a 1-year expiration date, and store at room temperature. (Basic fuchsin, 0.8% [wt/vol], may also be used for counterstain.)

Caution: Ethanol is flammable.

APPENDIX 3.2.1–2

Rejection Criteria for Sputum and Endotracheal Aspirates for Culture

I. RATIONALE

Despite the frequency of lower respiratory tract infection, diagnostic studies to detect and identify the etiologic agent are insensitive (8). Whether to perform a Gram stain or a culture has been the topic of repeated studies with conflicting conclusions from professional societies, particularly for evaluating cases of community-acquired pneumonia (1, 3, 7). Part of the problem with the Gram stain is the variability of sampling for smears and cultures (2, 6, 9). Everyone does agree that the culture of poorly collected respiratory specimens is a wasteful use of laboratory resources and can lead to erroneous reporting and treatment of patients (1, 5, 10). For laboratories that receive respiratory specimens for smear and culture, the following generally accepted policy should be followed.

II. REJECTION CRITERIA

- A. Do not reject sputum and endotracheal aspirates for culture for *Legionella* or AFB, or specimens from cystic fibrosis patients.
- B. Examine 20 to 40 fields from sputum smears under low power and endotracheal smears under both low power and oil immersion. Average the number of cells in representative fields that contain cells. Reject the following for culture, as poorly collected or not consistent with a bacterial infectious process.
 1. Sputum: ≥ 10 SECs/LPF (1, 5, 10)

■ **NOTE:** If the number of WBCs is 10 times the number of SECs and there is 3 to 4+ of a *single* morphotype of bacteria, accept the specimen for culture. Some authors suggest using >25 SECs/LPF as a criterion, but generally too few sputa are rejected with this policy (10).

APPENDIX 3.2.1–2 (continued)

2. Tracheal aspirates from adults: ≥ 10 SECs/LPF or no organisms seen (4)
3. Tracheal aspirates from pediatric patients: no organisms seen (11)
 - **NOTE:** if no organisms are seen in a specimen with numerous (4+) WBCs and cellular debris, it might be useful to flood the smear with acridine orange (procedure 3.2.2) and observe using fluorescent microscopy to confirm the absence of organisms in the debris. Both pseudomonads and *Haemophilus* can be missed in such smears, because they cannot be distinguished among the cellular debris (Mary K. York, personal observation). In addition, *Legionella* can be visualized with the acridine orange stain, although WBCs are often lacking in this infectious process.

III. REPORTING

When rejecting the specimen for culture, report one of the following as appropriate.

- A. "Smear contains ≥ 10 squamous epithelial cells per low power field, suggestive of poor quality; culture not performed. Please recollect if clinically indicated."
- B. "Smear is negative for bacteria after examination of 40 fields; culture not performed. Contact laboratory if further studies are clinically indicated."

IV. FOLLOW-UP

- A. Notify the caregiver that the specimen will not be cultured.
- B. Charge for the smear but not for the culture.

■ **NOTE:** Particularly for outpatient specimens and those that are grossly purulent, the culture should be inoculated immediately upon receipt without waiting for the results of the smear. Plates from rejected specimens can be discarded or separated from the other cultures and examined later to validate the laboratory policy and staff competency.

APPENDIX 3.2.1–3

Reporting Gram-Stained Vaginal Smears To Diagnose Bacterial Vaginosis and Vaginitis

I. RATIONALE

Bacterial vaginosis (BV) is a clinical syndrome characterized by an abnormal vaginal discharge in women in childbearing years accompanied by a rise in pH from 4.5 and an amine (fishy) smell, especially after addition of KOH to the discharge (6). The microbiota of the vagina shifts from predominantly lactobacilli to a mixture of *Gardnerella vaginalis*, *Prevotella* spp., *Mobiluncus* spp., and often other anaerobes and *Mycoplasma hominis* (1, 5). Greater than 10^7 CFU of these microorganisms per g of vaginal fluid are present with a decrease in the number of lactobacilli, which are no longer the predominant microorganisms (5). In addition, clue cells, vaginal SECs coated with bacteria such that the cell borders are obliterated, can also be present. BV is a risk factor for obstetric sequelae such as low birth weight and premature delivery. The syndrome has been associated with preterm birth, miscarriage, amniotic infections, and postpartum endometritis (2, 3). Treatment with topical metronidazole or clindamycin is effective, but the syndrome can recur (1). Preliminary diagnosis is usually made in the physician's office by checking the pH of the discharge with an indicator stick and adding KOH to detect the odor, although the usage of these inexpensive tests is reportedly low. The clinic-based microscopic evaluation of the vaginal fluid by wet mount is the most frequently used test, but laboratory-based testing is sometimes desired because no microscope is available or the evaluation of the wet mount is inconclusive.

The Gram stain with scoring of relative amounts of microbial morphotypes is the definitive laboratory method for diagnosis (4). *G. vaginalis* is a small gram-negative to gram-positive pleomorphic bacillus, varying from coccobacillus to longer forms up to 2 to 3 μm ; cells can palisade or appear coryneform and irregularly shaped. *Mobilucis* organisms are curved gram-negative rods. The relative numbers of lactobacilli (medium to large gram-positive rods) compared to gram-negative curved rods and gram-variable coccobacilli aid in the diagnosis of BV.

The Gram stain can be useful in the diagnosis of candidiasis in women, when the timing does not allow evaluation of the discharge in the physician's office by wet mount, pH, and odor. Vaginal culture for yeasts is more sensitive than Gram stain and may be useful for the detection of yeasts in women with symptoms consistent with yeast vaginitis whose wet mount examinations are negative. Candidiasis is characterized by a white discharge and a normal pH below 4.2. The Gram stain is less helpful in the diagnosis of purulent vaginitis, characterized by a macroscopically yellowish-green, foul-smelling discharge containing ≥ 30 WBCs per high-power field. The most common etiologic agent of this infection is *Trichomonas vaginalis*, which is seen on wet mount but not Gram stain.

II. SPECIMEN

Collect vaginal secretions from posterior fornix using sterile cotton or Dacron swab.

III. METHOD

Perform the Gram stain with Kopeloff's modification and 0.1% basic fuchsin counterstain. After flooding the slide with crystal violet, add 5 drops of sodium bicarbonate and blow slide to mix. Let stand for 15 s. Continue staining as usual for Gram stain. Examine for host cells and bacteria in the same manner as for a routine Gram stain, and, additionally, score as indicated in Table 3.2.1–A1, *only for women in childbearing years and postmenopausal women on estrogen replacement therapy*.

IV. QUALITY CONTROL

To ensure that smears are being read correctly, prepare a collection of smears showing a variety of scores between 0 and 10. Use these smears for competency testing and training. To determine the accuracy of the interpretation in the teaching collection, perform a culture of each specimen that shows either a preponderance of lactobacilli (scores of 0 to 3) or a preponderance of *Gardnerella* (scores of 7 to 10).

- A. Inoculate CHOC and incubate for 48 h.
- B. Determine the relative amount of lactobacilli (catalase negative, greening of the agar) compared to *Gardnerella* (nonhemolytic, catalase-negative, tiny Gram-variable bacilli) in the third and fourth quadrants of the plate.
- C. Do *not* use selective or differential media to perform the correlation.

APPENDIX 3.2.1–3 (continued)

Table 3.2.1–A1 Standardized scoring method for evaluation of Gram stains for BV

Quantitation of bacterial morphotype ^a	Points scored per morphotype				
	None	1+	2+	3+	4+
Medium to large gram-positive rods	4	3	2	1	0
Small gram-negative or -variable rods	0	1	2	3	4
Curved gram-negative or -variable rods	0	1	1	2	2

^a Modified from Nugent et al. (4) using quantitation from the Gram stain procedure. Circle in each row the number that corresponds to the quantitation visualized in the smear. Add circled numbers to arrive at total score. Interpret as follows: 0 to 3, normal; 4 to 6, intermediate; and 7 to 10, BV.

D. Cultures with 3 to 4+ lactobacilli should correlate with scores of 0 to 3. Cultures with 3 to 4+ *Gardnerella* should correlate with scores of 7 to 10.

V. REPORTING

Follow routine Gram stain reporting method to enumerate and report the following.

- A. WBCs and RBCs
- B. Clue cells
- C. Yeasts

D. Generally pathogenic morphotypes, such as intracellular gram-negative diplococci consistent with *Neisseria* spp.

Then report one of the following based on the score in Table 3.2.1–A1: 0 to 3, “Morphotypes consistent with normal vaginal microbiota”; 4 to 6, “Mixed morphotypes consistent with transition from normal vaginal microbiota”; or 7 to 10, “Mixed morphotypes consistent with bacterial vaginosis.”

3.2.2

Acridine Orange Stain

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Acridine orange is a fluorochromatic dye which binds to nucleic acids of bacteria and other cells. Under UV light, acridine orange stains RNA and single-stranded DNA orange; double-stranded DNA appears green, as first described by Strugger

and Hilbrich in 1942 (3). When buffered at pH 3.5 to 4.0, acridine orange differentially stains microorganisms from cellular materials (1). Bacteria and fungi uniformly stain bright orange, whereas human epithelial and inflammatory cells

and background debris stain pale green to yellow. Nuclei of activated leukocytes stain yellow, orange, or red due to increased RNA production resulting from activation. Erythrocytes either do not stain or appear pale green.

II. SPECIMEN HANDLING

☑ **NOTE:** The acridine-orange stain is an optional stain that can be helpful in detecting organisms not visualized by Gram stain, often due to a large amount of host cellular debris.

- A. For apparent plate growth that is not visualized by Gram stain (e.g., *Mycoplasma*), prepare smear as for Gram stain.
- B. Broths
 - 1. Gram stain-negative blood culture bottles that are detected as positive by the instrument
 - 2. Broths that look turbid but are negative by Gram stain
- C. For direct specimens (urine, CSF, body fluids), when WBCs are seen but no organisms are seen, or isolated, and physician requests additional studies for a difficult diagnosis, make a smear from the specimen as for Gram stain.

III. MATERIALS

- A. **Acridine orange stain** (*see* Appendix 3.2.2-1; also available from most microbiology stain supply vendors)
 - 1. Use the stain directly from the bottle.
 - 2. Store at 15 to 30°C in the dark.
- B. **Methanol, absolute**
- C. **Glass microscope slides**
- D. **Heat block at 45 to 60°C** (optional)
- E. **Immersion oil suitable for fluorescence**
- F. **Fluorescent microscope with the following**
 - 1. Filter system for fluorescein isothiocyanate, i.e., maximum excitation wavelength of 490 nm and mean emission wavelength of 520 nm
 - 2. ×1,000 magnification (100× oil immersion objective)

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Examine the acridine orange staining solution for color and clarity. The solution should be clear, orange, and without evidence of precipitate.
- B. Each time of use, stain a prepared slide of known bacteria, such as *Escherichia coli* mixed with staphylococci, and examine for the desired results. Record results and refer out-of-control results to the supervisor.
 1. Gram-negative rods and gram-positive cocci are fluorescent (orange).
 2. Background is nonfluorescent (green-yellow).

V. PROCEDURE

Observe standard precautions.

☑ **NOTE:** Acridine orange is a carcinogen when absorbed through the skin. Wear gloves when working with this stain.

- A. Prepare a smear of the specimen on a clean glass slide as for Gram stain (procedure 3.2.1). Spread specimen thinly with a sterile stick.
- B. Allow to air dry, or speed dry by placing the smear on the heating block.
- C. Fix smear with methanol by flooding the slide, draining the excess; allow to air dry.
- D. Flood slide with acridine orange stain for 2 min.
- E. Drain the excess stain and rinse thoroughly with tap water.
- F. Allow to air dry. The slide may be *gently* blotted on a clean sheet of filter paper or paper towel to decrease drying time.
- G. Read smear on the fluorescent microscope at $\times 1,000$ (oil immersion). Look for the distinct morphology of bacteria or fungi. No coverslip is needed.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. Record results of stain as negative or positive with the morphology of the organisms seen.
- B. Review Gram stain to see if organisms can be recognized.
- C. If organisms are not seen on direct Gram stain, report the following: "Culture (or specimen) positive for bacteria by acridine orange stain; bacteria not seen in Gram-stained preparation."
- D. If the acridine orange stain is positive from a blood culture, subculture for the most likely organism based on the morphology.
- E. If the smear is negative from a direct specimen, report "No bacteria seen by acridine orange-stained smear."

VII. INTERPRETATION

- A. Bacteria and fungi fluoresce bright orange. The background appears black to yellow green. Human epithelial and inflammatory cells and tissue debris fluoresce pale green to yellow. Activated leukocytes will fluoresce yellow, orange, or red, depending on the level of activation and amount of RNA produced, whereas erythrocytes either do not fluoresce or fluoresce pale green.
- B. The presence of one or more organisms per oil immersion field correlates with a colony count of approximately $\geq 10^5$ CFU/ml if unconcentrated specimen has been used to prepare the smear.
- C. *Ureaplasma* and *Mycoplasma* can be visualized by this method.

VIII. LIMITATIONS

- A. Nuclei or granules from disintegrated activated leukocytes, and certain types of debris, may fluoresce in acridine orange-stained smears. These may be differentiated from microorganisms on the basis of morphology.
- B. Acridine orange staining does not distinguish between gram-negative and gram-positive organisms. The Gram reaction may be determined by Gram staining directly over the acridine orange after removal of the immersion oil. Acridine orange staining may also be done over Gram stain (after removal of oil) if necessary.
- C. Intracellular organisms may be more difficult to see by the acridine orange stain, due to the staining of cellular nuclei.
- D. The acridine orange stain will detect some organisms, especially those that are gram negative, when they are poorly visualized by Gram stain.
- E. The sensitivity of the acridine orange smear is approximately 10^4 bacteria/ml (2).

APPENDIX 3.2.2-1

Include QC information on reagent container and in QC records.

Preparation of Acridine Orange Stain

I. MATERIALS

- A. Acridine orange powder, 20 mg
- B. Sodium acetate buffer, 190 ml
 - 1. Solution A: 100 ml of 1 M $\text{CH}_3\text{COONa}\cdot 3\text{H}_2\text{O}$
 - 2. Solution B: 90 ml of 1 M HCl

Caution: Acridine orange is a carcinogen; avoid all contact with skin. Avoid exposure to powder aerosol by performing reagent preparation in a fume hood and by wearing gloves.

II. PROCEDURE

- A. Acetate buffer: combine solutions A and B.
 - B. Add additional solution B as necessary to yield pH between 3.5 and 4.
 - C. Dissolve powder in buffer until solution is clear of precipitate.
 - D. Store stain away from light (e.g., brown bottle) at 15 to 30°C.
- ☑ **NOTE:** The final acridine orange concentration will be about 100 mg/liter.

Supplemental Reading

3.2.3

Wet Mount for Detection of Leukocytes and Microorganisms

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The presence of WBCs is one factor suggestive of an invasive infectious process. Wet mount examination of noninvasively collected specimens can be useful for rapid, inexpensive evaluation for WBCs and the detection of microorganisms such as yeasts, campylobacters, and *Trichomonas vaginalis*. The method can be done without expensive supplies and equipment, allowing rapid intervention into the disease process in the outpatient setting. The sensitivity of the technique varies with the experience of the microscopist and is generally about 60%.

Fecal leukocytes are produced in response to bacteria that invade the colonic mucosa, e.g., infections caused by *Shigella*, *Campylobacter*, some *Salmonella* organisms, enteroinvasive *Escherichia coli*, and *Yersinia*. Fecal leukocytes are also found in cases of ulcerative colitis, Crohn's disease, amebic dysentery, and antimicrobial agent-associated colitis, associated with *Clostridium difficile* toxin. Leukocytes are not associated with *E. coli* Shiga toxin infections, which is a useful characteristic of the presentation of the disease, since treatment with antimicrobial agents is contraindicated (5). Because of the variability in results for the presence of WBCs in stool and sensitivities of 50 to

60% in gastroenteritis (8) and as low as 14% for *C. difficile* colitis (9), the test cannot be used as a screening test but rather, as one of several tests to evaluate a patient's condition. It is most useful in the outpatient setting for timely evaluation of the patient, since culture confirmation of gastroenteritis is usually delayed several days. In the test, fecal samples from patients are examined microscopically at $\times 400$ magnification for the presence of fecal leukocytes. As an alternative, especially if there is a delay in transport of the specimen, the *LEUKO-TEST*, a rapid latex agglutination test for the presence of elevated levels of lactoferrin, can be done from stool specimens from adult patients, children, and infants not being breastfed (2, 3, 4). The latex particles are coated with antibody to lactoferrin (a breakdown product of fecal leukocytes).

Urinary leukocytes are present in infectious processes such as cystitis, glomerulonephritis, and catheter-associated urinary tract infection, and the report of their presence (pyuria) is helpful in the determination of disease. When WBCs are counted in a hemacytometer, the test has a high sensitivity for disease in infants (7). Urinary wet mounts can also demonstrate

the presence of motile trichomonads, although the sensitivity is lower than that of vaginal wet prep or culture (6). Additionally, the detection of WBCs in urine can be determined by the dipstick for leukocyte esterase (*see* Appendix 3.12–1 in procedure 3.12 for detailed method).

The presence of WBCs is one factor suggestive of an invasive reproductive tract infectious process, including pelvic inflammatory disease and cervical infection due to *Chlamydia trachomatis* or *Neisseria gonorrhoeae*. A wet mount of vaginal fluid can demonstrate the presence of leukocytes, specialized epithelial cells coated with bacteria known as “clue cells,” *T. vaginalis*, and yeasts. This rapid test is useful in the timely detection of bacterial vaginosis and vaginitis. Large numbers of WBCs are associated with *T. vaginalis* infection. Bacterial vaginosis is a clinical syndrome characterized by a shift in the vaginal microbiota from the dominant microbiota of *Lactobacillus* spp. to a mixed microbiota of *Gardnerella vaginalis*, *Prevotella* spp., *Mobiluncus* spp., and *Mycoplasma hominis*. Budding yeasts and/or pseudohyphae of yeasts can also be identified in the vaginal fluid and are an indicator of yeast vaginitis.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

■ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for caregivers. It is the responsibility of the laboratory director or designee to educate physicians and other caregivers on proper specimen collection.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

A. Specimen collection

1. Fresh stool specimen
 - a. Obtain specimen for wet mount and process within 2 h of collection.
 - b. Store specimen for lactoferrin assay at 4°C for up to 48 h either in no preservative or in Cary-Blair or similar culture transport system. Dilute 1:50 for testing.
2. Urine
Collect urine specimen and store at 4°C until testing within 2 h.
3. Vaginal fluid
 - a. Collect fluid from posterior fornix using sterile cotton or Dacron swab.
 - b. Prepare slide immediately (within 15 to 20 min) or place in Amies' gel transport system (Copan Diagnostics, Inc., Corona, Calif.) for submission to the laboratory (1).

B. Rejection criteria

1. Reject stools received greater than 2 h after collection.
2. Do not process stools for detection of an infectious process from inpatients more than 3 days after admission, since the test lacks a reasonable sensitivity in the diagnosis of *C. difficile* disease (9).
3. Do not perform the lactoferrin assay on specimens from breastfed infants, because they generally give a positive reaction (4).
4. Reject vaginal specimens that are not in preservative if they are greater than 2 h old.
 - a. Smears prepared at time of specimen collection are acceptable for cellular evaluation for up to 24 h.
 - b. Unless the specimen is in preservative or culture medium, it is acceptable for trichomonad evaluation only for 15 to 20 min (1).

III. MATERIALS

A. Reagents

1. Saline (0.9% NaCl), preferably at 35°C
2. Loeffler's methylene blue (optional)
 - a. Dissolve 0.3 g of methylene blue in 30 ml of ethyl alcohol.
 - b. Add 100 ml of distilled water.
3. Microscope slides and coverslips
4. *LEUKO-TEST* (TechLab, Blacksburg, Va.)—alternative for fecal specimens

5. Chemstrip LN (Bio-Dynamics, Division of Boehringer Mannheim Diagnostics, Indianapolis, Ind.)—alternative for urine (*see* Appendix 3.12–1 in procedure 3.12)

B. Equipment

1. Phase-contrast (preferred) or bright-field microscope
2. Hemacytometer for infant urine

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Controls for methylene blue stain and saline
 1. Negative control: each day of use, add 1 drop of saline to 1 drop of methylene blue and examine at $\times 400$. No bacteria or cells should be visible.
 2. Positive control: each day of use, examine 1 drop of buffy coat from an EDTA-collected blood sample for cellular components.
- B. Positive controls are not needed for wet mounts if no reagents are added, but evaluate competency with an ongoing program using positive and negative smears showing WBCs, clue cells, and trichomonads. Unfortunately, this is generally accomplished by viewing a collection of photographs.
- C. Follow package insert for controls for the *LEUKO-TEST*.

V. PROCEDURE

Observe standard precautions.

- A.** Specimen preparation
Wear gloves at all times during preparation and reading of smears.
- 1.** Fecal specimens
 - a.** Place 2 drops of saline separated by a wax pencil line on a microscope slide.
 - b.** Add a small drop of methylene blue to one side and a saline drop to the other.
 - c.** Mix each drop with a small portion of stool (preferably liquid stool or sample with blood or mucus).
 - 2.** Vaginal and urine specimens
 - a.** Place 1 or 2 drops of specimen onto slide.
 - b.** If vaginal swab is transported in Amies' gel, suspend into 2 or 3 drops of saline before placing onto the slide.
 - 3.** For urine specimens from pediatric patients, place the drop of urine in a hemacytometer (7).
- B.** Apply coverslip and examine by using the high dry objective, preferably under phase-contrast optics with a 10× eyepiece for a magnification of ×400.
- C.** Observe for and count leukocytes, RBCs, monocytes, and epithelial cells (clue cells in vaginal specimens) in 10 to 20 fields to get an accurate determination of the specimen content.
- ▣ **NOTE:** Clue cells are squamous epithelial cells with bacteria attached to the top and sides. Clue cells appear as granular cells with an undefined edge.
- D.** Observe for parasites that are motile, such as trichomonads.
- E.** In fecal specimens, observe the saline wet prep for bacteria with typical darting “campylobacter” motility.
- F.** Observe for budding yeast cells and pseudohyphae in vaginal exudate and urine but not in fecal specimens, where they are part of the normal microbiota.
- G.** Dispose of slides in sharps container, wipe microscope with 70% ethanol, and remove gloves.
- H.** Follow the package instructions for the latex agglutination procedure for the *LEUKO-TEST*.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A.** Report the number of WBCs and RBCs per high-power field (HPF). Average several fields and report as indicated.
- 1.** Greater than 5/HPF
 - 2.** 1 to 4/HPF
 - 3.** Less than 1/HPF
 - 4.** No cells seen
 - 5.** When using a hemacytometer for urine, report number per microliter.
- B.** Enter the presence of *Campylobacter*, “Motile organisms suggestive of *Campylobacter* species present.”
- C.** Enter the presence of parasites, such as *T. vaginalis* (see procedures 9.6.6 and 9.9.4 for details).
- ▣ **NOTE:** Vaginal infections with *T. vaginalis* are usually accompanied by greater than 30 WBCs/HPF.
- D.** For vaginal specimens, enter the presence of clue cells and yeast.
- E.** If the vaginal specimen is negative for parasites and was not preserved, or not processed within 15 min, report “Unable to determine presence of *Trichomonas vaginalis* in unpreserved specimen.”

VII. INTERPRETATION

- A. Urine**
1. Greater than 5/HPF is considered positive for pyuria. Such a result has a specificity of 90% for predicting catheter-associated infection with greater than 10^5 CFU/ml but a sensitivity of only 37% (procedure 3.12).
 2. Greater than 10/ μ l with the hemacytometer method is reported to have a sensitivity of 84% and a specificity of 90% for predicting pyuria in infants (7).
- B. Fecal WBCs**
1. The presence of >5/HPF had a sensitivity of 63.2% and a specificity of 84.3% in one study (8), but in another study a 52% sensitivity was seen only if >1 WBC/HPF was used as the cutoff (9).
 2. The results of fecal WBCs were not statistically or clinically significantly different from those of lactoferrin testing (8).
 3. *If WBCs are not present and RBCs are present in a stool submitted for culture, always perform a culture for E. coli O157 or a Shiga toxin test (5).*
- C. For vaginal specimens, the sensitivity of testing by wet mount for WBCs is not as important as the examination for clue cells, yeasts, and *T. vaginalis*, although *T. vaginalis* is more common in specimens with WBCs.**
1. The presence of budding yeast is associated with candidiasis.
 2. The presence of clue cells is indicative of bacterial vaginosis.

VIII. LIMITATIONS

- A.** Activated leukocytes disintegrate easily, decreasing the sensitivity of the assay with delays in transit.
- B.** The wet mount is dependent on the expertise of the microscopist, whose work should be reviewed at frequent intervals.
- C.** WBCs are often confused with trichomonads that are no longer moving, which can be avoided by careful examination for the characteristics of the parasite.
- D.** If there is a question in reading the test, the cells, but not yeasts, will dissolve with the addition of KOH (*see* procedure 8.3).
- E.** Delays in transit decrease the ability to detect trichomonads.

APPENDIX 3.2.3-1

Demonstration of *Treponema pallidum* in Specimens Using Dark-Field Microscopy

I. PRINCIPLE

Dark-field microscopy is used to demonstrate the presence of motile *Treponema pallidum* in lesions or aspirates in early-stage syphilis prior to healing of lesions (1, 2, 3).

II. MATERIALS

A. Dark-field microscope with parfocal 10×, 40× to 45×, and 100× oil immersion objectives, 10× oculars, dark-field immersion condenser (single or double deflecting), and a 6.0- to 6.5-V high-intensity lamp with variable transformer for regulating light intensity.

B. Microscope slides, 1 by 3 in.

C. Coverslip, 22 by 22 mm

D. Immersion oil, nondrying

III. SPECIMEN

Collect serous fluid from lesion for examination prior to antimicrobial therapy.

A. Clean surface of lesion with saline, and blot dry.

B. Gently remove any crusts, and discard.

C. Abrade superficially until slight bleeding occurs, using a needle, scalpel blade, or broken glass slide. Irrigate with sterile saline and wipe away the first few drops of blood, etc.

D. Apply gentle pressure at lesion base, touching *clear* exudate in ulcer base with a glass slide.

E. If no exudate is present, add a drop of saline to the lesion or insert a needle and syringe at lesion base, aspirate, and then draw a drop of saline into the needle. Express the material onto a slide.

F. Place coverslip immediately, and examine the slide by dark-field microscopy.

IV. MICROSCOPE EXAMINATION PROCEDURE

A. Search entire specimen with high dry objective for spiral organisms.

B. Center suspicious objects, and examine them under oil immersion objective.

C. Upon completion of examination, discard slide into container of appropriate disinfectant.

V. INTERPRETATION

A. *T. pallidum* organisms appear as delicate, corkscrew-shaped, rigid, uniform, tightly wound, deep spirals; coil appearance is maintained even while organisms are actively motile.

B. Observe for rotational motility around longitudinal base; backward and forward movement; flexion, bending, or twisting from side to side; and snapping motion.

C. Spirochetes are 6 to 14 μm long, which is slightly longer than the diameter of an erythrocyte.

VI. REPORTING RESULTS

A. When organisms are seen that have characteristic morphology, shape, and motility of *T. pallidum*, report “Treponemas resembling *T. pallidum* observed.”

B. When no treponemas are observed, report “No treponemas resembling *T. pallidum* observed.”

VII. LIMITATIONS

The specimen must be examined immediately (within 20 min) to observe motile organisms. If this is not possible, air dry the slide and submit to a laboratory, such as the CDC Syphilis Diagnostic Immunology Section, that has reagents for specific direct fluorescent-antibody examination for treponemas, or purchase reagents from Virostat, Portland, Maine (3).

Observe standard precautions.

Observe standard precautions.

3.3.1

Paratechnical Processing of
Specimens for Aerobic Bacteriology

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The initial processing of clinical specimens for bacteriology is a multifaceted endeavor involving a number of decision-making steps, including the need for processing the specimen for anaerobic bacteriology, mycology, virology, and parasitology, depending on the nature of the specimen. The need for direct tests, such as Gram stains, must also be considered. These issues will determine whether

the specimen requires any pretreatment before inoculation.

First, one must consider the specimen type and its anatomic origin. The second step is the selection of primary isolation media to be used for each specimen type. The final step is the selection of incubation temperature and atmosphere. A biological safety cabinet should be used during the

processing of all specimens, with the possible exception of urine specimens. This procedure covers only general processing instructions for routine cultures. Refer to the Specimen Collection, Transport, and Handling portions of procedures 3.4 through 3.15 for processing by specific anatomic site and the use of specialized media for processing for specific organisms.

II. SPECIMEN COLLECTION,
TRANSPORT, AND HANDLING

Observe standard precautions.

- A. Prepare specimen collection instruction manual and make available to physicians and other caregivers for proper collection, timing, and transport of specimens. This can be achieved by copying the Specimen Collection, Transport, and Handling portions from each of the procedures that follow. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.
 - **NOTE:** Proper specimen collection is critical to isolating the causative agent of infection.
- B. Along with the specimen, design a system to provide the following.
 1. Demographics of the patient: name, address, age, sex, location in the hospital or clinic, identifying number, name of physician of record, name of the physician who is ordering the test, and ICD9 code or diagnosis.
 2. Details of the specimen: type of specimen, anatomic site of collection (if variable), whether the specimen was collected from an invasive procedure (e.g., during surgery), and gross description, if variable.
 3. Specific culture, stain, and antigen test requests.
- C. Provide the above information on each request form, specimen container, and transport carrier.
- D. Determine acceptability of specimen, labeling and collection. See section 2 of this handbook for general rejection criteria and each procedure that follows for specific rejection criteria by specimen type.

III. MATERIALS

- A. The general media used for routine cultures in bacteriology are listed in Table 3.3.1–1.
- B. Stain reagents and supplies (*see* procedures 3.2.1 to 3.2.3.)
- C. Other supplies
1. Sterile petri dishes
 2. Pasteur pipettes
 3. Sterile scissors, forceps, and scalpels
 4. Sterile test tubes
 5. Sterile swabs and sticks
 6. Inoculating loops
 7. System for grinding tissue
- D. Equipment
1. Biological safety cabinet
 2. Incubators (35 to 37°C; both 5% CO₂ and ambient air)
 3. Bactincinerator or flame burner with automatic shutoff (optional)

Table 3.3.1–1 Common routine laboratory media^a

Medium	Abbreviation	Type ^b	Atmosphere	Inhibitor(s)	Purpose
Nonselective agars					
Chocolate agar	CHOC	N	5–10% CO ₂	None	To grow most bacteria, including <i>N. gonorrhoeae</i> and <i>Haemophilus</i>
Tryptic soy agar with 5% defibrinated sheep blood or Columbia agar with 5% defibrinated sheep blood	BAP	N	5–10% CO ₂ preferred; O ₂ for special circumstances	None	To grow most bacteria and determine the type of hemolysis: alpha (green), beta (clear), or gamma (none). Will not support <i>N. gonorrhoeae</i> , <i>Haemophilus</i> , <i>Legionella</i> , or <i>Bordetella pertussis</i> .
Gram-negative rod selective agars					
MacConkey agar	MAC	S, D	O ₂	Bile salts, crystal violet, lactose, neutral red	Gram-negative enteric agar that inhibits growth of gram-positive organisms and yeasts and inhibits the spreading of <i>Proteus</i> . Lactose-positive colonies are pink, and lactose-negative colonies are colorless.
Eosin-methylene blue	EMB	S, D	O ₂	Eosin, methylene blue, lactose, sucrose	Gram-negative enteric agar that inhibits (but does not prevent) the growth of gram-positive organisms and some yeasts. Enhances the growth of <i>Candida glabrata</i> and some molds. Enteric rods have various colors. Lactose- and sucrose-fermenting colonies are dark.
Gram-positive selective agars					
Phenylethyl alcohol with 5% defibrinated sheep blood	PEA	S	5–10% CO ₂	Phenylethyl alcohol	Inhibits most gram-negative bacteria. Used for growth of <i>Staphylococcus</i> and <i>Streptococcus</i> in mixed cultures. Has short shelf life.
Colistin-nalidixic acid Columbia agar with 5% defibrinated sheep blood	CNA	S	5–10% CO ₂	Colistin and nalidixic acid	Inhibits most gram-negative bacteria. Used for growth of <i>Staphylococcus</i> and <i>Streptococcus</i> in mixed cultures.
Selective agar for neisseriae Thayer-Martin	TM	S	5–10% CO ₂	Vancomycin, colistin, nystatin	To select for <i>Neisseria</i> in mixed cultures. For other related agars, see procedure 3.9.3.

Table 3.3.1-1 (continued)

Medium	Abbreviation	Type ^b	Atmosphere	Inhibitor(s)	Purpose
Broths: support the growth of most aerobic bacteria					
Brain heart infusion	BHI	E	Ambient air		BHI and TSB can be supplemented with 0.1% agar to support some anaerobic growth and with X and V factor or sheep blood to support growth of <i>Haemophilus</i> and other fastidious facultative anaerobic organisms. THIO does not support the growth of fastidious facultative anaerobic organisms.
Tryptic soy broth	TSB				
Brucella broth	BRUB				
Thioglycolate	THIO				
Chopped-meat broth	CMB				
Fastidious anaerobic broth (3)	FAB				

^a For enteric selective media for fecal cultures (e.g., Hektoen and XLD), refer to procedure 3.8.1. For specialized media for specific organism requests, refer to the specific procedure for that organism.

^b N, nutrient; D, differential; S, selective; E, enrichment.

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. For agar media, inspect each shipment or batch for cracks in media or plastic petri dishes, thin or unequal fill, hemolysis, evidence of freezing, desiccation, bubbles, and visible contamination and report deficiencies to manufacturer.
- B. Maintain records of date received or prepared, lot number, and expiration date of each medium.
- C. QC media, whether prepared in-house or procured from commercial vendors, with one or more organisms expected to grow and one or more organisms expected to be inhibited, if applicable. See NCCLS document M22-A2 (1) and procedure 14.2 for details, including preparation of stock cultures with controlled inocula of microorganisms.
- D. *Exception:* For media listed in Table 2 of NCCLS document M22-A2 (1) and procured from commercial sources, omit QC and verify that the vendor has controlled the media according to M22-A2.
 - **NOTE:** In 2003, NCCLS proposed additions to the list of commercially prepared media exempt from user QC. Refer to Table 1B of NCCLS document M22-P2 (2). At the time of this publication, the proposed document had not become standard. The user should verify the current standard and check with local regulatory agencies prior to discontinuation of user QC.
- E. Test each lot of CHOC and TM for QC, whether purchased commercially or prepared in-house. Refer to procedure 3.9.3 for QC of TM and related selective agars. For QC of CHOC, use the following positive controls; a negative control is not needed. Incubate plates for 24 to 48 h in 5 to 7% CO₂ at 35°C.

Test organism	Result
<i>Neisseria gonorrhoeae</i> ATCC 43069 or ATCC 43070	Growth
<i>Haemophilus influenzae</i> ATCC 10211	Growth

- F. Check and record incubator temperatures daily; include in records readings of humidity and CO₂ concentrations, if applicable.
- G. Set up a QA program to ensure that the specimens received are of the best possible quality (see section 14). Troubleshoot problems and follow with necessary revisions to existing procedures to improve quality.
- H. Prepare an alternative testing policy to be used when the laboratory is unable to perform testing if reagents, personnel, and methods of communication are not available. The following are examples.

IV. QUALITY CONTROL

(continued)

1. If media cannot be supplied by vendor, contact alternative vendor . . .
2. If incubator is inoperable, use alternative incubator located at . . .
3. If computer system is not operable, send manual reports according to details in the computer crash plan.

V. PROCEDURE

Observe standard precautions.

A. Timing

The most important specimens must be inoculated to media first. Look through the cultures and pull out all those that are invasively collected. The preferred order of setting up cultures is listed in Table 3.3.1–2. The delay of inoculation and processing of certain specimens can affect the quality of the culture and ability to isolate pathogens.

B. Specimen pretreatment

1. Work in a biological safety cabinet. Wear gloves, laboratory coat, and other protective equipment when working with specimens.
2. Verify that the patient names on the specimen and the request form agree, and assign an identifying number to the specimen.
3. Generally, look for the most purulent part of the specimen and use that for smears and culture.
 - a. Fluids, except urine
 - (1) For normally sterile body fluids
 - (a) Use the cytocentrifuge to concentrate smears from clear fluids.
 - (b) In addition to plate culture, inoculate broth culture, diluting the specimen 1:10 in broth.
 - (c) For joint and peritoneal fluid specimens, culture at least 10 ml of specimen.

■ **NOTE:** The culture of large volumes of specimen has been shown to have a higher yield than centrifugation of specimens for aerobic bacteria. Generally inoculation of up to 10 ml into the aerobic and 10 ml into the anaerobic blood culture bottle will increase the yield of the causative agent from joint and peritoneal body fluids.

Table 3.3.1–2 Order of specimen processing for bacteriology when multiple specimens are received at the same time

Order	Common tests or specimens	Maximum time to processing
1	STATS: specimens from surgery and normally sterile sites are processed before STATs from nonsterile body sites.	20 min after receipt
2	<i>N. gonorrhoeae</i> cultures submitted on plates or unpreserved swabs	20 min after receipt
3	CSF (treat all as STAT)	20 min after receipt
4	Tissues	1 h
5	Body fluids	1 h
6	Abscesses	1 h
7	Unpreserved stools for culture	30 min after collection, or place in transport medium immediately ^a
8	Sputum and other lower respiratory cultures	1 h at room temp, 2 h at 4°C
9	Blood	4 h at room temp after collection
10	Swabs in transport tubes	8 h at 4°C
11	Urine	Up to 24 h at 4°C
12	Group A and B streptococcal cultures	8 h at 4°C

^a *Shigella* sp. viability is compromised unless the specimen is placed in transport medium.

V. PROCEDURE (*continued*)

- (2) For other liquid specimens, inoculate plates and smears using a swab or pipette dipped into the liquid.
 - b. Tissues**

Refer to procedure 3.13 for details on preparation of tissues for smear and culture.
 - c. Swabs**
 - (1) Reject dry swabs not submitted in transport medium.
 - (2) Use the swab to streak the first quadrant of the plate. If a second swab is submitted, use for smear preparation.
 - (3) If only one swab is received or several plates and smears are to be prepared, place swab into a small amount of broth and vortex. Ream swab to expel all fluid and discard. Then use a pipette to inoculate agar plate media and to prepare smears.
 - **NOTE:** Use of the CultureSwab EZ II system (BD Diagnostic Systems) omits the need to extract the organisms from the swab.
 - d.** For prosthesis specimens and other surgical foreign-object specimens with no visible tissue or purulent fluid that can be cultured, add culture broth to the sterile specimen container and incubate at 35°C for 18 h. Then subculture broth and perform a Gram stain. Hold broth with rest of culture. If the object is from a genital source (e.g., intrauterine device), touch specimen to a CHOC plate and to anaerobic plates prior to adding broth.
 - e.** For catheter tips, refer to procedure 3.6 for quantitative and semiquantitative methods of culture.
 - f.** Refer to procedure 3.12 for options to inoculate quantitative urine cultures.
- 4. Saving specimens**
 - a.** Hold urine and stool not in preservative only long enough to resolve any labeling problems. These specimens should be recollected rather than recultured if there are indications to do so.
 - b.** Hold samples from other nonsterile sites for 1 to 2 days, usually at 4°C, to resolve any problems.
 - c.** Hold specimens from normally sterile sites for 7 days at 4°C, if possible. Rotate specimens such that older ones are discarded in favor of recently cultured specimens.
 - d.** Freeze CSF at -20°C in case PCR testing is requested after evaluation of cultures.
- C. Medium choices** (*see* Table 3.3.1-1)
 - 1.** Inoculate most specimens onto a BAP.
 - 2.** In addition, inoculate specimens from normally sterile sites, genital sites, and respiratory sites to CHOC (or, optionally, horse blood agar for respiratory specimens).
 - 3.** Add additional media based on nosocomially significant microorganisms.
 - 4.** For specimens from nonsterile sites, inoculate to either MAC or EMB to select for these organisms within normal microbiota.
 - 5.** Use Columbia colistin-nalidixic acid agar (CNA) or phenylethyl alcohol agar (PEA) to select for gram-positive organisms in specimens potentially contaminated with gram-negative microbiota.
 - 6.** Inoculate tissues from surgery and fluids from selected normally sterile sites to broth to detect low numbers of organisms.
 - 7.** Refer to the individual procedures that follow for details of inoculation of stool cultures and cultures for specific organisms to special media.
 - D.** Perform Gram stains on most respiratory and wound cultures, all cultures from normally sterile sites, and urine and genital cultures, on request. Gram stains

V. PROCEDURE (continued)

are not performed on throat, nasal, stool, or catheter tip cultures. For smear preparation, see procedure 3.2.1.

1. Prepare the smear after the culture has been inoculated to avoid contamination. Never touch the slide with a pipette or swab that will then be used for culture.
2. If there is insufficient specimen, omit the smear rather than the culture.
3. *If the smear result indicates a mixed culture and selective medium was not inoculated, add appropriate selective medium to the culture inoculation.*
4. Use a cytocentrifuge to prepare smears from normally sterile body fluids, especially CSF.

E. Inoculation technique

1. Label plates with at least the identifying number and date of culture. If convenient, label at least one plate with the anatomic site and patient name.
2. Generally inoculate onto plate by touching specimen to one quadrant with a swab, pipette, or sterile forceps containing the specimen.
 - a. Sterilize the inoculating loop in the microincinerator for 5 to 10 s. Allow to cool. Alternatively, use separate, sterile disposable loops or sticks.
 - b. Streak with gentle pressure onto one-fourth to one-third of the culture plate using the sterile loop, or stick, with a back-and-forth direction several times and without entering the area that was previously streaked. Avoid touching the sides of the petri dish.
 - c. Turn the plate a quarter turn. Pass the loop through the edge of the first quadrant approximately four times, while streaking into the second quadrant. Continue streaking in the second quadrant without going back to the first quadrant.
 - d. Rotate the plate another quarter turn and repeat the above procedure until one or two additional quadrants are streaked, as shown in Fig. 3.3.1–1.
3. For normally sterile specimens, use separate disposable loops, sticks, or needles for each plate. Alternatively, flame the loop or needle between each plate inoculation. Use biplates to save handling time and space (Fig. 3.3.1–2).
4. For inoculation of plates to detect beta-hemolysis, carefully stab the agar with the same loop both inside and outside the inoculated area to expose the organism to anaerobic conditions (Fig. 3.3.1–3) (usually done for throat cultures).

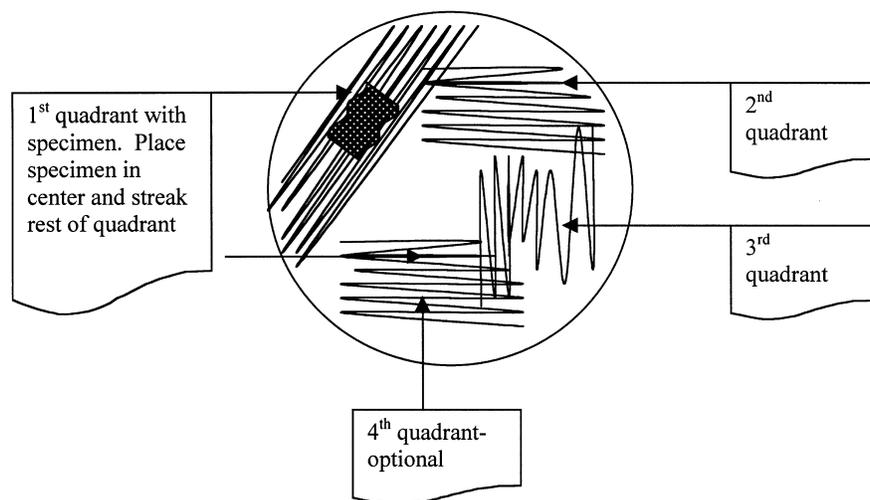

Figure 3.3.1–1 Appropriate method to streak plate for isolation of bacteria. Inoculate first quadrant with a few drops or pieces of specimen or by rolling a swab on a small area.

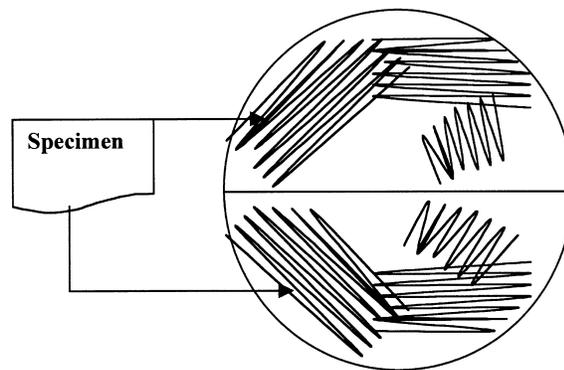

Figure 3.3.1–2 Inoculation of biplate, often used for specimens from sterile sites when blood agar and CHOC are needed. To avoid cross contamination of media with plate contaminants, always use a separate loop or flame loop between inoculation of each side of plate.

V. PROCEDURE (continued)

5. For urine, catheter tips, and quantitative cultures, do not streak in quadrants. Refer to the relevant procedures in this section.
6. Optional: for respiratory specimens or aerobic wound cultures, cross streak or dot the BAP with coagulase-negative staphylococci after the specimen has been inoculated to the plate, to allow for recognition of *Haemophilus* (Fig. 3.3.1–4). This technique may be done instead of or in addition to the CHOC plate inoculation. Refer to procedure 3.17.44 for further details.

F. Incubation

1. Separate all inoculated direct plates and broths according to the sorting system used in the laboratory (e.g., alphabetical by patient name, by specimen type, by ward, etc.).
2. Generally place in order by workstation in canisters and incubate in a humidified incubator at 35°C.
 - a. Supply humidity by an automatic humidifier or by placing a large pan of water at the bottom of the incubator.
 - b. Check humidity control or water level daily to maintain constant humidity.

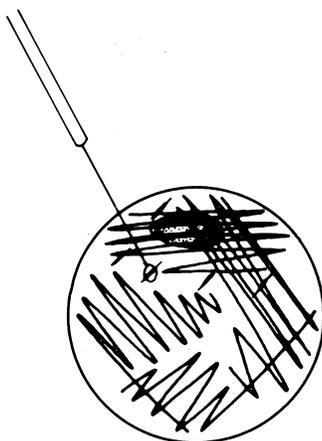

Figure 3.3.1–3 Optional method of streaking plate for throat cultures.

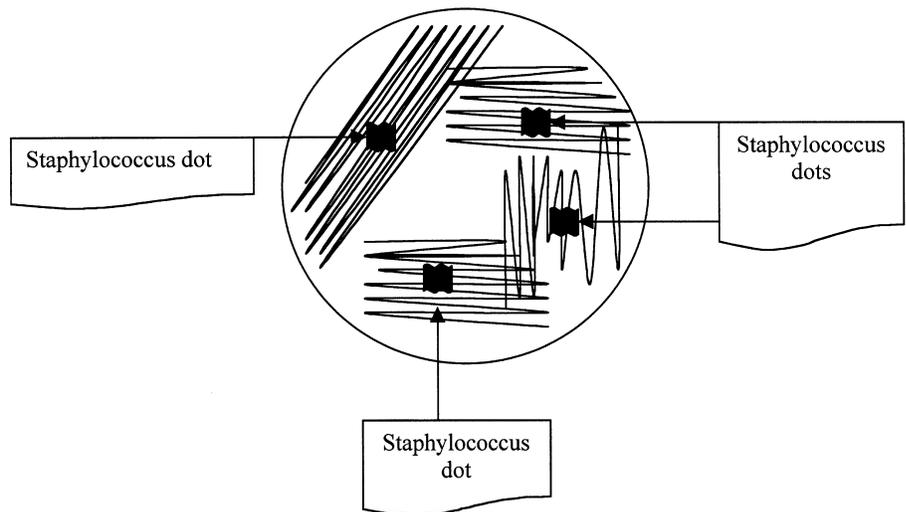

Figure 3.3.1–4 Alternative for detection of *H. influenzae* on BAP (e.g., respiratory specimens).

V. PROCEDURE (continued)

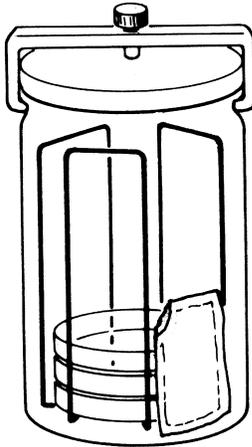

Figure 3.3.1–5 GasPak envelopes in airtight jar, used to produce 5 to 7% CO₂ atmosphere.

3. Provide 5 to 7% CO₂ for appropriate cultures, particularly those for possible isolation of *Streptococcus pneumoniae*, *Haemophilus influenzae*, and *Neisseria gonorrhoeae*, especially routine respiratory cultures, genital cultures, and normally sterile body fluid cultures. CO₂ can be supplied as follows.
 - a. By incubators with special controls and a CO₂ gas cylinder
 - b. By using a gas-generating envelope in an airtight jar (Fig. 3.3.1–5) or plastic container *or*
 - c. By placing the medium in a bag with a CO₂-generating ampoule or tablet.
4. Do *not* incubate the following in increased CO₂.
 - a. Stool culture selective agar
 - b. *Legionella* cultures
 - c. *Bordetella pertussis* cultures
 - d. Throat cultures when using BAP without selective media with antimicrobial agents
5. Increased CO₂ is optional for the following.
 - a. MAC or EMB
 - b. Broths and blood cultures
 - c. Group B streptococcal cultures
 - d. Diphtheria cultures
 - e. Urine cultures
6. Cultures for special organisms have special requirements. See the relevant procedures (e.g., for *Campylobacter*, *Bartonella*, and *Haemophilus ducreyi*).
7. Incubate anaerobic plates in an anaerobic environment, as discussed in section 4 of this handbook.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING SPECIMEN INFORMATION

- A. Document association of specimen identifying number with patient demographics (name, patient identifier, patient location) and information on the specimen (anatomic site, date and time of collection, and name of person ordering the test).
- B. Document type, container, and macroscopic description of specimen (e.g., color, consistency, etc.).
- C. Document all problems with specimens, culturing, and test requests in laboratory report and notify the collecting location of such problems.
- D. If ICD9 code is available, provide access to information to person examining culture.

VII. LIMITATIONS

- A. False-positive cultures result from specimen mix-up and from contamination of media used for culture.
- B. False-negative results are due to improper collection, delays in culture inoculation, inappropriate medium usage, and inappropriate incubation conditions.

3.3.2

Interpretation and Rapid Identification of Bacterial Growth on Primary Culture Media

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The initial interpretation of bacterial growth on primary culture media, which usually follows the first 24 to 48 h of incubation, is an opportunity for the skilled microbiologist to make a preliminary identification and to decide what addi-

tional tests and procedures must be performed to arrive at a definitive identification. Many of the tables in this procedure are useful for a staff training manual, but they need not be a part of the bench manuals for daily use.

II. SPECIMEN

Cultures of specimens incubated for routine bacterial culture at 35°C for 24, 48, or ≥ 72 h

III. MATERIALS

A. Reagents and biochemical tests

1. Aminolevulinic acid (ALA) test (procedure 3.17.3)
2. Bile solubility (procedure 3.17.6)
3. Bile-esculin (procedure 3.17.5)
4. Butyrate disk test (procedure 3.17.7)
5. Catalase reagent (procedure 3.17.10)
6. Coagulase and agglutination tests for detection of coagulase (procedures 3.17.13 and 3.17.14).
7. Gram stain reagents (procedure 3.2.1)
8. Hippurate test with ninhydrin (procedure 3.17.21)
9. Indole reagent (procedure 3.17.23)
10. Lencine amino peptidase (LAP) (procedure 3.17.26)
11. 4-Methylumbelliferyl- β -D-glucuronide (MUG) (procedure 3.17.34)
12. Mueller-Hinton (MH) agar for growth studies and disks (e.g., novobiocin) (procedure 3.17.4)

13. Optochin (procedure 3.17.38)
14. Ornithine decarboxylase (procedure 3.17.15)
15. Oxidase test reagent (procedure 3.17.39)
16. Pyrrolidonyl- β -naphthylamide (PYR) (procedure 3.17.41)
17. Urea disks (procedure 3.17.48)
18. Other tests for sugar fermentation, pigment enhancement, serology, DNA probes, gelatin, germ tube, H₂S, motility, and various kit identification systems

B. Supplies

1. Microscope
2. Microscope slides
3. UV (Wood's) light
4. Petri dishes and sterile sticks and inoculating loops

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A.** Verify that media meet expiration date and QC parameters per the current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
- B.** For QC requirements for biochemical tests, refer to the individual tests in procedure 3.17.

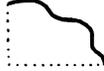

V. PROCEDURE

For specimens from lymph nodes and tiny colonies from normally sterile sites, examine cultures in a biological safety cabinet (4).

A. Initial examination of primary plates

- 1.** Describe colonial morphology for each agar medium.
 - a.** Note the different types of colonies on each agar plate.
 - (1) When making these initial assessments, look at the culture plates from different angles and use direct illumination of the plate.
 - (2) Use a light with a magnifying lens to observe slow-growing or very small colonies, which are often hidden between the much larger rapidly growing colonies.
 - b.** Describe the gross colonial morphology of each colony type. Refer to Table 3.3.2–1 for a list of terms.
- 2.** Enumerate each colony type per the criteria in Table 3.3.2–2.
 - a.** Do not enumerate as CFU in cultures (other than urine, quantitative cultures, and catheter tips) since the specimen has not been quantitatively sampled.
 - b.** On the work record, note the number of colonies on each of several media to distinguish suspected plate contamination from true presence of an organism in a culture.
 - c.** Be careful when one mold colony is larger than several smaller ones. The smaller ones could have arisen from the larger one; all could be contaminants.
- 3.** Interpret colonies on various primary culture media to determine the most likely genus. Refer to Table 3.3.2–3 for a list of common microorganisms and their characteristics on primary media. Refer to procedure 3.8.1 for media specific to the detection of stool pathogens.
 - a.** Note the appearance of organisms on general-purpose primary media.
 - b.** Be aware of organisms that will grow or are inhibited on various selective primary media. Commonly used primary culture media and the likely pathogens isolated from each medium are described in Table 3.3.2–4.
 - c.** Observe medium changes in the vicinity of the bacterial colonies that provide some indication of bacterial activity. Different dyes, sugars, and other ingredients are incorporated into the media to detect end products of bacterial enzymatic activity.
 - d.** Note hemolysis, which is helpful in characterizing microorganisms.
 - (1) Alpha-hemolysis is the reduction of hemoglobin to methemoglobin, producing a greenish discoloration; RBC membrane is intact on microscopic inspection.
 - (2) Beta-hemolysis is the lysis of RBCs, resulting in a distinct, clear, colorless zone surrounding and under the colony. The RBC membrane is destroyed.
 - (3) Gamma-hemolysis indicates no hemolysis. No destruction of RBCs occurs, and there is no change in the medium.

Table 3.3.2-1 Terms to describe gross colonial morphology

SIZE (diameter in mm)	Large = greater than 1mm in diameter Medium = 1mm in diameter Small = less than 1mm in diameter					
SHAPE	 Circular	 Filamentous	 Irregular	 Punctiform	 Rhizoid	 Spindle
ELEVATION	 Flat	 Raised	 Convex	 Dome shaped	 Umbonate	 Umbilicate
MARGIN (edge of colony)	 Entire	 Undulate	 Lobate	 Erose	 Filamentous	 Curled
COLOR	White, Black, Cream, Orange etc.					
SURFACE APPEARANCE	Glistening		Dull			
	Smooth		Rough			
	Granular		Creamy			
DENSITY (ability to see through the colony)	Opaque = can not see through the colony Transparent = can see through the colony Translucent = only with light shining through					
CONSISTENCY (best observed by picking up a colony with a loop or needle)	Butyrous (buttery)		Brittle			
	Viscid (sticky)		Membranous (pliable)			
	Friable (crumbles easily)					

V. PROCEDURE (*continued*)

- (4) Alpha-prime-hemolysis is a small zone of complete hemolysis that is surrounded by an area of partial lysis with green discoloration. Alpha-prime-hemolysis is best seen when magnification is used to observe the colonies.
- e. Check for pigment production. If needed, take a swab and pick up some colonies to check for pigment against a white background.
 - (1) Water-soluble pigments produce a discoloration of the surrounding medium, best seen on colorless agars.
 - (2) Nondiffusible (carotenoid) pigments are confined to the colonies themselves.

Table 3.3.2–2 Enumeration guidelines

Report	If the observation is growth
Isolated from broth only	In broth only
Scant growth	One to five colonies. For one colony of skin microbiota, may wish to add note regarding possible contamination.
1+ or few	In first quadrant only, ignoring a few colonies in the second quadrant
2+ or moderate	Up to second quadrant, ignoring a few colonies in the next quadrants
3+ or numerous	Up to third quadrant, ignoring a few colonies in the fourth quadrant
4+ or numerous	Up to fourth quadrant
Number + CFU/ml	For urine and quantitative cultures
Number + CFU	For intravascular catheter tips

V. PROCEDURE (continued)

- f. Include odors in the evaluation of colonies. Many bacteria have distinct odors that are strong clues to their presence and/or identification.
 - (1) *Pseudomonas aeruginosa* is described as having a fruity, grape-like odor.
 - (2) *Eikenella corrodens* often smells like bleach or crackers.
 - (3) *Proteus* species have been described as smelling like devil's food cake or burnt chocolate.

☑ **NOTE:** Because of the danger of laboratory-acquired infections with microorganisms whose aerosols are infectious (4), use care when smelling colonies. Do not hold plate near your face, and limit smell to what is obvious from opening the plate at arm's length.

B. Preliminary testing

1. Day 1

- a. Gram stain colonies that do not appear to be normal microbiota or gram-negative rods growing on gram-negative rod selective agars.
- b. Perform initial rapid identification procedures (catalase, oxidase, indole, etc.) for clinically relevant colony types as correlated with Gram stain and most likely pathogen. See Table 3.3.2–5 for appropriate testing.
- c. Some specimen types will yield mixed cultures of >3 morphotypes of bacteria. Depending on the source of the specimen and whether these colonies represent potential pathogens, report such cultures with morphologic descriptions and minimal workup.
- d. Set up definitive biochemical tests or other identification protocols on clinically relevant isolates, if sufficient pure culture material is available and identification from rapid tests is not definitive per Table 3.3.2–5.

☑ **NOTE:** The recommendations in Table 3.3.2–5, except as noted in the table, include the minimum required to identify the organisms listed with a greater than 95% accuracy as presented in the guidelines of the NCCLS (1). Further testing even from normally sterile sites is not needed if there is a definite identification from performance of the tests listed.
- e. Set up susceptibility tests as appropriate (references 2 and 3 and section 5).
- f. Make subcultures of nonisolated colonies to appropriate media for later evaluation.

Table 3.3.2–3 Colonial morphology on primary media

Organism(s)	Morphology on:		
	BAP or CNA ^a	CHOC	MAC/EMB ^b
<i>Escherichia coli</i>	Gray, mucoid, flat or convex, not swarming, may be beta-hemolytic ^c	Same as BAP	Pink/dark center and may have green sheen
<i>Proteus</i> spp.	Flat, gray, spreading ^c	Same as BAP	Colorless
<i>Pseudomonas aeruginosa</i>	Flat, gray-green, rough, may have spreading margins, metallic sheen, may be extremely mucoid ^c	Same as BAP	Colorless
<i>Neisseria gonorrhoeae</i>	Inhibited	Small, gray, entire, sticky	Inhibited
<i>Neisseria meningitidis</i>	Medium to large, creamy and gray, alpha-hemolytic ^c	Same as BAP, no hemolysis	Inhibited
<i>Haemophilus</i> spp.	Inhibited	Gray, raised, smooth, may be mucoid	Inhibited
<i>Moraxella catarrhalis</i>	Whitish, medium to large, raised or dome shaped ^c	Same as BAP	Inhibited
<i>Staphylococcus aureus</i>	Large, convex, white-yellow, creamy, opaque, may be beta-hemolytic	Same as BAP, no hemolysis	Inhibited/may be pinpoint
Coagulase-negative staphylococci	White-gray, raised, creamy	Same as BAP	Inhibited
Beta-hemolytic streptococci	Pinpoint to medium, zone of beta-hemolysis (clear zone) translucent, dull, gray	Same as BAP, no hemolysis	Inhibited
Viridans group streptococci	Pinpoint to medium, white-gray, caramel odor, alpha-hemolysis	Same as BAP	Inhibited
<i>Enterococcus</i> spp.	Gray, medium, usually no hemolysis	Same as BAP	Inhibited/may be pinpoint
<i>Streptococcus pneumoniae</i>	Umbilicate, alpha-hemolysis, transparent, may be mucoid, flattened, or teardrop shaped	Same as BAP	Inhibited
<i>Listeria monocytogenes</i>	Whitish gray similar to group B streptococcus, flat, narrow zones of beta-hemolysis	Same as BAP, no hemolysis	Inhibited
<i>Corynebacterium</i> spp.	White, dry, may be sticky	Same as BAP	Inhibited
Yeast cells	White, creamy, bread odor, “feet” extending from colony	Same as BAP	Inhibited/pinpoint

^a CNA, Columbia colistin-nalidixic acid agar.

^b EMB reaction is listed after MAC reaction separated by a slash, if they differ.

^c Inhibited on CNA.

V. PROCEDURE (continued)

- g. Reincubate all primary and subculture media for an additional 8 to 12 h.
- h. Examine broth cultures by following the procedure below.
- i. Prepare preliminary report.
- j. When colonies are too small to determine their characteristics and incubation has been less than 18 h, report as “too young to evaluate.” Reread plates later in the day.

Table 3.3.2–4 Commonly used primary plating media^a

Medium	Expected isolates	Comments
CHOC	Most microorganisms, including <i>Haemophilus influenzae</i> , <i>Neisseria gonorrhoeae</i> , and <i>N. meningitidis</i>	Low agar content provides increased moisture required by some organisms. Contains heme and often has enrichments, such as IsoVitaleX and cysteine for fastidious organisms. (CHOC without enrichment should not be used for routine cultures.)
BAP with 5% sheep blood	Gram-positive and gram-negative organisms	General-purpose medium. Hemolysis can be observed. Stabbing creates area of reduced O ₂ , which can demonstrate oxygen-labile hemolysin O.
PEA	Gram-positive organisms	Inhibits gram-negative bacilli.
CNA with 5% sheep blood	Gram-positive organisms	Colistin inhibits gram-negative organisms, and nalidixic acid inhibits <i>Proteus</i> spp. Hemolysis may be observed. Columbia agar base is enriched for gram-positive organisms.
EMB	Gram-negative enteric bacilli	Differentiates L+ or Su+ (black, purple, metallic sheen) from L– or Su– (colorless or transparent). <i>Pseudomonas aeruginosa</i> is violet with filamentous margin. L and/or Su fermenters are generally normal enteric bacteria. Gram-positive organisms are inhibited by EMB. The agar concentration can be increased to 5% to inhibit swarming of <i>Proteus</i> spp. Enterococci can appear pinpoint.
MAC	Gram-negative enteric bacilli	Differentiates L+ (pink) from L– (colorless). Gram-positive organisms are inhibited by bile salts. The agar concentration can be increased to 5% to inhibit swarming of <i>Proteus</i> spp.
TM or MTM agar	<i>Neisseria gonorrhoeae</i> , <i>Neisseria meningitidis</i>	Vancomycin inhibits gram-positive organisms, colistin inhibits gram-negative organisms, and nystatin inhibits yeast cells. Trimethoprim lactate is added to inhibit <i>Proteus</i> spp. <i>Neisseria lactamica</i> may grow.

^a Abbreviations: L, lactose; Su, sucrose; TM, Thayer-Martin; MTM, modified Thayer-Martin. For other abbreviations, refer to Table 3.3.1–1.

V. PROCEDURE (continued)

2. Day 2

- a. Read and record reactions and test results from previous day.
- b. Reexamine plates and broth for changes and for colony morphologies not present the previous day.
- c. Read anaerobic plates.
 - (1) Distinguish between organisms that are true anaerobes (i.e., those which grow markedly better or only under anaerobic conditions) and those that are facultative anaerobes (i.e., those which grow equally well aerobically and anaerobically) by performing Gram stains and comparing colonies on anaerobic plates to those present on aerobic plates.

Table 3.3.2–5 Common pathogens and rapid and conventional methods to identify them when suspected from colony morphology listed in Table 3.3.2–3

Organism	Presumptive identification	Additional tests for definitive identification ^a	Special requirements
Gram-negative rods			
<i>Escherichia coli</i>	1. Oxidase negative 2. Indole positive 3. Hemolytic	If not hemolytic, then either lactose positive and PYR negative or MUG positive	If lactose negative or not known, PYR will not identify. Confirm non-lactose fermenting from sterile sites with kit.
<i>Proteus mirabilis</i>	1. Spreading 2. Indole negative	No other testing if ampicillin susceptible. If ampicillin resistant, could be <i>Proteus penneri</i> .	If ampicillin resistant, confirm with positive ornithine or negative maltose fermentation.
<i>Proteus vulgaris</i>	1. Spreading 2. Indole positive	No other testing for definitive identification	
<i>Pseudomonas aeruginosa</i>	1. Oxidase positive 2. Indole negative 3. Fruity odor of grapes	Odor is definitive. If not fruity odor, blue-green pigment is definitive.	If not fruity or blue-green pigment, has green, fluorescent pigment, and grows at 42°C. ^b If cystic fibrosis patient, check colistin or polymyxin B; must be susceptible. Gelatin or lecithin will separate.
<i>Pseudomonas fluorescens/putida</i> ^b	1. Oxidase positive 2. Indole negative	Fluorescent but no odor or growth at 42°C	
<i>Vibrio/Aeromonas</i> ^b	1. Oxidase positive 2. Indole positive 3. MAC positive	Do kit and growth on MH agar with and without salt to identify (procedure 3.8.1)	If no growth on MAC, could be <i>Pasteurella</i> (see Table 3.18.2–3)
<i>Eikenella corrodens</i> ^b	1. Gram-negative rod 2. Oxidase positive 3. Catalase negative 4. No growth on MAC 5. Nonhemolytic	Odor of bleach; ornithine positive	
<i>Haemophilus influenzae</i>	1. Gram-negative coccobacilli 2. Good growth on CHOC in 24 h and not on BAP, or satellite growth on BAP around staphylococci	Negative ALA test for porphyrin	The nonpathogenic <i>Haemophilus haemolyticus</i> is beta-hemolytic on horse or rabbit blood agar and often on sheep BAP. It is ALA negative but often grows unaided on BAP since it hemolyzes the blood. <i>Francisella tularensis</i> takes 48 h to grow as a smaller colony on CHOC; it does not grow on BAP.
Gram-negative cocci			
<i>Moraxella catarrhalis</i>	1. Gram-negative diplococci 2. Oxidase positive 3. Colonies on BAP move when pushed	Positive butyrate test	Gram stain morphology of “diplococcus” separates from other <i>Moraxella</i> organisms, which are “coccobacilli”
<i>Neisseria gonorrhoeae</i> ^b	1. Gram-negative diplococci 2. Oxidase positive 3. No growth on nutrient or MH agar 4. 4+ positive catalase with 30% H ₂ O ₂	Sugar fermentation positive for glucose only, or identification with <i>Neisseria</i> kit, DNA probe, or serology (see procedure 3.9.3)	More than one test needed to confirm if negative result or abuse case
<i>Neisseria meningitidis</i> ^b	1. Gram-negative diplococci 2. Oxidase positive 3. Growth on BAP	Sugar fermentation positive for glucose and maltose only, or identification with <i>Neisseria</i> kit	(See Table 3.18.2–1.) Use caution when handling culture.

Table 3.3.2–5 (continued)

Organism	Presumptive identification	Additional tests for definitive identification ^a	Special requirements
Gram-positive cocci			
<i>Staphylococcus aureus</i>	<ol style="list-style-type: none"> 1. Catalase positive 2. Gram-positive cocci in clusters 3. Tube or slide coagulase or latex agglutination test positive 	No other testing for definitive identification, except nonhemolytic in urine, which need tube coagulase to confirm agglutination test	For isolates from sterile sites, do tube coagulase test for further accuracy. ^b See procedure 3.18.1.
Coagulase-negative staphylococci	<ol style="list-style-type: none"> 1. Catalase positive 2. Gram-positive cocci in clusters 3. Tube or slide coagulase or latex agglutination test negative 	Colony not sticky; check for <i>Staphylococcus saprophyticus</i> in urine (novobiocin resistant) and <i>Staphylococcus lugdunensis</i> in blood (PYR positive; ornithine positive ^b)	For isolates from sterile sites, do tube coagulase test with 24 h of incubation for further accuracy. ^b
<i>Streptococcus pyogenes</i> (group A)	<ol style="list-style-type: none"> 1. Gram-positive spherical cocci in pairs 2. Catalase negative 3. Hemolytic 4. Colony of >0.5 mm in diam with sharp edges 	PYR positive	Confirm with serology or negative bile-esculin, if site is not respiratory. ^b
<i>Streptococcus agalactiae</i> (group B)	<ol style="list-style-type: none"> 1. Gram-positive spherical cocci in pairs 2. Catalase negative 3. Small zone of hemolysis around translucent colony 	CAMP positive or hippurate positive	If invasively collected specimen or not hemolytic, confirm hippurate with PYR (negative) and CAMP or serology. ^b
Viridans group streptococci ^b	<ol style="list-style-type: none"> 1. Gram-positive cocci in pairs 2. Catalase negative 3. Alpha-hemolytic 4. Bile negative or colony whitish 	PYR negative	From sterile sites, do LAP and susceptibility to vancomycin or kit identification. Other genera can mimic streptococci (e.g., <i>Aerococcus</i> and <i>Leuconostoc</i>). ^b
<i>Enterococcus</i> spp.	<ol style="list-style-type: none"> 1. Gram-positive cocci in pairs 2. Catalase negative 3. Nonhemolytic 	PYR positive Hemolytic colonies could be group A streptococci. If hemolytic, enterococci are bile-esculin positive. ^b	From sterile sites, do LAP (positive) to verify genus. <i>Lactococcus</i> cannot be ruled out. ^b Do motility to separate species and <i>Vagococcus</i> .
<i>Streptococcus pneumoniae</i>	<ol style="list-style-type: none"> 1. Gram-positive, lancet-shaped cocci in pairs 2. Catalase negative 3. Alpha-hemolytic 	Bile soluble or Quellung positive	If bile-resistant but typical colonies, confirm with optochin susceptibility or DNA probe. ^b
Gram-positive rods			
<i>Bacillus</i> spp. (and related spore-forming genera) ^b	<ol style="list-style-type: none"> 1. Large gram-positive rods 2. Catalase positive 3. Spores present 	Motile (nonmotile should be checked for <i>Bacillus anthracis</i>)	<i>Bacillus cereus</i> group (not <i>B. anthracis</i>) is beta-hemolytic and penicillin resistant, with cells >1 μm in diameter.
Coryneform rods ^b	<ol style="list-style-type: none"> 1. Gram-positive rods, not large 2. Catalase positive 3. Nonhemolytic 4. Not pigmented 5. Nonmotile 	Not branching, or partially acid-fast	Kits are useful to identify to the species level. See procedure 3.11.7 for <i>Corynebacterium diphtheriae</i> culture.
<i>Gardnerella vaginalis</i> ^b	<ol style="list-style-type: none"> 1. Tiny gram-variable rod 2. Catalase negative 3. Tiny nonhemolytic colonies grow better on CNA^c and CHOC than BAP 	Beta-hemolytic on human blood or SPS ^c sensitive or hippurate positive	Confirmatory tests not needed for vaginal samples if direct Gram stain is consistent (Appendix 3.2.1–3).
<i>Lactobacillus</i> spp. ^b	<ol style="list-style-type: none"> 1. Gram-positive rods 2. Catalase negative 3. Alpha-hemolytic 	H ₂ S negative, vancomycin resistant	<i>Erysipelothrix</i> is H ₂ S positive and vancomycin resistant. Vancomycin susceptible could be <i>Actinomyces</i> .

(continued)

Table 3.3.2–5 Common pathogens and rapid and conventional methods to identify them when suspected from colony morphology listed in Table 3.3.2–3 (*continued*)

Organism	Presumptive identification	Additional tests for definitive identification ^a	Special requirements
<i>Listeria monocytogenes</i> ^b	<ol style="list-style-type: none"> 1. Tiny gram-positive rods without chaining 2. Catalase positive 3. Narrow zone of beta-hemolysis 4. Motile (tumbling) in wet mount 	Bile-esculin positive and CAMP positive	If wet mount motility is questionable, check motility at 25°C but not at 35°C in semi-solid agar.
Yeast cells	Budding yeast in smear	<ol style="list-style-type: none"> 1. “Feet” seen on BAP in 48 h or germ tube positive in ≤3h is <i>Candida albicans</i> 2. Tiny yeasts that are rapid trehalose positive or grow better on EMB are <i>Candida glabrata</i>. 	Growth at 45°C separates <i>C. albicans</i> from <i>Candida dubliniensis</i> . See section 8 of this handbook for test methods and other identifications.

^a For procedures on biochemical testing, refer to procedure 3.17; for information on multitest biochemical kit tests, refer to procedure 3.18.

^b All testing requirements for identifications are found in NCCLS document M35 (1), *except* those noted by this footnote, which are taken from the references listed in Supplemental Reading and in procedures 3.18.1 and 3.18.2. The identifications from the NCCLS document are greater than 95% accurate without further testing.

^c CNA, Columbia colistin-nalidixic acid agar; SPS, sodium polyanethol sulfonate.

V. PROCEDURE (*continued*)

- (2) Note each colony type of suspected anaerobe, and subculture it to a section of CHOC and a section of an anaerobic medium; incubate the CHOC aerobically and the other anaerobically.
 - (3) Refer to section 4 of this handbook for further identification protocols for anaerobic bacteria.
 - d. Set up additional tests as needed, using references for unusual and difficult identifications (*see* procedures 3.18.1 and 3.18.2 and references listed in Supplemental Reading).
 - e. Prepare updated or final report, notifying appropriate persons of clinically or epidemiologically important results.
 - f. For positive cultures or isolates, whether complete identification is performed or not, hold a representative plate at room temperature for 5 days in case the clinician notifies the laboratory of the need for further studies.
 - g. Get immediate help from a supervisor or laboratory director when the identification or extent of identification is not clear. Delays in identification can affect patient care.
 - h. Perform susceptibility testing (section 5) for those organisms deemed significant, provided that standard methods are available for testing (2, 3).
 - i. Send subculture of significant isolates to reference laboratory when unable to identify or when confirmation is required or desired. See procedure 15.5 for details for packaging and shipping.
3. For additional days, follow up identification and susceptibility testing procedures until all relevant isolates have been identified; then send a final updated report.

☑ **NOTE:** When a culture of a slow-growing organism, e.g., *Nocardia*, is requested, media should be held and examined for 7 days. (*See* section 6 of this handbook.)

V. PROCEDURE (continued)

4. Hold positive cultures for at least a few weeks for further studies for organisms from sterile sites (blood, CSF, joint fluid, ascites fluid, orthopedic tissues and bone, liver, and brain), depending on laboratory policy.
 - a. Save at least one isolate per patient.
 - b. There is no need to save skin microbiota in one of several cultures from normally sterile sites.
 - c. Use one of the following methods.
 - (1) Freeze in TSB with 15% glycerol or in sterile skim milk at -70°C .
 - (2) Inoculate onto semisolid medium, such as sulfide-indole-motility agar (procedure 3.17.22) or cysteine Trypticase agar.
 - (3) Hold strict anaerobes in chopped meat or freeze in rabbit blood or skim milk.
 - (4) Hold fastidious organisms on CHOC slants or deeps overlaid with mineral oil.
5. Handling of broth cultures
 - a. Incubate at 35°C and examine daily for 4 days.
 - b. For broths with apparent growth indicated by turbidity, fronds of growth, puff balls, pellicles, or sediment in the bottom of an otherwise clear tube, follow procedure below.
 - (1) If the direct plates have growth of fewer than three morphologic types and the broth is turbid, smear the broth for comparison with direct plates. Subculture if there is any suggestion that a different morphotype is present. Use appropriate plates to select for aerobes and anaerobes depending on the smear results.
 - (2) If direct plates are negative, smear and subculture turbid broths to BAP and CHOC, using care not to contaminate the broth. If the morphology is suggestive of anaerobes, inoculate anaerobic BAP.
 - (3) If an organism is seen in the broth but not on solid media on subculture, try more nutritious media or special incubation conditions to isolate the organism. Also, evaluate uninoculated broth for evidence of “dead” organisms in medium.
 - (4) If the culture grew coagulase-negative staphylococci and gram-positive cocci are in the broth, subculture the broth to rule out the presence of *Staphylococcus aureus*.
 - (5) When in doubt, resmear a turbid culture, but a subculture need not be repeated. Use of acridine orange stain may be helpful. See procedure 3.2.2.
 - (6) When broth is entered, record on tube the date and indicate that broth was smeared and subcultured. This will allow quick evaluation of broths on subsequent days.
 - (7) Hold broths that are positive for growth separately from the broths with no growth, until the culture is completed or 14 days, whichever is longer.
 - c. For broths with no apparent growth after 4 days at 35°C , hold at room temperature for a minimum of 7 days to ensure that some specimen is available, if further testing is indicated. Examine at discard for obvious growth only.

■ **NOTE:** In the case of a clinically important infectious disease for which a pathogen has not been detected, refer specimen to a reference laboratory for molecular studies.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. Report results of direct smear within 1 h of receipt for specimens from invasive procedures and 4 h for specimens from other sites.
- B. Reporting the presence of pathogens
 1. Enumerate each pathogen as indicated in Table 3.3.2–2.
 2. Report preliminary results on all cultures, including presumptive identifications.
 3. When reporting identifications that are suggestive but for which not all biochemical testing has been completed, preface the organism name with “probable” or “presumptive.”
 4. If the identification changes after further testing, make a note of the change in the report.
 5. If a species identification is not indicated, inform the physician by adding “NOS” (not otherwise specified) following the genus name and “spp.”
 6. Use the following guidelines to report repeated isolation of the same organism.
 - a. Do not perform full identification and susceptibility testing on microorganisms, if the patient has had a positive culture from the same source within the last (*x*) days with what apparently is the same organisms(s) and full identification and susceptibility testing were done on the previous isolate(s).

■ **NOTE:** For determination of (*x*) days, a good general rule is to repeat identifications every 7 days, if the morphology is the same. An exception would be for nonhemolytic staphylococci, all of which should be checked with a coagulase test. Policies on how often to repeat antimicrobial susceptibility testing (AST) vary and should be based on evaluation of local AST results and therapies used to treat disease. General guidelines include 7 days for oxacillin-susceptible staphylococci and most gram-negative rods, 4 days for *P. aeruginosa* and selected other gram-negative rods, and 30 days for vancomycin-resistant enterococci. If extended-spectrum beta-lactamases are present locally, additional susceptibility surveillance may be indicated.
 - b. Ensure that the current organism is morphologically consistent with the previous isolate(s) prior to reporting them as identical. Perform minimal procedures to confirm the identification (oxidase, indole, catalase, etc.), if possible.
 - c. Report the genus and species identification.
 - d. When referring identification to prior identification, indicate in the report that the identification is “presumptive” followed by the following comment after the organism name: “Refer to culture from [date] for complete identification [and susceptibility testing].” Use caution so that referred cultures are not referred to referred cultures.
 - e. If susceptibility testing was performed (e.g., not sure it is the same, previous positive overlooked, etc.), record these results but do not report them, unless they differ from the prior result. Such reporting can distort the data in the antibiogram produced by the laboratory for epidemiologic surveys.
 7. Possible plate and broth contaminants
 - a. Review plates for possible plate contaminants (especially if the broth has no growth) before reporting.

■ **NOTE:** If a broth turns positive with a gram-positive organism after the broth has been sampled, the organism may have been introduced at the time of sampling.

VII. INTERPRETATION

- A. Report culture results with emphasis on the clinical importance and relevance to the diagnosis and treatment of the patient.
- B. Reporting normal microbiota, mixed cultures, or questionable contamination with the same level of detail as done for clinically significant pathogens can lead to erroneous diagnoses and treatment of the patient.
- C. Use the Gram stain of the specimen as a guide to interpretation of results.
- D. Low levels of organisms can be difficult to detect. Conversely, if an organism is seen in the direct Gram stain but not in the culture, pursue other methods to isolate the agent, such as DNA probes, specialized media, stains, immunological tests, and incubation conditions.
- E. Decisions regarding the performance of susceptibility testing must also consider the significance of the organism and the ability of the susceptibility testing to provide information that is not already available; e.g., *S. pyogenes* organisms in throat cultures are uniformly susceptible to penicillin, and susceptibility testing for this antimicrobial is not indicated.

VIII. LIMITATIONS

- A. Accurate reporting of culture results is limited to the expertise of the microbiologist who is able to recognize, evaluate, and pursue significant bacteria in the culture.
- B. False-negative results occur when one of the following occurs.
 - 1. Cultures are delayed in processing.
 - 2. Incorrect atmosphere or temperature of incubation is used.
 - 3. Medium does not support growth of the microorganism.
 - 4. Organisms are present in low numbers or the volume of specimen cultured is too low to detect them.
 - 5. WBCs and other body defense factors inhibit growth.
 - 6. Collection or transport of the specimen was not optimal.
 - 7. The microorganism cannot be cultured by any method available at the present time.
- C. False-positive results are due to the following.
 - 1. Mix-up of cultures from different patients
 - 2. Reporting of contaminants from the laboratory or collection process as pathogens in a culture
- D. The lack of isolation of a pathogen does not necessarily mean that the laboratory was unable to detect the agent, because other diseases can have the same presentations as infectious diseases.

3.4.1

General Detection and Interpretation

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

When bacteria or fungi overcome the host's normal defense mechanisms and enter the bloodstream through the lymphatics or from extravascular sites, they can quickly disseminate throughout the body, causing severe illness. In addition, the by-products of their metabolism can lead to septic shock, among the most serious complications of infectious diseases. *Rapid recognition and immediate institution of appropriate treatment are essential.* Laboratory diagnosis of bacteremia and fungemia depends on blood cultures, which are probably the most important cultures performed by the microbiology laboratory. Because the culture methods are so sensitive, the procedure must be carefully controlled beginning at the preanalytical stage (collection), to avoid the misinterpretation of a procurement-as-

sociated skin commensal microorganism as an agent of infection.

One blood culture usually consists of blood from a single venipuncture inoculated into two separate bottles to accommodate the volume of blood removed (usually 20 ml for adults), since optimal blood-to-broth ratios are 1:5 to 1:10. The use of more than one formulation of medium (usually one aerobic and one anaerobic bottle) for each blood culture generally maximizes recovery of all possible pathogens. Adequate volume is the single most important factor in the laboratory detection of microorganisms in the bloodstream; the more blood cultured, the more likely a culture will be positive (11, 13, 14, 15, 26). In one study of adults, increasing the total volume cultured from 20 to 40 ml increased the yield by 19%; increas-

ing the volume from 40 to 60 ml increased the yield by an additional 10% (15). The total volume of blood drawn should be divided equally between at least two separate venipunctures, to allow evaluation of the recovery of a skin organism in a single positive set that could have resulted from contamination of the culture during collection (13). Sodium polyanethol sulfonate (SPS) is added as an anticoagulant, an antiphagocytic agent that inactivates complement, and a neutralizing agent to inhibit effects of many antimicrobial agents and antibacterial factors in blood (19). Media should contain 0.025 to 0.05% SPS; however, even at that level it can inhibit the recovery of some bacteria, such as *Neisseria* spp., *Streptobacillus moniliformis*, *Peptostreptococcus*, and *Gardnerella vaginalis* (21).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

■ **NOTE:** Refer to procedure 3.3.1 for additional details. This portion can be copied for preparation of a specimen collection instruction manual for physicians and caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

- A. See Appendix 3.4.1–1 for collection and testing for specialized microorganisms.
- B. Collect blood aseptically by venipuncture or from previously placed lines.

■ **NOTE:** Bone marrow culture should be reserved for culture for specific pathogens such as *Brucella*, *Salmonella*, *Listeria*, and fungi and mycobacteria; it adds little to detection of most other bacteria in the blood. Because of the complex nature of the collection procedure, it is more likely to result in a contaminated bacterial culture than a diagnostic one (M. K. York, unpublished data). Thus, routine cultures of bone marrow without a specific indication should be discouraged.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- C. Recommended total volume and numbers of blood cultures
1. Neonates to 1 year (<4 kg): 0.5 to 1.5 ml/tube, although at least 1.0 ml is preferred (14)
 NOTE: Two separate venipunctures are generally not possible.
 2. Children 1 to 6 years old: 1 ml per year of age, divided between two blood cultures. For example, for a 3-year-old, draw 1.5 ml from each of two sites, for a total of 3.0 ml of blood. Consult with the physician, who is responsible for ordering the amount to be collected, especially if the child is below normal weight or has had previous venipuncture for other reasons.
 3. Children weighing 30 to 80 lb: 10 to 20 ml, divided between two blood cultures
 4. Adults and children weighing >80 lb: 30 to 40 ml, divided between two blood cultures
 NOTE: At least 20 to 30 ml of blood in two draws is the minimal requirement (15).
- D. Timing of blood cultures
- NOTE:** Although drawing blood cultures before or during the fever spike is optimal for recovery, volume is more important than timing in the detection of agents of septicemia.
1. When acute sepsis or another condition (osteomyelitis, meningitis, pneumonia, or pyelonephritis) requires immediate institution of antimicrobial agent therapy, draw two blood cultures of maximum volume consecutively from different anatomic sites before starting therapy.
 2. For fever of unknown origin, subacute bacterial endocarditis, or other continuous bacteremia or fungemia, draw a maximum of three blood cultures with maximum volume.
 3. When it is appropriate to draw blood cultures from patients on antimicrobial therapy, they should be drawn when antimicrobial agents are at their lowest concentration.
 NOTE: Use of a resin- and/or dematiaceous earth-containing medium may enhance recovery of microorganisms, especially staphylococci. However, appropriate dilution and action of some anticoagulants and antifoaming agents may also diminish the effect of antimicrobial agents. *If multiple cultures were drawn prior to the start of therapy, additional blood cultures from patients on antimicrobial therapy during the same febrile episode should be discouraged, since they are rarely positive (7).*
- E. Skin antisepsis and collection of blood from venipuncture
1. Select a different venipuncture site for each blood culture.
 - a. If poor access requires that blood for culture be drawn through a port in an indwelling catheter, the second culture must be from a peripheral site, because cultures drawn through catheters can indicate catheter colonization but may not be indicative of sepsis (1).
 - b. Do not draw blood from a vein into which an intravenous solution is running.
 - c. Except from neonates, draw the two blood cultures in succession. If the phlebotomy must be performed at the same site (usually because of bad veins), perform the second venipuncture at that site.
 2. Prepare the site.
 - a. Vigorously cleanse with 70% isopropyl or ethyl alcohol to remove surface dirt and oils. Allow to dry.
 - b. Swab or wipe concentric circles of tincture of iodine, moving outward from the center of the site.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- c. Allow the iodine to dry (about a minute), and avoid touching the site.
 NOTE: If povidone-iodine is used, it must be allowed to dry completely (about 2 min); 2% chlorhexidine gluconate in isopropyl alcohol may be used in place of tincture of iodine.
 - d. *For pediatric patients, omit the iodine step and clean two additional times with separate preparation pads saturated with 70% isopropyl alcohol or ethyl alcohol (24).*
 3. Prepare the septum of the blood culture bottle and the rubber stoppers on bottles or tubes. Label the bottles with the patient name and the date and time of draw. Site of draw may also be listed.
 4. Vigorously wipe septa with 70% alcohol and allow to dry completely, usually for 30 to 60 s.
 NOTE: Wiping the septum with iodine is usually unnecessary but may be considered if there is a history of problems with *Bacillus* spores or mold contamination.
 5. While wearing gloves, insert the needle into the vein and withdraw the blood. Use a new needle if the first attempt is not successful. *Do not repalpate the skin after it is disinfected.*
 6. *Apply a safety device to protect the phlebotomist from needle exposure.*
 NOTE: Safety devices consist of domes with internal needles that attach either to a syringe or directly to the tubing used in collecting the blood. The external port of these devices will accommodate a syringe or the end of a butterfly needle depending on the product (e.g., blood transfer device [catalog no. 364880; Becton Dickinson and Co., Paramus, N.J.], BacT/Alert blood transfer device [bioMérieux Inc., Hazelwood, Mo.], Angel Wing adapter [Sherwood Davis & Geck, St. Louis, Mo.]).
 7. Inoculate first the aerobic bottle and then the anaerobic bottle with *no more* than the manufacturer's recommended amount of blood.
 - a. For direct inoculation into the bottles from the needle apparatus, mark the side of the bottle with the manufacturer's recommended draw.
 - b. If using a needle and syringe, use the volume markings on the syringe to note the volume. *Hold the syringe plunger during transfer to avoid transfer of excess blood into bottles having a significant vacuum.*
 NOTE: There is no need to change the safety device between bottle inoculations (19).
 8. Thoroughly mix bottles to avoid clotting.
 9. After phlebotomy, dispose of needles in sharps container and remove residual tincture of iodine from the patient's skin by cleansing with alcohol to avoid development of irritation.
- F. Collection of blood from intravascular catheters
 NOTE: Using either quantitative cultures (Appendix 3.4.1–2) or time to positive signal of cultures processed on an automated instrument, the comparison of cultures that are drawn through an indwelling intravenous catheter and through a peripheral site may be useful for diagnosis of catheter-related sepsis (1).
 1. Label bottles with patient name, site of draw, and date and time of draw.
 2. Disinfect the septum of the blood culture bottle and the rubber stoppers on bottles or tubes with 70% alcohol as for peripheral draw. Allow to dry completely, usually for 30 to 60 s.
 3. Using two separate alcohol preps, scrub catheter hub connection for 15 s with 70% alcohol. Air dry.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

4. While wearing gloves, disconnect tubing or cap of catheter and attach syringe to collect discard blood (suggested amounts are 3 ml for adults and 0.2 ml for pediatric patients), which is not used for culture.
 - ☑ **NOTE:** Avoid drawing from lines within an hour of completion of antimicrobial agent administration.
 5. Using a new syringe, collect blood for culture through the hub. Quickly reconnect tubing.
 6. Connect filled syringe to safety system adapter.
 7. Holding the syringe plunger for control, inoculate the bottles with *no more* than the amount recommended by the manufacturer.
 8. Thoroughly mix bottles to avoid clotting.
- G.** In addition to labeling the blood culture bottles or tubes with patient demographic information and collection time, indicate whether the collection was from a peripheral draw or a catheter draw and the initials of the phlebotomist.
- H.** Specimen transport
1. Do not refrigerate blood cultures. Generally hold at room temperature until processed, for a maximum of 4 h.
 2. Refer to manufacturer's instructions for the appropriate method to store cultures prior to incubation in automated culture systems.
 3. Provide method of transport that will ensure that bottles are not broken in transit. Ensure that users follow exactly the instructions for sending blood culture bottles through pneumatic tube systems.
- I.** Rejection criteria
1. Reject blood cultures that are received unlabeled.
 2. Do not process if the tube or bottle is cracked or broken.
 3. Labeled blood cultures are not rejected even if medium is expired, volume or number of bottles is insufficient, or bottles were received >12 h after collection, but develop an education plan to ensure that cultures are collected appropriately and numbers are not excessive. Document deficiency in report, as well as the effect on the reliability of the culture results.

III. MATERIALS

(See procedure 3.1 for vendor contact information.)

- A. Media** (see references 19 and 27 for review of literature on comparison of blood culture media listed below)
 1. Usually inoculate one aerobic and one anaerobic medium for each culture. In addition, or instead of the above, inoculate a similar medium containing resin or dematiaceous earth to absorb antimicrobial agents.
 - ☑ **NOTE:** For specialized patients (e.g., pediatric patients that do not have an abdominal abnormality), anaerobic cultures may not be indicated (3, 4, 12, 30). However, always inoculate at least two bottles for adults. Always include anaerobic cultures for febrile neutropenic patients and patients with diabetes or wound infections.
 2. Several companies supply media for automated systems, formulated to maximize detection based on the indicator system.
 - a. Bactec (BD Division Instrument Systems)
 - b. ESP (Trek Diagnostics)
 - c. BacT/Alert (bioMérieux Inc.).
 - ☑ **NOTE:** Follow manufacturer's instructions for inoculation, special handling, and incubation of blood culture media. Most systems accommodate 10 ml per bottle for adult bottles and less for bottles designed for pediatric use.

III. MATERIALS (*continued*)

3. Alternatives to automated systems
 - a. Broth media in bottles to be observed manually (TSB, supplemented peptone, THIO, anaerobic BHI)
 - b. Biphasic media (agar and broth in one bottle)
 - (1) BBL Septi-Chek (BD Microbiology Systems)
 - (a) Agar consists of CHOC, MAC, and malt agar.
 - (b) Broth options are BHI, BHI supplemented, TSB, TSB with sucrose, Columbia, THIO, and Schaedler broth.
 - (2) PML biphasic (PML Microbiologicals, Inc.)
 - (a) Agar consists of CHOC and BHI agar.
 - (b) Broth is TSB.
 - c. Lysis-centrifugation system of ISOLATOR (Wampole Laboratories).
- B. Reagents and media for biochemical tests**
 1. Agar plate media listed in Table 3.3.1–1
 2. Gram stain reagents
 3. Antimicrobial susceptibility testing (AST) system and beta-lactamase test (refer to section 5)
 4. δ -Aminolevulinic acid (ALA) reagent (procedure 3.17.3)
 5. Bile-esculin slants (procedure 3.17.5)
 6. 10% Bile (sodium desoxycholate [procedure 3.17.6])
 7. Catalase test reagent (procedure 3.17.10)
 8. Coagulase rabbit plasma and (optionally) staphylococcal agglutination tests (procedures 3.17.13 and 3.17.14)
 9. Disks (procedure 3.17.4)
 - a. 10 U of penicillin
 - b. 30 μ g of vancomycin
 - c. 1 μ g of oxacillin
 - d. Optochin (procedure 3.17.38)
 - e. 300 U of polymyxin B or 10 μ g of colistin
 10. Spot indole reagent (procedure 3.17.23)
 11. Broth for motility (procedure 3.17.31)
 12. Ornithine decarboxylase (procedure 3.17.15)
 13. Oxidase test reagent (procedure 3.17.39).
 14. L-Pyrrolidonyl- β -naphthylamide (PYR) substrate and developer (procedure 3.17.41)
 15. Multitest gram-negative and gram-positive commercial automated, semiautomated, and manual kit identification systems, referred to as “kits.” For detailed information on these products, refer to Evangelista et al. (6).
 16. Media for identification of yeast and mold (*see* section 8)
 - a. CHROMagar (optional)
 - b. Calf serum for germ tube
 - c. India ink
 - d. Phenol oxidase test (caffeic acid disk or birdseed agar)
 - e. Rapid trehalose test (section 8)
 - f. Urea agar (procedure 3.17.48)
 17. Other media as needed for special identifications
 - a. Acridine orange stain (procedure 3.2.2)
 - b. Media for H₂S detection (procedure 3.17.22)
 - c. Quellung test (procedure 3.17.42)
 - d. Leucine aminopeptidase (LAP) (procedure 3.17.26)
 - e. Salt (6.5%) broth (procedure 3.17.43)
 - f. Optional: serologic reagents for grouping *Salmonella* and *Shigella* (Appendix 3.8.1–1) or grouping beta-hemolytic streptococci into the Lancefield groups (procedure 3.11.8)
 - g. Rapid urea disk (procedure 3.17.48)
- C. Supplies**
 1. 3-ml syringes with safety apparatus or venting needle
 2. Alcohol (70 to 95%) and gauze
 3. Microscope slides

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A.** Verify that plate media meet expiration date and QC parameters per current NCCLS document M22. See procedures 14.2 and 3.3.1 for further procedures.
- B.** See individual tests in procedure 3.17 for biochemical test QC.
- C.** Blood culture bottles
- 1.** For in-house-prepared culture media, verify that each lot of media will support the growth of bacteria likely to be present in blood cultures, including, but not limited to, the following microorganisms (as listed in Table 2 of NCCLS document M22-A2 [17]).
 - a.** Aerobic bottles
 - (1) *Pseudomonas aeruginosa* (ATCC 27853)
 - (2) *Streptococcus pneumoniae* (ATCC 6305)
 - b.** Anaerobic bottles
 - (1) *Bacteroides fragilis* (ATCC 25285)
 - (2) *S. pneumoniae* (ATCC 6305)
 - c.** Method of testing
 - (1) Prepare a broth culture of each microorganism equivalent to a 0.5 McFarland standard.
 - (2) Inoculate each bottle with 0.01 ml (10 µl) of suspension.
 - (3) Incubate for up to 5 days and observe for visible growth.
 - 2.** Maintain records provided by manufacturers of commercial blood culture systems, documenting their QC testing.

▣ **NOTE:** Regulatory agencies do not require routine QC checks by the user of commercially purchased blood culture bottles.
- D.** Check CHOC on biphasic medium paddles for growth of *Haemophilus influenzae* and *Neisseria gonorrhoeae*.
- E.** Prior to institution of a blood culture system, determine that it will support the growth of a variety of microorganisms, including fastidious gram-negative rods and cocci. Use bottles supplemented with human blood from volunteers for testing fastidious microorganisms.
- F.** Contamination
- 1.** Have a system in place to determine if a culture has been collected from an intravascular catheter and whether a peripheral collection accompanied the line collection for adults. Educate clinicians on the need to collect both, to properly evaluate the culture results (1, 24).
 - 2.** Monitor positive blood culture results regularly for skin contamination.
 - a.** For purposes of determination of contamination rate, consider only skin contaminants from venipuncture as significant. These consist of the following.
 - (1) Coagulase-negative staphylococci (excluding pediatric and line collections)
 - (2) *Bacillus* species
 - (3) *Corynebacterium* species
 - (4) *Propionibacterium* species
 - b.** Exclude positive cultures as skin contaminants if more than one blood culture from the same patient is positive for any of the microorganisms listed above, provided that for coagulase-negative staphylococci the antibiograms are consistent with the isolates being the same strain.
 - c.** Include as skin contaminants all positive cultures, even if both bottles are positive or only one culture was collected (16).
 - d.** Calculate the contamination rate by dividing the number of cultures containing skin contaminants by the total number of cultures collected by venipuncture.

IV. QUALITY CONTROL

(continued)

3. Initiate additional training of staff involved with blood collection and processing if the contamination rate exceeds the expected rate for the institution. The rate should generally not exceed 3%, although many institutions have a goal to decrease the rate below 1% (24, 25) for cultures collected by venipuncture. When rates are high, separate calculations can be done for each phlebotomist and for each collection location.
- G. Validate true-positive blood culture rates.
 1. Calculate the true-positive culture rate by dividing the number of cultures positive by the total number of blood cultures received.
 2. The rate should be in the 6 to 12% range. If it is too low, too many cultures might have been drawn; if it is too high, not enough cultures may have been collected.
- H. Perform statistical analysis periodically to determine if the length of incubation is sufficient or can be decreased without loss of clinically meaningful information (2, 3, 5, 8, 20, 29).
 1. Tabulate the number of cultures positive on days 4 through 7.
 2. Delete those positives that are considered skin contaminants, as defined above.
 3. Delete those positives that are positive in another culture collected within 24 h before or after the delayed positive culture.
 4. For the remaining positive cultures, determine from chart review if they were considered contributing to true bacteremia.
 5. Review completed results with the infectious disease service to determine what is a reasonable incubation period for cost-effective detection of bacteremia.
- I. Use statistics to determine if bottles in use are appropriate for detection of local pathogens (10).
- J. Monitor compliance with volume and number of bottles submitted and number of cultures collected from catheter lines without an accompanying peripheral culture.

V. PROCEDURE

Observe standard precautions.

A. Laboratory processing of blood cultures

1. Safety
 - a. When working with blood cultures, keep the culture bottles within a bio-safety cabinet or behind a shield, or wear a face mask.
 - b. Always wear gloves, because blood cultures contain material from patients that may harbor blood-borne pathogens.
 - c. Use needleless transfer devices or safety needles, and never recap them.
 - d. Dispose of needles and syringes in puncture-proof container.
2. Incubate blood cultures for the predetermined period at 35°C (usually 5 days, unless quality monitors indicate less time). In special circumstances (e.g., *Brucella* cultures), incubate for longer than standard policy. See procedure 3.4.2.
3. Maintain incubation conditions to allow recovery of microorganisms (follow manufacturer's instructions) and maintain rotation or agitation of the media if at all possible.
4. Examine the cultures at least daily, whether detection of positives is by visual inspection or by an automated system. For visual inspection, observe for hemolysis, turbidity, gas production, pellicle formation, "puffballs," and clotting, which are indicative of microbial growth (Table 3.4.1-1).

Table 3.4.1–1 Visible signs of growth caused by organisms commonly encountered in blood cultures

Microscopic observation	Associated microorganisms
Hemolysis	Streptococci, staphylococci, <i>Listeria</i> spp., clostridia, <i>Bacillus</i> spp.
Turbidity	Aerobic gram-negative bacilli, staphylococci, <i>Bacteroides</i> spp.
Gas formation	Aerobic gram-negative bacilli, anaerobes
Pellicle formation	<i>Pseudomonas</i> spp., <i>Bacillus</i> spp., yeast cells
Clotting	<i>Staphylococcus aureus</i>
Visible colonies (“puffballs”)	Staphylococci, streptococci

V. PROCEDURE (continued)

5. For manual broth systems, perform at least one blind subculture to solid agar from visually negative bottles. Generally subculture after 72 h of incubation to detect most pathogens missed by visual inspection.

■ **NOTE:** Subculture of automated systems has little clinical utility (9).

6. Biphasic systems

- a. For systems with agar paddle, remove plastic cap from bottle and securely attach paddle in biological safety cabinet while wearing gloves.
- b. Invert bottle to inoculate agar, and incubate at 35°C.
- c. Invert twice daily for the first 2 days and then daily for the remaining days of incubation. Observe broth and paddle for growth prior to each inversion.

7. In special circumstances when cultures appear to be negative, perform a Gram stain (procedure 3.2.1), wet mount (procedure 3.2.3), or acridine orange stain (procedure 3.2.2) from the culture or its sediment to determine the presence of organisms.

8. Discard negative bottles safely in infectious-waste container.

B. Culture methods for positive blood cultures

■ **NOTE:** Since positive results with biphasic systems and ISOLATOR will be detected by the presence of colonies, subculture protocols for broth systems detailed below are not applicable. However, inoculation of biochemical tests for identification does apply.

1. Gram stain a thin smear from the broth or agar immediately when suggestive of growth 24 h a day for optimal patient care.
2. Following Table 3.4.1–2, subculture to agar media and biochemical tests based on the Gram stain results.

■ **NOTE:** The extent of identification of isolates considered to be procurement-associated skin microorganisms should be determined in consultation with the institution’s infectious disease specialists.

3. Develop and validate a laboratory protocol to inoculate a kit identification system for gram-negative rods and direct AST. Follow protocol, as indicated in Table 3.4.1–2. Examples of methods are listed below.

■ **NOTE:** RBCs may interfere with some tests.

- a. Dilute 2 drops of blood culture in 5 ml of water or saline and inoculate gram-negative rod manual kit test, such as API 20E, that will support a low inoculum (6).

■ **NOTE:** Citrate result is not reliable.

- b. Centrifuge in serum separator tube at 1,400 × g for 10 min, and adjust pellet on silicone layer equivalent to a 0.5 McFarland standard. Use inoculum for gram-negative kit identification system and susceptibility test system (23).

Table 3.4.1–2 Initial processing and reporting results from positive blood culture bottles^a

Gram stain result	BAP	BAP with disks ^b	CHOC	Anaerobe plate	Other tests	Report
Positive cocci in clusters	×	Oxacillin Penicillin Vancomycin			1 or 2 drops to coagulase plasma at 35°C ^c ; add AST ^d if coagulase positive or multiple “sets” positive	“Probable <i>Staphylococcus</i> spp.”; update to “Probable <i>Staphylococcus aureus</i> ” and notify physician if coagulase positive!
Positive cocci in chains or pairs	×	Penicillin Vancomycin Optochin CAMP test	×	×	1 drop to bile-esculin slant at 35°C ^c ; AST ^d if bile-esculin positive (Optional: Quellung or slide bile solubility if lancet-shaped pairs)	“Probable <i>Streptococcus</i> spp.”; update to “Probable <i>Enterococcus</i> ” if bile-esculin positive or “Probable <i>Streptococcus pneumoniae</i> ” if Quellung positive or bile soluble, and notify physician!
Small positive rods	×	Penicillin Vancomycin CAMP test	×	×	1 drop to bile-esculin slant at 35°C ^c ; wet mount	“Gram-positive rods”; update to “Probable <i>Listeria</i> ” if tumbling motile or bile-esculin positive
Large positive rods	×	Penicillin Vancomycin	×	Only if anaerobic bottle	For aerobic bottle, wet mount to rule out <i>B. anthracis</i>	“Gram-positive rods”; if diphtheroid-like or large and only in anaerobic bottle, report “Probable anaerobic gram-positive rods”
Negative rods	×	Polymyxin B or colistin disk	×	Only if anaerobic bottle	MAC or EMB; CNA or PEA; kit ^d ; AST ^d ; add BAP microaerobically if morphology is campylobacter-like	“Gram-negative rods” or “Probable <i>Campylobacter</i> ” if smear indicates gull wing shapes, or “Probable <i>Haemophilus</i> ” if morphology is consistent
Negative cocci	×	Penicillin	×	×	<i>Warning</i> : Staphylococci can appear gram negative; <i>Acinetobacter</i> organisms can appear as cocci.	“Gram-negative cocci” or “diplococci”; if tiny in sheets in anaerobic bottle, “anaerobic gram-negative cocci”
Yeast	×		×		CHROMagar; germ tube read at 2 h; India ink if round; 2 drops to urea slant at 35°C ^c	“Yeast”; update to “Probable <i>Cryptococcus</i> ” if urease positive or capsules present, and notify physician! Update to “ <i>Candida albicans</i> ” if germ tube positive.

^a Incubate aerobic plates in 5% CO₂ and anaerobic plates under anaerobic conditions. For any subsequent positive companion bottles or other positive bottles “collected” within the same 48 h as the first positive bottle, subculture only to BAP unless the Gram stain is different or the original culture did not grow on BAP. In addition, for subsequent positive cultures, inoculate MAC or EMB and either CNA (Columbia colistin-nalidixic acid agar) or PEA (phenylethyl alcohol agar) if gram-negative rods are present and a direct coagulase if gram-positive cocci in clusters are present.

^b Disk testing is a screen for identification of *Lactobacillus*, *Erysipelothrix*, *Bacillus*, *Leuconostoc*, *Pediococcus*, and vancomycin-resistant and -dependent *Enterococcus* or *Staphylococcus* organisms that are penicillin susceptible (see procedure 3.17.4 for details on potency and QC). Disks will also detect mixed cultures but are *not* a substitute for a standard susceptibility test. A streak of *S. aureus* ATCC 25923 perpendicular to but not touching the line of the initial inoculum will aid in identification of group B streptococci and *Listeria*.

^c Read test up to 4 h and update report and notify physician if test result is positive. Remove coagulase from incubator at ≤4 h and incubate at room temperature for remainder of 24 h.

^d For methods for preparation of inoculum for direct testing of automated or manual commercial multitest kit identification systems and for AST, see text.

V. PROCEDURE (continued)

- c. For MIC microtiter tray, place 1 drop of culture in 0.5 ml of BHI and incubate at 35°C for 3 to 4 h, with shaking; assume that it is equivalent to a 0.5 McFarland standard when entire volume is added to 5 ml of inoculation reagent. Check final inoculum with a colony count plate. Repeat AST if count is below 3×10^5 /ml. Refer to section 5 for details on AST methods.
 - d. For disk method, add 10 drops of the blood culture or the broth of specimen in the case of a sterile fluid to 5 ml of TSB and inoculate Mueller-Hinton agar. If growth is not confluent at 18 h, repeat test or confirm with MIC method.
 - e. Alternatively, subculture to solid medium and incubate for 5 h. Scrape sufficient growth from plate to make inoculum for identification and AST. *This method is preferred for AST for S. pneumoniae but not staphylococci.*
4. Follow-up workup of positive blood culture isolates
- a. Gram-negative rods growing on MAC or EMB
 - ▣ **NOTE:** The presence of these isolates in blood cultures is most commonly associated with septic shock. Process and report as quickly as possible.
 - (1) As soon as results are available, read kit identification test and report results if there is a good probability that the result is accurate.
 - (2) Perform spot indole and oxidase to confirm kit results.
 - (3) Immediately report AST when available.
 - (4) Use caution to be sure that the culture is not mixed prior to reporting AST results (e.g., colistin or polymyxin B resistant). If the culture is mixed, contact physician to provide some information.
 - (5) For isolates identified as *Salmonella* or *Shigella*, perform serologic grouping to confirm identification.
 - b. *Haemophilus* or other fastidious gram-negative rods that do not grow on MAC or EMB
 - ▣ **NOTE:** If colistin or polymyxin B resistant, the organism may be a poorly staining gram-positive rod.
 - (1) Set up ALA test if growth is only on CHOC—*H. influenzae* organisms are negative. See Table 3.18.2–2.
 - (2) Do beta-lactamase test.
 - (3) Do catalase, oxidase, and rapid urea if growing on both BAP and CHOC, and see procedure 3.18.2; for *Brucella* identification, see procedure 3.4.2.
 - c. Staphylococci
 - (1) Do catalase. Should be positive.
 - (2) Confirm that it is not sticky or bright yellow. If clearly yellow, call it a *Micrococcus* sp. See procedure 3.18.1 for other testing. If it is sticky, see Table 3.18.1–4b for possible *Rothia mucilaginosa* (*Stomatococcus mucilaginosus*).
 - (3) If there is a large zone of inhibition (>20 mm) around the penicillin disk, perform beta-lactamase test from zone around oxacillin disk. Omit testing if the AST is available and shows penicillin resistance.
 - ▣ **NOTE:** Penicillin-susceptible coagulase-negative strains may be *Micrococcus* (see procedure 3.18.1).
 - (4) Do latex agglutination test for clumping factor and protein A as a confirmation of a negative tube coagulase test. See charts for gram-positive cocci in procedure 3.18.1 if results are discrepant or for other confirmatory tests.
 - (5) Do PYR if tube coagulase is negative, regardless of slide coagulase result. If positive, set up ornithine decarboxylase to rule out *Staphylococcus lugdunensis*.

It is imperative that these cultures be handled in a biosafety hood.

V. PROCEDURE (continued)

- **NOTE:** Isolation of *S. lugdunensis* is more often associated with endocarditis and poor outcome than isolation of other coagulase-negative staphylococci; thus, it should be differentiated from other species (22). It is also problematic for susceptibility testing, since the breakpoints for oxacillin susceptibility of coagulase-negative staphylococci do not correlate well (18). *S. lugdunensis* is rarely, if ever, resistant to oxacillin, although the MIC is generally ≥ 0.5 $\mu\text{g/ml}$. See section 5 for options for testing.
- (6) Read and report AST.
 - (7) Check vancomycin disk. If resistant, see procedure 3.18.1 for identification. If coagulase positive, see section 5 for further AST on possible vancomycin-intermediate staphylococci.
- d. Streptococci and other catalase-negative cocci
- (1) *S. pneumoniae* (should have zones around optochin and vancomycin disks.)
 - (a) Set up AST.
 - (b) If the growth is confluent and the zone size is >20 mm to penicillin, report preliminary result as “Susceptible to penicillin by nonstandard method.”
 - (2) If beta-hemolytic
 - (a) Do catalase—should be negative
 - (b) Check CAMP. Report “*Streptococcus agalactiae*” if positive.
 - (c) Do PYR. If PYR positive and bile-esculin negative, report “*Streptococcus pyogenes*.”
 - (d) Otherwise, Lancefield group and report.
 - (3) Viridans group streptococci (have no zone around the optochin disk and a zone around the vancomycin disk).

■ **NOTE:** *Leuconostoc* and *Pediococcus* look like streptococci, but they are vancomycin resistant. See Table 3.18.1–4.

 - (a) Do catalase—should be negative
 - (b) A repeat Gram stain from original broth should show chains and pairs.
 - (c) Do PYR (result should be negative). If PYR positive, refer to Table 3.18.1–4.
 - (d) Do LAP. If positive, report “Viridans group streptococcus” and identify further according to laboratory policy. If present in only one culture, call physician to see if it is a significant isolate for identification and AST.

■ **NOTE:** For accuracy, strains may require several subcultures anaerobically prior to biochemical testing, especially with kit systems that require preformed enzymes for reactions. They also tend to present with various morphologies on plate culture. If there is any question of identification, set up growth at 42°C and 6.5% salt.
 - (e) If there is no zone around the penicillin disk, notify caregiver that strain may be penicillin resistant. Set up MIC method for susceptibility to penicillin and an extended-spectrum cephalosporin (see section 5).
 - (f) If there is no growth on BAP but growth on CHOC, set up satellite test (procedure 3.17.44) to determine if it is nutritionally variant streptococcus.

■ **NOTE:** Nutritionally variant streptococci satellite around staphylococci.

V. PROCEDURE (continued)

- (4) Enterococci
 - (a) Do catalase—should be negative or weakly positive
 - (b) Do PYR. If positive and bile-esculin was positive, report “*Enterococcus* species; identification to follow.”
 - (c) Set up species identification and AST per policy.
 - (d) If vancomycin resistant by disk
 - i. Inoculate broth for motility (procedure 3.17.31) and incubate at 30°C for 2 h to rule out motile species. If nonmotile, report “Vancomycin resistant by preliminary test.”
 - ii. Check for yellow pigment by sweeping with a cotton swab from direct BAP; swab will appear bright yellow.
 - iii. Confirm vancomycin result with MIC method.
 - iv. Use kit or sugar fermentation to differentiate *Enterococcus faecium* from *Enterococcus faecalis*.
 - (5) Other cocci: if sticky or vancomycin resistant or PYR positive and catalase negative or weakly positive and do not look like *Enterococcus* on Gram stain, see procedure 3.18.1.
- e. Gram-positive rods
- (1) Do catalase test.
 - (a) Catalase positive
 - i. Small rods with small zone of hemolysis and bile-esculin positive, set up motility tests at 22 and 35°C using semisolid agar. *Listeria* organisms are motile at 22°C. Check CAMP test. *Listeria monocytogenes* is positive.
 - ii. Large rods. Check for spores and motility.
■ **NOTE:** *Bacillus cereus* is hemolytic and motile; *Bacillus anthracis* is nonhemolytic and nonmotile.
 - iii. If present in only one culture of several collected, limit workup of diphtheroids (bile-esculin-negative, catalase-positive rods) unless physician indicates that the isolate may be significant. If isolate is significant and is penicillin resistant (no zone around the penicillin disk), notify caregiver, even though the test is not standard. Identify with commercial kit and/or biochemical tests (see procedure 3.18.1).
■ **NOTE:** *Corynebacterium jeikeium* is associated with catheter-related sepsis.
 - (b) Catalase-negative and vancomycin resistant: set up H₂S to rule out *Erysipelothrix* organisms, which are H₂S positive.
■ **NOTE:** *Erysipelothrix* and often lactobacilli are vancomycin resistant. Notify physician of vancomycin result.
 - (2) Refer to gram-positive rod flowcharts (procedure 3.18.1) for reporting and further testing.
- f. Potential anaerobic microorganisms: refer to section 4.
- g. Yeasts: refer to section 8.
- (1) Do phenol oxidase test if urease positive; omit test if patient has recent positive culture or cryptococcal antigen test.
 - (2) If urea negative
 - (a) Repeat germ tube if it was negative or questionable.
 - i. Call “*Candida albicans*” if germ tube positive.
 - ii. If hyphae are seen, call “*Candida*” species.
 - iii. If hyphae are not seen and isolate grows better on BAP than EMB, call “Yeast, not *Cryptococcus*.”
 - iv. If growth is better on EMB and the yeast is tiny on smear, call “Probable *Candida glabrata*” and set up rapid trehalose test.

V. PROCEDURE (continued)

- (b) Read CHROMagar at 48 h for species identification, or see section 8 for other methods.
- h. If there is no growth on initial subculture
 - (1) Subculture bottle anaerobically if anaerobic plates were not inoculated.
 - (2) Subculture to buffered charcoal-yeast extract agar for growth of *Afiplia* or other fastidious gram-negative rods.
 - (3) Subculture to BAP and incubate microaerobically for campylobacters.
- i. Hold positive cultures for at least a few weeks for further studies. See procedure 3.3.2 for methods to freeze isolates.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. For “No growth cultures,” indicate the length of incubation: “No growth after *x* days of incubation” for both preliminary and final reports.
- B. Positive cultures
 - 1. Immediately report Gram stain results of all positive cultures, or additional organisms found in previously positive cultures, to the physician of record, with as much interpretive information as possible (using Table 3.4.1–2 for guidelines).
 - 2. Follow immediately with a written or computer-generated report including the following.
 - a. Number of positive cultures compared with total number of specimens collected for specific patient.
 - ☑ **NOTE:** There is no justification for telling the physician that one or both bottles in the set are positive, because the number of positive bottles in a set does not reliably differentiate contamination from true infection (16).
 - b. Date and time of collection and receipt
 - c. Date and time positive result is reported and whether it was from a catheter draw or a peripheral draw.
 - ☑ **NOTE:** Such information is useful in the diagnosis of catheter-related sepsis (1).
 - d. Name of person taking report
 - Example:** Positive culture reported to Dr. X on 07/01/04 at 1300 h.
 - 3. For single positive cultures with microorganisms generally considered skin contaminants (coagulase-negative staphylococci, viridans group streptococci, corynebacteria, *Propionibacterium* [28]), perform only minimal identification and do not perform AST. For single positive cultures with these potential skin contaminants or with *Clostridium perfringens* (28), report result with a comment similar to the following: “One set of two positive. Isolation does not necessarily mean infection. No susceptibility tests performed. Contact laboratory for further information.”
 - ☑ **NOTE:** Weinstein et al. (28) reported that 10 of 13 *C. perfringens* isolates from blood cultures in their institution were considered contaminants.
 - 4. Provide genus and species identification as soon as possible, using tests in Table 3.3.2–5 and charts in procedures 3.18.1 and 3.18.2.

VI. REPORTING RESULTS*(continued)*

5. For subsequent positive cultures, it is not necessary to repeat biochemical testing if the microorganism has the same Gram and colony morphology as the first isolate. Perform a few spot tests (catalase, coagulase, indole, PYR, etc.) to verify that it is the same strain. Report as “Probable [genus and species]; refer to prior positive for complete identification and susceptibility testing.”

VII. INTERPRETATION

- A. The report of a positive culture generally means that the patient is bacteremic. However, skin microbiota may infect the culture, causing a false-positive result or pseudobacteremia. Pseudobacteremias have many other causes.
 1. If organisms are seen but not cultured, dead organisms can be found in the medium components and produce a positive smear.
 2. *Bacillus* or other bacteria can be present on the nonsterile gloves of the phlebotomist (31).
 3. Laboratory contamination of equipment or supplies used in culture may contaminate the patient specimens.
- B. Mixed cultures can be present and account for a significant number of bacteremias. Be aware of this when examining smears and plates.
- C. Performance and reporting of AST are critical for timely patient care and increase the chance of appropriate therapy and cure.

VIII. LIMITATIONS

- A. Low levels of organisms may not be detected in the incubation interval of the culture.
- B. The media used may not support the growth of some organisms. Use of multiple formulations increases the yield.
- C. SPS may inhibit the growth and viability of the organism.
- D. Other diseases can present similarly to bacteremia, since there are many causes of fever of unknown origin.
- E. Bacterial metabolism may not produce sufficient CO₂ for detection in automated systems.
- F. There are a number of fastidious microorganisms that infect the blood that cannot be grown in routine culture of blood. These are presented further in the appendixes and other procedures that follow.

APPENDIX 3.4.1–1

Specialized Processing of Blood for Detection of Unusual Microorganisms or Conditions

- A. Transfusion reactions
Collect blood cultures both from the patient and from the transfused product.
1. See procedure 13.13 for processing transfused blood.
 2. Never discard the transfused product; return it to the transfusion service.
 3. Always keep good records of what was cultured.
- B. If the laboratory is notified that the isolation of unusual pathogens in blood is sought, perform an acridine orange stain (procedure 3.2.2) from the blood cultures prior to discarding bottles that do not indicate growth.
- C. Inoculate special media or perform special testing listed below for the following organisms (listed alphabetically).
1. *Bartonella* spp. (formerly *Rochalimaea*)
Collect ISOLATOR tube and see procedure 3.4.3.
 2. *Borrelia* spp. (relapsing fever)
 - a. Visualize in a Wright or Giemsa smear of citrated blood. Prepare smears as for malaria (see procedure 9.8). *Borrelia* organisms are 10 to 20 μm long and 0.2 to 0.5 μm wide, with uneven coils. Scan at $\times 400$ and verify identification at $\times 1,000$ magnification. Read at least 60 fields on a thin smear and 20 fields on a thick smear.
 - b. Look for twisting motion in a dark-field exam.
 - c. Concentrate by centrifugation at $200 \times g$, remove plasma, and examine buffy coat as described above.
 - d. Culture and mouse inoculation are done in research laboratories. Blood is generally shipped cold.

☑ **NOTE:** *Borrelia burgdorferi* is best detected by PCR analysis of urine, blood, CSF, or lymph node aspirate.
 3. *Brucella* spp.
Most blood culture systems will grow *Brucella* if incubation is extended with blind subculture; see procedure 3.4.2 for optional techniques and details.
 4. *Ehrlichia*
 - a. This parasite can occasionally be detected as an intracellular morula or intracytoplasmic inclusion in the WBCs visualized in a Giemsa or Wright stain of blood or buffy coat smear.
 - b. PCR and serologic methods are better tests.
 5. *Histoplasma* (see section 8)

☑ **NOTE:** Although yeast cells are usually detected in aerobic broth systems, culture using biphasic media, an ISOLATOR tube concentrate, or the buffy coat from an SPS or heparin tube to specialized fungal media may allow faster and more extensive recovery of *Histoplasma* (2). For *Cryptococcus*, the cryptococcal antigen test is recommended for rapid diagnosis. The Myco/F lytic bottle (BD Diagnostic Systems) is designed for enhanced recovery of yeasts and mycobacteria. Bone marrow specimens are excellent for recovery of *Histoplasma*.
 6. *Legionella* spp.
Refer to procedure 3.11.4.
 7. *Leptospira* spp.
Refer to procedure 3.14 prior to collection of specimens.

APPENDIX 3.4.1–1 (continued)

8. *Malassezia furfur* (usually seen in catheter-related infections in infants receiving lipid-rich total parenteral nutrition) (1)
 - a. Automated systems may not give a positive signal for *M. furfur* (2).
 - b. Preferred method: collect a few milliliters of blood from the potentially infected catheter port.
 - (1) Prepare slide by spreading blood in a thin film and perform Gram stain.
 - (2) Streak BAP or noninhibitory fungal medium for isolated colonies.
 - (3) Add a drop of pure virgin olive oil (sterilization not necessary) the size of a dime onto the agar surface to provide essential nutrients.
9. Mycobacteria (see section 7)

■ **NOTE:** Collect specimen in special culture media supplied by the manufacturer of automated instruments or culture buffy coat from either SPS- or heparin-collected blood. ISOLATOR can also be used to concentrate the organisms. Testing should generally be limited to those patients with CD4 counts of less than 200 cells/ μ l, since the yield of mycobacteria is low from immunocompetent individuals. However, bone marrow is an appropriate specimen for culture from all patients.
10. Mycoplasmas (see procedure 3.15)
11. *Streptobacillus moniliformis* (cause of “rat bite fever” and “Haverhill fever”)
 - a. The specimens of choice are blood and joint fluid. Because this organism is inhibited by SPS and requires more blood to grow, inoculate *twice* the amount of blood or joint fluid recommended by the manufacturer into the blood culture bottle. Pediatric bottles are good for this. Growth appears as crumbs in the liquid. Alternatively, collect citrated blood and inoculate it into several THIO tubes (2 ml/10 ml of THIO).

■ **NOTE:** Lymph nodes and abscesses are also good specimens for isolation of *S. moniliformis*. Inoculate as indicated below for subcultures.
 - b. Culture specimen or subculture positive blood culture broths as follows.
 - (1) Prepare agar with 20% rabbit, calf, or horse serum.
 - (a) Melt 20 ml of BHI, TSA, or heart infusion agar.
 - (b) Cool to 45 to 50°C.
 - (c) Add 4 to 5 ml of rabbit, calf, or horse serum.
 - (d) Mix, pour into petri dish, and allow to solidify.
 - (e) Inoculate with a few drops from the specimen or the positive culture.
 - (2) To THIO with 20% rabbit, calf, or horse serum added (2 ml/10 ml of broth), inoculate with a few drops from the positive culture or up to 2 ml of the specimen.
 - c. Incubate plates in high humidity with 5 to 10% CO₂.
 - d. *S. moniliformis* is gram negative and catalase, indole, nitrate, and oxidase negative and does not grow on MAC (3). It may be pleomorphic and show long filaments, chains, and swollen cells in broth culture. It is arginine positive. Confirmatory identification is usually done in a reference laboratory.

APPENDIX 3.4.1–2

Processing of the Lysis-Centrifugation System of ISOLATOR

I. PRINCIPLE

The ISOLATOR system (Wampole Laboratories, Cranbury, N.J.) consists of Vacutainer tubes for blood collection that contain lysing, antifoaming, and anticoagulating agents. The lysis of cells followed by centrifugation results in concentration of the microorganisms from the blood specimen into liquid Fluorinert, a water-immiscible substance. The Fluorinert mixture is cultured on plate media, resulting in simultaneous detection, enumeration, and isolation of organisms (2, 3). Because the system utilizes plates, it is not a sealed system; airborne contamination can be a problem in the inoculation and evaluation of the cultures (1, 4).

II. SPECIMEN

Collect specimen as for other blood cultures, and fill tube after careful disinfection of the stopper. Process within 8 h of collection.

III. MATERIALS

- A. Collection tube contains a lysis fluid of saponin, polypropylene, SPS, Fluorinert, and EDTA. Draw is either 1.5 ml for pediatric and bone marrow patients or 10 ml for adults.
- B. ISOSTAT press and rack
- C. ISOSTAT supernatant and concentrate pipettes and white cap
- D. Fixed-angle centrifuge
- E. Plate media for desired culture

IV. PROCEDURE

- A. Invert the tube several times to ensure adequate mixing at the time of collection.
- B. Centrifuge at $3,000 \times g$ for 30 min in a fixed-angle rotor.
- C. Place tube in ISOSTAT press.
- D. Wipe spun ISOLATOR tube, especially the top, with alcohol. Be generous with the alcohol; leave a drop on the top of the cap. Allow to dry. Do not disturb the microbial concentrate during the transfer. If it is disturbed, respin the tubes for another 30 min and allow the centrifuge to stop manually.
- E. Disinfect ISOSTAT press hammer with alcohol and allow to dry.
- F. Aseptically position cap over tube, and press down with ISOSTAT press. Do not touch top of tube. Gently pull the handle down as far as possible. The spike will penetrate the stopper and firmly seat the cap.
- G. Don gloves and place tube and plates for inoculation in biologic safety cabinet.
- H. Aseptically remove a supernatant pipette from the pouch. Squeeze bulb of pipette, collapsing it completely, and insert pipette into tube through the cap membrane. Do not touch pipette stem. Release bulb slowly, allowing the supernatant blood to be drawn into the pipette. When bubbles appear, remove the pipette *without* squeezing the bulb, and discard in a biohazardous-waste container. If bubbles were not present in the pipette, repeat the procedure with another pipette.
- I. Vortex the contents for at least 20 s.
- J. Aseptically remove a concentrate pipette from the package. Squeeze the pipette bulb, collapsing it completely, and insert into the tube through the cap membrane so that the stem reaches the bottom of the tube. Release bulb slowly, allowing the pellet to be drawn into the pipette.
- K. Remove pipette from tube and distribute the entire concentrate equally on media that will allow recovery of the organism sought. Spread evenly over surface of each plate, using separate loops or spreaders. Avoid the edges of the plates.
- L. If the lysis-centrifugation system is used alone, inoculate a portion of the sediment onto anaerobic plates or into anaerobic broth for recovery of anaerobes.
- M. Incubate the media under the correct conditions and for sufficient time to recover all pathogens sought.
- N. Incubate agar side down for the first 24 h of incubation to maintain contact of the inoculum with agar and to prevent concentrate from dripping onto the lid. After the initial incubation, incubate plates agar side up. Generally plates are incubated for 4 days unless unusual fastidious organisms are suspected.

It is imperative that these cultures be handled in a biosafety hood.

APPENDIX 3.4.1-2 (continued)

V. INTERPRETATION

- A. The ISOLATOR system can be used for quantitative counting of microorganisms in blood. Use the formula below.

CFU/ml = total number of CFU on all plates/total number of plates on which organism is expected to grow \times (times) number of plates inoculated per blood volume

Example: Number of colonies: BAP—2; CHOC—3; CHOC—2; CHOC—1; CHOC—2. Therefore: 10 CFU/5 plates \times 5 plates/1.5 ml = 7 CFU/ml (pediatric blood) or BAP—5; CHOC—7; CHOC—7; fungal selective agar—0. Therefore: 19/3 \times 4/10 = 2.5 CFU/ml adult (10-ml tube).

- B. The number of plate contaminants can be problematic in the interpretation of the results with this system. Generally one colony of coagulase-negative staphylococci is ignored, but the laboratory should work to achieve no contamination and monitor the results to reduce false-positive reporting of larger numbers of skin microbiota.

3.4.2

Brucella Cultures

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Brucella is a fastidious, aerobic, small, gram-negative coccobacillus that is slow growing and difficult to isolate. It is zoonotic, with four species being recognized as causing infection in humans: *Brucella abortus* (cattle), *Brucella melitensis* (goats, sheep, and camels), *Brucella suis* (pigs), and *Brucella canis* (dogs). Although species identification is of interest, it is *not* clinically important and is difficult to perform. Key characteristics of the species can be found in Shapiro and Wong (7).

Infections are seen in essentially two patient populations. The first group is individuals who work with animals and who have not been vaccinated against brucellosis. This patient population includes farmers, veterinarians, and slaughterhouse workers. *B. abortus* and *B. suis* are the agents most likely to cause infections in this group of individuals. They become infected either by direct contact or by aerosol from infected animal tissues.

Brucellosis is also seen in individuals who ingest unpasteurized dairy products

contaminated with brucellae. This is most likely to occur in individuals who travel to or migrate from rural areas of Latin American and the Middle East where disease is endemic in dairy animals, particularly goats and camels. *B. melitensis* is the most common agent seen in this patient population. Brucellae are included in the microorganisms at risk for being used in a bioterrorist event; refer to procedure 16.6 for further information on this agent's role in bioterrorism.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

It is imperative that these cultures be handled in a biosafety hood.

- A. Aseptically collect blood or bone marrow (from the iliac crest [5]) during a fever episode.
- B. Refer to procedure 3.4.1 for collection. Place specimen immediately in blood culture bottles.
 - **NOTE:** CSF, lymph nodes, joint fluid, and liver or spleen biopsy specimens may be positive for *Brucella*, which will be detected by routine culture of these specimens. Follow this procedure to confirm the identification.

III. MATERIALS

- A. **Media**
 1. Primary media
 - a. Biphasic blood culture
 - (1) Septi-Chek (CHOC, MAC, and malt agar with BHI or Columbia broth) (BD Diagnostic Systems)
 - (2) PML biphasic media (CHOC and BHI agar with TSB) (PML Microbiologicals, Inc.)
 - (3) Castaneda bottles (TSB or brucella broth and agar) (2)
 - b. Automated blood culture system
 - **NOTE:** Automated systems may require subculture to detect growth. The pediatric lysis-centrifugation method using a volume of 1.5 ml was not as sensitive as automated methods in one study (11).
 2. Media for blind subculture or for positive cultures
 - a. BAP preferably with BHI base
 - b. CHOC
 - c. Brucella agar

III. MATERIALS (*continued*)**B. Reagents**

1. Gram stain reagents
2. Catalase test (procedure 3.17.10)
3. Oxidase test (procedure 3.17.39)
4. Rapid urea-phenylalanine deaminase (PDA) disks (3) (Remel Inc.; Hardy Diagnostics) (procedures 3.17.40 and 3.17.48)

5. 10% Ferric chloride

6. Antiserum to *Brucella* from febrile agglutination test**C. Supplies**

1. Incubator with 5 to 10% CO₂
2. Microscope slides

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. Verify that plate media meet expiration date and QC parameters per current NCCLS document M22. See procedure 14.2 and procedure 3.3.1 for further procedures.
- B. For QC of blood culture broths, refer to procedure 3.4.1.
- C. See individual tests in procedure 3.17 for biochemical test QC.
 - ☑ **NOTE:** Specific QC using *Brucella* organisms is not recommended because of the danger to laboratory workers handling such cultures. The confirmation of the identification of suspicious isolates generally should be done in a reference laboratory to avoid exposure of laboratory personnel to the organism.

V. PROCEDURE

Observe standard precautions.

A. Laboratory processing of blood cultures

When working with suspected *Brucella* isolates, all manipulations of the culture, including oxidase and catalase tests and Gram staining, should be performed in a biological safety cabinet to minimize the possibility of exposure to aerosols of this organism. Gloves should be worn to protect from skin exposure to the culture. Laboratory-acquired cases of *Brucella* are not uncommon and include infections resulting by absorption of culture droplets through intact skin (4, 7, 8).

1. For biphasic systems, invert twice daily for the first 2 days and then daily for the remaining days of incubation. Incubate for 21 days.
2. Automated broth systems
 - a. Incubate broths for a minimum of 7 days and a maximum of 10 days.
 - b. Subculture an aliquot at day 10 to BAP, CHOC, or brucella agar and incubate plates in 5 to 10% CO₂ for at least 72 h.

☑ **NOTE:** When using the BACTEC 9240 system in one study, no positives were detected by the system after an incubation time of 10 days (1). Subcultures were not done in this study. In a study using Peds Plus medium, all but 1 of 42 positive cultures were detected by the BACTEC instrument in 6 days; blind subculture yielded only the 1 additional positive (10). The success of this medium may be due to the decreased amount of sodium polyanethol sulfonate in the pediatric bottle. In another study with the BacT/Alert system, a terminal subculture at 10 days detected all but one of the 7 positive cultures that were not detected by the instrument prior to that time (10).

B. Laboratory processing of positive cultures from any site

1. Look for colonies typically showing “dust-like” growth after overnight incubation on BAP and CHOC. Colonies are tiny but smooth, glistening, raised with an entire edge, and white to cream color at 48 to 72 h.
 - a. Gram stain suspicious colonies or broth; brucellae are tiny, gram-negative coccobacilli.
 - b. Perform catalase, oxidase, and rapid urea tests. Brucellae are *positive* by all three tests.

It is imperative that these cultures be handled in a biosafety hood.

V. PROCEDURE (continued)

- c. Optional: if the urea test is positive and the disk or tablet contains phenylalanine, do the following.
 - (1) Add 2 drops of 1 N HCl to acidify the alkaline urea reaction (optional).
 - (2) Perform PDA test by adding ferric chloride to tube. Brucellae are negative for PDA.

■ **NOTE:** If a microorganism having the above reactions is isolated from a normally sterile site and is growing on BAP throughout the inocula, rather than just satelliting around a colony of staphylococci, it is presumptively identified as *Brucella* at this point and the physician should be informed.
2. If the colony is growing only on CHOC, subculture to CHOC, MAC, and BAP with a spot of *Staphylococcus aureus* ATCC 25923 added after inoculation of BAP with the suspected colony. If equivalent growth is seen on CHOC and BAP, but *not* on MAC or EMB, and the organism does not satellite around the staphylococcus, it is likely to be *Brucella* (procedure 3.17.44).

■ **NOTE:** The most common organisms misidentified as *Brucella* spp. are *Haemophilus* spp., which will satellite around the staphylococcus on the BAP. Brucellae grow on the entire BAP without inhibition.
3. Confirm identification with serologic test or send to a reference laboratory for serologic confirmation.
 - a. Prepare a suspension of the isolate in 1.0% formalinized saline to match a no. 2.0 McFarland standard.
 - b. Let sit overnight to kill the organisms.
 - c. Set up tube agglutination test using the positive control antiserum from the febrile agglutinin test and normal rabbit serum as a negative control.
 - d. As a positive control, test the positive control antiserum with the antigen in the febrile agglutinin test.

POSTANALYTICAL CONSIDERATIONS

VI. INTERPRETATION

- A. If a gram-negative coccobacillus is isolated from a blood, lymph node, tissue, or joint culture and meets the following criteria, it is preliminarily identified as *Brucella*.
 1. Catalase positive
 2. Oxidase positive
 3. Urea positive (may be delayed), PDA negative
 4. Grows on both BAP and CHOC without satelliting around staphylococcus
 5. Does not grow on MAC

■ **NOTE:** If the microorganism is not identified as *Brucella* by these tests, consider other fastidious gram-negative rods, such as *Haemophilus aphrophilus*, *Eikenella*, *Actinobacillus actinomycetemcomitans*, *Capnocytophaga*, and *Kingella kingae* (HACEK group), which are urea negative (Tables 3.18.2–4 and 3.18.2–5). However, some brucellae are urea negative.
- B. The identification is confirmed if the isolate agglutinates with specific antiserum.
- C. Organisms confused with *Brucella* (see Table 3.4.2–1)
 1. If the isolate is from a urine culture, it could be *Oligella ureolytica*, a uropathogen with the same phenotypic characteristics as *Brucella*.
 2. *Psychrobacter phenylpyruvicus* has the same phenotypic characteristics but is rare and is PDA positive.
 3. *Haemophilus* does not grow on BAP without association with a staphylococcus colony.
 4. Some *Bordetella* spp. are urea positive but grow on MAC and are motile.

^aReactions extracted from references 7 and 9. NA, not applicable; V, variable; CCB, coccobacilli.^b*O. ureolytica* is primarily a uropathogen.^c*A. acinomyetemcomitans* is urea negative and rarely oxidase positive. Urea-positive *Acinobacillus* organisms are from animal sources.^dGrows only on CHOC, or on blood agar associated with staphylococcus colony.^eUse rapid urea test to increase sensitivity.^fTSI, triple sugar iron agar.

VII. REPORTING RESULTS

- A. For negative cultures, indicate the length of incubation: e.g., “No growth of *Brucella* after *x* days of incubation” for both preliminary and final reports, where “*x*” indicates the number of days of incubation.
- B. Positive cultures
 1. Report suspected cases to the physician and to infection control.
 2. Report preliminary and final identification to the genus level as soon as available following the testing listed in this procedure.
 3. Since brucellosis is a reportable disease in most states, notify the local or state health department of a positive culture (*also see* procedure 16.6).

VIII. LIMITATIONS

- A. When evaluating patients, leukocyte counts are often within normal limits and liver function tests are not abnormal. Such a nonspecific presentation makes it difficult to consider this pathogen.
- B. *Brucella* isolation is often delayed compared to that of other bloodstream pathogens, with peak isolation occurring at 3 to 4 days, compared to 6 to 36 h for most other pathogens.
- C. The laboratory diagnosis of brucellosis is made primarily by recovery of organisms from blood cultures. Overall blood cultures are positive in 50 to 90% of cases, but the chances of recovery decrease over time. Joint and bone marrow specimens may also be a good source of *Brucella*.
- D. In suspected cases, serologic testing of serum for *Brucella* agglutinins is a rapid method to diagnose brucellosis. Options include agglutination tests (Rose Bengal, Wright’s tube, Wright’s card, and Wright-Coombs), indirect immunofluorescence, complement fixation, and ELISAs. The standard with which all other methods are compared is Wright’s tube agglutination test. A titer equal to or greater than 1/160 is considered significant (6). These tests can have variable sensitivity since there is no standard for antigen preparations and methodology, even for the “standard” Wright’s tube agglutination test.
- E. Antimicrobial susceptibility tests are not necessary and should not be reported, since they erroneously show susceptibility to some agents. The correct identification is sufficient information for appropriate therapy. Tetracyclines (generally doxycycline) are the most active drugs and should be used in combination with streptomycin (or gentamicin or rifampin, if streptomycin is unavailable) to prevent relapse.

3.4.3

Bartonella Cultures

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The genus *Bartonella* comprises at least 19 species of gram-negative short (0.25 to 0.75 by 1 to 3 μm) rod-shaped bacteria, 7 of which have been implicated in human diseases (15). Arthropod vectors transmit the organism, and cats constitute the major reservoir of the species most commonly recognized (*Bartonella henselae*). *B. henselae* is the classic agent of cat scratch disease (CSD) and is globally endemic. It is also the agent of bacillary angiomatosis (BA) and peliosis (BP) in immunocompromised patients as well as in the immunocompetent (1, 6, 11). *Bartonella quintana* was historically responsible for outbreaks of trench fever in World War I, but it has more recently been found to cause BA and BP (2, 6). Both species have been associated with bacteremia and, not uncommonly, endocarditis. *Bartonella elizabethae*, *Bartonella clarridgeiae*, *Bartonella grahamii*, *Bartonella vinsonii* subsp. *arupensis*, and *Bartonella vinsonii* subsp. *berkhoffii* have been rarely associated with bacteremic or CSD-like illnesses (15).

Bartonellosis (or Carrión's disease), caused by *Bartonella bacilliformis*, can be

acquired by persons traveling to the Andes mountains of Peru, Colombia, and Ecuador. It has been found only in humans and is associated with exposure to sand fly vectors found on the western slopes of the Andes at elevations of approximately 2,500 to 9,000 ft (3). South American bartonellosis occurs in two forms, i.e., Oroya fever and verruga peruana, or Peruvian wart. Oroya fever is characterized by a severe acute-onset anemia, at the peak of which a majority of RBCs are infected with one to six organisms each, and massed intracellular bartonellae in vascular endothelial cells produce a diagnostic lesion that bulges into the lumen of the vessel. Verruga peruana is characterized by cutaneous eruptions ranging from small disseminated elevations to distinctive red-purple "cranberries." Verruga peruana is visually alarming but is benign and self-limiting. Conversely, Oroya fever is often life-threatening, and if not treated (with oral chloramphenicol), all of the erythrocytes become infected by the bacteria (13). In survivors of Oroya fever, verruga per-

uana may occur after the anemia and bartonellemia have subsided. In areas where the organism is endemic, verruga peruana is common but Oroya fever is rarely seen. The converse is true in areas of nonendemicity (3). Asymptomatic human infection may account for the continued presence of the disease. This organism remains the biggest threat to human health of all the *Bartonella* species (3). The causative agent, *B. bacilliformis*, is found in or on RBCs and vascular endothelial cells of infected patients. Diagnosis is generally made by serology, Wright stain of the peripheral blood, or culture.

Isolation of all *Bartonella* species is usually from blood and requires special procedures and long incubation (6, 9, 11). Contamination of cultures is common, and efforts must be taken to avoid loss of cultures from overgrowth with molds. Diagnosis is more often made serologically (4) or by histologic examination of biopsy samples of nodes, skin, or liver. PCR is also helpful for diagnosis (10).

II. SPECIMENS

■ **NOTE:** Cultures should only be performed by or submitted to a laboratory that is familiar with the culture and identification of the organism. Freshly prepared culture media optimize the chance for isolation of *Bartonella* spp.

A. Process aseptically collected tissues, such as lymph nodes or liver, by direct smear, by inoculation into endothelial tissue culture cells, or by plating on blood agar or CHOC. Direct detection of *Bartonella* using molecular methods is usually performed in a reference laboratory (10). Smears may also be stained with Wright or Giemsa stain. Excised verrugae can also be stained or examined with specific antiserum.

II. SPECIMENS (continued)

- B.** In cases of Oroya fever, collect thick and thin blood smears (preferably before antimicrobial therapy) from fresh drops of peripheral blood for staining with Wright or Giemsa stain (procedure 9.8.6 or 9.8.5, respectively).
- C.** Collect 10 ml of blood for culture into an ISOLATOR tube using sterile technique (*see* Appendix 3.4.1–2). Prior antimicrobial treatment negates the ability to culture the organism. Collection of more than one specimen may increase the yield of a culture.
- **NOTE:** Automated blood culture systems have yielded *Bartonella*, but the organism typically does not produce sufficient CO₂ to be detected by the instrument. On day 8, remove a small aliquot of blood culture broth and stain with acridine orange (procedure 3.2.2) or observe motile organisms by wet mount using phase-contrast. If growth is observed, subculture to CHOC (11). La Scola and Raoult successfully cultured 1 ml of blood collected into a Vacutainer tube containing lithium heparin (Becton Dickinson Systems, Rutherford, N.J.) and plated it onto Columbia sheep blood agar (9). The ISOLATOR method in combination with rabbit blood agar has the best yield for most species (7, 14).

III. MATERIALS

- A. ISOLATOR system (Appendix 3.4.1–2)**
- B. Anaerobic jar or bag and CO₂-generating system**
- C. Sterile M199 tissue culture medium (Gibco, Invitrogen, Carlsbad, Calif.) for dilutions**
- D. Media**
1. Fresh CHOC (double poured [40 ml per plate] and less than 3 weeks old has higher yield)
 2. Heart infusion agar with 5% rabbit blood
 3. In addition to the media listed above, the following media have been used successfully for culture of *B. bacilliformis*.
 - a. Columbia agar with 10% whole horse, rabbit, or sheep blood (2, 3)
 - b. Biphasic media consisting of the following
 - (1) A solid medium of 10% defibrinated sheep blood, glucose, tryptose, NaCl, and agar
 - (2) A liquid RPMI 1640 medium (Mediatech, Fisher Scientific) enriched with HEPES buffer, sodium bicarbonate, and 10% fetal bovine serum (8)
- **NOTE:** In some cases successful culture of *Bartonella* can only be achieved by initial cultivation in an endothelial tissue culture cell line or in liquid RPMI 1640 medium (2).

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A.** Test each medium with a known *Bartonella* species (e.g., *B. henselae* ATCC 49793, *B. quintana* ATCC 51694, *B. bacilliformis* ATCC 35685 or ATCC 35686) to verify the ability to grow the organism.
- B.** Check each medium for sterility by incubation of sample plates and animal blood products prior to culture.
- C.** Refer to procedure 3.3.1 for other QC requirements.

V. PROCEDURE

It is imperative that these cultures be handled in a biosafety hood.

- A. Process ISOLATOR as in Appendix 3.4.1–2, with the following exceptions.
 1. Use gloves, and wash gloves with alcohol during each step to avoid contamination of the culture.
 2. Centrifuge ISOLATOR tube for 45 min at $3,000 \times g$ in a fixed-angle rotor.
 3. Pop the top of the ISOLATOR tube using alcohol-soaked wipes with plastic backs for protection.
 4. Using the ISOLATOR supernatant pipette, remove all the supernatant blood without disturbing the Fluorinert. Discard blood in infectious-waste container.
 5. Add 0.2 ml (4 drops) of M199 to the pellet with a sterile pipette. Mix well with the pipette.
 6. Prior to inoculation, expose the plates and lids to UV light in a biologic safety cabinet while drying completely.
 7. Inoculate the plates with the entire volume of Fluorinert. Use 0.3 ml/plate of chocolate and blood media. Streak for isolation.
 8. Place the plates in the anaerobe jar or bag, moisten with sterile water and sterile gauze, and activate a CO₂-generating system.
 9. Incubate bag or jar at 37°C for most species; however, incubate at 25 to 30°C without increased CO₂ for *B. bacilliformis* and *B. clarridgeiae*.
- B. Examine plates for growth weekly for up to 5 weeks.
 1. Wear sterile gloves and swab often with alcohol. Work quickly and subculture if growth is observed or if contaminants are growing on the plate.
 2. Tiny colonies may be visible as early as day 4 under $\times 60$ to $\times 100$ magnification.
 3. *B. bacilliformis* colonies may be friable, small, dark, and round with an entire edge and may appear to have a halo under certain lighting conditions. A second colony type which may also be present is lighter, larger with an irregular edge, and not friable. Both cause an indentation of the agar under the center of the colonies (12).
- C. If tiny colonies are observed, perform a Gram stain with extended exposure to safranin or using carbol fuchsin as a counterstain. Examine for the presence of small, gram-negative, curved bacilli. These will be suggestive of *Campylobacter* or *Helicobacter* in morphology. Colonies visualized with a stereoscope take two forms: irregular, dry, and cauliflower-like or small, circular, tan, moist colonies that pit the agar.
- D. Perform wet mount motility and observe for twitching motility.
- E. Perform catalase and oxidase tests, which are either negative or weakly positive. Perform urea test, which should be negative (11).

■ **NOTE:** *Bartonella* organisms do not ferment or oxidize common carbohydrates or grow anaerobically. Other organisms, including *Mycobacterium tuberculosis*, could grow on the media used for culture. They are likely to be detected by Gram stain or wet mount and should be identified using charts and tables in other sections of this handbook.
- F. Confirm identification, using specific genetic or immunofluorescence tests and cellular fatty acid analysis.

■ **NOTE:** There are no Food and Drug Administration-cleared assays to identify this organism.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING AND INTERPRETATION OF RESULTS

- A. Very slowly growing, small, gram-negative, curved bacilli with twitching motion, that are catalase and oxidase negative or weakly reacting but are urea negative, isolated from a blood culture are likely to be one of the *Bartonella* spp.
 - B. Confirm identification usually by submitting the isolate to a reference laboratory. Serologic testing of the patient may be useful pending confirmation of the isolate's identity.
 - C. For blood smears stained with Wright or Giemsa stain for *B. bacilliformis*, a presumptive diagnosis of bartonellosis can be made if all of the following three conditions are met.
 - 1. The patient has lived in or visited an area in which the disease is endemic.
 - 2. The patient's clinical signs are consistent with bartonellosis.
 - 3. Large numbers of RBCs are infected with multiple organisms. The organisms stain reddish violet and are pleomorphic and may be seen as slender rods (straight or bent) or as oval to round forms; they may be found singly or in segmenting chains. Forms range from tiny dots to large irregular shapes and spindles. Vascular endothelial cells swollen with rounded masses of organisms are diagnostic of Oroya fever.
- ▣ **NOTE:** Excellent color plates are available in reference 13. The severe anemia is macrocytic and often hypochromic, with various aberrations; Howell-Jolly bodies and basophilic granules may be seen in addition to the bartonellae. In verruga peruana, the bartonellae are scattered among young cells and are definitive in the presence of the distinctive histology of the verrugae.

VII. LIMITATIONS

- A. Culture is generally unsuccessful if the patient has been treated with macrolide or aminoglycoside antimicrobial agents.
- B. Contamination of cultures is common, and every precaution should be taken to guard against mold growth. Exposure of plates and equipment to UV light and wearing gloves during all steps in the culture inoculation and observation of the cultures are important.
- C. Caution must be used in the interpretation of growth on the media, since mycobacteria, which are gram positive, and the yeast *Histoplasma* may be isolated from patients with similar symptoms.
- D. Many species of *Bartonella* are difficult to grow and identify. See reference 14.
- E. *Bartonella*-like structures due to other pathological conditions and other agents (e.g., *Haemobartonella* and *Eperythrozoon* spp.) may cause confusion in the diagnosis of Oroya fever. These other causes of RBC inclusions should be suspected in patients who have had no contact with an area of endemicity.
- F. Smears and cultures of specimens taken very early and late in the disease may be negative.
- G. Asymptomatic individuals may yield positive cultures or test positive for *Bartonella* antibodies.
- H. Reference laboratories offer serologic testing by either immunofluorescence assay (IFA) or EIA methods. Immunoglobulin G and M antibodies to crude and partially purified *Bartonella* antigens have been detected by EIAs. Antigens in both the IFA and EIA cross-react with *Chlamydia* and *Coxiella* antibodies, as well as with species within the *Bartonella* genus (5).

3.5

Body Fluid Cultures (Excluding Blood, Cerebrospinal Fluid, and Urine)

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Infection of normally sterile body fluids often results in severe morbidity and mortality; therefore, rapid and accurate microbiological assessment of these samples is important to successful patient management. Most organisms infecting these sites are not difficult to culture, but determining the significance of low numbers of commensal cutaneous microorganisms does present a challenge (10). With the increased use of prostheses, immunosuppressive therapeutic regimens, and long-term care of individuals with chronic debilitating disease, the likelihood of true infection with commensal organisms has increased, making accurate diagnoses difficult. Care must be taken during specimen collection and transport to ensure that the specimen is not contaminated. Any microorganism found in a normally sterile site must be considered significant, and all isolates must be reported.

Culture of the specimen should include the most likely organisms to cause infec-

tion. Joint infections are commonly caused by *Staphylococcus aureus*, but *Streptococcus pyogenes*, *Neisseria gonorrhoeae*, anaerobes, *Kingella kingae*, and *Brucella* spp. may be likely causes of infectious arthritis (2, 6, 9, 10, 11, 20, 21). The lysis-centrifugation method (Appendix 3.4.1–2) is more sensitive than plate culture without lysis, but automated blood culture systems have been shown to be faster than lysis-centrifugation and have a higher yield (9, 18, 20, 21, 22). Pediatric bottles have the advantage of containing less sodium polyanethol sulfonate (SPS), which inhibits some organisms (20, 21). For prosthetic-joint infections, the importance of preoperative joint fluid cultures cannot be overemphasized. The diagnosis is increased by culture of large volumes, by culturing anaerobically, and by culturing more than one specimen (2, 5, 6, 8, 11, 18). Typically the Gram stain shows inflammation, without the presence of bacteria. In fact, a Brit-

ish collaborative study group has recommended that Gram stains be abandoned for evaluation of elective revision arthroplasty, since they are not helpful to diagnosis (2).

Peritoneal fluid can be contaminated with numerous mixed gastrointestinal microbiota in cases of ruptured intestine, but in patients with chronic ambulatory peritoneal dialysis (CAPD) or spontaneous bacterial peritonitis (SBP), the likely pathogen is usually present in very low numbers. In CAPD the pathogens are staphylococci, viridans group streptococci, and non-glucose-fermenting, gram-negative rods (19). Numerous studies have shown that culture of large volumes of fluid in blood culture bottles, rather than concentration by centrifugation, will result in a higher yield (1, 4, 5, 8, 14, 17, 19). Blood culture bottles are superior to the lysis-centrifugation system for diagnosis of SBP (17).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Refer to Table 3.5–1 for commonly submitted body fluids and synonyms.

■ **NOTE:** Because the body may respond to infections with infiltration of fluid, some of these sites may have fluid accumulation only during infection.

B. There are many other drainage devices that are named for the person or company inventing or popularizing them, e.g., Axiom sump drain, Shirley sump drain, Tenchoff catheter, Abramson drain, Chaffin drain, Lakey tube biliary drain, Wheaton T-tube biliary drain, etc. Since improved versions are introduced continually, each laboratory should familiarize itself with the systems used locally. Calling the departments of surgery and invasive radiology and communicating with the hospital's distribution department would provide the names and descriptions of drainage devices used to collect specimens.

Table 3.5.–1 Types of body fluids submitted for culture

Fluid	Location	Synonym	Definition of synonym
Joint	At the union of two bones	Synovial	Viscid fluid of the joint cavity
Pleural	Within the membrane surrounding the lungs	Empyema Thoracentesis	Fluid with purulent exudate Fluid collected by aspiration following puncture of chest wall
Peritoneal	Within the membrane lining the abdominal cavity	Abdominal Ascites Paracentesis CAPD PV fluid	Same as peritoneal Abnormal accumulation of fluid in the cavity Fluid collected by aspiration following puncture of cavity Fluid from peritoneum of patient on CAPD Fluid from peritoneum of patient with a shunt tube inserted from the ventricles of the brain, under the skin into the peritoneal cavity
Pericardial	Within the membrane lining the cavity of the heart		
Cul-de-sac	A blind pouch between the anterior wall of the rectum and the posterior wall of the uterus	Culdocentesis	Fluid obtained by transvaginal puncture and aspiration of the cul-de-sac
Amniotic	Within the membrane of the fetus	Amniocentesis	Fluid obtained by puncture and aspiration of amniotic fluid

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

(continued)

Observe standard precautions.

C. Specimen collection

■ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for physicians and other caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

1. Body fluid specimens collected by percutaneous aspiration for pleural, pericardial, peritoneal, amniotic, and synovial fluids

■ **NOTE:** Use care to avoid contamination with commensal microbiota.

a. Clean the needle puncture site with alcohol, and disinfect it with an iodine solution (1 to 2% tincture of iodine or a 10% solution of povidone-iodine [1% free iodine]) to prevent introduction of specimen contamination or infection of patient. (If tincture of iodine is used, remove with 70% ethanol after the procedure to avoid burn.)

b. Aseptically perform percutaneous aspiration with syringe and needle to obtain pleural, pericardial, peritoneal, or synovial fluid. Use safety devices to protect from needle exposure.

c. Immediately place a portion of the joint fluid or peritoneal fluid collected from patients with CAPD or SBP into aerobic and anaerobic blood culture bottles, retaining some (0.5 ml) in syringe for Gram stain and direct plating.

(1) Use the minimum and maximum volumes recommended by the bottle manufacturer (generally up to 10 ml is the maximum for each bottle).

(2) Alternatively, inoculate the blood culture bottles after receipt in the laboratory.

d. Submit other fluids and the remainder of specimens placed in blood culture bottles in one of the following.

(1) A sterile, gassed-out tube or a sterile blood collection tube without preservative (e.g., sterile Vacutainer brand red-top tube). Avoid the use of anticoagulants, but if they must be used, use either sodium heparin or SPS, although some organisms are inhibited by even these

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

anticoagulants. Citrate and EDTA are the least desirable anticoagulants.

- (2) Anaerobic transport vial (for small-volume specimens)
- (3) The collection syringe, from which the air has been expelled and the needle removed, using a protective device to avoid injury. Cap the syringe with a sterile cap prior to transporting it to the laboratory.

☑ **NOTE:** Syringes that are capped with a Luer-Lok (with needle removed) are acceptable, if they are not transported in a vacuum tube system. Ensure that there is no leakage during transport, which could result in contamination of the culture. All of the transport methods listed above are acceptable for aerobic, anaerobic, fungal, and acid-fast bacillus (AFB) cultures, as well as stains.

2. Drainage tube specimens

☑ **NOTE:** Submission of drainage fluids should be discouraged in favor of direct aspiration of the area being drained, which is more sensitive in the detection of etiologies of infection (7). In addition, these specimens may be contaminated with skin microbiota, leading to inappropriate treatment. One method to discourage these cultures is to add a comment to the report: “*Bacterial cultures of drainage fluids in place for more than 2 days often yield inaccurate results with potentially misleading therapeutic consequences. Direct image-guided aspiration is preferred*” (7). Educate physicians that culture of surgical drainage from clean orthopedic surgeries is not indicated (3).

- a. Disinfect the collection tubing and aseptically aspirate fluid from the tubing.
- b. Submit in sterile, leakproof cup or in one of the transport containers listed above.
- c. Do not inoculate blood culture bottles, since they are unlikely to increase the yield of significant microbiota.

D. Specimen transport

1. Submit to laboratory as soon as possible and, if from a normally sterile site, alert laboratory that specimen has been submitted.
2. Do not refrigerate.
3. Label specimens with patient demographics and date, time, and site of collection: e.g., left knee joint fluid.
4. Record the patient diagnosis for improved processing of specimen.

E. Rejection criteria

1. If only blood culture bottles are received, a Gram stain cannot be performed.
2. Collect prior to antimicrobial therapy for greatest diagnostic sensitivity.
3. Do not submit specimens from drains after they have been infused with antimicrobial agents.
4. Call physician when fluid specimens are received on a swab.

☑ **NOTE:** Swabs afford the least desirable sample for culture of body fluids and should be discouraged as devices for transport, since the quantity of sample may not be sufficient to ensure recovery of a small number of organisms.

5. Contact physician if specimen is insufficient for the number of tests requested.

☑ **NOTE:** Routine bacterial culture is sufficient for culture for *Candida* species, if blood culture bottles are used or specimen is centrifuged. Fungal cultures of joint and abdominal specimens are occasionally indicated (especially for *Blastomyces dermatitidis* and *Histoplasma capsulatum*) but should be discouraged routinely. AFB cultures should not be routine but should be limited to those with a clinical indication.

6. Invasively collected specimens in leaky containers must be processed, but alert the physician of the possibility of contamination.

III. MATERIALS**A. Media**

1. BAP
2. CHOC
3. Nonselective anaerobic medium, e.g., CDC anaerobic sheep blood agar. See section 4 for media and methods.
4. Special selective media for recovery of fastidious or unusual organisms (e.g., charcoal-yeast extract agar for *Legionella*). Refer to the table of contents for procedures for specific microorganisms.
5. Add media selective for gram-negative or gram-positive organisms (see Table 3.3.1–1) based on Gram-stained smear of the specimen, which shows multiple morphologies of microorganisms.
6. Broth known to support the growth of both fastidious aerobic organisms and anaerobes, to detect small numbers of organisms (6, 10, 11, 13, 15). Common broth culture media are as follows.
 - a. Blood culture bottles (added supplements have not been shown to be important [5, 8])

- b. Anaerobic BHI or TSB with 0.1% agar with or without yeast extract
 - c. Fastidious anaerobe broth or fastidious broth (Quelab Laboratories, Inc., Montreal, Quebec, Canada; Remel, Inc., Lenexa, Kans.) (15)
 - d. Brucella broth
 - e. THIO is least desirable as a broth to grow low numbers of aerobic organisms and yeasts. It is excellent for anaerobic organisms (13, 15).
7. See procedure 3.17 for biochemical test reagents and procedure 3.3.1 for medium descriptions.

B. Gram stain reagents**C. Other supplies**

1. Cytocentrifuge and holders
2. Cleaned glass slides
3. Sterile Pasteur pipettes
4. CO₂-generating system and 35°C incubator

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
- B. For QC of blood culture broths, refer to procedure 3.4.1.
- C. See individual tests in procedure 3.17 for biochemical test QC.
- D. Periodically check laboratory processing to ensure there is no break in sterile technique and that media, stain reagents, collection tubes, slides, and other supplies are not contaminated with dead organisms.
 1. Filter sterilize (through a 0.22- μ m-pore-size membrane filter) fluid from saved specimens, and periodically process along with patient samples.
 2. No organisms should be detected on Gram stain, and these cultures should yield no growth.

V. PROCEDURE

Observe standard precautions.

A. Inoculation

1. Process specimen as soon as it is received.
 - **NOTE:** Use of biosafety cabinet will avoid contamination of the culture or specimen as well as protect laboratory processing personnel.
2. Record volume of specimen.
3. Record gross appearance, i.e., color, viscosity, light-transmitting properties, and presence of a clot.

V. PROCEDURE (continued)

4. Inoculate BAP and CHOC with 2 or 3 drops of specimen.
 - a. If only blood culture bottles were received, subculture immediately to CHOC to isolate microorganisms that prefer agar plates for growth (e.g., *N. gonorrhoeae*).
 - b. If little specimen is received (1 or 2 drops), inoculate only CHOC and rinse tube with broth culture medium. Omit Gram stain. Note on report the volume received.
5. If greater than 0.5 ml of specimen is received, do the following.
 - a. Inoculate up to 1 ml into 10 ml of broth culture media.
 - b. For greater than 2 ml of pericardial, peritoneal, amniotic, or synovial fluid specimens not received in blood culture bottles, inoculate aerobic and, if there is sufficient volume of specimen, anaerobic blood culture bottles. Do not add less than the amount recommended by the manufacturer, as the excess SPS may be inhibitory to growth of the infecting organism.
6. Inoculate anaerobic medium with 2 or 3 drops of specimen, *if* an anaerobic broth or blood culture bottle was not inoculated. For pleural fluid or drainage fluid, perform only on request and if specimen was transported anaerobically.
7. For peritoneal fluid contaminated with bowel contents, add MAC or EMB, Columbia colistin-nalidixic acid (CNA) or phenylethyl alcohol agar, and selective media for anaerobic isolation of mixed anaerobic microbiota, and omit broth cultures.
8. For requests to culture for microorganisms that do not grow on routine laboratory media (e.g., *Legionella*), inoculate special media as appropriate (refer to Appendix 3.4.1–1 for details on isolation and detection of these microorganisms).
9. Dispersion of clots
 - a. Pour the sediment containing clotted material into a sterile tissue grinder.
 - b. Add a small volume (<0.5 ml) of sterile broth to the grinder, and gently homogenize this mixture to disperse the clots and release any trapped bacteria.
 - ☑ **NOTE:** Do not grind the clots if a fungal culture is also requested for the sample. Tease the clots apart. Vigorous grinding can kill hyphal filaments.
- B. Prepare Gram stain by placing 1 or 2 drops of fluid specimen on an alcohol-rinsed slide.
 1. Allow the drop(s) to form one large drop. Do not spread the fluid.
 2. Air dry the slide in a biosafety cabinet or covered on a slide warmer.
 3. Fix smear with methanol and stain (see procedure 3.2.1 for staining details).
 - ☑ **NOTE:** The use of a cytocentrifuge for preparation of the Gram stain from clear aspirates or nonviscous body fluids is highly recommended (16).
- C. Incubation
 1. Incubate plates at 35 to 37°C in 5% CO₂. Alternatively, use a CO₂-generating system to provide the proper atmosphere if a CO₂ incubator is unavailable.
 2. Incubate broths at 35 to 37°C in ambient air.
- D. Save some specimen at 4°C for 1 week for further testing.
- E. Gram stain
 1. Interpret Gram stains immediately.
 2. If positive
 - a. Notify the physician immediately.
 - b. For invasively collected specimens, refer to positive blood culture workup (Table 3.4.1–2) for additional tests that can be performed on the direct specimen.
 - c. *If mixed morphologies are seen in Gram stain, retrieve the specimen and inoculate selective aerobic (e.g., MAC and CNA) and anaerobic plates to select for mixed pathogens.*

V. PROCEDURE (*continued*)**F. Culture examination**

1. Examine all plated and broth media for macroscopic evidence of growth at 24 h.
2. If no visible growth is observed on the culture media, reincubate.
 - a. Read aerobic plates daily for 4 days for invasively collected specimens and 2 days for drainage cultures.
 - ☑ **NOTE:** For specific requests or where patient history or clinical state suggests a slow-growing pathogen (e.g., *Brucella*), additional incubation time is appropriate.
 - b. For broth cultures, refer to procedure 3.3.2 for general guidelines and incubation.
 - c. Incubate blood culture bottles for 5 to 7 days. Extend incubation if *Brucella* culture is requested.
3. Cultures with growth
 - a. Notify physician of positive culture findings.
 - b. Correlate culture results with those of the direct Gram stain.
 - c. Identify all organisms, using the rapid tests listed in Table 3.3.2–5. For less common pathogens refer to procedures 3.18.1 and 3.18.2.
 - d. Do not perform complete identification if the physician indicates that the organism is a probable contaminant or that the isolate is one or two colonies of a coagulase-negative staphylococcus on one plate medium with no growth in the broth.
 - e. For peritoneal specimens that contain mixed gastrointestinal microbiota and no predominant organism, generally group organisms into “enteric,” “anaerobic,” and “skin” microbiota and do not identify further. However, screen the culture for the usual fecal pathogens (*see* procedures 3.8.1 and 3.8.2). Detection of yeasts, *S. aureus*, *Pseudomonas aeruginosa*, or, possibly, vancomycin-resistant enterococci may represent etiologies not covered by empiric regimens and should be listed individually.
 - ☑ **NOTE:** Empiric antimicrobial therapies are selected for the treatment of gastrointestinal tract microbiota, including anaerobes, enteric gram-negative bacilli, and enterococci. To attempt to isolate and report each of these agents is labor-intensive and does not add to the requirement to treat the patient with agents that are effective against all the usual microbiota.
 - f. Perform antimicrobial susceptibility testing as appropriate per NCCLS standards (12).
 - g. Hold positive culture plates or tubes for at least 7 days or, preferably, freeze isolates for long-term retrieval.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. Refer to procedure 3.3.2 for general reporting procedure.
- B. When reporting negative results, indicate the incubation time in the report.
- C. If a plate contaminant is suspected, add a notation: “Unable to differentiate laboratory contamination of plate media from true infection; suggest repeat culture of appropriately collected specimen.”
- D. Report the probable genus and species as soon as preliminary tests are completed. For mixed abdominal microbiota, a general statement listing the groups of organisms may be sufficient, e.g., “Numerous enteric rods, numerous mixed anaerobic microbiota, including *Clostridium perfringens* and *Staphylococcus aureus*, present.”
- E. Document notification of positive findings.

VII. INTERPRETATION

- A. Generally, a positive culture indicates infection with the organism.
- B. WBCs are usually present with infections of body fluids.

VIII. LIMITATIONS

- A. False-positive cultures can result from contamination of the specimen with skin microbiota.
- B. False-negative results can be caused by low numbers of organisms, prior antimicrobial treatment, or the fastidious nature of the infective organism.
- C. Many organisms that cannot be easily cultured cause arthritis. These include *Borrelia burgdorferi*, the agent of Lyme disease.

3.6

Catheter Tip Cultures

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Intravascular (intra-arterial or intravenous) catheter insertions cause a break in the skin barrier amenable to infection. The continued presence of this foreign body predisposes further to infection, which can result from either colonization of the catheter by the cutaneous microbiota or, less commonly, hematogenous seeding due to hub contamination. Since infected catheters are usually exposed directly to sterile spaces, there is a risk that the infection will result in bacteremia. Intravascular catheter-related infections are a major cause of morbidity and mortality in the United States. The Infectious Disease Society of America practice guidelines for management of these infections include culture of both catheters and blood (8). The most common infecting organisms are *Staphylococcus aureus*, enterococci, *Candida* spp., *Pseudomonas aeruginosa*, *Enterobacteriaceae*, and resident skin organisms, such as coagulase-negative staphylococci and *Corynebacterium* spp. The significance of this last group of organisms is not always clear, since the catheter is removed through the skin.

Several methods have been used to diagnose catheter-related sepsis. Semiquantitative (roll plate) cultures, catheter flush

cultures, and quantitative (sonication) cultures are more reliable diagnostic methods than qualitative cultures, where the tip is cultured in broth and a single contaminating microbe can give a positive result (8, 13). The semiquantitative technique is reported to distinguish infection from contamination, with counts of ≥ 15 CFU considered significant (6). The quantitative method and flush culture method use ≥ 100 CFU as the significant count (12). If such counts are accompanied by signs of local or systemic infection, they are indicative of catheter-related infection (8). Quantitative and semiquantitative methods have high specificity in the diagnosis of catheter-related septicemia, but the quantitative sonication method is reported to be 20% more sensitive than the semiquantitative culture method in the diagnosis of catheter-related bloodstream infection (11). Quantitation with sonication (see Appendix 3.6–1) is thought to be more sensitive because it is able to detect lumen colonization. At this time it is unclear whether the greater sensitivity of the quantitative method is clinically significant (8). Most laboratories perform the semiquantitative method, because of its

ease of use and because there is a lack of scientific studies showing that the quantitative method offers added benefit.

The submission of two blood cultures (one peripheral and one through the catheter) is an alternate method to diagnose catheter-related bacteremia without removal of the catheter. A blood culture from a peripheral site and a blood culture through the catheter are submitted simultaneously, for comparison of time to positivity. If the culture through the catheter is positive >2 h before the peripheral culture is positive with the same microorganism, it is likely that the infection is catheter related (1, 7). Quantitative blood cultures can also be performed using the ISOLATOR system (Appendix 3.4.1–2). If the blood collected through the catheter has a count that is 5- to 10-fold greater than the count of the same microorganism from the peripheral vein, there is evidence of catheter-related sepsis (8). Alternatively, for staphylococci, comparison of the clone from the catheter and the peripheral site can also predict catheter-related sepsis. (See procedure 13.12 for further information on catheter cultures from an infection control perspective.)

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

■ **NOTE:** Refer to procedure 3.3.1 for additional details. This portion can be copied for preparation of a specimen collection instruction manual for caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

Observe standard precautions.

- A. Collect two blood cultures, one through the catheter and one from a peripheral site at the time the catheter is submitted for culture.
- B. Clean the skin with 70% alcohol prior to catheter removal.
- C. Observing aseptic technique, hold the exposed end of the catheter and carefully remove the catheter from the patient with a sterile instrument, taking care to avoid contact with exposed skin. Holding the distal end over a sterile tube, cut the tip with a sterile scissors, dropping the last 2 to 3 in. into the tube.
- D. Avoid drying by sealing the tube and submit to the laboratory as soon as possible.
- E. Rejection criteria
 1. Do not accept urinary Foley catheter tips.
 2. Do not accept catheter tips which arrive in saline or transport medium.
 3. Smears of catheter tips add little to the diagnosis of catheter-related sepsis.
 4. Submit catheter tips for culture only if there are signs of infection, i.e., inflammation at the insertion site, fever, signs of sepsis, or documented bacteremia in which the source is not apparent. The routine culture of catheter tips without signs and symptoms of infection (e.g., those submitted without an accompanying peripheral blood culture) should be discouraged (3).
 5. For ventricular-peritoneal shunts, peritoneal or spinal fluid is preferred to the catheter tip. If tip is submitted, culture it, but request submission of fluid. Refer to procedure 3.7 for workup of such cultures.
 6. Skin swabs from the catheter site are not acceptable specimens. If there is evidence of local tissue infection, an appropriately collected aspirate of the wound is preferable. Refer to procedure 3.13.1.

III. MATERIALS

- A. BAP
- B. MAC or EMB (optional)
- C. Forceps
- D. Olive oil

Decant olive oil into a sterile container for use, but there is no need to sterilize the oil.

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.

V. PROCEDURE

Observe standard precautions.

- A. Using a sterile forceps, remove catheter tip from transport tube.
- B. Lay catheter tip on BAP.
- C. Roll the tip back and forth across the entire surface of a BAP (and, optionally, either MAC or EMB, in addition to the BAP) using sterile forceps and exerting slight downward pressure.
- D. If the tip is too long, using sterile scissors, cut the end closest to the top of the tube (proximal end) prior to rolling on the plates (Fig. 3.6–1). The proximal end may be rolled on a second plate, if desired.

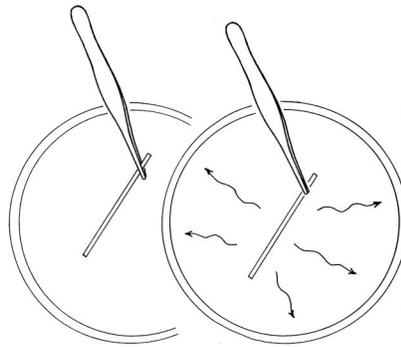

Figure 3.6-1 Inoculation of catheter tip to agar plate.

V. PROCEDURE (continued)

- E. If the specimen is from the total parenteral nutrition or is the catheter tip from a hyperalimentation line, culture also for *Malassezia furfur*.
1. Using a sterile pipette, add a small drop of olive oil to the initial area of roll after inoculation of the blood plate.
 2. Do not allow the oil to spread beyond a small area of the plate.
- ☑ **NOTE:** The diagnosis of catheter infection with *M. furfur* is difficult with most blood culture systems. However, the organism load in the catheter is high and a Gram stain of a drop of blood from the catheter hub will generally demonstrate the infecting organisms, without removal of the catheter.
- F. Incubate plates at 35°C in CO₂.
- G. Hold all culture plates for 4 days to look for yeasts, including *M. furfur*, that grow as pinpoint colonies in 3 days.
- H. Read the semiquantitative plates at 24, 48, 72, and 96 h.
1. Count each type of colony isolated, comparing growth on each medium. Only enumerate the growth on the BAP; MAC or EMB is used only to provide separation of colony types.
 2. Identify to at least the genus level any of the following.
 - a. Each organism present from vascular catheter tips with colony counts of >15 CFU
 - b. For >15 CFU of gram-positive rods, perform only Gram stain and catalase and check hemolysis. It is not necessary to identify to the species level.
 - c. For counts of <15 CFU, identify only significant pathogens (e.g., *Candida albicans*, Group A streptococci, and gram-negative rods).
 3. Save plates with growth for 1 week for comparison in case blood cultures become positive.
 4. Do not perform antimicrobial susceptibility testing on isolates unless the blood culture is positive and comparative results are desirable.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. For any morphotype with a count of >15 CFU
1. Enter the number of CFU isolated for each organism; i.e., 18 CFU followed by the organism name, at least to the genus level.

☑ **NOTE:** Organisms are *not* enumerated in catheter tip cultures as few, moderate, and numerous.
 2. For gram-positive rods, report as “Coryneform rods; not otherwise specified” if reactions are appropriate per Table 3.3.2-5.

VI. REPORTING RESULTS

(continued)

3. If different morphologies of coagulase-negative staphylococci are present, report “[number] CFU of coagulase-negative staphylococci (mixed morphologies).”
- B. If any morphotype has <15 CFU
 1. Report significant pathogens by name.
 2. Group together mixed skin microbiota organisms (i.e., coagulase-negative *Staphylococcus*, diphtheroids, non-*Candida albicans* yeasts, *Acinetobacter*, or viridans group streptococci) as, e.g., “25 CFU of mixed skin microbiota.”
 3. Report minimal identification of pure cultures of skin microbiota, e.g., staphylococci or gram-positive rods.
- C. If organisms are too numerous to count, report as “>100 CFU.”
- D. Report preliminary negative cultures as “No growth at *x* days,” where “*x*” is the number of days of incubation. Report final negative cultures as, e.g., “No growth at 4 days.”
- E. If gram-negative rods or *S. aureus* is isolated and no blood culture was submitted, add the following note to the report: “Submit blood cultures to diagnose catheter-related sepsis.”

VII. INTERPRETATION

- A. Since the treatment of catheter infection is removal of the catheter and antimicrobial treatment for isolate(s) in blood cultures (8), do not routinely perform susceptibility testing from catheter tip isolates.
- B. The presence of >15 CFU suggests the catheter as a potential source of bacteremia, which occurs with about 10% of colonized catheters.

VIII. LIMITATIONS

- A. Semiquantitative catheter tip cultures are estimated to have a sensitivity of 85% in diagnosis of catheter-related bacteremia, but the specificity to diagnose catheter-related sepsis is low (13). Blood cultures collected from peripheral sites are helpful in confirmation of the diagnosis of catheter-related sepsis (1, 4, 6).
- B. Infections of the catheter hub lumen may be missed by culture of only the tip.
- C. Efforts to diagnose catheter-related sepsis using unpaired quantitative blood cultures drawn from the catheter are less sensitive than tip cultures (13).
- D. Catheter cultures can be helpful in determination of the cause of fever.
- E. Some authors have shown that quantitative catheter tip cultures have a greater sensitivity and specificity than the semiquantitative method of Maki et al. (6) in the diagnosis of catheter-related sepsis; however, these methods are more labor-intensive (2, 5, 9, 11, 12, 13). See Appendix 3.6–1 for method.
- F. Siegman-Igra et al. (13) suggest that antimicrobial treatment of patients with positive catheter tip cultures but negative blood cultures increases medical costs unnecessarily, because of the low specificity of catheter tip cultures. For this reason, susceptibility testing of catheter tip isolates is not indicated. If concomitant blood cultures are positive, antimicrobial testing of the blood isolate is appropriate. Exceptions include performing antimicrobial testing when specifically requested by a physician and when testing the catheter tip isolate would provide more rapid results than waiting for the companion blood culture isolate to be tested (8).
- G. In simulated studies, rolling catheters, impregnated with antiseptics, on a blood plate inhibited the ability of the organisms to grow on the agar (10). This suggests that alternative methods must be found to diagnose infections in antiseptic-impregnated catheters.

APPENDIX 3.6–1

Sonication Method for Culture of Catheter Tips (1)

I. PROCEDURE

- A. Place catheter tip in 10 ml of TSB.
- B. Sonicate for 1 min at 55,000 Hz and 125 W.
- C. Vortex for 15 s.
- D. Add 0.1 ml of broth to 9.9 ml of saline. Vortex.
- E. Drop 0.1 ml of broth and 0.1 ml of saline suspension onto separate BAP and MAC (or EMB). Spread with spreader (Excel Scientific, Rightwood, Calif.).
- F. Incubate for 48 h in 5% CO₂ and count colonies.

II. INTERPRETATION

- A. Multiply the number of colonies on the broth culture plate by 10² CFU.
- B. If too numerous to count, multiply the number of colonies on the saline culture plate by 10⁴ CFU.
- C. A count of greater than 10² CFU is considered significant for catheter-related infection.

III. REPORTING RESULTS

- A. Report the genus and species of organisms present preceded by their count in CFU. If organisms are too numerous to count on the higher dilution plate, report as "Greater than 10⁶ CFU." See item VI in procedure 3.6 for further details.
- B. If no organisms are present, report "No growth at 1:100 dilution."

IV. LIMITATION

Although this method is more reliable than the roll plate method (2), it is not clear whether the difference is clinically significant. Blood cultures remain a very important part of detection of catheter-related sepsis.

APPENDIX 3.6–1 (continued)

References

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Bacterial meningitis is the result of infection of the meninges. Identification of the infecting agents is one of the most important functions of the diagnostic microbiology laboratory because acute meningitis is life-threatening. *CSF from a patient suspected of meningitis is an emergency specimen that requires immediate processing to determine the etiologic agent.*

CSF is obtained by transcutaneous aspiration, and therefore, all organisms recovered from the culture are potential pathogens and must be reported to the physician immediately. Because the number of organisms in the CSF can be as low as 10^3 CFU/ml (6), concentration of the Gram stain by cytocentrifugation is important for rapid diagnosis. Cytospin concentration can increase the sensitivity up to 100-fold compared with both uncentrifuged and conventional centrifuged fluid (13). Concentration for culture is unnecessary, since the plate inoculum is suffi-

cient to detect the usual low numbers of organisms (3, 6, 9).

Aerobic bacteria commonly cause bacterial meningitis (Table 3.7-1), but anaerobes may be present in CSF when a meningeal abscess or a similar infectious process is adjacent to the meninges. These include traumatic head injury or prostheses, such as metal cranial plates and shunt drains. Inoculation of anaerobic media is not recommended for diagnosis of community-acquired meningitis. For shunt infections a backup broth that will grow anaerobes and aerobes in low numbers is recommended (3, 8).

Direct antigen testing is rarely performed because the cost-benefit is low. The sensitivity of testing for certain serogroups of *Neisseria meningitidis* is poor. While the sensitivity of testing for *Haemophilus influenzae* serogroup B is high, the disease has virtually disappeared in

countries with active neonatal vaccination programs. For streptococcal and *Escherichia coli* K-12 infections, the Gram stain is usually positive, except possibly in cases of partially treated meningitis. To maintain reagents for the latter indication is of low benefit. In a study of 103 episodes of meningitis, antigen tests had a sensitivity of 9% for Gram stain-negative specimens, with a 33% sensitivity overall (5).

PCR is becoming the method of choice for rapid, sensitive diagnosis of meningitis, especially for organisms that are present in low numbers or for organisms that are difficult to grow, particularly when the patient is partially treated with antimicrobial agents, e.g., *Borrelia*, *Ehrlichia*, *Mycobacterium tuberculosis*, *Mycoplasma*, and *Streptococcus pneumoniae* (2, 4, 7). Unfortunately, many of these tests are not available commercially.

Table 3.7-1 Common bacterial organisms causing acute meningitis by age or condition

Age	Organism(s)
Neonate	<i>E. coli</i> , <i>S. agalactiae</i> (group B streptococci), <i>Listeria monocytogenes</i>
<2 mo	<i>S. agalactiae</i> , <i>L. monocytogenes</i> , <i>E. coli</i>
<10 yr	<i>H. influenzae</i> , <i>S. pneumoniae</i> , <i>N. meningitidis</i>
Young adult	<i>N. meningitidis</i>
Adult	<i>S. pneumoniae</i> , <i>N. meningitidis</i>
Elderly	<i>S. pneumoniae</i> , gram-negative bacilli, <i>L. monocytogenes</i>

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

▣ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for physicians and other caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

A. Specimen collection

▣ **NOTE:** This is a medical procedure that is performed by a physician guided by appropriate precautions.

1. Lumbar puncture

- a. Disinfect the puncture site with antiseptic solution and alcohol in a manner identical to phlebotomy skin preparation for blood culture to prevent specimen contamination and introduction of infection.
- b. Insert a needle with stylet at the L3-L4, L4-L5, or L5-S1 interspace. When the subarachnoid space is reached, remove the stylet; spinal fluid will appear in the needle hub.
- c. Measure the hydrostatic pressure with a manometer.
- d. Slowly drain the CSF into the sterile leakproof tubes.
- e. Submit the most turbid tube to microbiology. Otherwise no. 2 is the preferred tube.
- f. Submit an appropriate amount commensurate with the tests required to make the diagnosis, using a guideline of a minimum of 2 ml of fluid for each culture request: routine, fungal, and acid-fast bacillus (AFB).

2. Ommaya reservoir fluid or ventricular shunt fluid

- a. Clean the reservoir site with antiseptic solution and alcohol prior to removal of fluid to prevent introduction of infection.
- b. Remove fluid via the reservoir unit, and place it in a sterile tube.

3. Collect prior to antimicrobial therapy for highest sensitivity.

B. Specimen transport

1. Submit to laboratory as soon as possible and alert laboratory that specimen is in transit.
2. Do not refrigerate.
3. Label specimens with demographic information and time, date, and site of collection, e.g., ventricular shunt, lumbar puncture.
4. Complete requisition with demographic and specimen collection information. Record the patient diagnosis for improved processing of specimen.
5. Limit requests to those reflecting patient's condition.

C. Rejection criteria

1. Call physician to prioritize requests if there is insufficient volume.

▣ **NOTE:** Fungal and AFB cultures of the CSF are infrequently indicated in acute community-acquired meningitis. Refer to Appendix 3.7-1 for a sample laboratory policy to communicate to caregivers. Since the fungal pathogens in CSF (*Cryptococcus neoformans*, *Coccidioides immitis*, and *Histoplasma capsulatum*) are best and most rapidly diagnosed by serologic methods or cultures of other sites, fungal CSF culture should be discouraged. However, the fungi that cause CSF disease grow well on the media inoculated for routine culture. For fungal requests, incubate the routine culture plates for a longer period and inoculate a fungal broth (Sabouraud) with a large volume of specimen to increase the yield of *Cryptococcus* and *Coccidioides*. *M. tuberculosis* is best diagnosed by PCR. Refer to sections 7 and 8 of this handbook.

2. Specimens in leaky containers must be processed, but alert the physician of the possibility of contamination.
3. Direct antigen testing is not recommended.

III. MATERIALS

- A. Media**
1. BAP
 2. CHOC
 3. Broth known to support the growth of both fastidious aerobic organisms and anaerobes, such as anaerobic BHI or TSB with 0.1% agar and 5% sheep blood or fastidious anaerobe broth or fastidious broth (Quelab Laboratories, Inc., Montreal, Quebec, Canada; Remel, Inc., Lenexa, Kans.) (1, 11, 12).
 - ☑ **NOTE:** Since THIO is mainly a broth for anaerobes and does not support the growth of the most common pathogens in CSF, it cannot be recommended for CSF culture (11, 12).
 4. See procedure 3.3.2 for common biochemical tests and media and procedure 3.17 for detailed procedures for biochemical tests.
- B. Gram stain reagents**
- C. Other supplies**
1. Cytocentrifuge
 2. Sterile Pasteur pipettes

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A.** Verify that plate media meet expiration date and QC parameters per current NCCLS document M22. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
- B.** Periodically check laboratory processing to ensure that there is no break in sterile technique and that media, stain reagents, collection tubes, slides, and other supplies are not contaminated with dead organisms.
1. Filter sterilize (through a 0.22 μm -pore-size membrane filter) CSF from saved specimens, and periodically process along with patient samples.
 2. No organisms should be detected on Gram stain, and these cultures should yield no growth.

V. PROCEDURE

Observe standard precautions.

- A. Inoculation**
1. Process specimen as soon as received.
 - ☑ **NOTE:** Use of biosafety cabinet will avoid contamination of the culture or specimen as well as protect laboratory processing personnel.
 2. Verify patient name on both label and requisition.
 3. Record the following.
 - a. Volume of CSF
 - b. Gross appearance of CSF, i.e., clear, bloody, cloudy, xanthochromic
 4. Inoculate media.
 - a. Using a sterile pipette, aspirate fluid from the bottom of the collection tube.
 - b. Place 2 or 3 drops each onto BAP and CHOC. Streak in quadrants using a separate loop or flamed loop for streaking each plate.
 - c. If greater than 1 ml is available for routine culture from a ventricular source or shunt, inoculate 1 ml to broth. If the site of the collection is unknown, use the patient location as an aid to determination of the need for anaerobic culture or use of a backup broth.
 - (1) Specimens from the emergency department usually are from community-acquired meningitis.
 - (2) Specimens from the neurology service likely represent those requiring broth culture.
 - (3) If large volumes of specimen are received, they usually are from shunts or reservoirs.

V. PROCEDURE (*continued*)

5. If a CSF specimen tube appears to be empty or contains only 1 to 5 drops of fluid and if more specimen cannot be obtained sterilely from other laboratory departments, proceed as follows.
 - a. If 1 drop is available, use a sterile Pasteur pipette and prepare a smear for Gram stain from a portion of the specimen.
 - b. Using a sterile Pasteur pipette, place about 0.5 ml of broth medium into the specimen tube. Recap the tube, and invert it to mix the contents.
 - c. Use all the broth to inoculate media and do smear.
 - d. Note on report the volume received.
- B. Gram stain
 1. Place 5 or 6 drops of sample plus 1 drop of 37% formalin into a cytospin specimen chamber. Follow procedure for operation of centrifuge from manufacturer.
 2. As an alternative, when the specimen is cloudy or the quantity is not sufficient for concentration, prepare the smear by placing 1 or 2 drops of CSF on an alcohol-rinsed slide.
 - a. Allow the drop(s) to form one large drop. Do not spread the fluid.
 - b. Air dry the slide in a biosafety cabinet or covered on a slide warmer.
 3. Fix smear with methanol. (See procedure 3.2.1 for staining and reading smear.)
 4. Interpret CSF Gram stains immediately.
 5. Any bacteria seen are considered significant. However, confirm low numbers only seen in one or two fields with a second smear. If positive, do the following.
 - a. Notify the physician immediately.
 - b. If sufficient specimen is left, refer to blood culture workup of positive broths (Table 3.4.1–2) for additional tests that can be performed on the direct specimen.
- C. Save some CSF at 4°C and/or at –20°C for 1 week for PCR or other subsequent requests.
- D. Incubation
 1. Incubate plates at 35 to 37°C in 5% CO₂. Alternatively, use a CO₂-generating system to provide the proper atmosphere if a CO₂ incubator is unavailable.
 2. Incubate broths at 35 to 37°C in ambient air.
- E. Culture examination
 1. Examine all plate and broth media for macroscopic evidence of growth at 24 h.
 2. If no visible growth is observed on the culture media, reincubate.
 - a. Read aerobic plates daily for 4 days.
 - b. If the Gram stain is positive and there is no growth on the plates or a fungal culture was ordered, hold all plates for at least 1 week.
 - c. Examine broth media daily for 4 days and hold for 7 days before discarding.
 - d. Refer to procedure 3.3.2 for general guidelines.
 3. Cultures with growth
 - a. Notify physician of positive culture findings.
 - b. Identify all organisms, using the rapid tests listed in Table 3.3.2–5.
 - (1) Perform rapid bile solubility spot test (procedure 3.17.6) on all alpha-hemolytic streptococci to identify *S. pneumoniae*. If positive, report *S. pneumoniae*.
 - (2) Perform catalase and Gram stain of organisms growing on BAP and/or CHOC. Identify further according to Gram stain and rapid tests in Table 3.3.2–5. *Listeria* and group B streptococci are significant CSF pathogens.

V. PROCEDURE (continued)

It is imperative that these cultures be handled in a biosafety hood.

- (3) Perform oxidase test on gram-negative diplococci. If positive and colony is grayish to white, perform commercial kit containing δ -glutamyl-aminopeptidase (see Table 3.18.2–1). If positive, report *N. meningitidis*.
 - (4) For all staphylococci, perform the tube coagulase for confirmation of slide or latex coagulase results.
 - (5) For less common pathogens, refer to procedures 3.18.1 and 3.18.2.
 - (6) Generally determine the probable genus and usually the species identification of most CSF pathogens within 2 h of visible growth on the plates.
- c. Do not perform complete identification or antimicrobial susceptibility testing (AST) if the isolate is clearly a plate contaminant or the isolate is a coagulase-negative staphylococcus (CoNS) isolated from broth only.
 - **NOTE:** Isolates of CoNS and *Corynebacterium* are probably contaminants in community-acquired infection but may or may not be a cause of infection in shunt infections and those with head injuries (3, 8, 9). A few colonies of catalase-positive, gram-positive rods growing only on CHOC should be subcultured to BAP to check hemolysis and rule out *Listeria* before being reported as corynebacteria.
 - d. Perform AST on enteric and nonfermenting gram-negative rods, enterococci, *S. pneumoniae*, *Staphylococcus aureus*, and other significant staphylococci.
 - (1) For *H. influenzae*, perform beta-lactamase test. Perform AST to penicillin or ampicillin if beta-lactamase test is negative and either agent will be used for therapy.
 - (2) For *Listeria*, *Streptococcus agalactiae*, and *N. meningitidis*, do not perform AST or beta-lactamase testing, which can lead to erroneous results. Resistance to penicillin in these isolates is rare; confirm any non-penicillin-susceptible isolates in a reference laboratory (10). For the penicillin-allergic patient, consult with the physician to guide AST.
 - e. Hold positive culture plates for at least 7 days or, preferably, freeze isolates for long-term retrieval.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. Report the Gram stain results as soon as possible, usually within 1 h of receipt.
- B. Report probable genus and species as soon as preliminary tests are completed.
- C. Refer to procedure 3.3.2 for general reporting.
- D. Document notification of physician of positive findings.

VII. INTERPRETATION

- A. Generally a positive culture indicates infection with the organism.
- B. Lack of WBCs in CSF does not rule out infection, especially in listeriosis (5).
- C. The most common cause of community-acquired bacterial meningitis is *S. pneumoniae*. Performance of the rapid bile solubility spot test (procedure 3.17.6) or the Quellung test (procedure 3.17.42) on all alpha-hemolytic streptococci seen in Gram stain is key to rapid diagnosis.
- D. Isolation of enterococci from CSF is always a cause for concern. The presence of the organism may be an indication of strongyloidiasis.

VIII. LIMITATIONS

- A. False-positive results can result from contamination of the specimen or the culture with skin microbiota.
- B. False-negative results can be caused by low numbers of organisms, prior antimicrobial treatment, or the fastidious nature of the infective organism.

APPENDIX 3.7-1

Suggested Policy for Caregivers for Microbiological Examination of Cerebrospinal Fluid

I. RATIONALE

While it is common for CSF to be submitted for routine, fungal, and AFB culture, the yield of the last two cultures is low. The cost of these cultures is high. In addition, the quantity of specimen submitted for these cultures is often too low to perform all cultures with a high sensitivity. Yet such requests deplete the specimen volume, which could be used for other testing. More importantly, these tests take from 4 to 8 weeks to be completed and yield a diagnosis.

The sensitivity of cryptococcal antigen (CRAG) testing is close to 100% from serum and 98% from CSF in diagnosing both fungemia and meningitis with *Cryptococcus* in the untreated patient. The sensitivity of the India ink wet mount is 50%, and this is a poor test. Since cryptococcal disease is not an acute emergency, there is no need to have the CRAG test available on a STAT basis. Testing should be done at least once daily.

The sensitivity of AFB and *Coccidioides immitis* culture of CSF is 30%, and that is only if 10 ml is submitted for culture. The current recommendation is to perform a PCR assay if tubercular (TB) meningitis is suspected and to perform serology on the CSF specimen to diagnose *C. immitis*. The sensitivities of these methods are close to 100%. They require little specimen and can be performed within 2 to 4 days of specimen receipt. *Coccidioides* serology should be ordered when a patient has signs and symptoms and has traveled to areas where this organism is endemic. The symptoms that suggest TB meningitis are mental status changes over a period of time, WBCs (lymphocytosis), positive purified protein derivative test or history of exposure, and increased protein and decreased glucose in the CSF. *Histoplasma capsulatum*, the other agent of fungal meningitis, is best diagnosed by culture of blood or bone marrow. Both *Histoplasma* and *Coccidioides* are found only in certain geographic regions.

II. POLICY

- A. The following tests in microbiology should be ordered routinely on CSF.
 1. Gram stain using cytospin concentration
 2. Routine culture, held for 1 week; notify laboratory if it is from a shunt or trauma.
 3. Cryptococcal antigen test (offered 7 days a week; done in place of India ink)
 4. All specimens will be held at both 4 and -20°C for 1 week for further testing if indicated after reporting the initial results, including chemistry and hematology.
- B. The following will be done only by special request after initial specimen testing.
 1. PCR for *M. tuberculosis*
 2. Serology for *Coccidioides*
 3. AFB culture
 4. Fungal culture
 5. PCR for herpesvirus group
 6. Viral culture for enteroviruses (other viral agents cannot easily be cultured)

3.8.1

Fecal Culture for Aerobic Pathogens of Gastroenteritis

■ **NOTE:** For isolation of *Campylobacter jejuni/coli*, see procedure 3.8.2.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Gastroenteritis can be caused by bacteria, parasites, or viruses. With such a wide array of pathogens and the need for cost containment, physician input and practice guidelines (9) can help the laboratory determine which tests are appropriate for detecting the etiological agent of diarrhea. When a routine stool culture is requested, only the most common bacterial agents of diarrhea may be detected (*Salmonella* spp., *Shigella* spp., and *Campylobacter jejuni*). *Salmonella* and *Shigella* are screened by using differential and selective direct plating media (Table 3.8.1–1), which are based on lactose fermentation and H₂S production (25). Since some non-pathogenic, gram-negative rods found in normal feces may give the same reactions as enteric pathogens, biochemical screening and agglutination are necessary for identification. Routinely, culture for *C. jejuni* is performed, but because the method for isolation is different from the method to detect other pathogens, details are presented in a separate procedure (see procedure 3.8.2).

Other pathogens, such as *Yersinia enterocolitica*, *Aeromonas* spp., *Plesiomonas shigelloides*, *Vibrio cholerae*, and other *Vibrio* spp., including *Vibrio parahaemolyticus*, may be detected in routine culture, but there is a better chance of detection if the physician specifies the suspect organism. For many of these cultures, selective media for these agents are inoc-

ulated. If requests for culture for these organisms are infrequent, a reference or public health laboratory may be used for testing. In addition, several organisms produce toxin-mediated disease. While the organism may be detected in culture, detection of the toxin that is responsible requires other laboratory tests. These organisms include verocytotoxin-producing *Escherichia coli* (VTEC), enterotoxigenic *E. coli*, *Clostridium botulinum*, *Clostridium difficile*, *Bacillus cereus*, and *Staphylococcus aureus*. Commercial tests are available for VTEC and for *C. difficile*. For other toxins, testing is available only from public health or reference laboratories. In addition, other genera of gram-negative rods (*Hafnia*, *Edwardsiella*, DF-3, and even *Klebsiella*) have been implicated in gastroenteritis and may be isolated in culture.

VTEC, also known as Shiga toxin-producing or enterohemorrhagic *E. coli* (EHEC), produces a toxin mediated by a bacteriophage, which has been implicated in hemorrhagic colitis (HC) and has been associated with hemolytic-uremic syndrome (HUS) (14). VTEC is the fourth leading cause of diarrhea in the United States, with severe complications from HUS and HC, especially in children. Over 60 *E. coli* serotypes produce the toxin, but *E. coli* O157:H7 is responsible for at least half of the cases (8, 15, 19). Since it has a unique biotype, *E. coli* O157 can easily be

detected on selective medium (10). A direct assay for the verocytotoxin can detect the presence of toxin in stools infected with other strains or confirm that an *E. coli* O157 strain is a toxin producer (see procedure 11.8). At a minimum, testing for *E. coli* O157 or, preferably, verocytotoxin should be performed routinely on bloody stools from all patients, especially children. Testing on all stools sent for diagnosis of diarrhea is preferred from a public health standpoint but may not be cost-effective for hospital laboratories if the prevalence of disease is low (24).

Fecal cultures should not be performed for patients being treated with broad-spectrum antimicrobial agents, because it is likely that the antimicrobial therapy is responsible for the diarrhea (9). They may have overgrowth with other bacteria, including *Pseudomonas aeruginosa*, and *Candida* spp., the role of which in disease production is not clear. Their presence may be reported, along with a statement indicating that the organism was the predominant organism recovered and that expected enteric organisms were not present, suggesting antimicrobial inhibition. In such cases, the *C. difficile* toxin assay (procedure 3.8.3) is more meaningful. Generally these patients have been hospitalized for more than 3 days; after that time requests for routine stool cultures should be rejected.

Table 3.8.1–1 Commonly used primary plating and broth media for isolation of *Salmonella* and *Shigella*^a

Medium (abbreviation)	Type	Expected isolates	Inhibitors or indicators	Reactions of lactose fermenters	Reactions of pathogens	Comments
Hektoen enteric agar (HEK) (17)	D, S plate	<i>Salmonella</i> and <i>Shigella</i> spp. (especially for <i>Shigella</i> spp.)	Bile salts, ferric ammonium citrate, sodium thiosulfate, lactose, sucrose, salicin, bromthymol blue, fuchsin	Yellow-orange or salmon pink; pink precipitate around colonies, may have black centers.	<i>Shigella</i> is green. <i>Salmonella</i> is blue or green; may have black centers.	Inhibits <i>Citrobacter</i> but is small and blue-green, if present. <i>Proteus</i> and <i>Providencia</i> are yellow or green; may have black centers. Detects H ₂ S.
MacConkey agar (MAC)	D, S plate	Gram-negative enteric bacilli	Bile salts, crystal violet, lactose, neutral red	Pink	Colorless or transparent	5% Agar will inhibit swarming of <i>Proteus</i> spp.
Salmonella-shigella agar (SS)	D, highly S plate	<i>Salmonella</i> and <i>Shigella</i> spp. (<i>S. sonnei</i> inhibited)	Bile salts, lactose, citrate, thiosulfate, ferric citrate, brilliant green, neutral red	Pink, red; may have black centers.	Colorless or transparent; may have black centers.	Detects H ₂ S.
Xylose, lysine, deoxycholate agar (XLD) (25)	D, S plate	<i>Salmonella</i> and <i>Shigella</i> spp. (especially for <i>Shigella</i> spp.)	Deoxycholate, thiosulfate, ferric ammonium citrate, xylose, lactose, sucrose, lysine, phenol red	Yellow; may have black centers.	<i>Salmonella</i> and <i>Shigella</i> are red. <i>Edwardsiella</i> and <i>Salmonella</i> may be red with black centers.	<i>Providencia rettgeri</i> , <i>Morganella morganii</i> , and <i>Proteus</i> spp. are yellow even though they are lactose negative. Detects H ₂ S.
Gram-negative (GN) broth	E broth	<i>Shigella</i> and possibly <i>Salmonella</i> spp.	Deoxycholate, citrate, dextrose, mannitol	Initially enhances growth of mannitol-fermenting rods		Subculture at 6–8 h.
Selenite-F	E broth	<i>Salmonella</i> and <i>Shigella</i> spp. (some shigellae may be inhibited)	Selenite, lactose	Selenite is toxic to <i>Escherichia coli</i> and some other enteric bacteria.		Subculture at 18–24 h. Selenite broth with cystine may inhibit some salmonellae.

^a Either bile salts, deoxycholate, or Selenite is present in each medium to inhibit gram-positive microbiota. Abbreviations: D, differential; E, enriched; S, selective. Ferric ammonium citrate reacts with hydrogen sulfide (H₂S) from organism to produce black color of colony.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. Have patient obtain stool specimen.
 - a. Patient should pass the stool into a clean, dry pan or special container mounted on the toilet for this purpose.
 - b. Transfer at least 5 ml of diarrheal stool, 1 g of material or a walnut-sized portion of stool, or the amount of fecal specimen that displaces to the line of commercial transport vials to one of the following:
 - (1) Clean, leakproof container with a tight-fitting lid *or*
 - (2) Buffered glycerol saline (preferred for *Shigella* spp. but inhibits *Campylobacter*)

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- (3) Modified Cary-Blair medium (modified to contain 1.6 g of agar per liter rather than 5 g/liter)
- Purchase from most commercial medium sources *or*
 - Prepare as follows.

Dispense the following ingredients into 991 ml of H₂O.

sodium thioglycolate	1.5 g
disodium phosphate	1.1 g
sodium chloride	5.0 g
phenol red	0.003 g
agar	1.6 g

Heat to dissolve and cool to 50°C. Then add 9 ml of 1% CaCl₂. Adjust pH to 8.4; dispense in vials and steam for 15 min. Cool and tighten caps.

- Whether purchased or prepared in-house, QC transport medium to determine if it will support the viability of *Shigella* and *Campylobacter*. See section 14, Table 14.2–2, for details; medium is listed under “Transport.”

☑ **NOTE:** Do not fill commercial transport vials above indicator line. Overfilling of transport vial results in improper specimen preservation.

- Stool enrichment broths (*see* Table 3.8.1–1).

☑ **NOTE:** Generally, fecal specimens are not placed directly into these broths at collection, but it can be done.

- Anaerobic transport tube for *C. difficile* culture, not toxin assay (culture is only for epidemiologic or nosocomial studies).

☑ **NOTE:** Do not use toilet paper to collect stool, because it may be impregnated with barium salts, which are inhibitory to some fecal pathogens. The specimen should not be mixed with urine, but semisolid to solid feces can be scooped out of urine, if necessary.

2. Rectal swabs

- Pass the tip of a sterile swab approximately 1 in. beyond the anal sphincter.
- Carefully rotate the swab to sample the anal crypts, and withdraw the swab.
- Send the swab in Cary-Blair medium or buffered glycerol saline.

- Submit duodenal, colostomy, or ileostomy contents in leakproof cup or transport vial.

B. Timing and transport

- Submit specimen during the acute stage of infection (usually 5 to 7 days), because pathogens decrease in number with time.
- Submit and culture fresh stool within 30 min of collection to allow for isolation of *Shigella* spp., which are extremely fragile.
- Store and transport stool in transport medium at 4°C and submit within 24 h for best recovery of pathogens.
- Generally submit two stools per patient from different days to diagnose bacterial causes of gastroenteritis.

C. Labeling

- Provide a place on laboratory order form or computer entry screen to indicate if the stool is bloody.
- Label specimen and accompanying requisition with patient name, hospital medical record number, room number (location), physician, culture site, and date and time of collection.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

3. Document when specimen is received; if it is liquid, formed, or solid; or if it contains mucus.

D. Rejection criteria

1. Reject stools not in transport medium received >2 h after collection, as changes occur that are detrimental to most *Shigella* spp. If recollection is not possible and the doctor requests that the stool be processed, set up the culture and enter a note: "Delay in specimen receipt by laboratory may compromise recovery of pathogens."
2. If specimen in transport medium is delayed for more than 3 days at 4°C or is delayed for more than 24 h at 25°C, request recollection since yield will be compromised.
3. Reject routine fecal cultures received from patients hospitalized for >3 days, unless the patient is known to be human immunodeficiency virus positive or in cases of a cluster epidemic within the institution.
4. Notify caregiver if transport tube is filled above line, indicating that too much specimen was submitted in vial.
5. If transport vial indicator has turned yellow, reject specimen, since *Shigella* organisms are killed at low pH.
6. Do not process hard, solid stools that cannot be sampled for inoculation.
7. Do not process dry swabs.
8. Do not process stools with barium.
9. Reject more than three stools from the same patient in a 3-week period or multiple specimens received on the same day.
10. Do not use specimens submitted in bacteriology transport tubes for parasitology examination.

III. MATERIALS

A. Media for routine stool culture (see Table 3.8.1–1 for descriptions and abbreviations)

1. BAP
2. MAC
3. Choose one or more (to increase yield) of the following to select for *Salmonella* and *Shigella*.
 - a. HEK
 - b. XLD
 - c. SS (do not use as only selective medium)
4. Enrichment broth (choose one)
 - a. Selenite-F (generally for *Salmonella* enrichment)
 - b. GN broth (for both *Salmonella* and *Shigella* enrichment, but requires subculture at 6 to 8 h)
 - ☑ **NOTE:** The use of enrichment broths for detecting small numbers of *Salmonella* or *Shigella* spp. can be justified for culturing stools of workers in sensitive occupations, such as day care workers and food service employees. Laboratories that have historical data showing very poor recovery of additional pathogens not seen on initial plates can make a case for abandoning routine use of enrichment broths. Generally enrichment broth in-

creases the yield of *Salmonella* and *Shigella* by 10%.

5. If selected other pathogens are requested or indicated, choose additional selective media from Table 3.8.1–2 to enhance recovery of these stool pathogens. Also use these media based on prevalence of disease and public health requirements in specific geographic areas (e.g., use bismuth sulfite agar for cluster epidemics of *Salmonella*).

B. Biochemical tests

1. For screening and detection of *Salmonella*, *Shigella*, and *Yersinia*
 - a. Spot indole reagent (procedure 3.17.23)
 - b. Oxidase reagent (procedure 3.17.39)
 - ☑ **NOTE:** False-negative results are common if indole or oxidase test is done from selective medium. Test only from BAP.
 - c. Urea agar slants or disks (procedure 3.17.48)

Table 3.8.1–2 Special highly selective media for specific pathogen requests

Medium	Abbreviation	Inhibitors or indicators	Pathogen selected and colony description	Notes ^a
BAP with ampicillin (16)	BAP-A	20 µg of ampicillin/ml	<i>Aeromonas</i> is oxidase positive and may be hemolytic	Increases the yield of isolation of pathogen.
Bismuth sulfite		Brilliant green, bismuth sulfite, ferrous sulfate, dextrose	<i>Salmonella</i> (especially <i>S. typhi</i>) is black, with or without brownish-black zones, or green with no zones.	Especially good for <i>Salmonella</i> serovar Typhi outbreaks; <i>Morganella</i> is not inhibited but appears green.
Brilliant green agar		Brilliant green, lactose, sucrose, phenol red	<i>Salmonella</i> is red, pink, or white surrounded by red zone.	Fermenters are yellow to yellow-green; agar is inhibitory to <i>Salmonella</i> serovars Typhi and Paratyphi.
Inositol-brilliant green-bile salt agar	IBB	Brilliant green, bile salts, inositol	<i>P. shigelloides</i> forms white to pink colonies (5).	Coliforms are either green or pink.
Cefsulodin-Irgasan-novobiocin (16, 22)	CIN	Deoxycholate, crystal violet, cefsulodin, Irgasan, novobiocin, mannitol, neutral red	<i>Y. enterocolitica</i> , <i>Aeromonas</i> spp., and other yersiniae have deep red center with a transparent margin, or “bull’s-eye” appearance.	Incubate at 25°C for 48 h. <i>Citrobacter</i> , <i>Pantoea agglomerans</i> , and <i>Serratia liquefaciens</i> are red. <i>Enterobacter cloacae</i> and <i>S. marcescens</i> colonies are raised and mucoid, with diffuse, pink coloration.
Cycloserine-cefoxitin-egg yolk agar ^b	CCEY ^b	Cycloserine, cefoxitin, cholic acid, egg yolk, <i>p</i> -hydroxyphenylacetic acid, lysed horse or sheep blood	<i>Clostridium difficile</i> colonies are large (4 mm) and gray with whitish centers; they fluoresce chartreuse under long-wave UV light on anaerobic BAP or CCEY; typical barnyard odor.	Incubate under anaerobic conditions for 48–72 h; gram-positive rod with rare spores.
MAC-sorbitol with cefixime and tellurite	CT-SMAC	MAC with sorbitol (rather than lactose), cefixime, and tellurite	<i>E. coli</i> O157:H7 is colorless; other coliforms are pink or inhibited.	Better selection than SMAC, which can also be used (8)
MAC broth	MAC broth	MAC without agar	VTEC, especially non-O157 strains	Use 50 µl of overnight culture to perform EHEC EIA. May incubate at 25°C to enrich for <i>Yersinia</i> (23).
Thiosulfate citrate bile salts ^c	TCBS ^c	Bile salts, citrate, thiosulfate, 1% NaCl, sucrose, bromthymol blue	<i>V. cholerae</i> is yellow; <i>V. parahaemolyticus</i> is green or blue. Some <i>Vibrio</i> spp. are inhibited.	<i>Proteus</i> is yellow; other enteric bacteria are inhibited but blue to translucent if they grow. Enterococci may also grow.
Alkaline peptone water	APW	1% NaCl, pH 8.5	Vibrios are selected.	Subculture to TCBS at 24 h (18).

^a Incubate at 37°C in O₂ unless otherwise stated.

^b Since as many as 20% of asymptomatic hospitalized patients may be colonized with *C. difficile*, tests for presence of toxin in stool are more specific for diagnosis of *C. difficile*-associated diarrhea. Isolation of the organism should only be done for epidemiologic studies, with confirmation that the isolated strain is a toxin producer. CCFA (containing cycloserine, cefoxitin, fructose, egg yolk, and neutral red) can also be used for isolation. Do not use a medium with neutral red to demonstrate colonial fluorescence (3).

^c Prepare TCBS fresh for use from powder or by melting previously prepared or purchased “deeps.” If made from powder, boil but do not autoclave prior to use.

III. MATERIALS (continued)

- d. Kligler's iron agar (KIA) or triple sugar iron agar (TSI) slants (procedures 3.17.22 and 3.17.25)
 - e. Andrade's glucose with a Durham tube for gas production (optional) (procedure 3.17.9)
 - ☑ **NOTE:** This medium allows easy reading of gas production and can be used for motility and Voges-Proskauer (VP) reaction.
 - f. Pyrrolidonyl- β -naphthylamide (PYR) (procedure 3.17.41)
 - g. Semisolid motility medium (procedure 3.17.31)
 - h. Kit identification system (API 20E, IDS panel, Vitek GNI Plus card [bioMérieux, Inc.]; MicroScan gram-negative identification panels [Dade Behring MicroScan Microbiology Systems]; BD CRYSTAL [BD Diagnostic Systems]; etc.)
 - i. Acetate for problematic *Shigella* identifications (procedure 3.17.2)
 - j. Antisera for grouping (see Appendix 3.8.1-1)
 - (1) *Salmonella* polyvalent and Vi (optional, A, B, C1, C2, and D)
 - (2) *Shigella* groups A, B, C, and D or
 - (3) *Salmonella* and *Shigella* colored latex agglutination reagents (Wellcolex; Remel Inc., Lenexa, Kans.)
2. For *Vibrio* and *Aeromonas*
 - a. O/129 disks—150 μ g (procedure 3.17.36)
 - b. Mueller-Hinton agar (MH) with and without 4% salt
 - c. Esculin slants or broth (optional for identification of *Aeromonas* to species level) (procedure 3.17.5)
 - d. O1 antiserum and toxigenicity kit (optional)
 - ☑ **NOTE:** *Vibrio* toxin testing is performed by latex test, DNA probe, EIA, or tissue culture. One source is Unipath Co., Oxoid, Ogdensburg, N.Y. (*V. cholerae* toxigenicity kit, VET-RPLA).
 3. For *E. coli* O157
 - a. 4-Methylumbelliferyl- β -D-glucuronide test (MUG) (procedure 3.17.34)
 - b. *E. coli* O157 (and H7) antiserum or latex antibody test (see Appendix 3.8.1-2)
 4. For *E. coli* O157 and non-O157 VTEC
 - a. MAC broth
 - b. EHEC EIA (see procedure 11.8)

C. Supplies

1. Incubator at 35°C
2. Petri dishes, slides, or disposable black cards for agglutination tests
3. Sticks and loops

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
 1. Visual inspection
 - a. Inspect for cracks in media or plastic petri dishes, unequal fill, hemolysis, evidence of freezing, bubbles, and contamination.
 - b. Check XLD; it should be reddish and relatively clear prior to inoculation. Excessive heating causes precipitation.
 - c. Record and report deficiencies to manufacturer.
 2. Most agar media that are purchased from commercial sources are not required to have additional user control with microorganisms expected to give appropriate reactions.
 - a. These media currently include BAP, CIN, MAC, HEK, XLD, SS, Selenite-F, and GN broth
 - b. For QC of these media, if prepared in-house, refer to section 14 of this handbook, except for CIN.

Table 3.8.1–3 QC of specialized media for detection of fecal pathogens

Test medium	Test organism	Inoculation method ^a	Incubation			Result
			Time (h)	Temp (°C)	Atmosphere	
BAP-A <i>Note:</i> Proposed in 2003 for exemption from user QC for commercially prepared media (20a)	<i>Aeromonas hydrophila</i> ATCC 7965	A	18–24	35	Aerobic	Growth
	<i>Escherichia coli</i> ATCC 25922	B	18–24	35	Aerobic	Partial to complete inhibition
Bismuth sulfite	<i>Salmonella enteritidis</i> ATCC 13076	A	18–24	35	Aerobic	Growth; black with metallic sheen
	<i>Escherichia coli</i> ATCC 25922	B	18–24	35	Aerobic	Partial inhibition; small brown to yellow-green colonies
Brilliant green	<i>Salmonella enteritidis</i> ATCC 13076	A	18–24	35	Aerobic	Growth; colorless to light pink
	<i>Escherichia coli</i> ATCC 25922	B	18–24	35	Aerobic	Partial inhibition; yellow-green colonies
	<i>Staphylococcus aureus</i> ATCC 25923	B	18–24	35	Aerobic	Inhibition
Campylobacter agars	<i>Campylobacter jejuni</i> ATCC 33291	A	24–48	42	Microaerobic	Growth
	<i>Escherichia coli</i> ATCC 25922	B	24–48	42	Microaerobic	Partial to complete inhibition
CCEY or CCFA	<i>Clostridium difficile</i> ATCC 9689	A	24–48	35	Anaerobic	Growth; large, gray (CCEY) or yellow (CCFA) colonies that fluoresce chartreuse under UV light (CCEY only)
	<i>Clostridium perfringens</i> ATCC 13124	B	24–48	35	Anaerobic	Partial to complete inhibition
	<i>Bacteroides fragilis</i> ATCC 25285	B	24–48	35	Anaerobic	Partial to complete inhibition
	<i>Escherichia coli</i> ATCC 25922	B	24–48	35	Aerobic	Partial to complete inhibition
	<i>Staphylococcus aureus</i> ATCC 25923	B	24–48	35	Aerobic	Partial to complete inhibition
CIN <i>Note:</i> Exempt from user QC for commercially prepared media (20)	<i>Yersinia enterocolitica</i> ATCC 9610	A	24–48	25	Aerobic	Growth; red center, transparent border
	<i>Aeromonas hydrophila</i> ATCC 7965	A	24–48	35	Aerobic	Growth; red center, transparent border
	<i>Enterococcus faecalis</i> ATCC 29212	B	24–48	35	Aerobic	Partial to complete inhibition
	<i>Pseudomonas aeruginosa</i> ATCC 27853	B	24–48	35	Aerobic	Partial to complete inhibition
	<i>Escherichia coli</i> ATCC 25922	B	24–48	35	Aerobic	Partial to complete inhibition
CT-SMAC	<i>Escherichia coli</i> O157:H7 ATCC 35150	A	24	35	Aerobic	Clear colonies seen; no fermentation of sorbitol
	<i>Escherichia coli</i> ATCC 25922	B	24	35	Aerobic	Partial to complete inhibition. Pink colonies seen;
	<i>Proteus mirabilis</i> ATCC 12453	B	24	35	Aerobic	fermentation of sorbitol Partial to complete inhibition
TCBS <i>Note:</i> Proposed in 2003 for exemption from user QC for commercially prepared media (20a)	<i>Vibrio parahaemolyticus</i> ATCC 17802	A	18–24	35	Aerobic	Growth; blue-green-centered colonies
	<i>Vibrio alginolyticus</i> ATCC 17749	A	18–24	35	Aerobic	Growth, yellow colonies
	<i>Escherichia coli</i> ATCC 25922	B	18–24	35	Aerobic	Partial inhibition; small, clear colonies

^a Abbreviations are as follows. A, for testing nutritive properties. Inoculate each medium with 10 µl of a 1:100 dilution of standardized cell suspension (0.5 McFarland). If isolated colonies are not obtained, use a 10-fold-lighter inoculum. B, for testing selective properties. Inoculate each medium with 10 µl of a 1:10 dilution of standardized cell suspension (0.5 McFarland). Although ATCC strains are listed, any organism that will yield the identical result is acceptable. For medium abbreviations, refer to Table 3.8.1–2.

IV. QUALITY CONTROL (continued)

Include QC information on reagent container and in QC records.

- c. For QC of CIN, see Table 3.8.1–3.
- d. Refer to NCCLS document M22-A2 (20) or section 14 for instructions on preparation of QC microorganisms for testing.
3. Each lot of media for specialized organisms must have QC testing with appropriate microorganisms, regardless of whether it is prepared in-house or purchased from a commercial source.
 - a. These media include BAP-A, brilliant green agar, bismuth sulfite, IBB, campylobacter agars, CT-SMAC, CCFA, and TCBS (see Table 3.8.1–2).
 - b. Refer to Table 3.8.1–3 for list of QC microorganisms and their reactions.
4. QC each lot of transport media with *Campylobacter jejuni* ATCC 33291, *Shigella flexneri* ATCC 12022, and *Y. enterocolitica* ATCC 9610 by following the method outlined in Table 14.2–2 for QC listed under “Transport.”
- B. Test antisera with known positively and negatively reacting organisms or commercial somatic O or H antigens prior to use of each new lot and every 6 months thereafter. See Appendix 3.8.1–1.
- C. For QC of specific reagents or biochemical media, refer to individual procedures.

V. PROCEDURE

Observe standard precautions.

- A. Perform wet prep for fecal leukocytes from fresh stools on request from outpatient specimens (see procedure 3.2.3).

NOTE: The presence of WBCs is one factor suggestive of invasive infection in cases of community-acquired gastroenteritis (see Table 3.8.1–4 for expected results). They are not helpful for diagnosis from hospitalized inpatients (21). Placement into transport medium destroys the laboratory’s ability to determine relative numbers of WBCs or the presence of blood in the stool.
- B. Culture methods
 1. Inoculation of media
 - a. Inoculate plates using a swab dipped into the transport tube.
 - b. Roll swab over one small area of the BAP and MAC media and streak in quadrants for isolated colonies.
 - c. Use larger amounts of the specimen for HEK, XLD, and SS agars and streak with a heavier-handed method to account for the inhibitory activity of the media.

Table 3.8.1–4 Microscopic and gross observations of fecal specimens associated with various infections^a

Organism or toxin	Other observations	Cells seen in smear	
		PMNs	RBCs
<i>Campylobacter</i>	Darting motile rods	Yes	Yes
<i>Clostridium difficile</i> toxin		Yes	Yes
<i>Escherichia coli</i> O157 H7, enterohemorrhagic	Watery	No	Yes
<i>Escherichia coli</i> , enteroinvasive	Mucous	Yes	Yes
<i>Escherichia coli</i> , enterotoxigenic	Watery	No	No
<i>Salmonella</i> spp.	Motile rods	Few	Yes
<i>Shigella</i> spp.	Lack of motile rods	Yes	No
<i>Vibrio cholerae</i>	Rice water	No	No
<i>Staphylococcus</i> toxin		No	No
Viruses		No	No

^a Data are only a guideline, and in any infection, observations are variable. For example, only 50% of *C. difficile*-associated cases of diarrhea demonstrate the presence of PMNs.

V. PROCEDURE (continued)

- d. Inoculate Selenite-F or GN broth with the swab that has been heavily saturated with stool from the transport vial.
 - e. For bloody stools and stools from pediatric patients, inoculate CT-SMAC plate to detect *E. coli* O157 and/or MAC broth to detect non-O157 VTEC.
 - f. Refer to Table 3.8.1–2 for selective media and enrichment broths for specific organism requests.
2. Incubate all agars, except CIN, in ambient air at 35 to 37°C for 24 h.
 - a. Incubate CIN and MAC broth for *Yersinia* requests in ambient air at 25°C for 48 h.
 - b. Incubate Selenite-F for 18 to 24 h in ambient air at 35 to 37°C. Then subculture to selective media, e.g., MAC and HEK or XLD.
 - c. Incubate GN broth for 6 to 8 h. Then subculture broth to MAC and HEK or XLD.
 - **NOTE:** If enrichment broths are incubated for excessive periods, the nonpathogenic enteric bacteria can overgrow the pathogens and negate the value of the enrichment procedure. If it is not possible to subculture broths at the appropriate time interval, subculture as soon as feasible, and closely monitor recovery rates. Alternatively, test enrichment broth directly for the presence of *Salmonella* and *Shigella* using commercial colored latex agglutination reagents.
 - d. Incubate MAC broth for 24 h at 35 to 37°C for VTEC assay (procedure 11.8).
 3. Save all stools in transport vial for 24 to 48 h at 4°C in case a toxin assay is later requested.

C. Examination of culture media

1. BAP and BAP-A

- a. Sweep through colonies to test for oxidase production. Pursue all oxidase-positive colonies, unless colony smells and looks like *P. aeruginosa*.
 - **NOTE:** Most *Vibrio*, *Plesiomonas*, and *Aeromonas* organisms, but not all, are indole positive and beta-hemolytic (11, 12, 13). Despite their salt requirement, most vibrios grow on BAP and MAC.
- (1) Subculture any oxidase-positive colonies to BAP and either TSI or KIA.
- (2) Identify further all those with TSI or KIA reactions of acid/acid or alkaline/acid (see Fig. 3.8.1–1).
- (3) Set up kit identification (use saline as diluent, if needed, for strains that require salt for growth).
- (4) Inoculate O/129 disks to both MH with and without 4% salt, as needed to verify identification.
 - **NOTE:** Kits can misidentify *Vibrio vulnificus* as *V. parahaemolyticus*, *Aeromonas* as *Vibrio fluvialis*, and *Vibrio damsela* as *V. cholerae* (1). Use O/129 disk tests and salt tolerance to prevent initial misidentifications and potential public health consequences (see Fig. 3.8.1–1 and Table 3.18.2–8). *Aeromonas* organisms need not be identified to the species level, since it is difficult and may not be clinically important. For complete identifications, see references 11, 12, and 13.
- (5) Unless reagents are available, submit *V. cholerae* to the health department for O1 serogrouping and toxin testing.
- (6) Submit other *Vibrio* spp. if identification is questionable. Not all *Vibrio* spp. grow on TCBS or are indole positive.

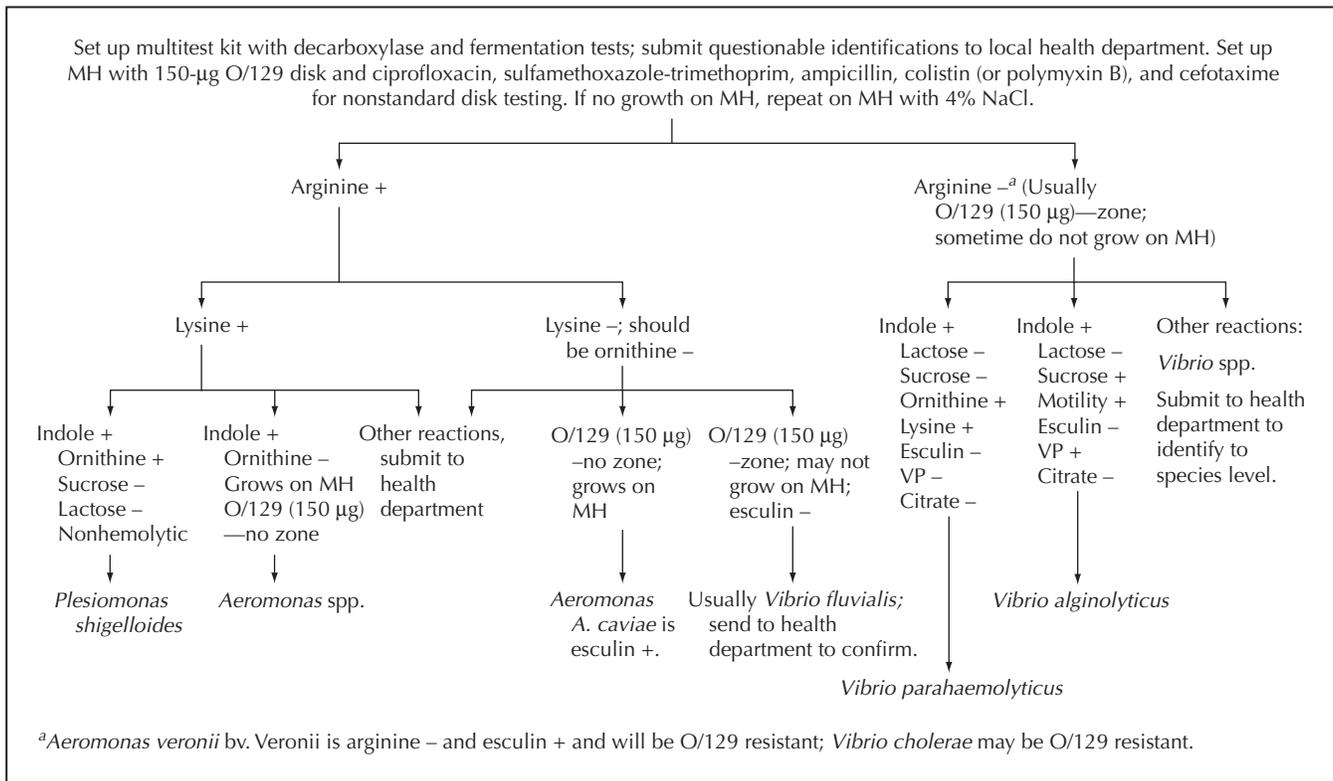

Figure 3.8.1-1 Flowchart for the identification of oxidase-positive stool pathogens from BAP or from either TCBS or CIN. Most are also indole positive. Biochemical reactions for species identification are available on many commercial kits. *Note:* Growth on TCBS implies that the organism is a *Vibrio* sp., but not all *Vibrio* spp. grow on TCBS. Abbreviations: MH, Mueller-Hinton agar; ID, identification; K, alkaline; A, acid; r/o, rule out.

V. PROCEDURE (continued)

- (7) Perform antimicrobial susceptibility testing (AST) on isolates, since results are variable. Use disk method with MH with salt if isolate will not grow in routine method.
- b.** Identify numerous *P. aeruginosa* and *S. aureus* organisms; do not perform AST.
- c.** Identify and report any amount of *B. cereus* organisms, if present.
 - (1) Screen beta-hemolytic colonies for large spore-forming, gram-positive rods.
 - (2) *B. cereus* is also catalase positive, motile, lecithinase positive, and penicillin resistant.
- d.** Look for overgrowth of numerous or pure yeast, or other unusual findings (e.g., DF-3), and report without AST.

■ **NOTE:** DF-3 has been associated with diarrheal disease (2). It is a nonhemolytic, catalase-negative, oxidase-negative, indole-negative, nonmotile, gram-negative coccobacillus that does not grow on MAC. It ferments glucose without gas and is nitrate reductase negative.
- e.** Note the absence of enteric gram-negative rods.
- f.** Do not report enterococci in stool.

V. PROCEDURE (continued)

2. HEK, XLD, SS, and MAC
 - a. Work up potential pathogens directly from HEK, XLD, SS, and MAC plates at 24 h and from broth subculture plates at 36 to 48 h (18 to 24 h of incubation). Screen plates for lactose-negative and/or H_2S -positive colonies. Refer to Table 3.8.1-1 for colony morphologies of stool pathogens.
☑ **NOTE:** On days when stool cultures are not examined, place plates in refrigerator until they can be examined. After 24 h, alkaline reversion of colonies may make them appear lactose negative. Do not pick colonies after 24 h.
 - b. MAC or SS: pick one representative colony of each morphologic type of colorless colonies.
 - c. XLD: pick one representative colony of each morphologic type of red to red-orange colony and any colony with a black center.
☑ **NOTE:** Species of *Edwardsiella* and *Salmonella* decarboxylate lysine and ferment xylose but not sucrose or lactose. The xylose/lysine ratio in XLD permits these organisms to exhaust the xylose and then attack the lysine, causing a reversion to an alkaline pH, and thus produce red colonies (25).
 - d. HEK: pick one representative colony of each morphologic type of green and blue colonies that are not pinpoint and any colony with a black center.
☑ **NOTE:** *Salmonella* and *Shigella* spp., when surrounded by many bright fermenting *Enterobacteriaceae*, may appear to be faint pink with a green tinge, but there is usually a clear halo around the colonies in the area of precipitated bile. This halo is most apparent when the plates are held up to a light. The colonies are more translucent than those of other *Enterobacteriaceae* (17).
 - e. Subculture each colony picked to BAP, KIA or TSI, urea agar (optional; may use rapid urea disks instead), and Andrade's glucose (optional).
☑ **NOTE:** For laboratories with few stool culture requests or when the colony morphology indicates typical *Salmonella* or *Shigella*, use of kit identifications initially, rather than screening, may be more economical.
 - f. Next day, read biochemical tests. Follow the flowchart in Fig. 3.8.1-2.
 - g. Test for agglutination for *Salmonella* and *Shigella* somatic (O) antigens when the screening biochemical tests fit. See Appendix 3.8.1-1 for procedure. Alternatively, use Wellcolex latex kit or send isolate to reference laboratory for typing.
☑ **NOTE:** *Shigella* spp. are genetically *E. coli*. If there is a question between *E. coli* and *Shigella*, 80% of *E. coli* organisms are acetate positive; shigellae are 100% negative (7). *Shigella* spp. are also negative for motility, citrate, and lysine.
 - h. If the kit gives a genus and species name, be sure that it corresponds to the serologic grouping.
 - i. For *Shigella* spp., identification to the species level is performed using the grouping sera, in combination with the kit biochemical tests.
 - (1) Group A—*Shigella dysenteriae*
 - (2) Group B—*S. flexneri* (often indole positive)
 - (3) Group C—*Shigella boydii*
 - (4) Group D—*Shigella sonnei* (indole negative and *o*-nitrophenyl- β -D-galactopyranoside positive)
 - j. If the kit identifies the isolate as *Salmonella* or *Shigella*, but it fails to serogroup, repeat typing, using a boiled suspension of the organism in saline.

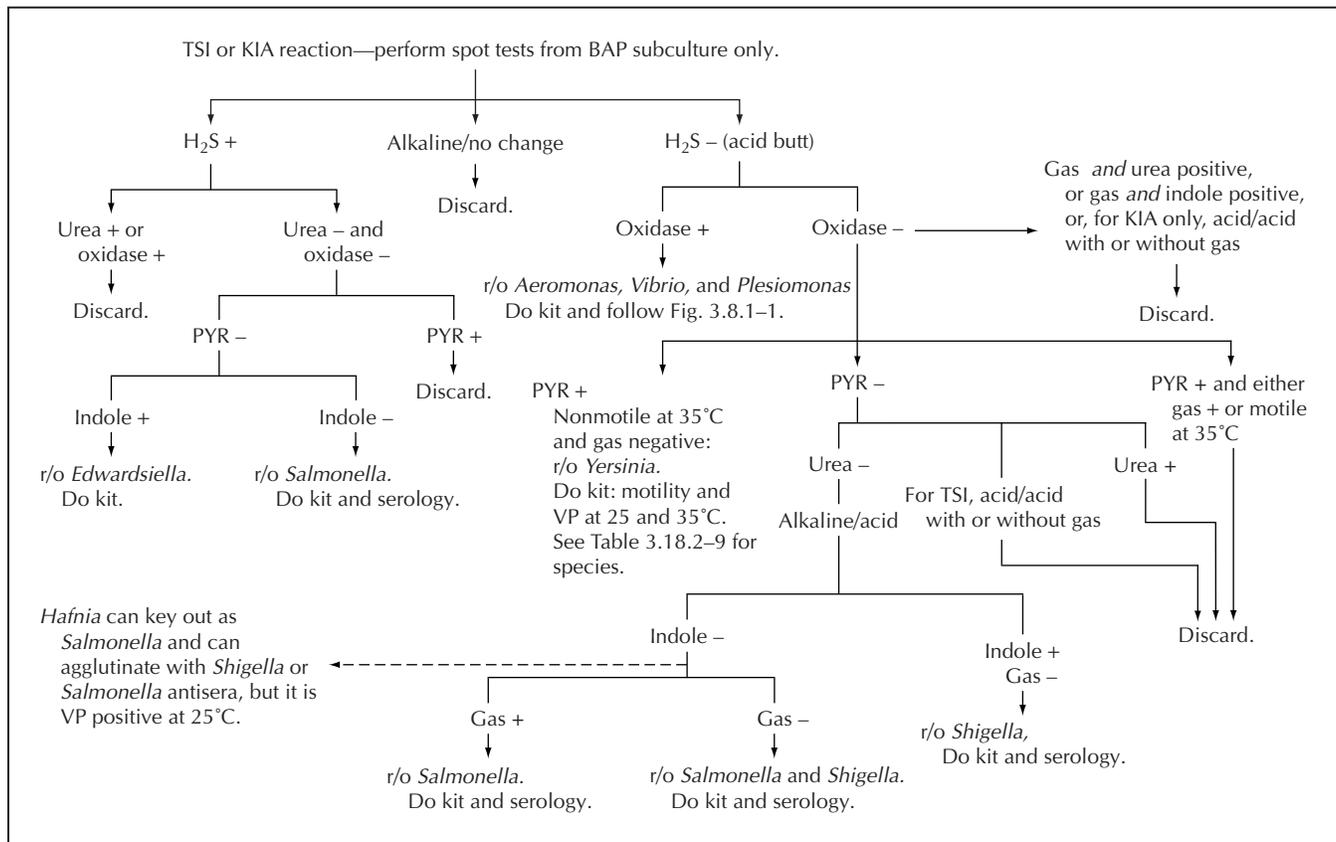

Figure 3.8.1-2 Flowchart for identification of stool pathogens from routine stool cultures. Set up either TSI or KIA, BAP, and urea agar (or rapid urea tube) from all lactose-negative or H₂S-positive colonies on enteric selective agars. Reactions of the slant are listed with a slash before the butt reaction. Optionally for H₂S-negative colonies, Andrade's glucose tube with Durham tube for gas will eliminate most questionable production of gas and provide a broth for VP testing. Perform spot tests (indole, oxidase, PYR) only from BAP. r/o, rule out.

V. PROCEDURE (continued)

k. Check the following.

- (1) Mannitol-negative *S. flexneri* may be identified as *S. dysenteriae* but type as group B.
- (2) If kit codes as *Salmonella* serovar Pullorum or *Salmonella* serovar Gallinarium, perform additional biochemical tests, including VP at 25°C, as these are often *Hafnia* spp. Serovar Pullorum agglutinates with *Salmonella* group D antiserum.

l. Check biochemical reactions and serogroup to determine species identification of *Salmonella* serovar Typhi, *Salmonella* serovar Cholerae suis, or *Salmonella* serovar Paratyphi A. Confirm with appropriate tests as indicated in Table 3.8.1-5.

- (1) Only serovar Typhi will type in both group D and in Vi antisera, is ornithine decarboxylase negative, and produces no gas and little H₂S from carbohydrates in KIA or TSI.

▣ **NOTE:** Serovar Paratyphi C will also agglutinate in Vi antiserum.

- (2) Serovar Paratyphi A will type in group A antiserum and is citrate and lysine decarboxylase negative.
- (3) Serovar Cholerae suis will type in group C antiserum and is arabinose and trehalose negative.

Table 3.8.1–5 Biochemical differentiation of selected members of the *Salmonella* group^a

Test	Serogroup Choleraesuis	Serogroup Paratyphi A	Serogroup Typhi	Other
<i>Salmonella</i> group	C	A	D	A–E
Arabinose fermentation	–	+	–	+
Citrate utilization	V	–	–	+
Glucose gas production	+	+	–	+
Lysine decarboxylase	+	–	+	+
Ornithine decarboxylase	+	+	–	+
Rhamnose fermentation	+	+	–	+
Trehalose fermentation	–	+	+	+

^a Symbols: –, ≤9% of strains positive; V, 10 to 89% of strains positive; +, ≥90% of strains positive.

V. PROCEDURE (continued)

- m. Submit all *Salmonella* (and *Shigella*, if typing is not available or if submission is required by local policy) isolates to the health department for confirmatory identification and for typing.
- n. Perform AST on enteric pathogens, except for most *Salmonella* cultures, since treatment may prolong the carrier state or lead to a higher rate of clinical relapse. Perform AST on *Salmonella* if one of the conditions below is met.
 - (1) *Salmonella* serovar Typhi
 - (2) Isolate is also present in urine or a normally sterile body site.
 - (3) Child is under the age of 6 years.
 - (4) Physician request
3. Screen CIN at 24 and 48 h.
 - a. Look for any colonies with a deep red center with a sharp border surrounded by a translucent zone.
 - b. Inoculate BAP and identification kit.
 - c. Check oxidase reaction. If positive, follow Fig. 3.8.1–1 to identify *Aeromonas*.
 - d. If oxidase negative, inoculate Andrade's glucose (or methyl red-VP [MR-VP] broth) and motility semisolid medium at both 25 and 35°C.
 - e. Read VP and motility at 24 h to confirm kit identification.
 - (1) *Y. enterocolitica* and *Yersinia pseudotuberculosis* are nonmotile and VP negative at 35°C and motile at 25°C (6).
 - (2) *Y. enterocolitica* is VP positive at 25°C, but *Y. pseudotuberculosis* is VP negative.
 - (3) Both are usually urease positive.
 - (4) See Table 3.18.2–9 for biochemical reactions of significant members of this genus.
 - (5) Confirm atypical reactions by submitting species to reference laboratory or health department.
 - f. Perform AST on *Aeromonas* and *Yersinia* spp.
4. Screen TCBS at 24 and 48 h.
 - a. Look for yellow colonies (potential *V. cholerae*, *V. fluvialis*, and *Vibrio furnissii*) and blue colonies (potential *V. parahaemolyticus*, *Vibrio mimicus*, and *Vibrio hollisae*). Pinpoint colonies should also be examined.
 - b. Subculture one representative colony of each morphologic type of any colony to BAP and KIA or TSI.
 - c. Follow Fig. 3.8.1–1 for identification of oxidase-positive colonies that ferment glucose.

V. PROCEDURE (continued)

- d. Expediently send cultures with suspected *V. cholerae* to the local public health laboratory for typing and toxin testing, unless reagents are available.
- e. Refer to item V.C.1 for other details of testing.
 - ☑ **NOTE:** For outbreaks, TCBS, in conjunction with enrichment in alkaline peptone water (APW), incubated for 24 h, followed by subculture onto TCBS significantly increased the yield of *V. cholerae*. Subculture of APW at 5 h is not necessary or practical (18).
- 5. Screen CT-SMAC plate for *E. coli* O157 at 24 h of incubation.
 - a. Pick at least four sorbitol-negative (transparent or colorless) colonies.
 - b. Subculture to BAP.
 - c. If isolate is oxidase negative and indole positive, perform MUG test.
 - d. If isolate is MUG negative, screen using the *E. coli* O157 latex agglutination kit (see Appendix 3.8.1–2).
 - e. If agglutination positive, confirm as *E. coli* by kit identification.
 - ☑ **NOTE:** *E. coli* O157 may be sorbitol positive by the kit tests. Isolation of *E. coli* O157 from a diarrhea stool, particularly with the presence of blood or symptoms typical of HC or HUS, is indicative of a verocytotoxin-producing strain.
 - f. Confirm with H7 flagellum antiserum and/or toxin testing, if symptoms are not typical of HUS or HC. For toxin testing, submit to the health department or reference laboratory or see procedure 11.8.
- 6. Test 50 µl of MAC broth or plate sweep of culture with one of the EHEC serologic assays 24 h after inoculation with stool. See procedure 11.8.
- 7. Depending on state requirements, submit *V. cholerae*, *Salmonella* spp., *Shigella* spp., *E. coli* O157, or other stool pathogens to the health department. Send repeat isolates of *Salmonella* spp. per local health department policy.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. Record biochemical results on colonies being screened on appropriate worksheets, noting media sampled and enumeration.
- B. Negative cultures
 - 1. For routine stool culture, report “No *Salmonella*, *Shigella*, or *Campylobacter* spp. isolated.” See procedure 3.8.2 for *Campylobacter* culture.
 - 2. In addition, report negative culture results for specific organism cultures, such as *E. coli* O157, *Yersinia*, and *Vibrio*, by listing the organisms sought specifically: e.g., “No *Yersinia* spp. detected.”
 - 3. Add “to date” for preliminary reports and delete for final reports.
- C. Additional comments
 - 1. If gram-negative enteric microbiota are not present in the culture, add a comment: “No normal enteric gram-negative rods isolated.”
 - 2. Report overgrowth of predominant *S. aureus* and *P. aeruginosa* as “Predominating or pure culture of [organism name].”
 - ☑ **NOTE:** The presence of *S. aureus* may or may not indicate gastrointestinal disease or food poisoning. Toxin must be detected in stool or food for disease, which is rarely done.
 - 3. Report yeast, if found in pure or predominating culture, without genus or species identification.
 - 4. In the setting of diarrhea and no other likely cause, report a pure culture of unusual microbiota, such as DF-3 or *Klebsiella* spp.

VI. REPORTING RESULTS

(continued)

D. Positive cultures

1. Report presumptive presence of any enteric pathogens listed in Table 3.8.1–6 with or without quantitation, depending on laboratory's policy to track positive cultures from enrichment broth only.
2. Report the pathogen with the preliminary designation as “probable” until the identification is confirmed by both biochemical testing and serology.

Table 3.8.1–6 Summary of detection media and identification methods for fecal pathogens^a

Pathogen(s)	Media	Initial observation	Initial testing	Confirmatory	Comments
<i>Salmonella</i> and <i>Shigella</i>	MAC, HEK, XLD	See Table 3.8.1–1	Follow Fig. 3.8.1–2	Serology	
<i>Yersinia enterocolitica</i>	MAC, CIN	Red on CIN, colorless on MAC	Kit	Motility and VP at 25 and 35°C	
<i>Aeromonas</i> spp.	BAP, BAP-A, MAC, CIN	Oxidase positive, usually indole positive, red on CIN	Kit; follow Fig. 3.8.1–1	O/129 disk Esculin (optional)	Lactose positive or negative
<i>Plesiomonas shigelloides</i>	BAP, MAC	Oxidase positive, indole positive	Kit; Follow Fig. 3.8.1–1		Lactose negative
<i>Vibrio</i>	BAP, MAC, TCBS	Oxidase positive, may be colorless on MAC, yellow or blue on TCBS	Follow Fig. 3.8.1–1; kit; may need to add salt to inoculum.	O/129 disk, salt tolerance	<i>V. mimicus</i> is VP negative, colistin susceptible; <i>V. cholerae</i> is VP positive, colistin resistant.
<i>Edwardsiella tarda</i>	MAC, HEK, XLD	Colorless on MAC, black center on HEK or XLD	Kit; indole positive	None	
<i>Bacillus cereus</i>	BAP	Hemolytic	Large gram-positive rods	Catalase positive, motile, lecithinase positive, and penicillin resistant	Toxin testing may be done by health department.
EHEC	CT-SMAC	Colorless	Kit; MUG negative	Serotyping	Toxin assay more sensitive to detect other strains.
Other <i>E. coli</i> strains Enteropathogenic Enteroinvasive Adherent Enterotoxigenic	NA	NA	NA	NA	Send stool to reference laboratory or health department for toxin, invasion, or adherence testing.
<i>Clostridium difficile</i>	CCEY or CCFA	Large, gray (CCEY) or opalescent yellow (CCFA) colonies that fluoresce chartreuse on anaerobic BAP or CCEY	Gram stain showing large gram-positive rods, “horse barn” odor	None	Perform toxin testing. (See procedure 3.8.3.)
<i>Clostridium botulinum</i>	NA	NA	NA	NA	Send stool and serum to public health department.

^a For *Campylobacter* species, see procedure 3.8.2. NA, not applicable.

VI. REPORTING RESULTS (continued)

3. Enter preliminary note indicating that “Isolate has been sent for confirmatory identification to [name and location]” when isolate has been sent for serologic testing.
4. *Salmonella* reporting
 - NOTE:** *Salmonella* nomenclature is a topic of worldwide debate at the present time (4). There is only one species of *Salmonella* that infects humans; some call this species *Salmonella enterica* and others refer to it as *Salmonella choleraesuis*. In addition, the species is divided into six subspecies and over 2,000 serotypes. Serotypes are grouped into several serogroups noted alphabetically as A, B, C₁, C₂, etc. Serotype names are called either serovars or serotypes and are not in italics. Some texts capitalize the serotype name and others do not. Because the long names are cumbersome and laboratory computer systems do not italicize, *Salmonella enterica* subsp. *enterica* serotype Typhimurium is usually called *Salmonella typhimurium* or *Salmonella* serovar Typhimurium on laboratory reports.
 - a. Report the following to the serotype level: *Salmonella* serovar Paratyphi A, *Salmonella* serovar Choleraesuis, or *Salmonella* serovar Typhi, using Table 3.8.1–5.
 - b. Report isolates that are serologically A, C, or D, but are *not* biochemically serovar Paratyphi A, serovar Choleraesuis, or serovar Typhi, as follows.
 - (1) *Salmonella* serogroup A—not Paratyphi A
 - (2) *Salmonella* serogroup C—not Choleraesuis
 - (3) *Salmonella* serogroup D—not Typhi
 - c. Report other *Salmonella* isolates by group, if tested, or by genus only until the species name is available from the reference laboratory.
 - d. By accepted convention, report final identifications of *Salmonella*, followed by the serovar name only (4).
 - 5. When confirmation is obtained, report *V. cholerae*, including the serogroup (O1 or non-O1), serotype of O1 strains (Inaba, Ogawa, and Hikojima), biotype (e.g., classical or El Tor), and presence of toxin.
 - 6. Report sorbitol-negative colonies which show positive agglutination with O157 latex test reagent and a positive identification of *E. coli* as “*E. coli* serotype O157.” If tested for toxin, report as, e.g., “*E. coli* O157, toxin producer.”
 - 7. Other pathogens listed in Table 3.8.1–6 are generally reported without confirmation by a reference laboratory, unless there is a question.
- E. Notification
 1. For hospitalized patients, notify infection control and the nursing care unit immediately by telephone with presumptive identification (agglutination positive without biochemical confirmation) of suspicious enteric pathogens so that proper patient isolation protocols can be instituted.
 - NOTE:** Patients shedding pathogens in their stool are placed on both standard precautions and contact isolation.
 2. For patients who have been discharged from the hospital or whose specimens were received as outpatient specimens, communicate the final result of the presence of any of the enteric pathogens to the person responsible for the patient’s care.
 3. Because of its life-threatening consequences, contact the physician expeditiously if *V. cholerae*, *E. coli* O157, *Salmonella* serovar Typhi, or *Salmonella* serovar Paratyphi C is isolated.
 4. For hospitalized patients, notify the physician if there will be a delay in reporting a highly suspicious culture (e.g., problems with agglutination, etc.).
 5. Report all reportable enteric pathogens to the appropriate public health agency as required by the local regulatory and government jurisdictions.

VI. REPORTING RESULTS*(continued)*

Usually these include *Salmonella*, *Shigella*, *Yersinia*, *Vibrio*, *E. coli* O157, and *Campylobacter*.

- a. Check with local regulations to determine which agents are reportable in your state.
- b. Because of their epidemiologic consequences, *immediately* notify the local health department of suspected *V. cholerae*, *Salmonella* serovar Typhi, *Salmonella* serovar Paratyphi A, or *Salmonella* serovar Choleraesuis.

F. AST

1. Report AST on *Shigella*, *Aeromonas*, *Plesiomonas*, *Edwardsiella*, *Vibrio*, *Yersinia*, and selected cases of *Salmonella*.
2. Generally report only ampicillin, sulfamethoxazole-trimethoprim, and a quinolone. For special cases, or for multiply resistant strains, also report a third-generation cephalosporin. Add a comment to reports of *Salmonella* and *Shigella* that first- and second-generation cephalosporins and aminoglycosides are not appropriate for treatment of these pathogens.
3. Suppress quinolone results for children under the age of 12 years, since these drugs inhibit bone growth.
4. For *V. cholerae*, also report doxycycline or tetracycline.
5. Susceptibility testing is contraindicated for *E. coli* O157 and other EHEC organisms, since treatment of disease with antimicrobial agents can induce bacterial cell lysis and release of toxin. Add a comment to the report, "Antimicrobial therapy may not be indicated for treatment of this pathogen."

VII. INTERPRETATION

- A. The isolation of a stool pathogen may not identify the cause of the disease. For example, *Salmonella* is present in the carrier state, without disease, and *Plesiomonas* is a questionable pathogen.
- B. Isolation of an organism whose toxin is responsible for disease may not indicate that the organism possesses the genetic ability to produce the toxin or that the toxin was produced in the patient.

VIII. LIMITATIONS

- A. Because the media used for culture are highly selective, some pathogens that should grow may be inhibited. The more media inoculated, the more likely a pathogen will be isolated.
- B. Use of enrichment broth or the use of both XLD and HEK will detect more pathogens, but the cost-benefit may not make the expense and time practical.
- C. Without a specific request for *Vibrio* or *Yersinia*, selective medium will not be inoculated and these pathogens may or may not be detected in culture.
- D. Pathogens present in small numbers may not be detected. Testing of two separate specimens increases the yield.
- E. Many pathogenic *E. coli* organisms are difficult to detect, since there is no medium for their selection.
- F. CT-SMAC will not detect VTEC strains other than *E. coli* O157.
- G. The agent that is causing the patient's diarrheal disease may not have yet been recognized as a stool pathogen and will thus go undetected.
- H. The physician must consider other agents, such as viruses and parasites, that can be responsible for disease.

APPENDIX 3.8.1–1

Observe standard precautions.

Detection of Somatic O Antigen Serogroups of Bacteria

- I. PRINCIPLE

Gram-negative rods possess somatic antigens in their cell walls, called O antigens, that are useful in the identification of specific serovars or serotypes. These antigens are polysaccharide side chains of endotoxin in the outer membrane of the cell wall. Antibody to these antigens will agglutinate a suspension of the organism.
- II. SPECIMEN

Prepare milky suspension of pure culture from fresh plate in normal sterile saline. If culture is not pure, erroneous results can occur.
- III. MATERIALS
 - A. Antisera
 1. *Salmonella* polyvalent, A, B, C1, C2, D, E, etc., and Vi; *Shigella* groups A, B, C, and D; *E. coli* O157; *V. cholerae* O1, or any other serotype
 2. Store antisera at 4°C.
 - B. Petri dishes and either glass slides or disposable cards with black background (preferred)
- IV. QUALITY CONTROL

Test each lot of reagent with a known positively and negatively reacting organism prior to putting into use it and every 6 months thereafter. Organisms can be stored in formalin at 4°C for QC use.
- V. PROCEDURE

Mix drop of antiserum with drop of suspension of organism. Rotate slide for 1 min and observe for agglutination.
- VI. INTERPRETATION

Positive agglutination is an indication that the strain contains O antigen.
- VII. REPORTING RESULTS

Report presumptive identification as “[organism name]” followed by serotype alpha and numeric designation.
- VIII. LIMITATIONS
 - A. Some organisms with either capsules or flagella can give a false-negative result. Boil the suspension for 5 min or test *Salmonella* using Vi antigen for the capsule of this genus.
 - B. Serological identification should be confirmed with biochemical testing, since serotypes can be shared or cross-react with other species.

Supplemental Reading

Ewing, W. H. 1986. *Edwards and Ewing's Identification of Enterobacteriaceae*, 4th ed. Elsevier Science Publishing Co., New York, N.Y.

APPENDIX 3.8.1–2

Detection of *Escherichia coli* O157 by Latex Agglutination

I. PRINCIPLE

The *Escherichia coli* serotype most frequently isolated in cases of HC and HUS is O157:H7. Detection of this serotype from a strain of *E. coli* is presumptive for the agent of HUS and HC. Cytotoxin testing confirms the identification as a strain that produces verocytotoxin. Colonies are mixed with latex particles coated with antibody against the cell wall O antigen of *E. coli* O157. *E. coli* O157 will bind with the antibody, causing the latex particles to visibly agglutinate. Bacteria which are not O157 will not bind to the antiserum and will not result in agglutination (1, 2, 3).

II. SPECIMEN

Indole-positive, oxidase-negative, MUG-negative, non-sorbitol-fermenting colonies from CT-SMAC medium. Test multiple colonies if a negative result is obtained.

III. MATERIALS

A. *E. coli* O157 kit stored at 2 to 8°C. Some suppliers are listed below.

1. Oxoid Incorporated, Ogdenburg, N.Y.
2. Pro-Lab Diagnostics, Austin, Tex.
3. Remel Microbiology Products, Lenexa, Kans.
4. Meridian Diagnostics, Cincinnati, Ohio

B. Kits usually contain the following.

1. One dropper vial of *E. coli* O157 latex reagent containing latex particles coated with purified rabbit immunoglobulin G (IgG) which reacts with *E. coli* somatic antigen O157
2. One dropper vial of negative control latex containing latex particles coated with purified rabbit IgG which does not react with *E. coli* serotype O157
3. One dropper vial of positive control suspension containing *E. coli* serotype O157:H7 antigen
4. A negative control *E. coli* suspension (a culture of *E. coli* ATCC 25922 can be used in place of the negative control)
5. Test cards
6. Mixing sticks

IV. QUALITY CONTROL

Check each lot of reagents prior to use and every 6 months thereafter with the suspension of *E. coli* O157:H7 (positive control) and a suspension of *E. coli* (ATCC 25922) (negative control).

V. PROCEDURE

Follow manufacturer's instructions and observe for agglutination. An example is below.

- A. Bring reagents to room temperature before testing.
- B. Resuspend colony in 0.5 ml of normal sterile saline in a culture tube to McFarland 3 to 5.
- C. Place 1 drop of *E. coli* O157 latex reagent onto a test circle.
- D. Using a sterile Pasteur pipette, add 1 drop of the colony suspension to the test circle. Alternatively, add a drop of saline to the card and emulsify the colony directly in the saline until a smooth suspension is obtained.
- E. Mix reagent with the bacterial suspension in the test circle.
- F. Rock card gently and examine for agglutination over a 1- to 2-min period.
- G. Specimens showing positive agglutination within 2 min must be examined further.
- H. Test positive specimens again by repeating the procedure using negative control latex reagent.

VI. INTERPRETATION

- A. Positive agglutination indicates the presence of *E. coli* serogroup O157 in the recommended time. Grade the agglutination as follows.
 1. 4+ : large clumps against a very clear background
 2. 3+ : large and small clumps against a clear background
 3. 2+ : small but definite clumps against a slightly clouded background
 4. 1+ : fine granulation against a milky background
 5. Negative: a homogeneous suspension of particles with no visible clumping.
- B. A lack of agglutination indicates the absence of *E. coli* serogroup O157.
- C. Results cannot be interpreted if there is agglutination of both the test and control latex.

APPENDIX 3.8.1–2 (continued)

VII. REPORTING RESULTS

- A. Report positive agglutination with O157 latex test reagent, no agglutination with negative control reagent, and identification as *E. coli* as “*E. coli* serotype O157.”
- B. Testing for the H antigen or VTEC may be needed. See procedure 3.8.1 for further testing.

VIII. LIMITATIONS

- A. Some strains of *E. coli* are difficult to emulsify in saline and may give a stringy-type reaction with both the test and the control reagents. If this stringiness is found, suspend the colony in 0.5 ml of saline. Allow the lumps to settle, and retest the smooth supernatant.
- B. Neither growth of colorless colonies on CT-SMAC nor a positive reaction in the *E. coli* O157 latex test will directly confirm the isolate as a toxin-producing strain.
- C. The latex test does not confirm the isolate as having the H7 flagellar type or that the strain is a toxin producer. Further studies are needed to determine these characteristics.
- D. Other serotypes which produce verocytotoxin are not detected in this assay.
- E. Some strains of *Escherichia hermannii* may cross-react with *E. coli* O157 antiserum and the latex test due to a shared antigen. *E. hermannii* may be differentiated from *E. coli* by the former’s ability to ferment cellobiose and yellow pigmentation, which may be delayed.

3.8.2

Fecal Culture for *Campylobacter* and Related Organisms

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Using recently developed genetic techniques, the genus *Campylobacter* was divided into three genera based on 16S rRNA homology tests (22). The groups *Campylobacter*, *Helicobacter*, and *Arcobacter* are microaerobic to anaerobic organisms. These curved, helical, gram-negative rods are among the most challenging bacteria for the clinical microbiologist to cultivate and identify. In addition, the disease spectrum with these genera ranges from “well established” (as in the association of *Campylobacter jejuni* and diarrhea) to “speculative” (associated with clinical strains such as *Arcobacter* species that have unproven etiology) to “emerging” (such as *C. upsaliensis* and *Helicobacter rappini* [*Flexispira rappini*]).

Table 3.8.2–1 lists the taxonomic positions, known sources, and common disease associations for campylobacters, helicobacters, arcobacters, and other, unrelated genera that are sometimes confused with campylobacters (16). In Table 3.8.2–2, clinical diseases and their possi-

ble causative agents are listed. Because of diverse growth requirements, such as temperature, atmosphere of incubation, etc., most clinical laboratory methods are designed to recover only the most common pathogenic strains of these genera. While this procedure focuses on fecal cultures, these basic methods can be used to identify campylobacters from most cultures. For *Helicobacter pylori*, refer to procedure 3.8.4.

It is estimated that *Campylobacter* causes approximately 2.4 million cases of disease each year in the United States. *C. jejuni* is the most commonly identified bacterial pathogen isolated from fecal cultures, with greater than 90% of campylobacter infections caused by *C. jejuni* (6). *C. jejuni* gastroenteritis is a self-limiting disease, but severe infections occur in the young and immunocompromised. The procedure that follows is designed to detect and identify *C. jejuni*. Although other species have been associated with gastroenteritis, they are more difficult to isolate

and identify to the species level. Consequently, culture of these other species cannot be justified in most clinical laboratories.

Because *Campylobacter* spp. and *Escherichia coli* O157:H7 are the major contributors to blood in the stool, it is important to detect the presence of the infecting organism, since the use of antimicrobial treatment for *E. coli* O157 infection is thought to increase the risk of hemolytic-uremic syndrome. The drug of choice for treatment of campylobacters was ciprofloxacin, because it is effective for both *Campylobacter* and other enteric pathogens. The use of quinolones in the poultry industry has increased resistance of campylobacters to quinolones, with rates of 10% (1) to as high as 40% (14). Erythromycin is returning as the drug of choice for treatment, although occasional resistance is also seen with this agent. Newer macrolides are also effective but are more expensive.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. See procedure 3.8.1 for fecal and rectal swab collection.
2. *Campylobacter* can be isolated from routine anaerobic cultures of blood or wound specimens. If isolate does not grow on subculture, incubate in a microaerobic atmosphere at 35°C for possible campylobacter or helicobacter isolation.

Table 3.8.2–1 Taxonomic position, known sources, and common disease associations of *Campylobacter*, *Arcobacter*, *Helicobacter*, and related species^a

Taxon ^b	Known source(s)	Disease association(s)	
		Human	Veterinary
rRNA homology group I			
<i>Campylobacter fetus</i> subsp. <i>fetus</i> (‘ <i>Campylobacter fetus</i> subsp. <i>intestinalis</i> ’)	Cattle, sheep	Septicemia, gastroenteritis, abortion, meningitis	Bovine and ovine spontaneous abortion
<i>Campylobacter fetus</i> subsp. <i>venerialis</i> (‘ <i>Campylobacter fetus</i> subsp. <i>fetus</i> ’)	Cattle	Septicemia	Bovine infectious infertility
<i>Campylobacter hyointestinalis</i> subsp. <i>hyointestinalis</i> ^c	Pigs, cattle, hamsters, deer	Gastroenteritis	Porcine and bovine enteritis
<i>Campylobacter hyointestinalis</i> subsp. <i>lawsonii</i> ^b	Pigs	None at present	Unknown
<i>Campylobacter concisus</i>	Humans	Periodontal disease, gastroenteritis	None at present
<i>Campylobacter mucosalis</i> (‘ <i>Campylobacter sputorum</i> subsp. <i>mucosalis</i> ’)	Pigs	None at present	Porcine necrotic enteritis and ileitis
<i>Campylobacter sputorum</i> bv. <i>Sputorum</i> (incorporating bv. <i>Bubulus</i> ^d)	Humans, cattle, pigs	Abscesses, gastroenteritis	None at present
<i>Campylobacter sputorum</i> bv. <i>Faecalis</i> (‘ <i>Campylobacter faecalis</i> ’)	Sheep, bulls	None at present	None at present
<i>Campylobacter curvus</i> (‘ <i>Wolinella curva</i> ’)	Humans	Periodontal disease, gastroenteritis	None at present
<i>Campylobacter rectus</i> (‘ <i>Wolinella recta</i> ’)	Humans	Periodontal disease	None at present

<i>Helicobacter canis</i>	Dogs	Gastroenteritis	Canine gastroenteritis
<i>Helicobacter muridarum</i> ^c (“ <i>Helicobacter muridae</i> ”)	Rodents	None at present	Murine gastritis
<i>Helicobacter hepaticus</i> ^c	Mice	None at present	Murine necrotizing hepatitis
<i>Helicobacter pametensis</i> ^c	Birds, pigs	None at present	None at present
<i>Helicobacter</i> sp. strain Bird-B ^c	Birds	None at present	None at present
<i>Helicobacter</i> sp. strain Bird-C ^c	Birds	None at present	None at present
<i>Helicobacter mustelae</i> ^e (“ <i>Campylobacter pylori</i> subsp. <i>mustelae</i> ”)	Ferrets, mink	None at present	Gastritis in ferrets

Table 3.8.2–1 (continued)

Taxon ^b	Known source(s)	Disease association(s)	
		Human	Veterinary
Other campylobacter-like organisms phylogenetically distinct from rRNA superfamily VI			
<i>Anaerobiospirillum succiniciproducens</i>	Dogs	Gastroenteritis, septicemia	None at present
<i>Anaerobiospirillum</i> sp. strain Malnick et al. 1983	Dogs, cats	Gastroenteritis	None at present
<i>Lawsonia intracellularis</i> (“ileal symbiont intracellularis,” “ <i>Campylobacter intracellulare</i> ”)	Pigs, hamsters, ferrets	None at present	Proliferative enteritis in pigs and hamsters

^a Table adapted from reference 16.

^b All organisms listed belong to rRNA superfamily VI. Organisms in boldface type are associated with human sources. Validly published or most commonly used nomenclature of the taxa described are given priority, with superseded (in quotation marks) or less common nomenclature given in parentheses. Names that have not been validly published are given in single quotation marks. Abbreviations: CNW, catalase negative—weak; NNC, nitrate-negative *Campylobacter*; NARTC, NA-resistant thermophilic *Campylobacter*; CLO, *Campylobacter*-like organism; IDO, intracellular *Desulfovibrio* organism.

^c Likely phylogenetic position of taxon in rRNA superfamily VI based on 16S rRNA sequence comparisons or DNA-DNA hybridization data.

^d Biovar descriptions conform with recent suggestions by On (16).

^e Original phylogenetic position in rRNA superfamily VI emended with reference to available 16S rRNA sequence comparisons. Brackets indicate that the taxon is generically misnamed.

^f The proposed name of ‘*H. heilmannii*’ did not distinguish between the two phylogenetically distinct taxa referred to as ‘*G. hominis* 1’ and ‘*G. hominis* 2.’

^g Taxonomic position based upon marked morphological similarity to ‘*Gastrospirillum*’ spp.

^h Most current taxonomy indicates *C. hyoilei* to be indistinguishable from *C. coli*. (23).

ⁱ *Helicobacter canadensis* is a newly described agent of human gastroenteritis and is closely related to *H. pullorum* (5).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

B. Specimen transport

1. Process within 1 to 2 h or place in transport medium.

■ **NOTE:** *C. jejuni* is stable in feces for 3 days at 4°C and 2 days at 25°C and is unstable at freezing temperatures. It has a similar stability at the respective temperatures in modified Cary-Blair medium, which will inhibit the growth of normal fecal microbiota (10).

2. Transport in modified Cary-Blair medium (formulation modified with reduced agar content of 1.6 g/liter rather than 5 g/liter).

a. Purchase from commercial source *or*

b. Prepare as follows.

(1) Dispense the following ingredients into 991 ml of H₂O.

sodium thioglycolate	1.5 g
disodium phosphate	1.1 g
sodium chloride	5.0 g
phenol red	0.003 g
agar	1.6 g

(2) Heat to dissolve and cool to 50°C. Then add 9 ml of 1% CaCl₂.

(3) Adjust pH to 8.4; dispense in vials and steam for 15 min.

(4) Cool and tighten caps.

3. Avoid phosphate-buffered glycerol transport media.

4. If there is a delay in transport, refrigerate transport vial at 4°C.

C. Refer to procedure 3.8.1 for other collection, labeling, transport, QC, and rejection criteria.

Table 3.8.2–2 Human disease associations of *Campylobacter* species by clinical syndrome

Organism(s)	Human disease association						
	GI ^a	Bacteremia	Meningitis	Abortion	Periodontitis	Wounds/abscesses	Other
<i>C. jejuni</i>	×	×	×	×			Guillain-Barré syndrome
<i>C. jejuni</i> subsp. <i>doylei</i>	×						
<i>C. coli</i>	×						
<i>C. fetus</i> (subsp. <i>fetus</i> and <i>venerealis</i>)	×	×	×	×			
<i>C. upsaliensis</i>	×	×				×	
<i>C. hyointestinalis</i>	×						
<i>C. showae</i>					×		
<i>C. concisus</i>	×				×		
<i>C. curvus</i>					×		
<i>C. mucosalis</i>	×						
<i>C. rectus</i>					×	×	
<i>C. sputorum</i>						×	
<i>C. gracilis</i> (<i>Sutterella wadsworthensis</i>)					×	×	
<i>C. lari</i>		×					Urinary tract infections
<i>C. sputorum</i>						×	
<i>C. ureolyticum</i>					×		
<i>Arcobacter butzleri</i>	×	×					
<i>A. cryaerophilus</i>	×	×					
<i>H. fennelliae</i>	×	×					Proctocolitis
<i>H. cinaedi</i>	×	×				×	Cellulitis, proctocolitis
<i>H. pullorum</i>	×						
<i>H. canadensis</i>	×						
<i>H. westmeadii</i>		×					
<i>H. pylori</i>							Duodenal and gastric ulcer, mucosa-associated lymphoid tissue, gastric carcinoma
“ <i>Flexispira rappini</i> ”	×	×					

^a GI, gastrointestinal.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

D. Other rejection criteria

1. Reject fecal specimen if it has been frozen.
2. Reject fecal specimen in transport media other than *modified* Cary-Blair medium.

III. MATERIALS

A. Media

☑ **NOTE:** The use of more than one type of selective medium increases the yield from stools by as much as 15% (3). Cephalothin, colistin, and polymyxin B in some selective media are inhibitory to *C. fetus*, *C. jejuni* subsp. *doylei*, and *C. upsaliensis* and may inhibit some strains of *C. jejuni* and *C. coli*. Cefoperazone is now considered

to be the preferred antimicrobial agent, as it inhibits *Pseudomonas* species and other gram-negative normal microbiota but does not inhibit growth of campylobacters

1. Blood-free charcoal contains Columbia agar, charcoal, pyruvate, and hemin and cefoperazone, vancomycin, and amphotericin B (or cycloheximide) (3).

III. MATERIALS (continued)

2. Blood-free charcoal-cefoperazone-desoxycholate agar (CCDA) contains desoxycholate, charcoal base (CM 739; Oxoid), and cefoperazone (8).
 3. Campy-CVA contains brucella agar with 5% sheep blood, cefoperazone, vancomycin, and amphotericin B.
- B. Stain reagents**
1. Gram stain (procedure 3.2.1) with carbol fuchsin or 0.1% basic fuchsin for colony smears
 2. Acridine orange (procedure 3.2.2) for problem cultures
 3. Wet mount (procedure 3.2.3) for direct specimen
- C. Other supplies**
1. A microaerobic environment
 - **NOTE:** Most campylobacters require a microaerobic environment of approximately 5% O₂ and 85% N₂ for optimal growth. Increased H₂ appears to be a growth requirement for the more fastidious campylobacters (*C. sputorum*, *C. concisus*, *C. curvus*, *C. mucosalis*, and some strains of *C. hyointestinalis*). These strains are not of significance in fecal cultures, but they may be isolated from blood and may require anaerobic incubation for growth.
 - a. Use an anaerobic jar, without a catalyst, and a gas mixture containing 10% CO₂-5% H₂-balance N₂. Evacuate and fill jar two times to achieve a final atmosphere of 5% O₂, 7% CO₂, and 4% H₂.
 - b. Alternatively, use a leakproof Saranex zipper bag (Associated Bag Company, [800] 926-6100) and fill once with 5% O₂, 10% CO₂, balance N₂ (Campy Gas Cylinder, catalog no. S0730; PML Microbiologicals, Inc., Wilsonville, Oreg., [800] 547-0659, <http://www.pmlmicro.com>)
 - c. See Table 3.8.2-3 for commercial gas systems.
 2. Incubator at 42 and 35°C
 3. Identification—media and biochemical tests
 - a. Heart infusion agar with 5% rabbit blood (BBL catalog no. 297472; BD Diagnostic Systems), BAP, or brucella agar with 5% sheep blood for disk tests and temperature growth tests
 - b. Heart infusion broth (HIB) or BHI for inoculum preparation (BD Diagnostic Systems)
 - c. Oxidase (procedure 3.17.39)
 - d. Catalase (3% H₂O₂) (procedure 3.17.10)
 - e. Hippurate (procedure 3.17.21 and reference 12)
 - f. Indoxyl acetate disks (procedure 3.17.24 and reference 19)
 - g. Rapid urea hydrolysis (procedure 3.17.48 and references 11 and 17)
 - h. Disks—store at -20°C (BD Diagnostic Systems; Remel, Inc.).
 - (1) Nalidixic acid (NA) disks, 30 µg
 - (2) Cephalothin or cefazolin (CF [abbreviation stands for either drug]) disks, 30 µg
 - (3) Ciprofloxacin, 5 µg, and erythromycin, 15 µg, disks (optional)
 - i. Nitrate test (procedure 3.17.35)
 - j. Triple sugar iron (TSI) (procedure 3.17.22)
 - **NOTE:** For use in the identification of campylobacters, TSI must be freshly prepared and used within 1 week (*CDC Campylobacter Reference Lab Procedure Manual*). Incubate test at 35°C for 72 h before calling result negative.

Table 3.8.2-3 Commercial systems for generating microaerobic environments and the approximate atmospheric content

System	Final atmosphere
BBL Campy Pak	6.9% O ₂ , 5.5-7.0% CO ₂ , 0.2% H ₂
BBL Campy Pouch	7.5-9.0% O ₂ , 11.5-14% CO ₂ , 0.5-1.5% H ₂
BBL Bio Bag [™] Cfj	10.5-15% O ₂ , 7-15% CO ₂ , 6.5-12.5% H ₂
Oxoid CampyGen ^a	6% O ₂ , 15% CO ₂
Mitsubishi Pack-Campylo ^a	6% O ₂ , 14% CO ₂

^a This system produces negligible H₂ and may not grow H₂-requiring species.

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
- B. QC test *each lot* of campylobacter medium for growth requirements and inhibition of fecal microbiota, per NCCLS document M22-A2 (15). See Table 3.8.1–3 for QC organisms and testing details.
- C. QC each lot of transport media with *C. jejuni* ATCC 33291 by following the method outlined in section 14, Table 14.2–2, for QC listed under “Transport.”
- D. Test each new lot of CF and NA disks before use in the manner described in item V.D.6 below.
 1. *E. coli* ATCC 25922; zone size range for NA = 22 to 28 mm; that for CF = 15 to 21 mm
 2. *C. jejuni* ATCC 33291; >20-mm zone for NA; no zone for CF
 - **NOTE:** QC erythromycin and ciprofloxacin disks as part of the QC for susceptibility testing, using the usual QC organisms listed in section 5.
- E. Test each lot of gas system to ensure that it supports the growth of *C. jejuni*.
- F. For testing the ability of an organism to grow in a microaerobic atmosphere at various temperatures, perform QC on each incubator or temperature condition, when put into use for this test, with the following to determine if incubator temperatures and atmospheric conditions are in control.
 1. *Arcobacter cryaerophilus* ATCC 43158 (aerobic growth; no microaerobic growth at 42°C)
 2. *C. jejuni* ATCC 33291 (no microaerobic growth at 25°C)
 3. *C. fetus* subsp. *fetus* ATCC 27374 (microaerobic growth at 25, 35 to 37, and 42°C)

V. PROCEDURE

Observe standard precautions.

- A. **Microscopic (rarely performed but can be helpful in isolated cases)**
 1. Perform Gram stain in selected cases during the acute phase of diarrhea for visualization of campylobacters (sensitivity, 66 to 94%) (18, 20).
 2. Visualize motile campylobacters in wet mounts of very fresh stools (<30 min old) as darting across the field in a zigzag fashion (procedure 3.2.3).
 3. Use acridine orange stain for problem cultures (procedure 3.2.2).
- B. **Direct antigen detection**
 ProSpecT *Campylobacter* microplate assay for stool specimens (Remel, Inc.) is an EIA for detection of *Campylobacter* specific antigen found in *C. jejuni* and *C. coli*. There is no differentiation between the two species. The test cross-reacts with *C. upsaliensis* but not other species of *Campylobacter* (7). Performance analysis demonstrated the assay to be 96 and 89% sensitive and 99% specific in two independent studies (7, 21), with a cost in excess of that of culture. See Appendix 3.8.2–1 for details.
- C. **Culture**
 - **NOTE:** Use of enrichment broth cultures (Preston enrichment, CampyTHIO, Campylobacter enrichment) has been reported to increase isolation of campylobacters when specimens are obtained after the acute stage of diarrhea and the broth is incubated overnight at 42°C and subcultured to selective media. However, the value of these enrichments has not been studied adequately, although the use of two primary media or the addition of the filtration technique also increases recovery.
 1. Feces—routine plating
 - a. Place 1 to 3 drops of stool or broth from transport vial on one or two of the following selective agars: blood-free charcoal, CCDA, or Campy-

V. PROCEDURE (*continued*)

CVA. Alternatively inoculate plates using a swab dipped into the transport vial, and completely roll the swab on the medium plate in an area the size of a nickel.

- b. Streak in four quadrants.
- c. Place the plate *immediately* in a microaerobic environment.
- d. Incubate at 42°C for 72 h to screen for thermotolerant *Campylobacter* and *Helicobacter* species.

■ **NOTE:** If detection of species other than *C. jejuni* and *C. coli* is desired, incubate a second plate at 35 to 37°C. Since most species that do not grow at 42°C will grow at 40°C, use of a 40°C incubator will allow one temperature to be used for all species.

2. Feces—filtration technique

■ **NOTE:** This technique has been successful for isolation of campylobacters that are susceptible to antimicrobial agents in media. Passage of motile campylobacters through the pores of the filter allows for selective separation of campylobacters from the nonmotile stool constituents. This method will yield a large variety of *Campylobacter* species, not all of which have been clearly linked with disease.

- a. Place a sterile cellulose acetate membrane filter, with a 47-mm diameter and a 0.65- μ m pore size (Sartorius Corp, Edgewood, N.Y., [800] 635-2906, <http://www.sartorius.com>), directly on the surface of a BAP.
- b. Add 6 to 8 drops of the stool directly on the filter.
- c. Incubate for 45 min to 1 h in ambient air at 35 to 37°C.
- d. Remove filter with sterile forceps, taking care not to allow any residual stool on the filter to drip on the plate. *Do not streak for isolation.*
- e. Immediately place the plate in a microaerobic environment at 35 to 37°C for a *minimum of 72 h or up to 6 days* for recovery of fastidious and slow-growing organisms (4).

D. Identification methods

1. Examine direct plates for growth of campylobacters.
 - a. On freshly prepared media, colonies are gray, flat, irregular, and spreading; sometimes they may appear mucoid.
 - b. Some strains will appear as a thin film on the medium and require careful observation to detect growth (best done by scraping a loop over the surface of the medium). They can also appear as colonies that tail along the line of streaking.
 - c. On less fresh medium, colonies, 1 to 2 mm in diameter, appear as gray, round, convex, and glistening, with little or no spreading.
 - d. Colonies can be yellowish to gray or pinkish and are nonhemolytic.
 - e. *Helicobacter cinaedi* and *Helicobacter fennelliae* growth on fresh media in a moist environment may spread as a uniform film over the entire surface of the plate. *H. fennelliae* has the distinct odor of hypochlorite. They require 5 to 10% hydrogen for growth and generally do not grow at 42°C.
 - f. Check aerobic BAP (procedure 3.8.1) for oxidase-positive colonies at 24 h, which are likely *Pseudomonas* or *Aeromonas*. Then reincubate if negative and recheck at 96 h. If positive at 4 to 5 days and not at 48 h, *Arcobacter* could be present.
2. Perform Gram stain on suspicious colonies using basic fuchsin or carbol fuchsin counterstain promptly after removal from the microaerobic environment.
 - a. Look for small gram-negative rods shaped like spirals, gull wings, archery bows, or commas, consistent with *Campylobacter* species. Coccoidal forms may be seen in the Gram stain, especially in older cultures or cultures exposed to ambient air for prolonged periods.

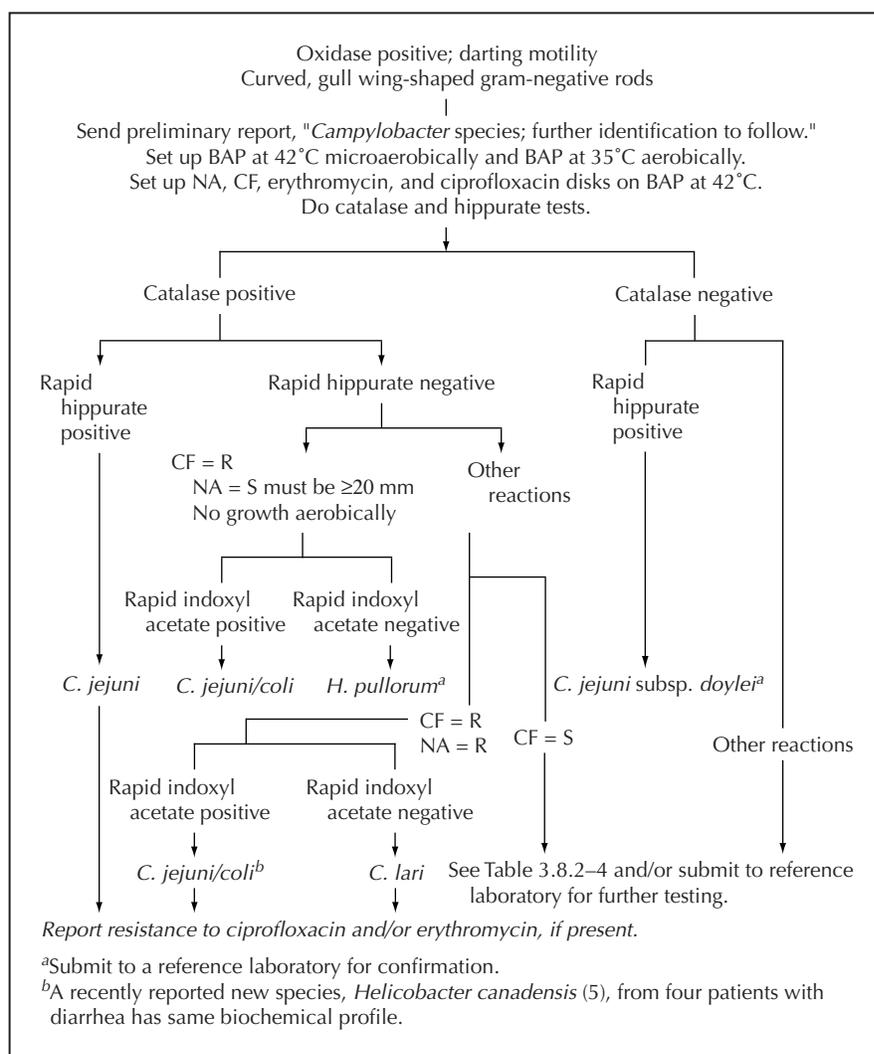

Figure 3.8.2–1 *Campylobacter* identification flowchart for minimum identification of *C. jejuni* from stool specimens. Abbreviations: R, no zone; S, zone.

V. PROCEDURE (continued)

- (3) Mark lines across the bottom of each plate approximately 3/4 in. apart to indicate where inoculum will be placed. Three cultures can be streaked on each agar plate. Label lines with culture numbers.
- (4) Moisten a cotton swab in the bacterial suspension and make a single streak across each plate, rotating the swab one-third of a turn before inoculating the next plate.
- (5) Incubate each plate under its stated temperature and atmospheric conditions for 3 days.
 - (a) Aerobic at 35°C (to screen for *Arcobacter* species)
 - (b) Microaerobic at 35°C (to screen for nonthermotolerant *Campylobacter* and *Helicobacter* species)
 - (c) Microaerobic at 42°C (to screen for thermotolerant *Campylobacter* and *Helicobacter* species)
 - (d) Microaerobic at 25°C (to screen for *C. fetus*).

Table 3.8.2-4 Phenotypic reactions of clinically important *Campylobacter* and *Helicobacter* species^a

Identification test	<i>C. jejuni</i>	<i>C. jejuni</i> subsp. <i>doylei</i>	<i>C. coli</i> <i>C. jejuni</i> , hippurate negative	<i>C. lari</i> ^b	<i>C. fetus</i> subsp. <i>fetus</i>	<i>C. upsaliensis</i>	<i>A. cryaerophilus</i> / <i>A. butzleri</i> ^c	<i>C. hyointestinalis</i>	<i>H. cinaedii</i> / <i>CLOIB</i> ^d	<i>H. fennelliae</i> ^d	<i>H. pullorum</i>
	Oxidase	+	+	+	+	+	+	+	+	+	+
Catalase	+	V	+	+	+	0/W	V	+	+	+	+
Aerobic growth, 35–37°C	0	0	0	0	V ^e	0	+	0	0	0	0
Microaerobic growth, 25°C	0	0	0	0	V	0	+	V	0	0	0
Microaerobic growth, 35–37°C	+	+	+	+	+	+	+	+	+	+	+
Microaerobic growth, 42°C	+	V	+	+	V	+	V	+	V	V	+
Hippurate hydrolysis	+	+	0	0	0	0	0	0	0	0	0
Indoxyl acetate	+	+	+	0	0	+	+	0	0	+	0
NA resistant	0 ^f	0	0 ^f	+	+	0 ^f	V	+	0	0	0
CF resistant	+	V	+	+	V	0	V	0	0	V	+
Nitrate reduction	+	0	+	+	+	+	V	+	+	0	+
H ₂ S in TSI agar	0	0	V ^g	V	0	0	0	+	0	0	0
Urea hydrolysis ^h	0	0	0	0	0	0	0	0	0	0	0

^a +, positive reaction; 0, negative reaction; w, weakly positive; V, variable reaction, NA, not available. See procedure 3.8.4 for *H. pylori* identification.

^b Urease-positive thermophilic campylobacters or *C. lari*-like strains may be found (11).

^c Growth at 42°C; catalase negativity suggests *A. butzleri*.

^d *H. cinaedii/CLOIB* can be separated by DNA homology tests. *H. cinaedii/CLOIB*, *H. fennelliae*, and *H. pylori* can be definitively identified by cellular fatty acid analysis (9).

^e Rare *C. fetus* subsp. *fetus* strains are aerobic.

^f These species are historically sensitive to NA; however, resistant strains are seen in as high as 35% of isolates due to acquired fluoroquinolone resistance, which may make this assay less useful in identification.

^g H₂S in TSI suggests *C. coli*.

^h There are isolated reports of other *Helicobacter* species that are urease producing other than *H. pylori* (24).

V. PROCEDURE (continued)

- (6) Interpretation: record the amount of 72-h growth as follows.
 - (a) No growth
 - (b) Trace
 - (c) 1 + (light)
 - (d) 2 + (moderate)
 - (e) 3 + (heavy)

9. Other tests

- a. Cellular fatty acid analysis (MIDI Laboratories, Newark, Del., [302] 737-4297, <http://www.midi-inc.com/>) (9)

■ **NOTE:** This method cannot differentiate *C. jejuni* and *C. coli*, the two most common species.

- b. Species-specific PCR or 16S rDNA sequencing (CDC *Campylobacter* Laboratory, Atlanta, Ga.; MIDI Laboratories)
- c. *C. jejuni*-specific DNA probe (16) (BioProbe; Enzo Diagnostics, Farmingdale, N.Y., [631] 694-7070, <http://www.enzobio.com>).

- d. AccuProbe *Campylobacter* culture identification test (Gen-Probe, Inc., <http://www.gen-probe.com/>) for DNA identification of *C. jejuni/coliform* colonies does not differentiate among these three species.

■ **NOTE:** The AccuProbe system uses a single-stranded DNA probe with a chemiluminescent label that recognizes RNA sequences that are unique to *C. jejuni*, *C. coli*, and *C. lari*. Following the release of the target RNA, the DNA probe forms a stable DNA:RNA hybrid. A selection reagent inactivates unhybridized probe and the labeled DNA:RNA hybrids are detected in a luminometer.

- (1) Label a sufficient number of probe reagent tubes to test the number of culture isolates and a positive (*C. jejuni* ATCC 33560) and negative (*C. fetus* ATCC 27374) control.
- (2) Pipette 50 µl of lysis reagent into all tubes.
- (3) Transfer a 1-µl loopful of cells or several small colonies (<48 h old) to the tubes and swirl the loop to remove the cells. Test a positively and negatively reacting organism with each run.
- (4) Pipette 50 µl of hybridization buffer into all tubes and mix by vortexing.
- (5) Incubate tubes for 15 min at 60°C in a water bath or dry-heat block.
- (6) Remove and cool the tubes. Pipette 300 µl of selection reagent to each tube and mix by vortexing.
- (7) Incubate tubes for 5 min at 60°C in a water bath or dry-heat block.
- (8) Cool the tubes to room temperature and read results in the luminometer within 30 min. Cutoff values for positive and negative signals are established by the manufacturer for the type of luminometer used.

■ **NOTE:** The AccuProbe assay was compared to standard culture and biochemical identification using 301 isolates of thermophilic *Campylobacter* species (*C. jejuni*, *C. coli*, *C. lari*), 41 isolates of other *Campylobacter* spp., and 300 other bacterial cultures from 53 genera at three clinical sites. The sensitivities and specificities were 100 and 99.1%, 100 and 100%, and 100 and 100%, respectively. One false positive was detected with *C. hyointestinalis* (product insert).

- e. Oxoid Dryspot *Campylobacter* test (latex agglutination), product code DR0150

■ **NOTE:** The Oxoid Dryspot *Campylobacter* test is a latex agglutination test for the identification of enteropathogenic campylobacters from solid culture media. *C. jejuni*, *C. lari*, *C. coli*, *C. fetus*, and *C. upsaliensis* will give positive results. Isolates of other *Campylobacter* spp. such as *C. fetus* subsp. *fetus* will give variable results.

V. PROCEDURE (continued)

- (1) Test 48-h colonies with morphology suggestive of *Campylobacter* spp. from *Campylobacter* selective media.
- (2) Remove the reagents from the refrigerator and allow to reach room temperature.
- (3) Label a sufficient number of reagent tubes to test the number of culture isolates (and a positive and negative control, which should be tested with each new lot and every 6 months thereafter).
- (4) Add 1 drop of extraction reagent 1 into the extraction tube.
- (5) Remove sufficient suspect growth to fill the internal diameter of the sterile loop.
- (6) Thoroughly suspend the cells in the drop of reagent 1. Allow the loop to stand in reagent 1 for 3 min. Do not discard the loop.
- (7) Add 2 drops of extraction reagent 2 to the extract. Mix using the retained loop.
- (8) Using a paddle pipette, place 1 drop (50 μ l) of the neutralized extract onto the test circle and 1 drop onto the control circle.
- (9) Using the flat end of the paddle pastette, mix the extract into the dry control reagent spot until completely resuspended. Spread to cover the reaction area. Use the same pastette to repeat this procedure for the test reagent.
- (10) Pick up and rock the card for 3 min. Look for agglutination under normal lighting conditions. Do not use a magnifying glass.
- (11) Interpretation
A result is positive if agglutination of the latex particles occurs within 3 min; this indicates the presence of *Campylobacter* spp. A negative result is obtained if no agglutination occurs and a smooth blue suspension remains in the test area after 3 min of mixing. This indicates that the isolate is not *C. jejuni*, *C. coli*, *C. upsaliensis*, or *C. lari*. Reactions occurring after 3 min should be ignored. The test is uninterpretable if the control reagent shows agglutination. This indicates that the culture causes autoagglutination.
- (12) The performance of the Oxoid Dryspot *Campylobacter* test was evaluated at one clinical center in Finland. The sensitivity and specificity in the study were 100 and 100%, respectively. In addition, a total of 93 stock cultures and clinical isolates were tested at a clinical center in the United Kingdom. Strains were cultured on Columbia blood agar and/or modified CCDA and CAT (charcoal-based medium containing cefoperazone, amphotericin, and teicoplanin) agars at 37 or 42°C, under microaerobic conditions for 48 to 72 h. The assay detected all *C. jejuni*, *C. coli*, *C. lari*, *C. upsaliensis*, *C. hyointestinalis*, and *C. mucosalis* isolates tested, six of eight *C. fetus* subsp. *fetus* isolates, and one of two *H. pylori* isolates. Other species of *Campylobacter*, *Arcobacter*, and *Helicobacter* as well as 23 other genera of organisms failed to react in the kit.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

A. Direct smears

1. If Gram stain of fecal specimens demonstrates the presence of gull wing-shaped, curved, gram-negative rods, report as “Presumptive *Campylobacter* species.”
2. If wet mount of stool demonstrates darting motility, report as “Presumptive *Campylobacter* species.”

B. Culture

1. All *Campylobacter* and *Helicobacter* strains are oxidase positive, vibrio-like, or spiral gram-negative rods that have darting motility.
2. Report “Presumptive *Campylobacter* species” if the following criteria are met.
 - a. Growth has typical colonial morphology on selective media in a microaerobic environment incubated at 42°C.
 - b. Curved, gram-negative rods are demonstrated on Gram stain from colony.
 - c. Organism exhibits darting motility.
 - d. Organism is oxidase positive and catalase positive.
3. Use the biochemical tests listed in Table 3.8.2–4 and the flowchart in Fig. 3.8.2–1 to differentiate *Campylobacter* and *Helicobacter* species of human importance. Report *C. jejuni*, *C. jejuni* subsp. *doylei*, *C. jejuni/coli*, *C. lari*, or *Helicobacter pullorum* based on the flowchart in Fig. 3.8.2–1.
4. If isolate is not identified by Fig. 3.8.2–1, report species as denoted by biochemical characterization in Table 3.8.2–4.
5. If unable to identify isolates using the above schemes or to confirm identification, submit to a reference laboratory. Report “*Campylobacter*-like organism; submitted to reference laboratory for definitive identification.”
■ **NOTE:** For definitive identification, cellular fatty acid analysis and/or molecular analysis may be required.

C. Susceptibility testing

1. Standardized antimicrobial susceptibility testing methods for testing the susceptibility of *Campylobacter* isolates, with the exception of the agar dilution method, are not available.
2. However, the lack of a zone around either erythromycin or ciprofloxacin disks indicates that the isolate is likely resistant to the antimicrobial agent.
■ **NOTE:** In over 200 disk diffusion tests with erythromycin and ciprofloxacin, there was consistently a bimodal distribution of results, with most results either at ≥ 25 mm or showing no zone (6 mm). More recently, zone sizes have been found to be smaller, but the bimodal distribution is still valid. No *Campylobacter* isolates have been found that are susceptible to NA (large zone) but resistant to ciprofloxacin (no zone) (R. Nadarajah, personal communication).
3. If there is no zone around the ciprofloxacin or erythromycin disk, enter the following: “By a nonstandard susceptibility test method, isolate is resistant to [drug].”
4. Do not report any isolate as susceptible, since there are no standardized interpretive criteria for *Campylobacter*.

D. Notification

1. Notify caregiver of positive findings.
2. Report *Campylobacter* in fecal cultures to the local health department, per local reportable-disease regulations.

VII. INTERPRETATION

- A. Treatment with hydration and electrolyte balance is the cornerstone of therapy for *C. jejuni*. In cases with high fever, bloody stools, and symptoms lasting greater than 1 week, antimicrobial treatment is indicated and can reduce the symptoms and severity as well as reduce the likelihood of complications, such as Guillain-Barré syndrome. Because of these complications, resistance to quinolones needs to be communicated to the physician.
- B. *C. jejuni* is a major cause of bloody diarrhea that can have serious sequelae. Isolation of other species in fecal cultures, especially *C. upsaliensis*, *Arcobacter* spp., and *H. pullorum*, is generally associated with milder diseases.
- C. Because campylobacters and helicobacters are biochemically inert bacteria, few phenotypic tests are available in the clinical laboratory to group them by species. Most clinical laboratories are capable of characterizing the common species that are of medical importance.

VIII. LIMITATIONS

- A. Methods presented here are designed to recover and identify only the most common pathogenic strains of *Campylobacter*, with isolation and definitive identification of *C. jejuni*, the most common species. The optimal methods to recover campylobacters from clinical specimens have yet to be determined. While confidence can be placed in routine methods for detection of the most common agents in diarrhea (*C. jejuni* and *C. coli*), recovery procedures for other agents are not clearly defined.
- B. For recovery of campylobacters from nonfecal specimens, it is essential that there be communication between the clinician and the laboratory. It is impractical and unreasonable for a laboratory to routinely plate specimens under multiple atmospheric conditions and at different temperatures. An understanding of the critical growth requirements is necessary to establish optimal conditions for recovery of these organisms in clinical specimens.
- C. If *C. jejuni* is resistant to fluoroquinolones, it will be resistant to NA, and the disk will not be useful for identification.
- D. Other strains of *Helicobacter* besides *H. pylori* produce urease, including “*Flexispira rappini*”; these isolates are best identified with molecular assays (24).

APPENDIX 3.8.2–1

Direct Detection of *Campylobacter* by EIA Method (ProSpecT)

I. PRINCIPLE

Diagnosis of campylobacteriosis by isolation of the organism can take 2 days to a week. Direct detection of the *Campylobacter* surface antigen (SA) from fecal specimens in an EIA can be done the same day the specimen is received. In this test two molecules with molecular masses of 15 and 66 kDa are detected. Cross-reactivity studies indicate that the antigens are shared by *C. jejuni* and *C. coli*.

The test can be performed directly on extracts of fecal specimens or fecal enriched broth cultures. Diluted specimens are added to breakaway microplate wells on which rabbit polyclonal anti-*Campylobacter* SA antibody is bound. If antigen is present, it is captured by the bound antibody. When an enzyme conjugate (polyclonal rabbit anti-

APPENDIX 3.8.2-1 (continued)

Campylobacter SA labeled with horseradish peroxidase enzyme) is added, captured *Campylobacter*-specific antigen binds the enzyme conjugate to the well. After the substrate for the enzyme is added, it is converted to a colored reaction product. Color development can be detected visually or spectrophotometrically. In a negative reaction, there is no *Campylobacter* SA or an insufficient amount of antigen present to bind the enzyme conjugate to the well and no colored reaction product develops.

II. SPECIMEN COLLECTION AND HANDLING

A. Collection of direct stool (feces)

1. Unpreserved stool specimens, specimens in Cary-Blair medium, or specimens diluted in the ProSpecT bacterial specimen diluent can be stored at 2 to 8°C for up to 72 h, although this storage can be extended to up to 7 days if in Cary-Blair medium.
2. If testing is to be delayed, store frozen at -20°C or lower immediately after collection.
3. Optimal specimen results will be obtained if the specimen is tested immediately upon receipt in the laboratory.

B. Specimen preparation for assay

1. Direct method

Dilute unpreserved specimens approximately 1:3 by mixing 1 part specimen with 2 parts bacterial specimen diluent as follows.

- a. Add 0.6 ml of bacterial specimen diluent to a clean plastic or glass disposable tube.
- b. Thoroughly mix stool.
- c. Using a transfer pipette, remove approximately 0.3 ml of specimen (third mark from the tip of the pipette). Expel sample into bacterial specimen diluent and mix by drawing up and down once. Leave transfer pipettes in the tubes.
- d. For specimens that will not pipette, use an applicator stick to add 0.3 g (~6 mm in diameter) of specimen. Vigorously stir specimen into bacterial specimen diluent. Add a transfer pipette to the tube and mix by drawing up and down once. Leave transfer pipettes in the tubes.

2. For specimens in Cary-Blair transport, mix well and transfer to the microplate well.

3. Broth method

- a. Inoculate 150 µl or 3 drops of fresh stool or stool in Cary-Blair transport medium into 5 ml of GN broth (Table 3.8.1-1).
- b. Incubate at 35 ± 2°C under ambient atmospheric conditions for 18 to 24 h.
- c. Add 0.6 ml of bacterial specimen diluent to a clean 12- by 75-mm tube.
- d. Transfer 0.3 ml of broth culture into 0.6 ml of bacterial specimen diluent using a transfer pipette. Leave the transfer pipette in the tube.

III. MATERIALS

A. Reagents

1. The ProSpecT *Campylobacter* microplate assay (48- or 96-test microplate assay) catalog no. is 760-96 (Remel, Inc.).
 - a. 100 ml of bacterial specimen diluent, containing buffered solution with rabbit serum with 0.02% thimerosal
 - b. Microwell eight-well strips coated with rabbit polyclonal anti-*Campylobacter* SA antibody
 - c. Positive control containing *C. jejuni* culture supernatant suspended in negative control with fetal bovine serum and 0.02% thimerosal
 - d. Low positive control containing *C. jejuni* culture supernatant suspended in negative control with fetal bovine serum and 0.02% thimerosal
 - e. Negative control containing human fecal material with rabbit serum and 0.02% thimerosal
 - f. Enzyme conjugate: horseradish peroxidase-labeled rabbit polyclonal anti-*Campylobacter* SA and 0.01% thimerosal
 - g. Wash buffer: 10× concentrated buffered solution with 0.1% thimerosal
 - h. Color substrate in buffer
 - i. Stop solution containing 0.5 N hydrochloric acid (corrosive)
2. Store reagents at 2 to 8°C until use.

APPENDIX 3.8.2-1 (continued)

3. Preparation of wash buffer
 - a. Dilute 10× wash buffer concentrate to 1× by adding 1 part concentrate to 9 parts distilled or deionized water.
 - b. Label diluted wash buffer with 1-month expiration date, and store at 2 to 8°C.
- B. Materials
 1. Disposable applicator sticks
 2. Plastic or glass disposable tubes for specimen preparation, ~1 to 2-ml capacity
 3. 1- to 10-ml pipettes
 4. Wash bottle or dispenser for wash buffer or microwell plate washer
 5. Deionized or distilled water
 6. Plate reader capable of reading at 450 nm or 450 and 630 nm (optional)
 7. Vortex mixer with microplate adapter or shaker (optional)
- IV. QUALITY CONTROL
 - A. Test the positive and negative controls each time the test is performed.
 - B. Optionally, the low positive control may be run when an indeterminate or very low positive result is repeated. The low positive control may be included in the repeat run as an indication of the performance of the assay near the cutoff level.
 - C. The optical density (OD) of the negative control should be <0.100 at 450 nm or <0.070 at 450 and 630 nm. or colorless when read visually. If yellow color equal to 1+ or greater on the procedure card is present in the negative control, the test should be repeated with careful attention to the wash procedure.
 - D. The OD of the positive control should be >0.500 at 450 nm or 450 and 630 nm. Visually the intensity of color in the positive control should be equal to or greater than the 2+ reaction on the procedure card.
- V. PROCEDURE
 - A. Allow all reagents and specimens to reach room temperature (20 to 25°C) before use.
 - B. Open the foil pouch, remove the required number of microplate strip wells, and place into a microplate strip holder. Use one well for the negative control and one well for the positive control. If using fewer than eight wells, break off the required number of wells from the strips and return the unused microwells to the foil pouch. *Reseal pouch tightly to exclude moisture and return to the refrigerator.*
 - C. Add 4 drops of negative control to the first well. Add 4 drops of positive control to a second well. (Optionally, add 4 drops of low positive control to a third well.)
 - D. Using a transfer pipette, add 4 drops of diluted specimen or enriched broth culture, or 4 drops of specimen in transport medium per well. *Note:* Place the opening of the transfer pipette just inside the well to avoid splashing into adjacent wells.
 - E. Cover the microplate and incubate at room temperature (20 to 25°C) for 60 min. Begin timing after the addition of the last specimen.
 - F. Shake out or aspirate the contents of the wells. Wash by completely filling each well with diluted wash buffer (350 to 400 µl/well) a total of three times. After the last wash, remove all fluid from the wells.
 - G. Add 4 drops (200 µl) of enzyme conjugate to each well.
 - H. Cover the microplate and incubate at room temperature for 30 min.
 - I. Decant or aspirate. Wash each well five times.
 - J. Add 4 drops (200 µl) of color substrate to each well.
 - K. Cover the microplate and incubate at room temperature for 10 min.
 - L. Add 1 drop (50 µl) of stop solution to each well. Gently tap or vortex the wells until the yellow color is uniform. Read reactions within 10 min after adding stop solution.
 - M. Read visually or spectrophotometrically at 450 nm (single wavelength) and/or 450 and 630 to 650 (dual wavelength).
- VI. INTERPRETATION
 - A. Interpretation of visual results: refer to the procedure card for color interpretations.
 1. Negative: a colorless reaction is a negative result and indicates that no *Campylobacter* SA or an undetectable level of *Campylobacter* SA is present in the sample tested.
 2. Indeterminate: if faint yellow color that is less than the 1+ reaction develops, the test is indeterminate. Tests with indeterminate results should be repeated.

APPENDIX 3.8.2–1 (continued)

3. Positive: if yellow color of at least 1+ intensity develops in the test wells, the sample contains *Campylobacter* SA and the test is positive.
- B. Read spectrophotometric results at the single (450 nm) and/or dual (450 and 630 to 650 nm) wavelength. Tests with indeterminate results should be repeated.

Single wavelength

<u>Transport media</u>	<u>Fresh stool</u>
Negative: OD < 0.100	OD < 0.130
Indeterminate: OD = 0.100 to 0.130	OD = 0.130 to 0.170
Positive: OD > 0.130	OD > 0.170

Dual wavelength

<u>Transport media</u>	<u>Fresh stool</u>
Negative: OD < 0.070	OD < 0.100
Indeterminate: OD = 0.070 to 0.100	OD = 0.100 to 0.140
Positive: OD > 0.100	OD > 0.140

VII. LIMITATIONS

- A. The ProSpecT *Campylobacter* microplate assay was evaluated in three studies and was found to have sensitivities of 80, 89, and 96% (1, 2, 3). Specificities were 99%.
- B. The overall performance of the ProSpecT *Campylobacter* microplate assay for broth-enriched culture was a sensitivity of 90% and specificity of 100%, as indicated in the package insert.
- C. The test detects the presence of *Campylobacter* SA in diarrheal stools and cultures. Correlation between the amount of antigen in a sample and clinical presentation has not been established.
- D. A negative test result does not exclude the possibility of the presence of *Campylobacter* and may occur when the antigen level in the sample is below the detection level of the test.
- E. The ProSpecT *Campylobacter* microplate assay does not differentiate *C. jejuni* and *C. coli*, and there are other serotypes and subspecies that may or may not be detected.
- F. It is not known whether *C. upsaliensis*, *C. hyointestinalis*, or *C. helveticus* cross-reacts.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Clostridium difficile is an opportunistic pathogen present in healthy adults and children and is responsible for 300,000 to 3,000,000 cases of diarrhea and colitis in hospitalized patients in the United States every year (12). When the intestinal microbiota is altered, toxigenic *C. difficile* flourishes and toxin production increases. *C. difficile* toxin is responsible for 25% of antimicrobial agent-associated diarrhea cases and most all cases of pseudomembranous colitis (11). Patients with the latter present with pseudomembranous nodules or plaques in the distal and sigmoid colon and rectum, which lead to colonic dilation (toxic megacolon) or even perforation. If unrecognized or untreated, it can be fatal. The definitive diagnosis of pseudomembranous colitis is made by the endoscopic detection of pseudomembranes or microabscesses.

For hospitalized patients, *C. difficile*-associated diarrhea (CDAD) correlates with antimicrobial therapy within the last 30 days and either three unformed stools over a 24-h period or abdominal pain (6). Although clindamycin and cephalosporin usage is highly associated with the disease, any antimicrobial agent can precipitate toxin production, as can various anticancer chemotherapeutic agents and diseases, such as AIDS. Generally, the implicated antimicrobial agent is discontinued, and treatment with oral vancomycin or metronidazole may be needed. The latter agent is preferred to prevent the emergence of vancomycin-resistant enterococci.

Nosocomial spread of *C. difficile* can be a problem, particularly in hospitals with

neutropenic patients or long-term-care patients. The Society for Healthcare Epidemiology of America (SHEA) and America College of Gastroenterology have issued separate guidelines for prevention and control of *C. difficile* disease (3, 4). *C. difficile* produces two toxins, enterotoxin (toxin A) and cytotoxin (toxin B). Toxin A causes extensive tissue damage (lesions) to the mucosal wall of the intestine. Toxin B is a highly potent cytotoxin, with as little as 1 pg of the toxin causing rounding of tissue culture cells (9). The toxins are very unstable, even at refrigerator temperatures and in the frozen state. Several immunologic tests are available to detect the toxin, using antibody to the toxin. Culture for the organism is very sensitive but not specific, since it detects colonization with the organism, even when no toxin is produced (5). In addition, it takes several days for a positive result. Hence, it is used only to collect isolates for an epidemiologic investigation (see procedure 3.8.1 for culture methods). A latex agglutination test detects glutamate dehydrogenase, a nontoxin protein associated with *C. difficile* and other anaerobes that may correlate with CDAD. This test will yield false-positive results with non-toxin-producing isolates of *C. difficile*, *Clostridium botulinum*, *Clostridium sporogenes*, *Peptostreptococcus anaerobius*, and *Bacteroides asaccharolyticus* (10).

The reference method for laboratory diagnosis of CDAD has been detection of toxin B by cytotoxin (tissue culture) assay. Yet the sensitivity of this "gold standard" method has recently been reevaluated, and in some studies, it is reported to be about

85 to 90% (15) compared to cytotoxin assay of broth cultures from the organism isolated from anaerobic fecal cultures on pre-reduced selective medium (procedure 3.8.1). EIAs, for either toxin A or toxins A and B are less sensitive than tissue culture cytotoxicity (generally 70 to 82% sensitive [13, 15]) but may be more practical, because of their rapid turnaround time and the instability of the toxins, especially if a tissue culture assay must be sent to a reference laboratory. Many commercial tests detect toxin A, which is present in greater concentration. Some also detect toxin B, and a third type detects toxin A and glutamate dehydrogenase (Triage; Biosite Diagnostics, San Diego, Calif.). Tests that detect only toxin A may miss some isolates that produce toxin B only (2, 11). However, since toxin B is present in lower quantities, tests that detect both toxin A and toxin B may still not be able to detect low levels of toxin B in stool specimens and may not have much advantage over those tests that detect only toxin A. The Triage is less likely to miss a positive and has a reported sensitivity of 97.5% (package insert) to 89% compared to cytotoxin assay (15). However, the specificity of the test is 89%. Thus, those results that are toxin A negative and glutamate dehydrogenase positive should be confirmed by a toxin B assay or reported with a qualification that they may not be positive for the toxin (8). Since procedural methods for the immunologic tests are available in the package inserts and the options, sensitivities, and specificities are discussed elsewhere (1, 15), this procedure presents only the cytotoxin assay. However, the speci-

men collection, reporting, and some limitations apply to all methods.

Cytotoxin B tissue culture assay is based on the principle that a mixture of a bacterial-cell-free stool filtrate containing

C. difficile toxin will show cytopathic effect (CPE) (rounding of the cells) in a susceptible cell line. The filtrate of *C. difficile* toxin mixed with *C. difficile* antitoxin will

not produce a CPE. The neutralization of the toxin confirms the presence of *C. difficile* cytotoxin in the patient's stool sample.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Collect stool specimens in leakproof container, and transport and store without preservative at 2 to 8°C until processing (within 24 h of collection).

B. Also acceptable are lumen contents and surgical or autopsy samples of the large bowel.

C. Rejection criteria

■ **NOTE:** The SHEA recommends that testing not be performed on asymptomatic patients, even for test of cure (4, 5, 6).

1. A rectal swab will not provide enough specimen for the test and therefore is unacceptable.

2. Reject stools that are not liquid or soft.

3. Request repeat collection if there is not enough specimen for test; 10 to 20 ml of watery, diarrheal stool is preferred, or a minimum of 3 ml or 3 g is required.

4. Request recollection if test will not be performed within 24 h of receipt.

5. Meconium may interfere with the assay.

6. Discourage testing specimens from infants less than 1 year of age (reference 6 and SHEA guidelines). Include comment on report indicating lack of specificity of test for this population.

■ **NOTE:** Infants have been shown to be asymptomatic carriers, with colonization rates as high as 50% (7, 16, 17).

7. Limit testing of stools from cystic fibrosis patients (4), because these patients have been shown to have colonization rates as high as 32% (14).

8. Patients with positive tests should *not* have repeat testing for cure, unless they again become symptomatic after completion of therapy (6).

■ **NOTE:** In one study, limiting the number of stool samples processed for *C. difficile* toxin to one per 72 h would have reduced the number of duplicates by 40%, without adversely affecting the identification of toxin-positive patients (M. LaRocco, personal communication).

III. MATERIALS

A. Minimum essential medium (MEM) with 2% fetal bovine serum (FBS), gentamicin (50 µg/ml), vancomycin (500 µg/ml), and nystatin (10,000 U/ml) (*see* procedure 10.3 for details of preparation of tissue cultures and media)

B. 96-well flat-bottomed microtiter plate with monolayer of diploid fibroblasts (e.g., human fetal foreskin, MRC-5, Chinese hamster ovary K1 cells) and 0.1 ml of MEM per well

1. Preparation of cell monolayer

a. Make a suspension of cells at a concentration of 4×10^4 cells per ml in growth medium (90% MEM plus 10% FBS).

b. Inoculate 100 µl of suspension into each well.

c. Incubate at 35°C aerobically with 5% CO₂ for several days until a monolayer forms.

d. Aspirate growth medium and replace with 100 µl of MEM with 2% FBS.

e. To avoid drying of outer wells, add 200 µl of MEM with 2% FBS to perimeter wells and do not use them for the assay if they do not look healthy.

2. Store at 35°C aerobically with 5% CO₂.

III. MATERIALS (continued)

3. Use trays up to 3 weeks after preparation.
- **NOTE:** The Bartels (Issaquan, Wash.) cytotoxicity assay for *C. difficile* toxin utilizes a microtiter tray containing tissue culture cells, thus allowing laboratories not equipped for standard tissue culture to use the assay.
- C. *C. difficile* culture filtrate, lyophilized (Techlab Inc., Blacksburg, Va.)
 1. Contains toxins A and B
 2. Add 1 ml of sterile distilled water to vial.
 3. Aliquot small volumes (50 to 100 μ l) of the reconstituted filtrate in an airtight container at -20°C .
- D. *C. difficile* antitoxin, lyophilized (Techlab Inc.)
 1. Add 3 ml of sterile distilled water for stock.
 2. Aliquot small volumes (50 to 100 μ l) of the reconstituted antitoxin in an airtight container at -20°C .
 3. Place a 6-month expiration date on reconstituted antitoxin.
 4. For working dilution, dilute stock 1:25 with 98% MEM.
 - a. Add 0.1 ml of stock to 2.4 ml of MEM.
 - b. Prepare fresh every 2 weeks.
 - c. Store at 2 to 8°C .
 5. Determine the titer of each new lot of both toxin and antitoxin before use.
 - a. Make 10-fold dilutions from 10^{-1} to 10^{-5} in 98% MEM.
 - b. Remove MEM from right wells of double rows of microtiter plate.
 - c. Inoculate 0.1 ml of working dilution of antitoxin into each right well.
 - d. Inoculate 0.1 ml of culture filtrate into the right and left wells.
 - e. Incubate in 3 to 5% CO_2 at 37°C for 48 h.
 - f. The titer is the highest dilution showing typical 4+ toxin CPE and no CPE in the tube with antitoxin. The working dilution is 10 times this dilution. (If the highest dilution showing 4+ CPE is 10^{-5} the working dilution is 10^{-4} .)
- E. Materials required but not provided
 1. Pipettors that dispense 100 μ l
 2. Powderless disposable latex or polypropylene gloves
 3. 1-, 5-, and 10-ml sterile pipettes
 4. Refrigerated centrifuge, capable of centrifugation at $\geq 12,000 \times g$
 5. 15-ml round-bottomed polypropylene or other appropriate centrifuge tubes for specimen dilution and centrifugation
 6. Syringe, 3 ml
 7. Repeating pipetting device
 8. Millipore 0.45- μm -pore-size filters
 9. Incubator with 5% CO_2
 10. Inverted microscope

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Each time the test is run, even if on the same tray, set up the following controls after aspirating the maintenance medium (see Fig. 3.8.3-1).
 1. 100 μ l of toxin plus 100 μ l of MEM
 2. 100 μ l of toxin plus 100 μ l of antitoxin
- B. In addition, set up the following controls once per plate after aspirating the maintenance medium.
 1. 100 μ l of antitoxin plus 100 μ l of MEM
 2. 200 μ l of MEM
- C. Expected results
 1. Well with toxin shows typical CPE within 12 to 18 h. The cells round up and appear evenly throughout the cell sheet.
 2. Well with toxin plus antitoxin shows no CPE.
 3. Wells with MEM and wells with antitoxin alone show no CPE.

Day 1				Day 2							
A/1	2	3	4	5	6	7	8	9	10	11	12
B	Toxin	Toxin + A	Patient D 1:20	Patient D 1:20 + A	Toxin	Toxin + A					
C	MEM	A	Patient D 1:100	Patient D 1:100 + A	Patient F 1:20	Patient F 1:20 + A					
D	Patient A 1:20	Patient A 1:20 + A	Patient E 1:20	Patient E 1:20 + A	Patient F 1:100	Patient F 1:100 + A					
E	Patient A 1:100	Patient A 1:100 + A	Patient E 1:100	Patient E 1:100 + A	Patient G 1:20	Patient G 1:20 + A					
F	Patient B 1:20	Patient B 1:20 + A			Patient G 1:100	Patient G 1:100 + A					
G	Patient B 1:100	Patient B 1:100 + A									
H											

Figure 3.8.3–1 Example of worksheet diagram to accompany a 96-well microtiter tray previously inoculated with a monolayer of fibroblasts and subsequently inoculated with patient specimen, controls, toxin, and antitoxin. Day 1 is the first date the tray is used. Day 2 illustrates the controls omitted on subsequent days; i.e., MEM and antitoxin control wells are not needed. Patient stool specimens in dilutions of 1:20 and 1:100 are indicated as patient A, B, C, D, and E, inoculated on day 1, and patients F and G, inoculated on day 2. Note that outer wells are not used. A, antitoxin.

IV. QUALITY CONTROL (continued)

D. Troubleshooting

<u>Problem</u>	<u>Corrective action</u>
Positive control shows no CPE.	<ol style="list-style-type: none"> 1. Positive control has deteriorated. Dilute new aliquot. 2. Cells insensitive—rerun test with another cell lot.
Toxin-antitoxin well shows CPE.	<ol style="list-style-type: none"> 1. Antitoxin deteriorated. Dilute and use frozen aliquot of the same lot. 2. Dilute and use different lot of antitoxin. 3. Cell sheet contaminated. Try new lot of cells or reagents.

V. PROCEDURE

Observe standard precautions.

A. Preparation of stool sample

1. Add 3 ml of 98% MEM to a 15-ml centrifuge tube.
2. Add enough stool sample to bring the level of medium up to the 5-ml mark (2:5 dilution).
3. Vortex at the highest speed.
4. Centrifuge at $12,000 \times g$ for 15 min in refrigerated centrifuge.
5. Filter the supernatant into a tube using a 0.45- μ m-pore-size filter attached to a 3-ml syringe.
6. Add 100 μ l of supernatant to 300 μ l of 98% MEM in a 12- by 75-mm tube (final dilution, 1:10).
7. Add 100 μ l of the 1:10 dilution to 400 μ l of 98% MEM in a 23- by 75-mm tube (final dilution, 1:50)

V. PROCEDURE (*continued*)

- B.** Inoculation (*see* Fig. 3.8.3–1)
 1. Remove medium from right wells of double rows.
 2. Add 100 μ l of working dilution antitoxin to each right well immediately after medium is removed but before adding patient's specimen.
 3. Add 100 μ l of the 1:50 dilution of patient's specimen to the left and right wells of the double rows (1:100 dilution).
 4. Add 100 μ l of the 1:10 dilution of patient's specimen to the left and right wells of the double rows (1:20 dilution).
 5. The same pipette tip can be used for pipetting both dilutions of the same specimen if the higher dilution is inoculated first.
 6. Save dilutions and stool at 4°C for further testing.
 7. Inoculate toxin and toxin-antitoxin controls.
- C.** Incubate the tray for 12 to 18 h at 33 to 35°C with 3 to 5% CO₂.
- D.** Read for CPE at 12, 24, and 48 h.

POSTANALYTICAL CONSIDERATIONS**VI. INTERPRETATION**

- A.** If stool filtrate and stool filtrate plus antitoxin are both negative, this is interpreted as negative for *C. difficile* toxin.
- B.** If stool filtrate is positive and stool filtrate plus antitoxin is negative at the same dilution, this is interpreted as positive for *C. difficile* toxin.
- C.** If stool filtrate and stool filtrate plus antitoxin are both positive, this is an equivocal result.
 1. Wells with 1:20 dilution stool extract plus antitoxin can show breakthrough CPE in a strongly positive specimen. In this case a definite reduction (50%) in CPE of the 1:100 dilution stool extract plus antitoxin compared to the 1:20 dilution plus antitoxin well suggests presence of *C. difficile* toxin.
 - a.** If the well with the 1:100 dilution plus antitoxin also shows breakthrough CPE, set up further dilutions of 1:200, 1:400, etc., with and without the antitoxin.
 - b.** Use the 1:20 dilution extract to make further dilutions.
 - c.** Determine the highest dilution of stool extract plus antitoxin that shows no CPE. If the stool extract at that dilution shows CPE, the specimen is positive for *C. difficile* toxin.
 2. If CPE shows in stool extract-plus-antitoxin well of the highest dilution of stool extract that shows CPE, the CPE is not due to *C. difficile* toxin. Request another sample, since the results cannot be interpreted.
 3. If the cell sheet is deteriorating nonspecifically, request another sample, since these results cannot be interpreted.

VII. REPORTING RESULTS

- A.** Report positive results as "*C. difficile* toxin positive."
 1. Notify the caregiver who ordered the test.
 2. Report positives as soon as neutralized CPE is observed.
- B.** Report preliminary negative results as "No *C. difficile* toxin detected at 24 h; final reading at 48 h."
- C.** Report final negative results as "No *C. difficile* toxin detected."

VII. REPORTING RESULTS

(continued)

- D. For equivocal results (cells show rounding that is not neutralized by antitoxin), questionable weak results, or specimens that are toxic to the cell sheet (cell sheet falls off sides of well), report “Specimen result not interpretable. Suggest repeat sample.”
1. Notify caregiver to submit another specimen if diarrhea persists.
 2. Communicate this result as soon as possible to avoid delays in obtaining a repeat specimen. It is likely that if the patient has *C. difficile* toxin, the repeat specimen will be a strong positive.

VIII. LIMITATIONS

- A. The etiology of diarrhea caused by microorganisms other than *C. difficile* will not be established with this assay.
- B. Levels of toxin can be low. A negative result alone may not rule out the possibility of CDAD.
- C. Always evaluate assay result along with clinical signs and patient history.
- D. Certain isolates of *Clostridium sordellii* produce the same type of rounding on tissue culture cells as toxigenic *C. difficile*, due to the similarities of the toxins. *C. sordellii* has not been detected in patients with antimicrobial agent-associated diarrhea and colitis. It is also unlikely that *C. sordellii* will be present in human fecal specimens.
- E. False-positive results are associated with misinterpretation of CPE and its neutralization.
- F. Lack of homogeneity in a stool sample may lead to incorrect results. Thorough mixing of stool specimens is essential to avoid this problem.
- G. Stool specimens that appear to have large amounts of fat, mucus, or blood present are more likely to give toxic results.
- H. Healthy newborns are frequently toxin positive.

3.8.4

Helicobacter pylori Cultures

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

In 1984, a campylobacter-like organism, *Helicobacter pylori*, was reported to be present in high numbers in the deep mucus layer of the gastric surface epithelium in patients with chronic active gastritis (10). Since its discovery, *H. pylori* has been estimated to be present in 50% of the population (9, 10), and it is known to be associated with an increased risk for the development of peptic ulcer disease, gastric adenocarcinoma, and gastric non-Hodgkin's B-cell lymphomas (mucosa-associated lymphoid tissue) (2). While *H. pylori* is the primary agent of disease, there are increasing reports of evidence of other spiral organisms (e.g., *Helicobacter heilmannii*) present as part of the human microbiota (1, 2, 13), which are often uncultivable but may be responsible for gastritis.

There are a number of tests available to diagnose *H. pylori* infection which can be categorized into invasive (requiring endoscopy and biopsy) and noninvasive. The most common noninvasive test is serology to determine the presence of antibodies to the organism (*see* procedure 11.9). Sero-

logic testing, if positive, for a symptomatic patient who has not been previously treated supports the diagnosis of *H. pylori*. Caution should be exercised in interpretation in areas of high prevalence of *H. pylori*, as antibodies generally remain for life. These tests have been reviewed by Laheij et al. (5) and are not discussed further here. Another noninvasive test is the urea breath test (3), which is an accurate means of identifying the presence of *H. pylori* infection before and after antimicrobial therapy. The test is labor-intensive and requires expensive instrumentation for analysis (scintillation counter or mass spectroscope), yet for the patient it is simple, rapid, and relatively inexpensive. A stool EIA antigen test (Appendix 3.8.4-1) is also a sensitive noninvasive test that has been shown to be a good method for initial diagnosis and for monitoring eradication after antimicrobial therapy (12). However, the cost of this assay is high.

There are three tests available to diagnose the disease invasively from gastric biopsy specimens. Because of their ease of use, rapidity, and cost-effectiveness, rapid

urease biopsy tests are the most common test. Several commercial tests are approved for performance by nonlaboratory scientists ("waived" tests) in the gastroenterologists' offices, with sensitivities of 89 to 98% and specificities of 93 to 98% (3, 4). Other tests include histologic examination and culture. Culture is demanding, requires special conditions of transport and incubation, and does not provide a result in a timely manner, making it useful only in selected cases.

H. pylori organisms appear in gull wing formation on Gram stain, although after culture they may form a U shape. With age or after prolonged exposure to ambient air, the organisms may appear as coccoidal forms. Unlike most other campylobacters, *H. pylori* organisms possess abundant amounts of urease. They produce superoxide dismutase and catalase in much greater amounts than other campylobacters. The presence of gull wing or U-shaped gram-negative organisms from a gastric specimen that are microaerophilic and urease, catalase, and oxidase positive makes the diagnosis of *H. pylori*.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. Obtain biopsy specimens.
 - a. Pass an endoscope orally.
 - b. Obtain specimens through a channel in the endoscope by using one of the following procedures.
 - (1) Using biopsy forceps, obtain samples from the stomach or duodenum.
 - (2) Using a sheathed brush, brush suspicious areas several times to obtain adequate cellular material.
 - c. If a gastric ulcer is seen, obtain biopsy samples from the base, the surrounding gastric mucosa, and each of the four quadrants of the margin.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

2. Transport
 - a. Urease test
 - (1) Prewarm agar.
 - (2) Inoculate several biopsy samples by pushing into the urea agar, or inoculate into broth or other urea test (6).
 - (3) Seal tube and incubate at 25°C or, preferably, at 35°C until submitted to laboratory (7) or agar turns pink.
 - b. Submit biopsy samples within 3 h in 1 ml of modified Cary-Blair transport medium or place in saline on ice.

☑ **NOTE:** Prompt submission of biopsy specimens to the laboratory for homogenization and urease testing has a higher yield than direct inoculation.
 - c. Label all tubes and specimens with date and time of collection.
 3. Optional: collect a stool specimen for direct antigen test. Store at 4°C for up to 72 h or at –20°C until tested. Do not freeze-thaw more than two times.
- B. Rejection criteria**
1. Do not accept specimens in formalin for culture.
 2. For specimens not cultured within 3 h, document in the final report that specimen quality may have been compromised.
 3. Gastric washes are not acceptable specimens for culture.

III. MATERIALS

- A. Urease tests—choose from the following or use other commercially available sensitive test for urease detection (8).
 1. Pyloritek urease test (Bard, Inc., Billerica, Mass.)
 2. Rapid selective urea agar (Hardy Diagnostics; Remel, Inc.) (procedure 3.17.48)
 3. CLO test (Ballard Medical Products, Draper, Utah)
 4. HPFAST (GI Supply, Camp Hill, Pa.)
 5. 0.5 ml of Christensen's urea solution without agar (procedure 3.17.48)
- B. Optional: Premier Platinum HpSA direct antigen test (Meridian Diagnostics, Cincinnati, Ohio). See Appendix 3.8.4–1.
- C. Media for culture—for best results, choose one selective and one nonselective medium.
 1. Nonselective media: BAP, BHI with 7% horse blood, brucella agar, or CHOC
 2. Selective media: Modified Thayer-Martin medium, Campy-CVA, or Columbia agar with 10% egg yolk emulsion, 1% Vitox, and 40 mg of 2,3,5-triphenyltetrazolium chloride per liter with cefsulodin, trimethoprim, vancomycin, and amphotericin B (CEYE)

☑ **NOTE:** CHOC and CEYE were reported in one study to provide the best combination (11).
- D. Gram stain reagents
- E. Other supplies
 1. Microaerobic environment (see Table 3.8.2–3 in procedure 3.8.2)
 2. Catalase (procedure 3.17.10) and oxidase (procedure 3.17.39) reagents

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
- B. Check plate media for ability to support growth of *H. pylori* ATCC 43504.

IV. QUALITY CONTROL (continued)

C. Urea direct tests

1. Examine each lot visually to determine that no reaction has occurred and that the test is yellow or straw colored.
2. Prior to each use, make sure there are no signs of contamination or deterioration, (shrinking, cracking, or discoloration) and that the tube is yellow. Discard any defective tubes and obtain a new one.
3. Check each lot prior to putting it into use with a positively and negatively reacting organism.

Test organism	Result
<i>Proteus mirabilis</i> ATCC 12453	Positive; color change from the original yellow to pink-red, slower reaction time than <i>H. pylori</i>
<i>Escherichia coli</i> ATCC 25922	Negative; no color change observed

4. For proficiency, QC, and validation of direct urease test, obtain urease tablets (Kimberly Clark, Draper, Utah). As a positive patient control, insert the tablet into a negative test, as you would a biopsy sample. After 5 min, inspect for a positive color change. If the test remains negative, take corrective action.

V. PROCEDURE

Observe standard precautions.

A. Inoculation

1. Gently homogenize the tissue (refer to procedure 3.13.1 for details on grinding).
 - ☑ **NOTE:** This method of processing results in heavier yields of organisms compared to either mincing the specimen or direct plating of the specimen.
2. Place several pieces of biopsy material into one of the urea test media and incubate at 35°C under aerobic conditions.
3. Inoculate plate media and incubate under microaerobic conditions at 35°C. When using an airtight jar, add a moistened gauze pad in the bottom.
4. Inoculate additional CHOC plate at 35°C under aerobic conditions in 5% CO₂.

B. Direct tests

1. Examine the urea test for a pink to magenta color change at 30 min, 4 h, and 24 h, depending on the manufacturer's instructions for incubation and reading.
2. Gram stain and examine for gull wing-shaped, gram-negative rods.

C. Culture methods (also see *Campylobacter* procedure [3.8.2])

1. Incubate plates at 35 to 37°C for 3 to 5 days. Some strains require as long as 7 days for growth on primary isolation.
2. Examination of culture media
 - a. Colonies of *H. pylori* appear as small, gray, and translucent. Some strains demonstrate weak beta-hemolysis with growth on the microaerobic plates but *not* on the aerobically incubated plate.
 - b. Gram stain suspicious colonies. *H. pylori* organisms from solid media appear as slightly curved gram-negative rods.
 - c. Perform oxidase, catalase, and urea tests from colonies. *H. pylori* is positive in all three tests.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. Report direct results.
 - 1. Report results of urea test as “positive” if any pink to magenta color is observed or “negative” if there is no color change in 24 h.
 - 2. Report results of stool direct antigen test as “positive” or “negative for *Helicobacter pylori* antigen” per criteria in package insert.
 - 3. If the direct urease is positive (pink) and “gull wings” are seen on Gram stain, a preliminary culture report can be sent as “Probable *Helicobacter pylori* present.”
- B. Report culture as “*Helicobacter pylori*” if the following are true.
 - 1. The colony Gram stain demonstrates curved, gram-negative rods.
 - 2. Oxidase and catalase reactions are positive.
 - 3. Urease reaction is positive (usually within several minutes).
- C. Refer to procedure 3.3 for general criteria for reporting.

VII. INTERPRETATION

- A. The presence of a urease-positive curved rod in a gastric specimen is indicative of the presence of *H. pylori*, although there are reports of other urea-positive curved rods in gastric specimens (13).
- B. The presence of *H. pylori* indicates the need for aggressive treatment of the infection to eradicate the organism.
- C. There are a number of current protocols for therapy of *H. pylori*. In general, they consist of agents to decrease acidity to allow healing and multiple antimicrobial agents to eradicate the organism. Common regimens include amoxicillin, clarithromycin, and omeprazole (triple therapy) and bismuth, tetracycline, metronidazole and a proton pump inhibitor (quadruple therapy) (9). In addition, pharmaceutical companies have packaged antihelicobacter therapy in convenient dosing formats that include “PrevPak” and “Helidac.” In >90% of treated patients, there is healing of the gastric inflammation, prevention and healing of peptic ulcers, and loss of the symptoms of gastritis (1, 4).
- D. Perform antimicrobial susceptibility testing in cases of treatment failures.

VIII. LIMITATIONS

- A. No one test has 100% sensitivity in detecting *H. pylori*, and several tests, including serologic assays and tests described in this procedure, may be necessary.
- B. False-negative urease tests may occur when very low numbers of *H. pylori* organisms are present in the stomach or when the bacterium has a patchy distribution. Testing multiple biopsy samples will increase the likelihood of a positive test result.
- C. The urease test and culture are less sensitive if the patient has recently taken antimicrobial agents or bismuth. Suppression of *H. pylori* by these agents makes the organism difficult to detect by any means. Regrowth of *H. pylori* may be patchy in the first 3 weeks after treatment.
- D. After treatment, the stool antigen test and the urea breath test are the most accurate to monitor therapy and cure.
- E. Since there are now a number of urease-positive spiral organisms, the preliminary testing described in this procedure cannot be considered definitive without further molecular testing (1, 13).

APPENDIX 3.8.4–1

Helicobacter pylori Antigen Assay (HpSA)

- I. PRINCIPLE

A microplate EIA is commercially available for the qualitative detection of *Helicobacter pylori* antigens in human stool (HpSA) by a noninvasive method (1). The test can identify current infections and can be used to confirm the eradication of the microorganism after the end of the therapy. Unlike serologic tests (procedure 11.9), which are unable to differentiate between current and past infections, the HpSA test detects current infection only. The HpSA EIA is a standard microtiter well assay using polyclonal antibodies.
- II. SPECIMENS

Collect a stool specimen in an empty container.

 - A. Store for up to 3 days at 2 to 8°C before testing.
 - B. If testing cannot be performed within this time frame, store specimens frozen upon receipt at –20 to –80°C.
- III. MATERIALS

Premier Platinum HpSA, catalog no. 601348—48 tests (Meridian Diagnostics, Cincinnati, Ohio).

The kit contains antibody-coated microwells, a positive control and negative control, sample diluent, wash buffer, enzyme conjugate, substrate, stop solution, transfer pipettes, strip holder, strip sealer, and wooden stick applicators. Store kit at 2 to 8°C.
- IV. QUALITY CONTROL

Test the positive and negative controls upon receipt of new lots and each time patient testing is performed.
- V. PROCEDURE
 - A. Emulsify 5- to 6-mm-diameter portion of stool into 200 µl of sample diluent in a test tube.
 - B. Transfer 50 µl of diluted stools and controls in the appropriate wells in the microtiter plate.

APPENDIX 3.8.4-1 (continued)

- C. Add 1 drop of enzyme conjugate to each well, seal, and incubate at room temperature for 1 h.
 - D. Wash five times with the wash buffer.
 - E. Add 2 drops of substrate to all wells and incubate at room temperature for 10 min.
 - F. Add 1 drop of stop solution and read at dual wavelength (450 and 630 nm).
- VI. INTERPRETATION
- Cutoff values (absorbance at 450 nm) for HpSA test are ≥ 0.160 for positive results, 0.159 to 0.140 for indeterminate results, and < 0.140 for negative results.
- VII. LIMITATIONS
- A. At present no single test can be relied upon to detect definitely colonization by *H. pylori*, and a combination of two is recommended if this is feasible.
 - B. In a large prospective evaluation comparing the HpSA test to invasive tests, the sensitivity and the specificity of the HpSA were 94 and 92%, respectively, compared to biopsy-based tests (3).
 - C. In an evaluation of eradication (4) on day 35 after antimicrobial therapy, the urea breath test had a sensitivity of 94% and a specificity of 100%. The stool antigen test had a sensitivity of 94% and a specificity of 97%. On day 7 after treatment, the stool antigen test was predictive of eradication (positive predictive value, 100%; negative predictive value, 91%).
 - D. The test has been shown to be accurate for pediatrics patients, for whom serology tests are less sensitive (2).

3.8.5

Screen for Vancomycin-Resistant Enterococci in Fecal Cultures

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Since the first report of enterococci resistant to high concentrations of glycopeptide antimicrobial agents in 1988, a sudden and widespread increase in the incidence of infection and colonization with vancomycin-resistant enterococci (VRE) has occurred over the last two decades (5). Specific classes of antimicrobial agents appear to be responsible for the spread, including extended-spectrum cephalosporins and drugs with activity against anaerobic bacteria. The use of vancomycin to treat *Clostridium difficile* colitis has also been implicated (5). Transmission of VRE can be through patient-to-patient contact, health care workers, and contaminated environmental surfaces and patient care equipment. Control methods include routine screening for vancomycin resistance among clinical isolates, active surveillance for VRE in intensive care units, contact isolation to minimize person-to-person transmission, rigorous decontamination of patient contact areas, and restriction of the use of vancomycin and other antimicrobial agents (1, 2). Patients who are colonized with VRE should be identified so that special precautions can be instituted. Screening for VRE may facilitate removal of patients from isolation if they are no longer colonized with a VRE previously isolated. This procedure describes a method to screen for fecal carriage of VRE.

Various types of vancomycin resistance have been genotypically characterized, including *vanA*, *vanB*, *vanC*, *vanD*, and *vanE*. *vanA* and *vanD* are most often seen in *Enterococcus faecium*. *vanB* and *vanE* are mostly seen in *Enterococcus faecalis*. The mechanism of resistance of *vanA* and *vanB* is a plasmid-mediated transposon capable of altering the dipeptide terminus of peptidoglycan from a D-alanyl-D-alanine to the depsipeptide D-alanyl-D-lactate, which then binds vancomycin with a very low affinity. The MICs of vancomycin for enterococci with the *vanA* or *vanB* genotype are typically greater than 32 µg/ml. It is these genotypes that have been associated with spread of resistance within hospitals and nursing homes. Phenotypically, the definition of VRE includes those *E. faecalis*, *E. faecium*, and *Enterococcus raffinosus* organisms that are resistant to vancomycin with MICs usually ≥ 32 µg/ml (7). It does not include motile enterococci, *Enterococcus gallinarum*, and *Enterococcus casseliflavus*, which have intrinsic low-level vancomycin resistance mediated by *vanC*. These species do not account for the spread of vancomycin resistance and are generally susceptible to other agents, such as ampicillin and aminoglycosides. Al-

though most commercially available identification systems adequately differentiate *E. faecalis* from other species of enterococci, additional tests, including motility, are required to distinguish the motile enterococci, *E. gallinarum*, and *E. casseliflavus* from *E. faecium* and *E. raffinosus* (2). Such identification to the species level is necessary to limit the reporting of VRE to only those strains that are of epidemiologic concern.

Screening for fecal carriage of VRE is accomplished by fecal culture on the selective and differential medium bile-esculin-azide (BEA) broth and agar with vancomycin. Esculin is included to detect esculin-hydrolyzing enterococci, ferric citrate to provide ferric ions, bile salts to inhibit gram-positive bacteria other than enterococci, and sodium azide to inhibit gram-negative bacteria. Esculin forms glucose and esculetin when hydrolyzed by enterococci. Esculetin reacts with the ferric ions to produce dark brown to black color development in the medium, allowing recognition of the enterococci (3). The vancomycin concentration ranges from 6 to 10 µg/ml depending on the manufacturer; sensitivity and specificity will vary with the concentration used (6). Also see procedures 5.6 and 13.17.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. Collect fecal specimen and submit immediately or place in VRE broth.
 NOTE: The yield from feces has been shown to be greater than that from perirectal swabs (4).
2. Swabs of wounds or urine may also be submitted.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- B. Generally submit three specimens from different days to rule out the presence of VRE in a patient who was previously positive.
- C. Rejection criterion
Reject specimens if VRE were isolated from the patient in other cultures collected in the previous 2 weeks.

III. MATERIALS

- A. **Media**
 - 1. Agar
 - a. BEA agar with 6 µg of vancomycin per ml (Remel, Inc.) *or*
 - b. BEA agar with 10 µg of vancomycin per ml (Hardy Diagnostics) *or*
 - c. Vancomycin-supplemented Enterococcosel agar (BD Diagnostic Systems) with either 6 or 8 µg of vancomycin per ml
 - ☑ **NOTE:** With 10 µg of vancomycin per ml, BEA agar with vancomycin is less likely to support the growth of *E. casseliflavus* and *E. gallinarum*, owing to their low-level resistance. True VRE may be inhibited as well.
 - 2. VRE broth containing BEA broth with vancomycin
 - ☑ **NOTE:** Use of both broths in conjunction with agar culture has been shown to increase the detection of VRE by 50% but also increases the yield of motile enterococci (4).
 - 3. BAP
 - 4. Store media at 2 to 8°C. Allow media to come to room temperature before use.
- B. **Gram stain reagents**
- C. **Other reagents**
 - 1. Pyrrolidonyl-β-naphthylamide (PYR) (procedure 3.17.41)
 - 2. Catalase (procedure 3.17.10)
 - 3. 0.5 ml of BHI broth for motility (procedure 3.17.31)
 - 4. Methyl glucopyranoside MGP broth (procedure 3.17.30) (optional)

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further QC procedures, especially for in-house-prepared media.
- B. BEA broth or agar with vancomycin should appear clear and light amber.
- C. Subculture the following QC strains to VRE broth and agar containing vancomycin prior to use, and incubate at 35°C aerobically for 18 to 24 h. Verify that they produce the desired reactions listed. Repeat QC of agar containing vancomycin at weekly intervals with both enterococcal species (7).

Test organism	Result
<i>Enterococcus faecalis</i> ATCC 51299	Growth with blackening in medium surrounding colony or blackening and turbidity of broth
<i>Enterococcus faecalis</i> ATCC 29212	Inhibition (clear broth or no growth on agar)
<i>Escherichia coli</i> ATCC 25922	Inhibition (clear broth or no growth on agar)

V. PROCEDURE

Observe standard precautions.

- A. Inoculation
 1. Process specimen not in VRE broth as soon as received.
 - ☑ **NOTE:** Use of biosafety cabinet will avoid contamination of the culture or specimen as well as protect laboratory processing personnel.
 2. Inoculate first quadrant of vancomycin-containing BEA agar heavily with stool or swab; with a loop, streak in three other quadrants, as illustrated in Figure 3.3.1–1.
 3. Inoculate VRE broth with a small amount of fecal specimen.
- B. Incubate plate and broth at 35°C aerobically for up to 72 h.
- C. Check agar plates daily.
 1. If brown-black color is diffused in medium, then consider it to be bile-esculin positive. Using a stereoscope, check for different morphotypes. With a plate marker, number the colonies, and Gram stain each.
 2. Subculture only gram-positive cocci to BAP.
 3. Incubate subculture at 35°C for 24 h.
- D. Subculture turbid broth, if black, to vancomycin-containing BEA agar. Incubate for 24 h and subculture black colonies to BAP if they are gram-positive cocci on Gram stain.
- E. Perform catalase and PYR tests on suspected colonies from BAP. Because of exposure to vancomycin, the PYR test might be negative; it should turn positive on a second subculture.
- F. Lightly inoculate each different morphology of catalase-negative, PYR-positive, gram-positive cocci to 0.5 ml of BHI and incubate at 30°C for 2 h. Observe microscopically at ×400 for motile cocci.
 1. Nonmotile organisms are considered to be VRE.
 2. Optionally, inoculate MGP broth. VRE do *not* produce a yellow color.
 3. Further species identification and antimicrobial susceptibility testing (AST) are necessary only if patient has not had a prior positive result (*see* Table 3.18.1–3).
 4. Notify caregiver of positive culture findings.
 5. Hold positive culture plates for at least 7 days.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. If no VRE are present, report “No vancomycin-resistant *Enterococcus* organisms isolated.”
- B. If culture is positive for VRE, report “Vancomycin-resistant *Enterococcus* present.”
- C. Document notification to caregiver of positive findings.

VII. INTERPRETATION

- A. The presence of VRE in fecal specimens is an indication of carriage or colonization with the organism but does not indicate infection, since enterococci are a part of the normal intestinal microbiota.
- B. It is recommended that VRE be confirmed by an NCCLS MIC method (7) if the patient has not previously been positive for VRE.

VIII. LIMITATIONS

- A. Organisms other than enterococci (*Pediococcus*, *Leuconostoc*, and *Weissella*) may grow on these media and produce a positive reaction for esculin. These genera are PYR negative.
- B. False-negative results can be caused by low numbers of organisms or prior antimicrobial treatment.

3.9.1

Guidelines for Performance of Genital Cultures

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Specimens from genital sites are sent to the clinical microbiology laboratory for detection of microorganisms from females presenting with clinical syndromes such as cervicitis, vulvovaginitis, urethritis, bacterial vaginosis (BV), salpingitis (pelvic inflammatory disease [PID]), endometritis, or genital ulcers and from males exhibiting urethritis, epididymitis, prostatitis, or genital ulcers (Tables 3.9.1–1 and 3.9.1–2) (3). Specimens are also submitted from pregnant females to diagnose the presence of organisms that may cause disease in the neonate. Less commonly, specimens are sent from children and postmenopausal women (10, 11, 15, 18, 19).

The syndromes that are associated with female and male genital tract infections are listed in Tables 3.9.1–1 and 3.9.1–2, respectively, with the major pathogens for each syndrome indicated. For surgically collected specimens and those from normally sterile sites, a routine wound and abscess culture will detect most bacterial pathogens, as long as selective media for *Neisseria gonorrhoeae* are included. Anaerobic cultures are often indicated for these specimens (8), and mycoplasma cultures may be appropriate in selected cases (procedure 3.15).

The human vagina is lined with 25 layers of epithelium cells. Many indigenous microorganisms colonize these surfaces. Accurate diagnosis of genital infections from the male and female genitalia depends on the separation of microbial pathogens from the normal genital microbiota. The microorganisms colonizing the female genital tract have been studied extensively and include lactobacilli, *Corynebacterium* spp., *Gardnerella vaginalis*,

coagulase-negative staphylococci, *Staphylococcus aureus*, *Streptococcus agalactiae*, *Enterococcus* spp., *Escherichia coli*, anaerobes, and yeasts (12). For prepubescent females, diphtheroids and coagulase-negative staphylococci predominate; lactobacilli predominate in the adult female. Postmenopausal women are generally colonized with fewer lactobacilli but have a greater number of *Enterobacteriaceae* than premenopausal women. They also lack the presence of yeasts and mycoplasmas. Many adult female genital tract infections arise from endogenous microorganisms, the pathogenicity of which has been activated by host factors and other microorganisms. Various viruses, including herpes simplex virus (HSV), human papillomavirus (HPV), and human immunodeficiency virus, may also influence the receptivity of the host surface to microorganisms. The male urethra normally contains relatively few skin microbiota, consisting of coagulase-negative staphylococci, micrococci, *Corynebacterium* spp., and viridans group streptococci.

Because the agents of disease have diverse culture and detection requirements and selective media are often needed, a “routine” genital culture, with the intent to “detect what is there,” rarely has an indication. Occasionally such specimens are appropriate for prepubescent or postmenopausal women. Otherwise, laboratories should provide a special requisition, such as in Appendix 3.9.1–1, to be used to request the appropriate tests in the outpatient setting. For certain pathogens, such as *N. gonorrhoeae*, *Haemophilus ducreyi*, or *S. agalactiae* (group B streptococcus [GBS]), cultures are ordered specifically

for those pathogens, with proper collection and selection media. Because of the special nature of cultures for these pathogens, procedures to detect them are listed separately in this handbook following this procedure.

To diagnose vulvovaginitis and BV, routine bacterial cultures are *not* helpful (1, 20). In Table 3.9.1–3, the recommended tests are indicated to make these diagnoses. The Gram stain is useful to diagnose BV using the Nugent scoring system (14) (Appendix 3.2.1–3). A wet mount along with a yeast culture and *Trichomonas* culture (*see* procedure 9.9.4) are the recommended tests to diagnose vaginitis. It should be noted that by performing only a wet mount, without yeast or *Trichomonas* culture, 50% of either of these agents of vaginitis will be missed (3). Alternatively, a sensitive DNA probe assay is available that combines the detection of yeasts, *Trichomonas*, and *G. vaginalis* as a marker for BV (4).

For primary syphilis, a dark-field exam is useful but is rarely performed (Appendix 3.2.3–1). *Calymmatobacterium granulomatis* is detected by demonstration of Donovan bodies (intracytoplasmic cysts of enlarged mononuclear cells containing 10 or more deeply staining pleomorphic rods). These bodies are usually stained either by the Giemsa method or by silver stains of formalin-fixed biopsy material. (*See* procedure 9.8.5 for details of Giemsa stain preparation.) *Chlamydia* and herpes viral cultures are also important diagnostic tools in the evaluation of sexually transmitted diseases.

For the recognition of toxic shock syndrome (TSS), isolation of *S. aureus* is dif-

Table 3.9.1–1 Female genital infectious disease syndromes and associated microbial pathogens

Syndrome	Specimen(s)	Microbial pathogens ^a
Amnionitis	Amniotic fluid	<i>Capnocytophaga</i> spp. <i>Escherichia coli</i> <i>Gardnerella vaginalis</i> ^b <i>Haemophilus influenzae</i> <i>Haemophilus parainfluenzae</i> <i>Listeria monocytogenes</i> <i>Neisseria gonorrhoeae</i> <i>Pasteurella bettyae</i> * <i>Streptococcus agalactiae</i> <i>Streptococcus pyogenes</i>
Bartholinitis	Aspirate of Bartholin glands	Anaerobes <i>Chlamydia trachomatis</i> * <i>Escherichia coli</i> <i>Pasteurella bettyae</i> <i>Haemophilus influenzae</i> * <i>Neisseria gonorrhoeae</i> * <i>Proteus mirabilis</i> <i>Staphylococcus aureus</i> Streptococci * <i>Ureaplasma urealyticum</i>
Cervicitis	Swab of endocervical canal	<i>Capnocytophaga</i> spp. * <i>Chlamydia trachomatis</i> <i>Pasteurella bettyae</i> *HSV <i>Mycobacterium tuberculosis</i> * <i>Neisseria gonorrhoeae</i> <i>Streptococcus agalactiae</i>
Chancroid or genital ulcers	Ulcer scrapings Lymph node aspirate	* <i>Haemophilus ducreyi</i> <i>Calymmatobacterium granulomatis</i> <i>Treponema pallidum</i> HPV HSV
Endometritis	Transvaginal aspirate of endometrium	Actinomycetes ^c * <i>Bacteroides</i> spp. * <i>Chlamydia trachomatis</i> <i>Enterococcus</i> spp. <i>Escherichia coli</i> <i>Gardnerella vaginalis</i> <i>Haemophilus influenzae</i> <i>Klebsiella</i> spp. <i>Listeria monocytogenes</i> <i>Prevotella bivia</i> <i>Streptococcus agalactiae</i> <i>Streptococcus pyogenes</i>
Postpartum endomyometritis	Transvaginal aspirate of endometrium	<i>Bacteroides fragilis</i> * <i>Bacteroides bivius</i> * <i>Bacteroides disiens</i> * <i>Enterococcus</i> spp. * <i>Escherichia coli</i> * <i>Klebsiella</i> spp. Anaerobic cocci * <i>Streptococcus agalactiae</i>

(continued)

Table 3.9.1–1 Female genital infectious disease syndromes and associated microbial pathogens (*continued*)

Syndrome	Specimen(s)	Microbial pathogens ^a
Salpingitis (PID)	Culdocentesis Laparoscopy sample of fallopian tubes and peritoneal cavity	Actinomycetes ^c * <i>Bacteroides</i> spp. * <i>Chlamydia trachomatis</i> <i>Enterococcus</i> spp. <i>Escherichia coli</i> <i>Haemophilus influenzae</i> * <i>Neisseria gonorrhoeae</i> <i>Pasteurella bettyae</i> <i>Prevotella bivia</i> <i>Staphylococcus aureus</i> <i>Staphylococcus epidermidis</i> <i>Streptococcus agalactiae</i> Streptococci ^c
Skenitis	Aspirate of Skene's gland	* <i>Neisseria gonorrhoeae</i>
Urethritis, urethral syndrome	Urethral exudate	* <i>Chlamydia trachomatis</i> * <i>Escherichia coli</i> * <i>Neisseria gonorrhoeae</i>
Vaginosis	Vaginal exudate	<i>Gardnerella vaginalis</i> <i>Prevotella</i> spp. <i>Mobiluncus</i> Anaerobic cocci <i>Mycoplasma hominis</i>
Vulvovaginitis	Vulval swab; aspirate or biopsy sample of lesion Vaginal exudate	<i>Capnocytophaga</i> spp. * <i>Candida</i> spp. <i>Chlamydia trachomatis</i> <i>Enterobacteriaceae</i> HSV <i>Mycobacterium tuberculosis</i> <i>Neisseria gonorrhoeae</i> <i>Pasteurella bettyae</i> <i>Salmonella</i> spp. <i>Shigella</i> spp. <i>Staphylococcus aureus</i> ^d <i>Streptococcus pyogenes</i> * <i>Trichomonas vaginalis</i>

^a Major pathogens are marked with an asterisk.

^b Found in 50 to 80% of asymptomatic females.

^c Associated with use of intrauterine device.

^d In wounds, toxic shock syndrome, and tampon-associated ulcerations.

ficult and not sufficient for the diagnosis. Further characterization of the strain is necessary to confirm the diagnosis. Two commercial kits are available for testing, which is usually done in reference laboratories (Toxic Shock ELISA [Toxin

Technologies, Inc., Madison, Wis.] and TST-RPLA reverse passive latex agglutination [Oxoid, Columbia, Md.]). Alternatively, testing acute- and convalescent-phase sera for antibodies to the exotoxin (TSST-1) in a reference laboratory can be

helpful. Most patients with TSS lack antibodies at the onset of infection but then produce them in response to the infection. Greater than 90% of women have antibodies to the exotoxin.

Table 3.9.1–2 Male genital infectious disease syndromes and associated microbial pathogens

Syndrome	Specimen	Microbial pathogens ^a
Epididymitis	Swab or fluid from epididymus	* <i>Chlamydia trachomatis</i> <i>Enterobacteriaceae</i> ^b <i>Mycobacterium tuberculosis</i> * <i>Neisseria gonorrhoeae</i> <i>Pseudomonas</i> spp. ^b
Orchitis	Swab or fluid from testicles	* <i>Escherichia coli</i> * <i>Klebsiella pneumoniae</i> * <i>Pseudomonas aeruginosa</i> Staphylococci Streptococci
Prostatic abscess	Abscess fluid or aspirate	* <i>Staphylococcus aureus</i>
Prostatitis	Swab or prostatic fluid through urethra	* <i>Escherichia coli</i> * <i>Enterobacteriaceae</i> <i>Enterococcus</i> spp. <i>Neisseria gonorrhoeae</i> * <i>Pseudomonas</i> spp.
Urethritis	Swab or exudate from urethra	* <i>Chlamydia trachomatis</i> <i>Haemophilus influenzae</i> <i>Haemophilus parainfluenzae</i> * <i>Neisseria gonorrhoeae</i> <i>Pasteurella bettyae</i> <i>Ureaplasma urealyticum</i>

^a Major pathogens are marked with an asterisk.

^b Most commonly seen in men over 35 years of age.

Table 3.9.1–3 Diagnostic characteristics for vaginitis and vaginosis^a

Disease or condition	pH	Observation on wet mount	Amine odor ^b	Other test for diagnosis ^c
None (normal)	4–4.5	Long rod form bacteria	Absent	
Atrophic	>6		Absent	
Candidiasis	4–4.5	Pseudohyphae or budding yeasts	Absent	Yeast culture
BV	>4.5	Clue cells	Present	Gram stain
Trichomoniasis	5–6	Flagellated parasites ^d	Usually present	Trichomonas culture

^a Data for table extrapolated from Sobel (20).

^b A drop of 10% KOH is added to vaginal fluid and sniffed for release of fishy or amine odor.

^c These tests are *recommended* for increased sensitivity and might be offered as a panel by laboratory.

^d Caution: occasional contaminants from the environment, such as *Colpoda*, while ameboid in motion, may be seen.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

☑ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for physicians and other caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection. In many cases the procedures to collect the specimens listed below should be performed by qualified physicians with appropriate training.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

Observe standard precautions.

- A. Specimen collection** (see Appendix 3.9.1–1 and Table 3.9.1–3 for options for outpatient testing)
- 1. Female specimens**
 - a. Amniotic fluid**
 - (1) Aspirate fluid by catheter at cesarean section or at amniocentesis.
 - (2) Order body fluid culture (procedure 3.5).
 - b. Bartholin cyst**
 - (1) Decontaminate the skin with povidone-iodine, 3% chloroxylenol, and 3% cocamidopropyl PG-dimonium chloride phosphate (Techni-Care, Care-Tech, St. Louis, Mo.) or other surgical disinfectant, and aspirate material from the duct(s).

☑ **NOTE:** Bartholin glands are small mucus-secreting glands located beneath the posterior portion of the labia majora.
 - (2) Order aerobic and anaerobic wound and abscess cultures (procedure 3.13.1).
 - c. Cervical**
 - (1) Clear away vaginal mucus and exudate with large swab. Moisten speculum with warm water, not lubricants, which can be antibacterial. Using a small swab (not cotton or wood shaft) inserted through a speculum, sample endocervical canal. Avoid the vaginal walls during collection.
 - (2) See Appendix 3.9.1–1 and Table 3.9.1–3 for ordering options.
 - d. Culdocentesis**
 - (1) After cleaning the vaginal wall with surgical disinfectant, such as povidone-iodine or 3% chloroxylenol and 3% cocamidopropyl PG-dimonium chloride phosphate, perform transvaginal puncture of the cul-de-sac to aspirate fluid.

☑ **NOTE:** The cul-de-sac is the pouch between the anterior wall of the rectum and the posterior wall of the uterus. Collection is often done to diagnose PID without more invasive laparoscopy; however, results may not correlate with more invasive testing.
 - (2) Order aerobic and anaerobic wound and abscess cultures.
 - e. Endometrium**
 - (1) Insert endometrial suction curette or catheter-protected Dacron swab through the cervical os and transfer beyond the cervical opening into the uterine cavity. Collect sample from within the cavity.
 - (2) Order aerobic and anaerobic wound and abscess cultures (8).
 - f. Fallopian tubes and pelvic cavity**
 - (1) Collection: obtain aspirates and biopsy samples during laparoscopy. Also sample the pelvic peritoneum. Biopsies often yield better diagnostic specimens.
 - (2) Order aerobic and anaerobic wound and abscess cultures (8).
 - g. Skene's glands**
 - (1) Decontaminate the skin with surgical disinfectant, and aspirate material from the gland(s).

☑ **NOTE:** Skene's glands are paraurethral glands located at both sides of the outer end of the urethra.
 - (2) Order *N. gonorrhoeae* culture.
 - h. Vagina**
 - (1) Collect fluid from the vagina with sterile pipette or Dacron swab. Successful self-collection of vaginal swabs can be done (16).
 - (2) See Appendix 3.9.1–1 and Table 3.9.1–3 for ordering options.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

i. Vulva

- (1) Collect only if pain, erythema, or edema is present.
- (2) Clean the surface of the lesion with 0.85% NaCl and collect by one of the methods below.
 - (a) Sample exudate or area of erythema with swab for yeast culture.
 - (b) If there is a vesicle present, collect for HSV culture.
 - i. Unroof vesicle.
 - ii. Collect fluid with a sterile swab *or*
 - iii. Aspirate vesicular fluid with a 26- to 27-gauge needle and syringe.
 - iv. Then scrape the base of the vesicle with a sterile scalpel blade, and collect specimen with a Dacron swab by vigorously rubbing the base of the vesicle.
 - (c) If there is a crust on the lesion, gently remove it.
 - i. Moisten swab with saline and collect specimen by vigorously rubbing the base of the lesion for *H. ducreyi* culture.
 - ii. Alternatively, gently abrade the lesion with a sterile scalpel or needle until serous fluid emerges. (Try to avoid bleeding.) Irrigate with saline.
 - (i) For *H. ducreyi* culture, rub the base vigorously with a sterile swab or aspirate fluid with flamed smoothed Pasteur pipette or needle and syringe.
 - (ii) For *Treponema pallidum*, wipe away fluid, blood, and debris with sterile gauze. Apply gentle pressure to the base of the lesion until clear fluid is expressed. Touch a slide to the fluid, and cover the fluid on the slide with a coverslip. If no exudate is present, add a drop of saline to the lesion or insert a needle and syringe at the lesion base, aspirate, and then draw a drop of saline into the needle. Express the material onto a slide (*see* Appendix 3.2.3-1).
- (3) Order *T. pallidum* dark-field microscopy, *H. ducreyi* culture, or HSV culture or request yeast culture for most cases showing only erythema or edema.

2. Male specimens

a. Epididymis or testicular fluid

- **NOTE:** The specimen of choice for diagnosis of infected epididymis is urethral culture. If that does not yield a diagnosis, collect first-voided and midstream urine, and compare the yield from smear and culture of each specimen. Collect testicular fluid only if the diagnosis cannot be made otherwise.
- (1) Disinfect skin surface with surgical disinfectant. Use a needle and syringe to aspirate material from the epididymis or testicles.
 - (2) Choose from the following tests.
 - (a) Routine aerobic wound and abscess culture for bacteria, most commonly members of the family *Enterobacteriaceae* or pseudomonads and generally encountered in men over 35 years of age.
 - (b) *Mycobacterium tuberculosis*, generally occurring after involvement of the prostate or seminal vesicles.
 - (c) *Chlamydia trachomatis* and *N. gonorrhoeae* culture or probe test.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- c. Urethral discharge
 - (1) Express exudate onto swab from distal urethra.
 - (2) If there is no exudate, collect 1 h after urination. Wipe area clean, insert a urethrogenital swab 2 to 4 cm into the endourethra, gently rotate the swab, leave it in place for 1 to 2 s, and withdraw it.
 - (3) Order *N. gonorrhoeae* and *Chlamydia* culture or probe.
 4. Abscess material (e.g., bubo, lymph node, etc.)
 - a. Disinfect skin with surgical disinfectant.
 - b. Aspirate the lesion with needle and syringe (refer to Specimen Collection, Transport, and Handling in procedure 3.13.1 for other details).
 - c. Order Gram stain, aerobic and anaerobic wound and abscess cultures, and, if indicated from a lymph node, *Chlamydia* or *H. ducreyi* culture.
- B. Specimen transport**
1. Transport medium
 - a. For transport for specific organisms, refer to the separate procedures. Otherwise, submit swab in Amies transport tube.
 - b. Place immediately on ice or in the refrigerator until and during transport.
 - ☑ **NOTE:** Previous literature indicates that *N. gonorrhoeae* does not survive well at refrigeration temperatures, but recent studies indicate otherwise (see procedure 3.9.3).
 2. Label specimens and accompanying requisition with patient name, hospital medical record number, room number or clinic location, other patient demographics, and date, time, and site of collection.
 3. Indicate the pathogens sought on requisition or computer entry. Do not order “routine culture” from sexually active patients. These are rarely indicated and are performed mostly from prepubescent or postmenopausal females.
- C. Rejection criteria**
1. Do not accept vaginal swabs from women in childbearing years for “routine genital culture.” Using a form similar to that in Appendix 3.9.1–1, require that the disease or agent sought be ordered specifically.
 2. Reject specimens not received in transport medium, since the agents of genital infections lose viability easily.

III. MATERIALS

- A. Media**
1. CHOC
 2. Thayer-Martin (TM) or similar selective medium for *N. gonorrhoeae*
 3. BAP
 4. MAC or EMB
 5. Columbia colistin-nalidixic acid agar (CNA)
 6. Selective medium for yeasts (by separate request only).
 - ☑ **NOTE:** For invasively collected specimens, refer to other procedures in this handbook for culture, including anaerobic cultures.
- B. Identification methods**
1. Gram stain (procedure 3.2.1)
 2. Catalase test (procedure 3.17.10)
 3. Oxidase test (procedure 3.17.39)
 4. Indole test (procedure 3.17.23)
 5. Aminolevulinic acid (ALA) test (procedure 3.17.3)
 6. Pyrrolidonyl- β -naphthylamide (PYR) (procedure 3.17.41)
 7. Sodium polyanethol sulfonate (SPS) disks (procedure 3.17.45)
 8. Identification kits for gram-negative bacteria
 9. Other tests as indicated in procedures 3.3.2, 3.18.1, and 3.18.2
- C. Other supplies**
1. Incubator at 35°C, with 5% CO₂ or ambient air
 2. Self-contained CO₂-generating system for culture incubation if incubator is ambient air

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
- B. See procedures 3.3.1 and 3.9.3 for additional QC of CHOC and TM, respectively.

V. PROCEDURE

Observe standard precautions.

- A. Inoculation
 - NOTE:** Use of a biosafety cabinet will avoid contamination of cultures as well as protect laboratory processing personnel.
 - 1. If the specimen is not received on plates, inoculate plates from the swab in transport medium.
 - 2. See Appendix 3.9.1–1 for tests for reference to specific organism procedures. For specimens from wounds, abscesses, and normally sterile sites, refer to the wound and abscess procedure (3.13.1) or body fluid culture procedure (3.5).
 - 3. For cervical, vaginal, or other noninvasive genital source specimens submitted for unusual culture requests, inoculate the first five media listed above.
- B. Direct smear
 1. Prepare a Gram stain from the swab after plate inoculation.
 2. Stain slide (procedure 3.2.1) and, for women in childbearing years, observe for evidence of BV from vaginal specimens (Appendix 3.2.1–3), for yeasts, and for evidence of other bacteria associated with WBCs.
- C. Incubation
 1. Incubate plates at 35°C in 5% CO₂, or use other CO₂-generating system to provide the proper atmosphere and moisture.
 2. Observe for growth after 18 to 24 h of incubation. Hold negative plates for up to 72 h.
- D. Culture examination
 1. Observe plates after 24 h for growth of abnormal microbiota.
 2. Correlate growth with Gram stain result to determine the extent of workup.
 3. Identify the following pathogens if present, using identification kits or methods described in Table 3.3.2–5.
 - a. Examine non-lactose-fermenting, gram-negative rods for *Shigella* spp. or other enteric pathogens, especially from pediatric patients (13).
 - NOTE:** Do not examine cervical or vaginal specimens for other *Enterobacteriaceae*, as these microorganisms are normally found in the female genital tract.
 - b. *Streptococcus pyogenes* (18)
 - c. *S. agalactiae* (procedure 3.9.2)
 - d. *Listeria monocytogenes*
 - e. *N. gonorrhoeae* (procedure 3.9.3)
 - f. *Candida albicans*. Mention other yeasts. *Candida glabrata* has been implicated as a cause of vulvovaginitis (20).
 4. Identify the following only if the specimen was invasively collected or there is heavy growth and they are the predominant microorganism in the culture.
 - a. *Haemophilus* spp. (6, 9, 21)
 - b. Gram-negative rods
 - (1) Enteric gram-negative rods (exception: *Enterobacteriaceae* are part of the normal microbiota of the vagina and should not be reported).
 - (2) *Pseudomonas* spp. and other non-glucose-fermenting, gram-negative rods

Table 3.9.1–4 Biochemical reactions of *Haemophilus* and other fastidious gram-negative coccobacilli found in genital microbiota^a

Test	<i>H. influenzae/haemolyticus</i> ^b	<i>H. parahaemolyticus/paraphrophilus/parainfluenzae</i> ^b	<i>H. ducreyi</i>	<i>Capnocytophaga</i> DF-1 and DF-3 ^c	<i>P. bettyae</i> (HB-5)	<i>C. fetus</i>	<i>Kingella denitrificans</i> ^d	<i>Kingella kingae</i>

TSI ^f	NA	NA	NA	Acid slant and butt	Acid butt only	–	–	Rare acid in slant and butt

^a Strains in this table are characterized by no growth on MAC, with the exception of a rare *P. bettyae* strain. NA, not applicable; V, variable. This table is prepared from biochemical tables from Weyant et al. (22).

^b Separate by hemolysis on horse or rabbit blood, if desired; however, *H. haemolyticus*, *H. paraphrophilus*, and *H. parahaemolyticus* generally are not found in the genital tract.

^c *Capnocytophaga* spp. (DF-1) are rods with tapered ends and frequently have a yellow pigment; DF-3 is a coccobacillus. They both may hydrolyze esculin.

^d Not generally a pathogen but mimics *N. gonorrhoeae*; it will grow on BAP, is nitrate positive, and is a coccobacillus.

^e The nitrate reaction is first; if the gas reaction is known, it is listed second, preceded by a slash.

^f May not be able to demonstrate reactions without addition of rabbit serum, if organism is fastidious.

V. PROCEDURE (continued)

- (3) *Pasteurella bettyae* (CDC group HB-5). See Table 3.9.1–4.

■ **NOTE:** *P. bettyae* has been associated with genital infections, especially in neonates. It is an indole-positive gram-negative rod, but unlike *E. coli*, it is catalase negative and oxidase variable and does not grow or grows as pinpoint colonies on MAC (2, 22).

- (4) *Capnocytophaga* spp.

■ **NOTE:** This group of organisms have been associated with genital infections. They are catalase-negative, oxidase-negative glucose-fermenting gram-negative rods that do not grow on MAC. The glucose reaction may not be seen on triple sugar iron agar (TSI) or Kligler's iron agar. They are generally esculin positive (procedure 3.17.5).

- (5) *Campylobacter fetus* (see procedure 3.8.2)

c. *S. aureus*

d. *Streptococcus pneumoniae*

e. *Neisseria meningitidis*

f. *G. vaginalis*

- (1) For vaginal specimens, do *not* use selective medium to isolate this organism, because the importance of its isolation is determined by the quantity compared to that of lactobacilli in the culture (1, 5). *G. vaginalis* grows well on both CNA and CHOC.
- (2) When present in quantities less than the other normal microbiota, it should be included as part of normal vaginal microbiota. However, for children report its presence regardless of the quantity present.
- (3) If it is the predominant microorganism from the female vaginal tract and is isolated in 3 to 4 + quantities (third or fourth quadrant on the plate), report its presence.

V. PROCEDURE (continued)

- (4) Identification
 - (a) Colonies appear pinpoint and transparent, with no greening of the agar
 - (b) Gram-variable to gram-negative small, pleomorphic coccobacilli that do not elongate into filaments or chains
 - (c) Catalase-negative. To confirm the lack of catalase enzyme, streak colony on CHOC plate and add a dot of viridans group streptococci (*Streptococcus sanguis* ATCC 35557). A clear zone of inhibition around a dot of viridans group streptococci confirms the lack of catalase (17).
 - (d) SPS sensitive (1, 17) or hippurate positive (procedure 3.17.21) or beta-hemolytic on human blood agar

■ **NOTE:** The API CORYNE strip accurately identifies this microorganism (7). It is not necessary to confirm the identification with tests other than colony morphology, catalase, and smear, if the direct Gram stain is consistent with diagnosis of BV. Aroutcheva et al. (1) report that the strains isolated from cases of BV were more likely to have a negative hippurate or lipase test reaction than those from patients without BV. They also showed that the isolation of 3 or 4+ *G. vaginalis* from culture correlated well with BV, although 26% of the cases diagnosed by Gram stain were missed on culture using selective human blood-Tween bilayer media, which is reported to be superior to V agar (1).

- E. Susceptibility testing
 1. Perform antimicrobial susceptibility testing (AST) on significant counts of predominant enteric gram-negative rods and pseudomonads from invasively collected specimens.
 2. For fastidious rods that do not grow on MAC or EMB, perform a beta-lactamase test.
 3. AST on gram-positive microorganisms is not generally useful for making treatment decisions.
- F. Hold positive culture plates for at least 7 days should further testing be indicated.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. From surgical specimens and those from normally sterile sites, report the pathogens isolated. For cultures with mixed microbiota, grouping of pathogens may be indicated, e.g., "Mixed enteric rods or mixed anaerobes present."
- B. If no pathogens are isolated but normal microbiota is present, report as "Normal genital microbiota isolated" for vaginal and cervical specimens and as "Normal cutaneous microbiota isolated" for male urethral specimens.
 1. See item I of this procedure for list of organisms in the normal microbiota of male and female genitalia.
 2. Do not list genera and species of normal microbiota individually.
 3. If specific pathogens are requested, report "No [pathogen name] isolated."
- C. Positive reporting
 1. Quantitate pathogens (Table 3.3.2-2).
 2. Notify physician of pathogens of serious significance in pregnant females (e.g., *L. monocytogenes*) or communicable diseases (e.g., *N. gonorrhoeae*).
 3. Notify the local health department of isolation of agents of reportable diseases.

VII. INTERPRETATION

- A. The presence of any microorganism from a normally sterile site is generally considered significant.
- B. Isolation of *N. gonorrhoeae*, *S. pyogenes*, *H. ducreyi*, *Shigella* spp., and *C. albicans* is considered significant for disease from any genital site.
- C. The presence of other pathogens may or may not be a cause of disease and must be evaluated with consideration of relative amounts and symptoms or other conditions (e.g., pregnancy) in the patient.
- D. Susceptibility testing, except for significant predominant gram-negative rods, is not helpful and is not indicated because of the predictable susceptibility and resistance of the organisms. For isolation of fastidious aerobic and anaerobic gram-negative rods, report a beta-lactamase test.

VIII. LIMITATIONS

- A. Many agents of disease are difficult to culture, and the lack of isolation may not indicate that the pathogen is not the cause of disease.
- B. Communication between the laboratory and the physician is necessary to provide the appropriate cultures for the disease present, since agents such as *Ureaplasma* and *H. ducreyi* may not grow on routine laboratory media.
- C. Unless selective media and incubation are used, a routine genital culture will not detect carriage of GBS in all cases.
- D. Because of the difficulty in evaluating the significance of *G. vaginalis* in culture, unless it is clearly predominant and numerous, BV is best diagnosed by Gram stain.
- E. The presence of fastidious gram-negative rods in genital specimens may or may not indicate infection. Cases have been reported, but they are infrequent (2, 6, 9, 21).

APPENDIX 3.9.1–1

Sample Request Form for Submission of Specimens for Diagnosis of Genital Infections for Women in Childbearing Years and Sexually Active Adults

- Bacterial vaginosis:** Prepare a smear of vaginal discharge. Place slide in the slide holder and patient label on outside of holder.
Test: Gram stain (procedure 3.2.1).
- Candidiasis:** Prepare specimen for viewing by placing swab moistened with vaginal fluid (add small amount of saline if necessary) onto glass slide or submit swab in transport medium.
Test: wet mount for yeast (procedure 3.2.3) and yeast culture.
- Chancroid:** Submit aspirate and scraping of base of ulcer in transport medium. Contact laboratory prior to collection to arrange for appropriate transport.
Test: *Haemophilus ducreyi* culture (procedure 3.9.4).
- Chlamydia infection:** Submit cervical (females) or urethral (males) swab. First voided 20 ml of urine may be sent for nucleic acid amplification tests. Test can be done by probe technology if submitted in appropriate transport tube, but this is not accepted for abuse cases.
Test: chlamydia culture probe test (*see* procedure 10.6 and Table 12.1–2, respectively).
- Trichomonas infection:** Submit *vaginal* swab in InPouch after swirling swab in top portion of broth, or submit swab in charcoal transport tube.
Test: *Trichomonas* wet mount and culture (*see* procedures 3.2.3, 9.6.6, and 9.9.4).
- Gonorrhea:** Submit swab from cervix (females) or urethra (males) or rectum or throat in charcoal transport medium within 3 h of collection. First voided 20 ml of urine may be sent for nucleic acid amplification tests only. Test can be done by probe technology if submitted in appropriate transport tube, but this is not accepted for abuse cases or from throat or rectum.
Test: GC culture probe test (procedure 3.9.3 and Table 12.1–2, respectively).
- Herpes infection:** Submit aspirate and scraping of base of vesicle.
Test: herpes culture (*see* procedure 10.5). *Note:* Herpes serology can be used to document past infection.
- Genital mycoplasma infection:** Vaginal or cervical (females) or urethral (males) swab for culture. Other more invasive specimens are preferred _____. This test should only be ordered for symptomatic patients and not as a screening test.
Test: *Ureaplasma* culture (procedure 3.15).
- Prevention of neonatal group B streptococcal (GBS) disease:** Submit swab from *vaginal* and anal area in tube. Collection should be at 35 to 37 weeks gestation. Testing for GBS early in pregnancy is not recommended. Laboratory will enrich for organism in broth culture followed by plate culture.
Test: GBS culture (procedure 3.9.2).
- Syphilis:** *Note:* Diagnosis is generally done by serologic means. Collect lesion scraping and deliver to laboratory immediately.
Test: dark-field exam.
- Other:** State symptoms and organisms sought. _____

3.9.2

Group B Streptococcus Cultures

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Group B streptococcus (GBS) (*Streptococcus agalactiae*) has been recognized as the leading infectious cause of perinatal morbidity and mortality in the United States. In pregnant women, it is associated with asymptomatic bacteriuria, urinary tract infection, and amnionitis, and in women who have recently delivered, it causes endometritis and wound infection. Early-onset neonatal disease (during the first week of life) results from transmission of GBS during labor or delivery from mother to infant; late-onset disease (from 1 to 3 months after birth) is thought to be acquired in the nursery. Both are characterized by septicemia, pneumonia, or meningitis and can result in death or permanent neurological sequelae.

In 1986 Boyer and Gotoff (6), in a carefully controlled study, demonstrated that intrapartum ampicillin prophylaxis can prevent early-onset neonatal GBS disease in women with positive prenatal cultures for GBS and certain perinatal risk factors. In 1992 the American Academy of Pediatrics issued guidelines for prevention of neonatal GBS disease (1), which in-

cluded prenatal cultures at 26 to 28 weeks' gestation. In 1996 and 1997, the American Academy of Pediatrics (2), the American College of Obstetricians and Gynecologists (3), and the CDC (7, 8) issued guidelines that included a combination of treating all women in risk groups and/or culturing at 35 to 37 weeks' gestation to identify carriers for whom treatment would most likely prevent disease. The rationale for this change in the timing of culturing was that at any given time 20% of women are colonized with GBS, but it is colonization at the time of delivery that is associated with disease. By the end of 1998, it was estimated that in the United States in that year alone, 3,900 cases of GBS disease in neonates and 200 deaths from early-onset GBS were prevented by the guidelines (17). In 2002 (9), the CDC issued new guidelines based on 6 years of experience, stating the need for doing culture and providing more exact details for the culture techniques. A preincubation step in a selective broth containing antimicrobials was included as part of the guidelines, since it has been found to be

the most sensitive method. While it was hoped that a more rapid and sensitive method would be found, as yet, enrichment culture is the most sensitive method to detect female colonization.

GBS disease is increasing in nonpregnant adults, especially the elderly and those with significant underlying disease (12). Diabetes mellitus, neurological impairment, and cirrhosis appear to be risk factors. Skin, soft tissue infections, pneumonia, and urosepsis are common presentations, although meningitis and endocarditis are reported. Disease is frequently nosocomial, possibly related to catheter placement (12). For diagnosis of GBS disease in nonpregnant adults and in neonates, routine culture of the symptomatic body site (e.g., blood, CSF, and amniotic and joint fluid cultures) will detect this pathogen along with the other potential pathogens which can be isolated from those cultures. This procedure addresses only the perinatal screening culturing where the physician specifically orders culture for GBS to detect colonization.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

■ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for physicians and other caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

A. Collect specimen at 35 to 37 weeks' gestation. Using a single swab or two separate swabs, swab the distal vagina (vaginal introitus), followed by the rectum (i.e., insert swab through the anal sphincter).

■ **NOTE:** CDC recommendations (9) are to treat on the basis of risk factors if culture results are not available at the time of delivery. However, obtaining

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

cultures at delivery prior to therapy, if they were not obtained earlier, may be helpful in diagnosis of subsequent disease of the mother or neonate. If cultures are negative, other testing is indicated to determine the cause of neonatal disease. *The CDC recommends against performing rapid antigen tests on vaginal specimens during delivery or in place of prenatal culture, as they lack the sensitivity to provide accurate treatment guidelines (9).*

- B. If symptoms of sepsis or amnionitis are present, also submit amniotic fluid (procedure 3.5), blood, or urine for culture.
- C. Specimen transport
 1. Submit one or both swabs to the laboratory in a *single* tube of nonnutritive transport medium (Amies or Stuart's). It is not necessary to submit anal and vaginal swabs separately.
 2. Label specimens and accompanying requisition with demographic information on the patient (name, identifying number, age, and diagnosis), the date and site of collection, and the week of gestation.
 3. Store at 25°C or refrigerate at 4°C.
 4. Order culture for GBS; if the patient is penicillin allergic, also order testing for susceptibility to clindamycin and erythromycin.
 5. Submit to the laboratory within 4 days of collection.
- D. Rejection criteria
 - **NOTE:** According to an alert from the CDC on 24 March 1997, gravely erroneous information and potentially fatal misdiagnoses can result from the use of direct antigen testing to detect GBS directly in urine of pregnant women or infants.
 - 1. If a direct antigen assay is performed on CSF, always perform a culture for confirmation of viable organisms.
 - 2. Do not accept urine or vaginal swabs for direct antigen assay.
 - 3. For the neonate, screening cultures (e.g., axilla, throat, etc.) and urinary antigen tests are not recommended because of their lack of sensitivity and specificity for diagnosis.
 - **NOTE:** Collect blood, CSF, and respiratory secretions to diagnose disease in symptomatic neonates.

III. MATERIALS

- A. Media
 1. Selective streptococcal broth
 - a. LIM broth: Todd-Hewitt broth with 10 µg of colistin per ml and 15 µg of nalidixic acid per ml (available from most medium vendors)
 - b. Trans-Vag broth with 5% defibrinated sheep blood: Todd-Hewitt broth with 8 µg of gentamicin per ml and 15 µg of nalidixic acid per ml (Remel, Inc.).
 - **NOTE:** Fackrell and Dick (11) reported that LIM broth supported growth of GBS better than Trans-Vag broth but was equivalent to Trans-Vag broth with blood.
 2. Agar media
 - a. BAP
 - b. NNA: BAP with 30 µg of neomycin per ml and 15 µg of nalidixic acid per ml (BD Diagnostic Systems)
 - c. Selective streptococcal agar: BAP with neomycin and polymyxin B (Remel, Inc.; Hardy Diagnostics) or colistin and oxolinic acid (Remel, Inc.).
 - d. Columbia colistin-nalidixic acid agar (CNA)
- B. Identification methods
 1. Gram stain (procedure 3.2.1)
 2. Catalase test (procedure 3.17.10)
 3. One of the following
 - a. *Staphylococcus aureus* ATCC 25923 for CAMP test (procedure 3.17.8)
 - b. Rapid hippurate (procedure 3.17.21)
 - c. AccuProbe GBS RNA probe assay (GenProbe Inc., San Diego, Calif.)
 - d. Latex or coagglutination serologic test for streptococcal

III. MATERIALS (continued)

- grouping (see procedure 3.11.8 for options)
4. Other biochemical tests
 - a. Pyrrolidonyl- β -naphthylamide (PYR) (procedure 3.17.41)
 - b. Bile-esculin (procedure 3.17.5)
- C. Other supplies**
1. Incubator at 35°C with 5% CO₂ or other CO₂-generating system
 2. Disposable cards for serologic tests

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
- B. Test each lot of BAP with a known GBS to verify the ability of the media to produce a positive CAMP reaction (procedure 3.17.8), or obtain documentation from medium vendor that each lot is checked for the CAMP reaction.
- C. Refer to the individual biochemical test procedures for further QC requirements.
- D. Perform QC with each lot of both selective streptococcal broth and agar that contain antimicrobial agents (excluding CNA). Incubate aerobically overnight at 35°C.

Test organism	Result(s)
<i>Streptococcus agalactiae</i> ATCC 12386	Broth: growth; beta-hemolytic colonies upon subculture to sheep blood agar. Agar: growth of beta-hemolytic colonies
<i>Proteus mirabilis</i> ATCC 12453	Broth or agar: partial to complete inhibition
<i>Streptococcus pyogenes</i> ATCC 19615	Agar: test if agar is used to test for group A streptococcus. Growth of beta-hemolytic colonies

█ **NOTE:** NCCLS has proposed elimination of user QC of LIM broth and some selective streptococcal agars (15) purchased from commercial vendors. Consult with current regulatory agencies prior to discontinuation of user QC.

V. PROCEDURE

Observe standard precautions.

- A. Inoculation
 1. Inoculate broth from the swab.
 2. Optional, in addition to the broth inoculation: inoculate BAP, CNA, or selective streptococcal agar with swab immediately upon receipt.

█ **NOTE:** Dunne and Holland-Staley (10) have shown that the addition of a selective direct plate to the broth culture increased detection by 15%, because *Enterococcus faecalis* can overgrow in the broth cultures and inhibit the growth of *S. agalactiae*.
- B. Incubation
 1. Incubate selective direct plate at 35 to 37°C in 5% CO₂ (preferred) or ambient air. Alternatively, use other CO₂-generating system to provide the 5% CO₂.
 2. Incubate broth at 35 to 37°C in ambient air or in 5% CO₂.
 3. Subculture the broth after 18 to 24 h of incubation to BAP, if GBS have not been isolated on the direct plate.
 4. Incubate subculture plate at 35 to 37°C in ambient air or 5% CO₂ for 48 h.
 5. Optionally, in addition to subculture, test the broth after 18 to 24 h of incubation with either of the following.
 - a. A streptococcal grouping test that includes an extraction step; this method is reported to be more sensitive than plate culture (16).
 - b. AccuProbe GBS RNA probe assay or PCR method (4, 5) (Table 12.1.4)

V. PROCEDURE (*continued*)

- C. Culture examination
1. Observe plates at 24 and 48 h for large, gray, translucent colonies with a small zone of beta-hemolysis or no zone of hemolysis.
 2. Perform catalase test.
 3. Perform Gram stain if catalase negative.
 4. Identify gram-positive cocci in pairs and chains as *S. agalactiae* if they are catalase negative and demonstrate one of the following reactions.
 - a. Positive CAMP test
 - b. Positive with group B streptococcal grouping antisera
 - c. Positive GenProbe AccuProbe GBS test
 - d. Positive rapid hippurate
 - (1) If strain is nonhemolytic, a second test from the above list must be used for confirmation.
 - (2) If strain is hemolytic, perform PYR test (procedure 3.17.41). Enterococci are PYR positive but can be hippurate positive and hemolytic.
 5. If the isolate is hemolytic and not identified as *S. agalactiae*, perform PYR and esculin or bile-esculin test. *S. pyogenes* is PYR positive, hemolytic, and esculin negative. Enterococci can be hemolytic and PYR positive but are esculin positive.
- D. Perform disk diffusion testing for susceptibility to clindamycin and erythromycin, on request for penicillin-allergic patients (9) (*see* procedure 5.1). Place disks 15 to 26 mm apart.
- E. If antimicrobial susceptibility testing (AST) is not performed, hold positive culture plates for several (3 to 7) days should AST be requested at a later date.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. If the culture is negative, report “No group B streptococci isolated.”
- B. Positive reporting
1. Report the presence of *S. agalactiae* (group B) or *S. pyogenes* (group A) as soon as preliminary tests are completed.
 2. Do not report any enumeration.
 3. If the patient has been admitted to the hospital, notify the physician of positive results. For other patients, ensure that the results are easily available to the physician when the patient goes into labor.

☑ **NOTE:** A policy that may be useful for laboratories that lack a readily accessible computer system is to notify the patients themselves to be sure they tell their physicians when they go into labor.
 4. Document notification of physician.
 5. Include in the report the following: “If patient is penicillin allergic, contact laboratory for alternative susceptibility testing.”
 - a. Report a zone size of ≥ 21 mm with the erythromycin disk as susceptible to erythromycin (14).
 - b. Report a zone size of ≥ 19 mm with the clindamycin disk (14) and no inhibition or flattening with the erythromycin disk as susceptible to clindamycin.

VII. INTERPRETATION

- A. A positive culture indicates colonization with the organism, which may or may not indicate infection.
- B. Urinary tract infections with *S. agalactiae* should be treated.
- C. Virtually 100% of *S. agalactiae* strains are susceptible to penicillin (the drug of choice to treat colonization), negating the need for testing. If testing is performed, resistance should be confirmed in a reference laboratory (14).
- D. For penicillin-allergic women, erythromycin or clindamycin is used. Approximately 6 to 15% of strains are resistant to clindamycin, and 20% are resistant to erythromycin (13).

VIII. LIMITATIONS

- A. Methods that employ PCR for the detection of GBS are more rapid than culture techniques.
- B. False-negative cultures can result from contamination of the specimen with genital microbiota, especially *E. faecalis*, or from the inability to recognize non-hemolytic colonies.
- C. False-positive results can be caused by misinterpretation of the confirmatory tests. Occasionally enterococci can have a positive hippurate test result, but it usually is not rapid.
- D. *Listeria* colonies can be confused with *S. agalactiae*, if the Gram stain or catalase test is omitted. *Listeria* organisms are *catalase positive*, gram-positive rods that are hemolytic and CAMP and hippurate positive, but these are rarely seen in vaginal specimens.
- E. For neonates with sepsis, blood and CSF cultures should be performed to diagnose GBS disease along with other microorganisms responsible for sepsis, such as *Listeria monocytogenes*.
- F. While the methods presented here are designed to detect GBS colonization in pregnant females, disease in nonpregnant adults is increasing (8). The microbiologist must be aware of the organism's significance and report it when present in clinically significant specimens.

3.9.3

Neisseria gonorrhoeae Cultures

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The fastidious and fragile nature of *Neisseria gonorrhoeae* requires careful consideration of proper methods of specimen collection and transport. A good selective medium is required for reliable isolation of gonococci from patient specimens, especially those that might contain a variety of microorganisms, including saprophytic *Neisseria* spp. Methods for the identification of *N. gonorrhoeae* from extragenital sites and cultures taken from children must be chosen and performed with the utmost care, since a positive report can have far-reaching psychosocial and medico-legal implications. In the United States, culture identification of *N. gonorrhoeae* is the only definitive method of diagnosis from a legal standpoint.

In women, the endocervix is the primary site of infection, but the organism can also be recovered from the urethra, rectum, oropharynx, conjunctiva, and the ducts of Bartholin's glands. A vaginal swab is not considered optimal for the re-

covery of gonococci from women but can be a valuable specimen for the diagnosis of gonorrhea in preteen-aged girls. Ascending genital infection in women can lead to pelvic inflammatory disease and, occasionally, perihepatitis. Transmission of *N. gonorrhoeae* from mother to newborn will often present as conjunctivitis (ophthalmia neonatorum).

The urethra is the primary site of infection in men, but extragenital sites, including the rectum, oropharynx, conjunctiva, and epididymis, can act as sources of *N. gonorrhoeae*, in addition to first-voided urine. Extragenital cultures of the rectum, conjunctivae, and pharynx for *N. gonorrhoeae* are performed only when specifically requested and samples are procured by the clinician. Such a request is not uncommon, however, as part of the overall diagnostic evaluation for gonorrhea.

Culture-independent nucleic acid probe hybridization and amplification as-

says for the detection of *N. gonorrhoeae* from urethral and cervical specimens are currently available that circumvent problems associated with specimen transport and loss of organism viability inherent in culture-based methods. These assays include the PCR AMPLICOR CT/NG assay (Roche Molecular Diagnostics), the AP-TIMA Combo 2 assay (Gen-Probe, Inc.), the ligase chain reaction assay (Abbott Diagnostics), and the BD ProbeTecET system (BD Diagnostic Systems). The AMPLICOR assay is also cleared in the United States for testing urine from males only, while the latter three are all compatible for use with both male and female urine specimens. (See section 12 for further information on these tests and reference 18 for evaluation of different systems. Vendor contact information is provided in procedure 3.1.)

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. Cervical

- a. Do not use lubricant during procedure.
- b. Wipe the cervix clean of vaginal secretion and mucus.
- c. Rotate a sterile swab, and obtain exudate from the endocervical glands.
- d. If no exudate is seen, insert a sterile swab into the endocervical canal, and rotate the swab.

2. Vaginal

- a. Insert a sterile swab into the vagina.
- b. Collect discharge or vaginal secretions from the mucosa high in the vaginal canal.

■ **NOTE:** Vaginal specimens are not considered optimal for the diagnosis of gonorrhea in women and should be reserved only for the evaluation of

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

preteen-aged girls with suspected sexually transmitted diseases due to presumed sexual abuse.

3. Urethral

- a. Collect specimen 1 to 2 h or more after patient has urinated.
- b. Female: stimulate discharge by gently massaging the urethra against the pubic symphysis through the vagina.
 - (1) Collect the discharge with a sterile swab.
 - (2) If discharge cannot be obtained, wash external urethra with Betadine soap and rinse with water. Insert a urethrogenital swab 2 to 4 cm into the endourethra, gently rotate the swab, leave it in place for 1 to 2 s, and withdraw it.
- c. Male: insert a thin urethrogenital swab 2 to 4 cm into the endourethra, gently rotate it, leave it in place for 1 to 2 s, and withdraw it.

4. Epididymis

Use a needle and syringe to aspirate material from the epididymis.

5. Pharyngeal

- a. Depress tongue gently with tongue depressor.
- b. Extend sterile swab between the tonsillar pillars and behind the uvula. Avoid touching other surfaces of the mouth.
- c. Sweep the swab back and forth across the posterior pharynx, tonsillar areas, and any inflamed or ulcerated areas to obtain sample.

6. Rectal

- a. Pass the tip of a sterile swab approximately 2 cm beyond the anal sphincter.
- b. Carefully rotate the swab to sample the anal crypts, and withdraw it.

7. Urine

- a. Do not collect urine for culture of *N. gonorrhoeae*.
 - ☑ **NOTE:** Urine cultures provide reasonable sensitivity for men with gonorrhea provided a first morning-voided specimen is obtained and plated on appropriate selective and nonselective culture media. Urine culture is not a sensitive alternative for the diagnosis of gonorrhea in women.
- b. Collect no more than 20 ml of first morning-voided urine for nucleic acid testing.
 - ☑ **NOTE:** In contrast to routine urine cultures, the first part of the voided urine specimen, rather than the midstream urine, is collected for nucleic acid testing. The use of urine for the diagnosis of *N. gonorrhoeae* and/or *Chlamydia trachomatis* infection by nucleic acid amplification assays has been successfully adapted for several commercially available diagnostic kits. However, for females the sensitivity of the urine compared to an endocervical swab is generally 10% lower. Currently, the AMPLICOR CT/NG assay (Roche Molecular Diagnostics) is not Food and Drug Administration cleared for use with female urine samples (18).

8. Conjunctivae

- a. Collect purulent material on a swab.
 - (1) Roll sterile swab over the conjunctiva before topical medications are applied.
 - (2) Culture both eyes with separate swabs.
- b. Alternatively, obtain material with a sterile spatula and inoculate directly onto culture media.

B. Specimen transport

1. Direct inoculation

- a. Inoculate specimen directly onto the surface of nonselective and selective medium plates. Roll the swab across one quadrant of the plate and streak for isolation, or roll swabs across the surface of the plate in a “Z” or “N”

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

figure. Plates are cross-streaked for isolation when received by the laboratory.

- b. Place inoculated media in a holding jar or other system with a suitable CO₂-enriched (3 to 5%) atmosphere.
 - c. Transport systems that provide growth medium and an atmosphere-generating tablet in a self-contained transport pack can be substituted for direct medium inoculation and the holding-jar method. These include the following.
 - (1) JEMBEC (BD Diagnostic Systems)
 - (2) InTray GC (BioMed Diagnostics, San Jose, Calif.)
 - (3) Gono-Pak (BD Diagnostic Systems)
 2. If direct medium inoculation is not practical, collect specimens on one of the following swab-based transport systems.
 - a. Difco Cultureswab (BD Diagnostic Systems)
 - b. Copan Venturi Transystem (Copan Italia, Bovezza, Italy)
 - c. BD Culturette EZ (BD Diagnostic Systems)
 - d. Starplex Starswab (Starplex Scientific, Inc., Etobicoke, Ontario, Canada)

■ **NOTE:** The performance of each of these swab-based transport systems is comparable if specimens are submitted and cultured within 6 h of collection and either held at ambient temperature or refrigerated. However, recovery rates vary considerably if delivery is delayed (1, 13, 21). At 24 h, the Copan system held at either room temperature or 4°C and the Difco system held at refrigeration temperatures provide recovery rates of 96% (1). The addition of charcoal to Amies transport medium does not appear to increase recovery rates (21).
 3. For Gram stain of male urethral discharge or conjunctival exudate, transfer some of the specimen to a slide and spread in a thin film. Allow to air dry.

■ **NOTE:** Preparation of the smear at the time of specimen collection will avoid deterioration of the specimen, which results in false-negative smear reports. For children, a smear must be accompanied by a culture, since smears lack the specificity for accurate *N. gonorrhoeae* diagnosis.
 4. For molecular detection assays, use the manufacturer's product-specific collection devices. These devices cannot be used when culture has been requested.

■ **NOTE:** While cultures must be performed in all medico-legal cases and with specimens from prepubescent children, nucleic acid tests can be performed in addition to culture.
 5. Once collected, submit specimens for culture to laboratory as soon as possible. If 24-h laboratory coverage is not provided, alert the laboratory that a specimen is in transit.
 6. Store at ambient or refrigeration temperature after collection and during transport (1, 24).
 7. Ensure that specimens are labeled with demographic information on the patient and the site and time of collection.
 8. Record the patient diagnosis for improved processing of specimen.
- C. Rejection criteria**
1. Reject specimens on swabs in which significant desiccation has occurred or when instructions for correct use of the transport system have not been followed.
 2. Consider rejection of specimens if significant delay (e.g., >24 h) in transportation and plating occurs. However, a more practical approach might include a provision for culture in all cases of delayed transportation with an accompanying comment for cultures negative for *N. gonorrhoeae* (see item VI below). Accompany such a provision with active education and revision of policies to improve transport.

III. MATERIALS

A. Media

■ **NOTE:** For maximum recovery, culture media for isolation of *N. gonorrhoeae* should include both selective and nonselective agar formulations capable of supporting the growth of the organism. Selective media are designed to prevent overgrowth of contaminating normal microbiota. The addition of a nonselective medium such as CHOC allows for the growth of a small percentage of gonococci (approximately 2%) that are inhibited in the presence of vancomycin at concentrations of 4 µg/ml. Formulations such as GC-Lect reduce the concentration of vancomycin to 2 µg/ml (4, 12, 14, 15, 22, 24, 25). In selective medium formulations, anisomycin has a longer shelf life than nystatin to inhibit *Candida*. Trimethoprim is added to inhibit the growth of *Proteus* species. (For vendor information, see procedure 3.1.)

1. CHOC (omit for nasopharyngeal and rectal sites)
2. One of the following selective media
 - a. Modified Thayer-Martin medium (contains vancomycin, colistin, nystatin, and trimethoprim) is available from most medium manufacturers.
 - b. Martin-Lewis medium (contains vancomycin, colistin, and anisomycin) is available from most medium manufacturers. The vancomycin concentration is higher (400 µg/100 ml) in Martin-Lewis than in Thayer-Martin medium (300 µg/100 ml).
 - c. Thayer-Martin improved medium (TM improved) (contains vancomycin, colistin, anisomycin, and trimethoprim [Remel, Inc.]
 - d. TM improved without vancomycin, sold as a biplate with TM improved (Remel, Inc.)
 - e. Martin-Lewis medium with lincomycin (Hardy Diagnostics)
 - f. GC-Lect (contains lincomycin, vancomycin at 200 µg/100 ml, colistin, trimethoprim, and amphotericin B) (BD Diagnostic Systems)
 - g. New York City medium with the same antimicrobial agents as GC-Lect (BD Diagnostic Systems)

h. The following media provide both CO₂ generation and the media in a self-contained system that promotes survival of *N. gonorrhoeae* during transportation.

- (1) JEMBEC (BD Diagnostic Systems; Remel, Inc.)
- (2) Gono-Pak (BD Diagnostic Systems; Remel, Inc.)
- (3) InTray GC (BioMed Diagnostics)

3. Biplate formulations containing both CHOC and selective agar are available from several manufacturers.

B. Gram stain reagents (procedure 3.2.1)

C. Direct amplification tests

Refer to reference 18.

D. Identification tests

1. Oxidase reagent (see procedure 3.17.39)
2. 30% Hydrogen peroxide (Sigma, St. Louis, Mo.) for superoxol test (2, 23)
3. Nutritionally basic media, such as nutrient agar, TSA, or Mueller-Hinton (MH) agar
4. *Neisseria* identification systems
 - a. Carbohydrate utilization assay: Cysteine Trypticase agar (CTA) base with 1% carbohydrates (glucose, maltose, lactose, and sucrose) or carbohydrate degradation media with 20% carbohydrates (Remel, Inc.; see procedure 3.17.9)
 - b. Coagglutination
 - (1) Gonogen (New Horizons Diagnostics; BBL Microbiology, BD Diagnostic Systems)
 - (2) Phadebact GC monoclonal antibody test (Boule Diagnostics AB, Huddinge, Sweden)
 - c. Monoclonal antibody assay: GonoGen II (New Horizons Diagnostics; BBL Microbiology, BD Diagnostic Systems)
 - d. Substrate utilization
 - (1) RapID NH, BactiCard Neisseria, NET (Remel, Inc.)
 - (2) Gonocheck II (EY Laboratories, Inc., San Mateo, Calif.)
 - (3) Neisseria Screen (Key Scientific Products, Round Rock, Tex.)

III. MATERIALS (*continued*)

- (4) BBL CRYSTAL (BD Diagnostic Systems)
- (5) *Neisseria/Haemophilus* ID kit, API NH (bioMérieux)
- e. Fluorescent antibody: Syva MicroTrak *N. gonorrhoeae* culture confirmation test (Trinity Biotech plc., Co. Wicklow, Ireland)
- f. Probe hybridization: AccuProbe *N. gonorrhoeae* culture confirmation test (Gen-Probe, Inc.)

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
- B. Test each lot of identification kits and reagents, according to package insert or procedure 14.2. Generally the following QC organisms are used for sugar or kit tests. See Table 3.9.3–1 for expected reactions.
1. *N. gonorrhoeae* ATCC 43069
 2. *Neisseria meningitidis* ATCC 13077
 3. *Neisseria lactamica* ATCC 23970
 4. *Moraxella catarrhalis* ATCC 25240
- C. Perform QC of CHOC and selective media by lot; incubate for 24 to 48 h in 5 to 7% CO₂ at 35°C.

CHOC

Test organism	Result
<i>Neisseria gonorrhoeae</i> ATCC 43069 or ATCC 43070	Growth
<i>Haemophilus influenzae</i> ATCC 10211	Growth

Selective media for pathogenic *Neisseria* spp.

Test organism	Result
<i>Neisseria gonorrhoeae</i> ATCC 43069 or ATCC 43070	Growth
<i>Proteus mirabilis</i> ATCC 43071	Partial inhibition—test only if medium contains trimethoprim
<i>Staphylococcus epidermidis</i> ATCC 12228	Partial inhibition

V. PROCEDURES**A. Direct test**

1. Gram stain
 - a. Perform smears only on male urethra specimens.
 - b. Roll swab across slide after culture has been inoculated.
 - c. Fix smear with methanol. (*See* procedure 3.2.1 for staining and reading smear.)
2. Direct probe assays (18)

B. Culture methods

1. Inoculation
 - a. Process specimen as soon as received.
 - b. Inoculate medium by rolling the swab over one quadrant of the plate and streaking for isolation. If medium is received that has already been inoculated (either in a “Z” streak or down the center of the plate), it is best to cross-streak for isolation to ensure separation of mixed colony types.

Observe standard precautions.

Table 3.9.3-1 Biochemical reactions of *Neisseria* and related oxidase-positive diplococci and rods that may grow on Thayer-Martin or similar selective agar^a

Organism(s)	Superoxol, 30% H ₂ O ₂	Growth on basic agar media at 35°C ^c	Colistin (10 µg) disk	Glucose	Maltose	ONPG, or BGAL	Sucrose	PRO	GLUT	Butyrate ^d
<i>Neisseria gonorrhoeae</i>	4+	–	R	+ ⁻	–	–	–	+	–	–
<i>Neisseria meningitidis</i>	2–4+	V	R	+	+ ⁻	–	–	V	+	–
<i>Neisseria lactamica</i>	2+	+	R	+	+	+	–	+	–	–
<i>Neisseria cinerea</i> ^b	2+	+	V	V	–	–	–	+	–	–
<i>Neisseria flavescens</i> ^b	2+	+	S	–	–	–	–	+	–	–
<i>Neisseria elongata</i> ^b	2+	+	S	–	–	–	–	V	–	–
Other nonpathogenic <i>Neisseria</i> spp. ^b	2+	+	V	+	+	–	V	V	V	–
<i>Moraxella catarrhalis</i>	2–4+	+	V	–	–	–	–	V	–	+
<i>Kingella</i> species	–	+	R	+	V	–	–	V	–	–

^a Abbreviations: PRO, prolyl-iminopeptidase; BGAL, β-galactosidase; GLUT, δ-glutamyl-aminopeptidase; V, variable reactions; +, –, reaction is generally positive, but rare negative results occur, resulting in critical misidentifications if other tests are not also performed; R, resistant; S, susceptible. Polymyxin B can be substituted for colistin, or susceptibility can usually be determined by growth or lack of growth on Thayer-Martin or other selective agar with colistin or polymyxin B. Reactions are from package inserts, from <http://www.CDC.gov/ncidod/dastlr/gcdtr/ncident/index.html>, and from references 17 and 27.

^b This organism(s) does not usually grow on selective media for *N. gonorrhoeae*. *N. subflava* and *N. flavescens* colonies are yellow; *N. subflava* is the only species other than *N. meningitidis* to be GLUT positive.

^c Nutrient agar, MH agar, or TSA without blood at 35°C.

^d See procedure 3.17.7. Do not read after time period in package insert, as this delay may result in false-positive reactions. Many *Moraxella* spp. and *Acinetobacter* spp. are butyrate positive. Isolate must be a diplococcus for identification of *M. catarrhalis* to be accurate.

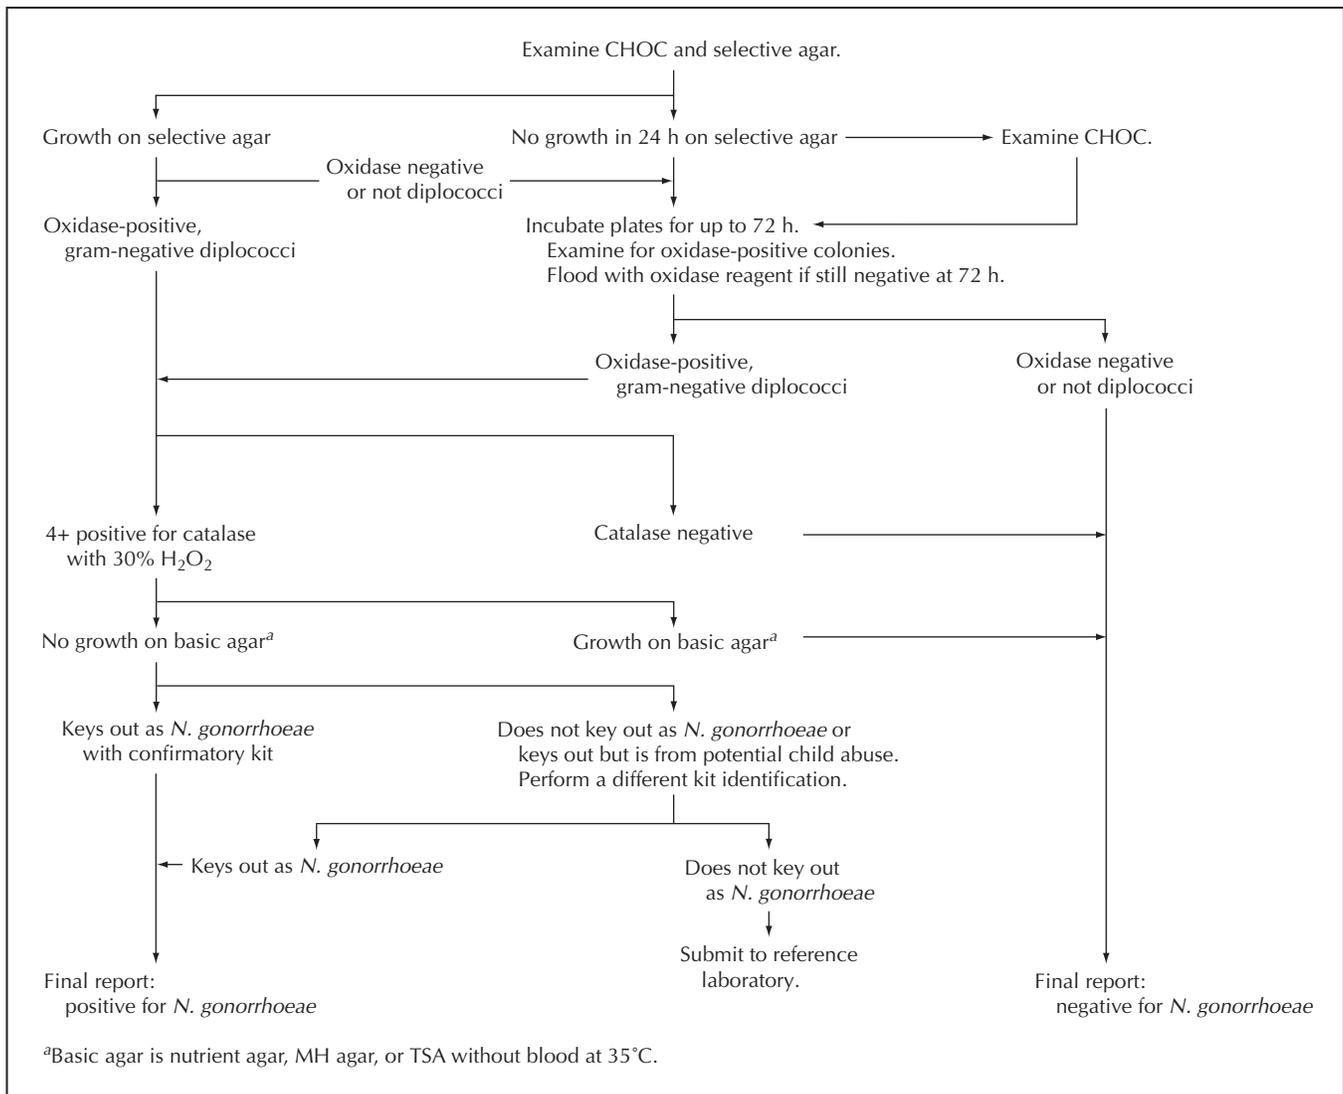

Figure 3.9.3-1 Laboratory diagnosis of *N. gonorrhoeae* by culture.

V. PROCEDURES (continued)

2. Incubation

- Incubate plates at 35 to 37°C in 5% CO₂ contained system.
- Alternatively, use a CO₂-generating contained system to provide the proper atmosphere if a CO₂ incubator is unavailable.
- If no other method is available, place in a jar and light a candle. Seal the jar quickly. When the candle is extinguished, the atmosphere contains approximately 3 to 5% CO₂.

3. Save specimen in case confirmation of identification is needed.

C. Culture examination

- Examine all plated media for macroscopic evidence of growth at 24 h.
- If no visible growth is observed on the culture media
 - Return cultures to incubator quickly to minimize loss of viability in the absence of CO₂.
 - Read aerobic plates daily for a total of 72 h before reporting as negative.

V. PROCEDURES (continued)

- c. Prior to discarding plates, flood plates with oxidase reagent. If a purple color colony is observed, immediately subculture to CHOC, since oxidase reagent is toxic to bacteria.
- 3. Cultures with growth (see Fig. 3.9.3–1)
 - a. Examine for typical colonies that are small, translucent, raised, gray, and mucoid with entire margins. When picked from the agar surface, they tend to come off as whole colonies.
 - b. Perform a Gram stain and oxidase test on suspicious colonies. If the Gram stain shows gram-negative diplococci with flattened adjacent sides or gram-negative cocci in clusters and the oxidase is positive, the isolate is presumed to be either a *Neisseria* sp. or *M. catarrhalis*.
 - c. If the specimen is sent for diagnosis of carriage of *N. meningitidis*, examine CHOC carefully and identify any oxidase-positive, gram-negative diplococci. These strains may not grow on selective agar.
 - d. Confirm identification to the species level. If the isolate is from an extra-genital site or from a child, perform two confirmatory assays that utilize distinct identification mechanisms (e.g., monoclonal antibody and carbohydrate utilization).
 - (1) Superoxol test (references 2 and 23 and procedure 3.17.10)
 - (a) Drop 30% hydrogen peroxide reagent onto colony.
 - (b) *N. gonorrhoeae* will give immediate, explosive bubbling.
 - (c) Other species, except some *N. meningitidis* and *M. catarrhalis* strains, show weak reactions. A positive result should only be considered presumptive for the identification of *N. gonorrhoeae*.
 - (2) Subculture typical colonies to a nutritionally basic medium, such as nutrient agar, TSA, or MH agar, and to CHOC for proof of viability. Failure of viable organisms to grow on one of these basic media after overnight incubation at 35°C with growth on CHOC indicates a presumptive pathogenic *Neisseria* sp.

It is imperative that these cultures be handled in a biosafety hood.

D. Culture confirmation

Choose one method as the primary method for use in the laboratory.

1. Growth-dependent carbohydrate degradation (procedure 3.17.9)
 - a. CTA supplemented with 1% carbohydrates
 - (1) Inoculate tubes containing glucose, maltose, sucrose, and lactose (*o*-nitrophenyl- β -D-galactopyranoside [ONPG] may be substituted for lactose) and a control tube containing no additional carbohydrate source.
 - (2) Incubate at least overnight, depending on inoculum density. *N. gonorrhoeae* produces acid only in glucose.
 - b. Alternatively, use carbohydrate degradation media with 20% carbohydrates.
 - (1) Use a heavy inoculum and incubate for 1 to 4 h, since the test depends on the presence of preformed enzyme activity and uses a buffered low-peptone base with 2% glucose, lactose, and sucrose and 0.3% maltose (28).
 - (2) Use the same interpretation as for growth carbohydrate degradation tests.
2. BBL GonoGen
 - **NOTE:** BBL GonoGen is a monoclonal antibody-based coagglutination test for the confirmatory identification of *N. gonorrhoeae* from culture. The assay is based on the recognition of a major outer membrane protein (protein I) of the organism.

V. PROCEDURES (continued)

- a. Suspend several colonies of suspected *N. gonorrhoeae* from culture medium in a tube containing 0.5 ml of distilled water to the equivalent of a McFarland no. 3 standard (Appendix 3.16–1).
 - b. Heat the suspension at 100°C for 10 min, cool to room temperature, and vortex to remove aggregates.
 - c. Place 1 drop of reagent G on a separate circle of a glass slide for each test isolate and for positive and negative controls.
 - d. Add 1 drop of the heat-treated suspension of organism to the drop of reagent G and mix. Add 1 drop each of the positive and negative control suspension to separate drops of reagent G and mix.
 - (1) A positive reaction produces clumping of the reagents with partial or total clearing of the organism suspension in 2 min or less.
 - (2) Test positive reactions of test isolates against the staphylococcus control reagent (reagent S) to verify specificity.
3. Phadebact GC monoclonal test
- **NOTE:** The Phadebact GC monoclonal test is a coagglutination assay in which two pools of monoclonal antibodies directed against a gonococcus-specific membrane protein (protein I) are coupled to the protein A of non-viable staphylococci. When the monoclonal antibody reagent is mixed with a sample containing gonococci, a matrix is formed causing a visible agglutination reaction.
- a. Prepare a slightly turbid suspension of cells in 0.5 ml of 0.9% saline from colonies presumptively identified as *N. gonorrhoeae*.
 - b. Heat the suspension in a boiling water bath for at least 5 min.
 - c. Cool the suspension to room temperature.
 - d. Place 1 drop of the gonococcal monoclonal reagent on a disposable slide.
 - e. Add 1 drop of the boiled colony suspension to the gonococcal reagent.
 - f. Mix the drops thoroughly but gently with a disposable loop.
 - g. Rock the slide and read the result within 1 min.
 - h. A positive and negative control should be included in each run.
 - i. A positive reaction is denoted by the appearance of visible agglutination.
4. GonoGen II
- **NOTE:** GonoGen II is a monoclonal antibody-based colorimetric test developed for the confirmatory identification of *N. gonorrhoeae* from culture. The assay is based on the recognition of a major outer membrane protein (protein I) of the organism.
- a. Label a 12- by 75-mm test tube for each isolate to be tested and for a positive and negative control.
 - b. Add 500 µl of GonoGen II solubilizing buffer to each tube and prepare a suspension of the test isolates equivalent to a McFarland no. 1 standard (Appendix 3.16–1).
 - c. Add 1 drop of the GonoGen II murine monoclonal antibody solution (antibody against protein I surface antigens of *N. gonorrhoeae*) to each tube, mix well, and incubate at room temperature for at least 5 min.
 - d. Transfer 2 drops of each test and control suspension into a separate test reaction well and allow the solution to absorb into the reaction well matrix.
 - e. A pink to red residual dot in the test well or a color reaction more intense than the negative control should be interpreted as a positive result.
5. BactiCard Neisseria
- **NOTE:** BactiCard Neisseria relies on four chromogenic substrates impregnated in a test reaction card to detect preformed enzymes produced by pathogenic *Neisseria* species. Enzyme activity will presumptively differentiate *N. gonorrhoeae*, *N. meningitidis*, *N. lactamica*, and *M. catarrhalis* (26).

V. PROCEDURES (continued)

- a. Rehydrate each substrate test circle with 1 drop of BactiCard rehydrating fluid.
 - b. From a pure culture 18 to 48 h old, growing on selective medium (not CHOC), smear several colonies of the isolate onto each substrate test circle with a wooden applicator stick.
 - c. Incubate at room temperature for 2 min.
 - d. Observe each test circle for the production of a blue-green color that indicates a positive test for enzyme activity or a pink to red color after addition of the color developer.
 - (1) *N. gonorrhoeae* is positive only for prolyl-iminopeptidase and negative for β -galactosidase, butyrate esterase, and δ -glutamyl-aminopeptidase (Table 3.9.3–1).
 - (2) Certain strains of *Kingella*, *Neisseria cinerea*, and *Neisseria subflava* could provide reactions consistent with *N. gonorrhoeae*. Care must be taken to only test isolates recovered from selective media that do not grow on nutrient agar (see Table 3.9.3–1).
6. Gonocheck II, NET and Neisseria Screen
- **NOTE:** Gonocheck II or NET or Neisseria Screen relies on three chromogenic substrates in a test tube to detect preformed enzymes produced by pathogenic *Neisseria* species. Enzyme activity will presumptively differentiate *N. gonorrhoeae*, *N. meningitidis*, and *N. lactamica* (27).
- a. Dispense 4 drops of reagent buffer into reagent tube.
 - b. Remove 5 to 10 colonies and emulsify into tube.
 - c. Incubate at 37°C for 30 min.
 - d. Yellow color is indicative of *N. meningitidis* (positive for δ -glutamyl-aminopeptidase), and blue color (positive for indolyl- β -D-galactosidase) is indicative of *N. lactamica* (Table 3.9.3–1). If the yellow color is faint, incubate for 60 min to confirm identification.
 - e. If there is no color change, remove white cap and recap with red cap (Gonocheck II). Invert to allow reagent in cap to mix with solution. (Alternatively, add reagent to the tube for Neisseria Screen and NET.) A red to pink color (positive for prolyl-iminopeptidase) when returned to the upright position indicates positivity for *N. gonorrhoeae*.
 - f. Certain strains of *Kingella*, *Neisseria cinerea*, and *Neisseria subflava* could provide reactions consistent with *N. gonorrhoeae*. Care must be taken to only test isolates recovered from selective media or from CHOC that do not grow on nutrient agar (see Table 3.9.3–1).
7. MicroTrak *N. gonorrhoeae* culture confirmation test
- **NOTE:** The MicroTrak test uses a fluorescein-labeled monoclonal antibody in a fluorescent microscopy assay to positively identify presumptive isolates of *N. gonorrhoeae*.
- a. Perform the assay on 18- to 24-h colonies. Subculture colonies older than 24 h before testing.
 - b. Place 5 μ l of distilled or deionized water in a 6-mm slide well.
 - c. Touch five colonies of the isolate to be tested with a loop and gently emulsify the cells into the drop of water to form an even suspension on the slide well. Prepare wells of known positive and negative controls in a similar fashion.
 - d. Allow the slide to air dry, and gently heat fix the smear.
 - e. Stain the slide with MicroTrak *N. gonorrhoeae* culture confirmation reagent (30 μ l per well) for 15 min at 37°C in a humidified chamber.
 - f. Remove excess reagent and rinse the slide for 5 to 10 s in a gentle stream of water. Shake off the excess water, and air dry the smear.
 - g. Add a drop of mounting fluid and place a coverslip on the well.

VI. REPORTING RESULTS*(continued)*

- B. Refer to procedure 3.3.2 for general reporting guidelines.
- C. Report negative cultures as “No *Neisseria gonorrhoeae* organisms isolated.” Additionally, a comment can be added as follows.
 - 1. “Specimen overgrown by normal microbiota. Please submit another specimen.”
 - 2. “Specimen contaminated with yeast cells, which are inhibitory to *Neisseria gonorrhoeae*.”
 - 3. “Specimen received 24 h after collection. Rates of recovery of *Neisseria gonorrhoeae* from specimens with delayed transport can be significantly reduced.”
- D. Report positive cultures with probable genus and species as soon as preliminary tests are completed.
 - 1. Document notification to physician of positive findings.
 - 2. Generally report *N. gonorrhoeae* to the local health department.
 - 3. In cases involving children or the possibility of legal intervention, isolates of *N. gonorrhoeae* should be frozen for long-term retrieval.
- E. Antimicrobial susceptibility testing (AST)
 - 1. Do not perform routine AST of *N. gonorrhoeae*. Perform AST only in cases of treatment failure (8) and for antimicrobial agents for which universal susceptibility has not been established. Refer to NCCLS guidelines (20) for special media and conditions of AST.
 - 2. Do not perform beta-lactamase test, because currently recommended therapies circumvent beta-lactamase production by *N. gonorrhoeae* (8).

VII. INTERPRETATION

- A. A positive culture indicates infection with the organism.
- B. Because of the labile nature of the organism, a negative culture does not rule out infection.

VIII. LIMITATIONS

- A. False-positive reports can result from misidentification of the organism.
- B. False-negative results can be caused by delayed or inappropriate transport.
- C. A single negative result produced by any of the confirmatory tests does not rule out an identification of *N. gonorrhoeae*. Further confirmatory testing should be performed.
- D. When carbohydrate degradation tests are used, a few strains of *N. gonorrhoeae* will be glucose negative and a few strains of *N. meningitidis* will be maltose negative. A second non-carbohydrate-based method should be used to identify these discrepant strains.
- E. Use reagent-grade carbohydrates if you make your own media to avoid glucose contamination in other carbohydrate reagents.
- F. The growth from a positive CTA glucose utilization test should be examined by Gram stain to ensure that the reaction is due only to *N. gonorrhoeae* and not a contaminant.
- G. More than one confirmatory method for identification of *N. gonorrhoeae* is essential for potential cases of child abuse, since nearly every method has some errors.
- H. Avoid use of candle jars, since superior products to generate CO₂ are available. If using candle jars, use only white wax candles. Colored candles yield toxic substances.
- I. *N. cinerea*, usually a saprophyte found in the pharynx, can be an occasional pathogen. It has been reported in cases of conjunctivitis, bacteremia, and peritonitis. The microorganism gives a positive glucose reaction in some rapid sys-

VIII. LIMITATIONS (continued)

tems and is also positive for hydroxyprolylaminopeptidase. Hence, this organism can be mistaken for *N. gonorrhoeae* unless additional testing is performed (6, 10). Further, differentiation of *N. cinerea* from glucose-negative *N. gonorrhoeae* can be difficult when using substrate-based identification kits (7). *N. cinerea* is, however, susceptible to colistin and thus will likely not be recovered on media containing this agent. In addition, most strains will grow well on nutritionally basic agar media such as TSA, MH agar, or nutrient agar.

- J. Monoclonal antibodies might not react with all strains of *N. gonorrhoeae*, and false-positive monoclonal antibody reactions have been reported with *N. meningitidis* (19).

3.9.4

Haemophilus ducreyi Cultures

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Haemophilus ducreyi is the etiologic agent of a sexually transmitted genital ulcer disease known as chancroid. The disease is common in Africa, Asia, and Latin America, but there are over 1,000 reported cases each year in the United States, mostly from the South and the southeastern region (12). Chancroid presents as an acute, localized infection with necrotizing ulcers. The soft chancre, which contains short streptobacillary gram-negative rods, can

resemble the ulcers of herpes simplex or syphilis. Two lesions often appear together which are soft on palpation, having a deep ulcerative center (1). In most cases, the disease is diagnosed clinically, but reports of sensitivities using that method alone range from 40 to 80% (12). Ruling out syphilis and other genital infections can increase the sensitivity. Recently, it has been noted that human immunodeficiency virus infection prolongs the disease

and can modify its presentation. Gram stains from the leading edge of the ulcer can be helpful early in the infection before the ulcer is contaminated with other microbiota, but culture is the definitive method of diagnosis. Unfortunately the organism is labile and difficult to grow without specialized media. West et al. (13) and others (12) have used PCR methods to detect the organism.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

■ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for physicians and caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

A. Specimen collection (1)

Refer to procedure 3.9.1 for further details on specimen collection.

1. Prior to collection, obtain two different selective agar plates (*see* item III.A) from the laboratory, if they are available.
2. Clean the surface of the lesion with 0.85% NaCl.
 - a. If there is a crust on the lesion, remove it.
 - b. Moisten swab with saline and collect specimen by vigorously rubbing the base of the lesion.
 - c. Alternatively, scrape the base of the ulcer with a sterile scalpel blade.
 - (1) Irrigate with sterile saline.
 - (2) Then rub the base vigorously with a sterile swab, or aspirate fluid with a flamed smoothed Pasteur pipette or needle and syringe.
3. Abscess

■ **NOTE:** Intact bubo aspirates are rarely positive for the organism unless they have ruptured.

 - a. Disinfect skin with alcohol and iodine.
 - b. Aspirate fluid with a needle and syringe.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

B. Specimen transport

1. Plates
 - a. Inoculate selective agar plates (*see* item III.A) with specimen.
 - b. Submit to laboratory immediately for incubation.
2. Transport medium
 - a. Inoculate Amies transport medium or a specially formulated THIO-hemin-based medium containing L-glutamine and albumin (3).
 - b. Place immediately on ice or in the refrigerator until and during transport.
 - **NOTE:** Dangor et al. (3) showed that at room temperature in any transport medium, the organisms do not survive 24 h. Organisms survived in Amies medium for 3 days at 4°C but were viable for longer periods in specially formulated THIO.
3. Label specimens with the patient's demographic information and the site of collection. Attach requisition listing the patient's name, address, medical record number, sex, age, collection location, site of collection, specific test request, and physician of record.

C. Rejection criteria

1. *H. ducreyi* is quite labile. Culture should not be attempted unless special medium is available or specimens can be transported in suitable transport medium on ice to a laboratory with specialized media.
2. Prior antimicrobial treatment reduces the ability to isolate the organism (4).

III. MATERIALS

A. Media

Inoculate any two selective media plus CHOC.

1. Selective media

■ **NOTE:** Plates that are commercially available are from Remel, Inc., as CHOC with vancomycin and CHOC with fetal bovine serum and vancomycin. Other media listed below must be prepared in-house.

- a. GC agar base with 1% IsoVitaleX (BD Diagnostic Systems), 5% fetal bovine serum, 1% hemoglobin, and 3 µg of vancomycin per ml (3, 4)
- b. GC agar base with 5% Fildes enrichment, 5% horse blood, and 3 µg of vancomycin per ml
- c. 5% Fresh rabbit blood agar with 3 µg of vancomycin per ml (11)
- d. Mueller-Hinton agar with 5% chocolatized horse blood, 1% IsoVitaleX, and 3 µg of vancomycin per ml (3, 4)

■ **NOTE:** Some isolates will grow on one medium but not others (12); some lots of fetal bovine serum are inhibitory. Use of two media and repeating cultures at 48 h increased the isolation rate to 92% for men with ulcers who had no

prior antimicrobial use or evidence of syphilis (5). Oberhofer and Black (8) demonstrated that Mueller-Hinton base was clearly superior to TSA base, although there was little difference between 5% sheep blood and supplemented CHOC. Vancomycin is used to inhibit gram-positive microbiota but may inhibit some strains of *H. ducreyi*.

2. Nonselective media: CHOC

B. Identification methods

1. Gram stain (procedure 3.2.1)
2. Catalase test (procedure 3.17.10)
3. Oxidase test (procedure 3.17.39). Do not use *N,N*-dimethyl-*p*-phenylenediamine dihydrochloride.
4. Indole test (procedure 3.17.23)
5. Aminolevulinic acid (ALA) test for porphyrin synthesis (procedure 3.17.3)
6. Sodium polyanethol sulfonate (SPS) disk (procedure 3.17.45) (Remel, Inc.)
7. Optional: one of the following
 - a. RapID NH (Remel, Inc.) (6)
 - b. RapID ANA (Remel, Inc.) (10)

C. Other supplies

1. Incubator at 33°C
2. CO₂-generating bag for culture incubation

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that plate media meet expiration date and QC parameters per current NCCLS document M22. See procedures 14 and 3.3.1 for further procedures.
- B. Perform QC with each lot of selective agar. Incubate aerobically overnight at 33°C in an airtight container with a CO₂-generating system.

Test organism	Result
<i>Haemophilus ducreyi</i> ATCC 33940	Growth in 48 h
<i>Staphylococcus epidermidis</i> ATCC 12228	Inhibition of growth if vancomycin in agar

V. PROCEDURE

Observe standard precautions.

- A. Inoculation
 - NOTE:** Use of biosafety cabinet will avoid contamination of the culture or specimen as well as protect laboratory processing personnel. If the specimen is not received on plates, inoculate plates from the swab in transport medium. Use CHOC without vancomycin and two selective media with vancomycin.
- B. Direct smear
 1. Prepare a Gram stain from the swab after plate inoculation.
 2. Stain slide (procedure 3.2.1) and observe for gram-negative coccobacilli arranged in short chains, clumps, or whorls with occasional “rail track” or “school of fish” arrangements (7).
 - NOTE:** Direct exam has a sensitivity of about 60% (4).
- C. Incubation
 1. Incubate plates at 33 to 34°C in 5% CO₂, using a CO₂-generating system to provide the proper atmosphere and moisture. Keep plates moist using sterile-water-moistened filter paper.
 - NOTE:** Recovery is substantially increased if the incubation is at 33°C rather than 35°C (9).
 2. Observe for growth after at least 48 h of incubation. Hold negative plates for 5 days.
- D. Culture examination
 1. Observe plates for variable-size, smooth, dome-shaped colonies that are buff-yellow to gray. Whole colonies move across the agar when touched with a loop (1, 7). Colonies are often pinpoint at 48 h and increase to 2 mm in diameter.
 2. Perform Gram stain; colonies will clump in saline. Gram-negative coccobacilli should be identified further.
 3. Rapidly perform the following tests from a young culture and determine if the reactions agree with those listed below (7).
 - a. No growth on MAC
 - b. Catalase negative
 - c. Oxidase positive—reaction may be slow and require 15 to 20 s
 - d. Indole negative
 - e. ALA negative (no fluorescence or porphyrin production)
 4. If the above reactions are consistent with the identification, confirm the identification as follows.
 - a. Test with SPS on CHOC.
 - NOTE:** *H. ducreyi* is susceptible, with a zone ≥12 mm; no other *Haemophilus* species are susceptible. The addition of 0.002% Tween 80 may aid in dispersion of the cells (10). *Capnocytophaga* is another genus of

V. PROCEDURE (continued)

- gram-negative coccobacillus that is reported to be SPS susceptible, but *Capnocytophaga* is ALA positive (10).
- b. Optional: perform either the RapID NH (6) or the RapID ANA (10) for further confirmation using enzyme reactions. *H. ducreyi* is asaccharolytic.
 - c. Submit to a reference laboratory if further confirmation is desired, especially until proficiency in the recognition of the colony morphology is determined.
- E. Hold positive culture plates for at least 7 days should antimicrobial susceptibility testing be needed. Since strains are usually beta-lactamase positive, there is no need to test for this enzyme (12).

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. If the culture is negative, report "No *Haemophilus ducreyi* isolated."
- B. Positive reporting
 1. *H. ducreyi* organisms are catalase-negative, oxidase-positive, gram-negative coccobacilli that are SPS sensitive and ALA negative.
 2. Report the presence of *H. ducreyi* as soon as preliminary tests are completed.
 3. Do not report any enumeration.
 4. Generally report positive results to the physician and to the local health department.
 5. Document notification of reporting to the physician and health department.

VII. INTERPRETATION

- A. A positive culture indicates infection in a patient with an ulcerative lesion.
- B. The CDC (2) recommends treating *H. ducreyi* with azithromycin, 1 g orally in a single dose; ceftriaxone, 250 mg intramuscularly in a single dose; or erythromycin base, 500 mg per os four times a day for 7 days.
- C. Mixed infections with other agents known to cause ulcerative sexually transmitted diseases are not uncommon. The presence of *H. ducreyi* does not rule out these other infections, which should be considered in the evaluation of the patient.

VIII. LIMITATIONS

- A. Methods that employ PCR for the detection of *H. ducreyi* are more rapid than culture techniques and may have an increased sensitivity (12).
- B. False-negative cultures can result from prior antimicrobial therapy, strain growth variability, and sampling and transport techniques. Culture using one medium can have a sensitivity from 65 to 75% (12); using two media will increase the sensitivity to more than 84%.
- C. False-negative reports can result from misreading the oxidase test as negative.
- D. False-positive results can be caused by misinterpretation of the confirmatory tests.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Inflammatory eye conditions may be due to a variety of diseases, and microorganisms play a major role in both acute and chronic diseases. The detection of infectious agents depends on knowledge of the site of infection and the severity of the process, because a variety of organisms cause infections of the eye. Unlike the pro-

cedures with other specimen types, it may be important for the physician to inoculate culture media at the bedside rather than transport the specimen to the laboratory for processing. This procedure describes the clinical syndromes associated with bacterial infections of the eye, the organisms associated with these syndromes, and

the procedure for isolation of these infectious agents. In addition to aerobic bacterial culture, Table 3.10–1 indicates the media to inoculate for anaerobic, fungal, and mycobacterial cultures. Refer to the respective sections of the handbook for workup of the microorganisms that are not covered in this procedure.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

■ **NOTE:** Most eye specimens are collected by an ophthalmologist. These specimens are inoculated onto culture media at the bedside, in the clinic or the physician's office. A variety of techniques are used to collect material from different parts of the eye. The conjunctiva is constantly contaminated by various bacteria from the environment and ocular adnexa. Therefore, specimens from the conjunctiva serve as a control when compared with specimens collected by more aggressive or invasive techniques. See section 2 for general principles of collection.

■ **NOTE:** Refer to procedure 3.3.1 for additional details on specimen collection. The following can be copied for preparation of a specimen collection instruction manual for physicians and other caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

Observe standard precautions.

- A. Provide fresh media to the clinical areas routinely collecting ocular cultures, and instruct physicians to immediately transport inoculated media and slides to the laboratory.
- B. Obtain viral and chlamydial samples before topical anesthetics are instilled.
 1. Obtain samples for chlamydial cultures with calcium alginate swabs.
 2. For viral cultures, use Dacron or cotton swabs with nonwood shafts.
- C. Collection by anatomic site (*see* Appendix 3.10–1 for definitions of syndromes)
 - **NOTE:** *Specimen collection must be performed by a qualified physician.*
 1. Conjunctiva (bacterial conjunctivitis) and lid margin (if staphylococcal blepharconjunctivitis is suspected)
 - a. Obtain the specimen with a sterile, premoistened cotton or calcium alginate swab.
 - b. Roll the calcium alginate or cotton swab over the conjunctiva before topical medications are applied.

Table 3.10–1 Handling of specimens^a

Clinical condition and specimen	Expected organism(s)	Primary isolation media	Probable contaminants	Additional comments
Bacterial conjunctivitis	<i>Haemophilus influenzae</i> <i>Staphylococcus aureus</i> <i>Streptococcus pneumoniae</i> <i>Neisseria gonorrhoeae</i> <i>Streptococcus pyogenes</i> <i>Moraxella</i> spp.	BAP CHOC	<i>P. acnes</i> <i>Peptostreptococcus</i> spp. Coagulase-negative staphylococci	<i>P. aeruginosa</i> or <i>Enterobacteriaceae</i> may be cause in immunocompromised or hospitalized patients. Perform anaerobic or fungal cultures if organisms are suspected. Smears Gram stain Giemsa or DFA for <i>Chlamydia trachomatis</i>
Bacterial keratitis (corneal scrapings)	<i>Pseudomonas aeruginosa</i> <i>S. pneumoniae</i> <i>Moraxella</i> spp. Viridans group streptococcus <i>S. aureus</i> Rapidly growing mycobacteria Contact lens associated <i>Bacillus</i> spp. <i>Serratia</i> spp.	BAP CHOC Fungal media, e.g., potato flake agar Lowenstein-Jensen or other mycobacterial agar and broth media	Coagulase-negative staphylococci Diphtheroids <i>P. acnes</i> Viridans group streptococci	Other causes <i>Enterobacteriaceae</i> <i>N. gonorrhoeae</i> <i>N. meningitidis</i> <i>H. influenzae</i> <i>Acanthamoeba</i> <i>Candida albicans</i> <i>Fusarium</i> spp. Smears of corneal scrapings should accompany cultures
Bacterial endophthalmitis	Postsurgical <i>S. aureus</i> Coagulase-negative staphylococci <i>S. pneumoniae</i> <i>Streptococcus</i> spp. <i>P. aeruginosa</i> <i>Propionibacterium acnes</i> (postcataract) Traumatic <i>Bacillus</i> spp. <i>Clostridium</i> spp. Immunosuppression and i.v. drug abusers <i>S. aureus</i> <i>H. influenzae</i> <i>S. pneumoniae</i> <i>Neisseria meningitidis</i> <i>Bacillus</i> spp. <i>Mycobacterium</i> spp.	BAP CHOC Fungal media, e.g., potato flake agar Supplemented blood agar (anaerobic) Lowenstein-Jensen Liquid anaerobic media, e.g., THIO	Coagulase-negative staphylococci Diphtheroids	Conjunctival cultures may be collected simultaneously to determine significance. Smears should accompany cultures of fluid. Postcataract surgery can result in chronic infection, occurring months to years after surgery. Any fungal or bacterial microorganism can be involved.
Preseptal cellulitis (aspirate)	<i>S. aureus</i> <i>S. pyogenes</i> <i>H. influenzae</i> (6–30 mo) Other streptococci	BAP CHOC Supplemented blood agar for anaerobes THIO (or other anaerobic blood medium)		Do Gram-stained smears. Trauma: <i>Clostridium</i> spp. and mixed anaerobes. Possible other etiologies <i>P. aeruginosa</i> Other gram-negative bacilli
Orbital cellulitis (aspirate or biopsy specimen)	<i>S. aureus</i> <i>S. pneumoniae</i> <i>P. aeruginosa</i> <i>H. influenzae</i> (under 5 yr) <i>S. pyogenes</i> Gram-negative bacilli	BAP CHOC Supplemented blood agar for anaerobes THIO or other anaerobic medium Fungal media, e.g., potato flake agar	Coagulase-negative staphylococci Diphtheroids	Mixed aerobic and anaerobic infections may occur in trauma cases. Obtain blood culture specimens simultaneously. Do smears along with cultures.

Table 3.10–1 (continued)

Clinical condition and specimen	Expected organism(s)	Primary isolation media	Probable contaminants	Additional comments
Miscellaneous Dacryoadenitis	<i>S. aureus</i> <i>S. pneumoniae</i> <i>S. pyogenes</i>	BAP CHOC	Coagulase-negative staphylococci Diphtheroids (<i>P. acnes</i>) Viridans group streptococci	Gram stains may help determine significance.
Dacryocystitis	<i>S. pneumoniae</i> <i>S. aureus</i> <i>S. pyogenes</i> <i>H. influenzae</i>	BAP CHOC Supplemented blood agar plate for anaerobes THIO or other anaerobic broth	Coagulase-negative staphylococci Diphtheroids Viridans group streptococci	Obtain smears along with cultures. With fistulae, contamination may be difficult to determine.
Canaliculitis	<i>Actinomyces israelii</i> <i>Propionibacterium propionicum</i> <i>Moraxella</i> spp. Diphtheroids Viridans group streptococci	BAP CHOC Supplemented blood agar for anaerobes Fungal media, e.g., potato flake agar THIO or other anaerobic broth	Coagulase-negative staphylococci Diphtheroids <i>P. acnes</i>	Do Gram stains to help determine significance of isolates and/or presence of <i>Actinomyces</i> spp.

^a Abbreviations: i.v., intravenous; DFA, direct fluorescent-antibody assay.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- c. Culture both eyes with separate swabs.
- d. Immediately inoculate the material at the bedside onto BAP and CHOC as listed in Table 3.10–1.
- e. Inoculate the swab from the right conjunctiva in horizontal streaks, and inoculate the swab from the left conjunctiva in vertical streaks, each on one half of the same agar plate.
- f. Inoculate specimens from the right and left lid margins, if collected, by making an R and an L to represent the respective sites on another agar plate.
- g. Obtain conjunctival scrapings for a smear preparation as follows.
 - (1) Instill 1 or 2 drops of proparacaine hydrochloride.
 - (2) Using a Kimura spatula, gently scrape across the lower right tarsal conjunctiva.
 - (3) Smear the material in a circular area 1 cm in diameter on a clean glass slide.
 - (4) Prepare at least two slides.
 - (5) Immerse the slides in 95% methyl alcohol or 100% methanol for 5 min.
 - (6) Repeat steps on the left conjunctiva.
2. Bacterial keratitis
 - a. Instill 1 or 2 drops of proparacaine hydrochloride.
 - b. Obtain conjunctival samples as described above, and then obtain corneal scrapings from the advancing edge of the ulcer by scraping multiple areas of ulceration and suppuration with a sterile Kimura spatula, using short, firm strokes in one direction. (Keep the eyelid open, and be careful not to touch the eyelashes.)
 - c. Obtain approximately three to five scrapings per cornea.
 - d. Inoculate each set of scrapings onto BAP and CHOC, using a C formation for each scraping.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- e. Prepare smears by applying the scrapings in a gentle circular motion over a clean glass slide or by compressing material between two clean glass slides and pulling the slides apart (*see* Fig. 3.2.1–1).
 3. Bacterial endophthalmitis
 - a. Collect an aspirate of the vitreous fluid or perform a paracentesis of the anterior chamber using a needle aspiration technique to collect intraocular fluid.
 - b. Collect specimens for conjunctival cultures along with the fluid to determine the significance of indigenous microbiota.
 - c. If a small volume of fluid is collected, inoculate cultures at the bedside by inoculating 1 or 2 drops of fluid onto culture media (Table 3.10–1).
 - d. Alternatively, submit in anaerobic transport tube or capped syringe after replacing the needle with a Luer-Lok.
 4. Preseptal cellulitis
 - a. Cleanse the skin with alcohol and tincture of iodine or iodophor.
 - b. In the absence of an open wound, the physician makes a stab incision in either the upper or lower lid with a no. 11 Baird-Parker blade.
 - c. If there is an open wound, collect the purulent material with a syringe and needle.
 - d. Inoculate media (Table 3.10–1), and prepare slides as described above for conjunctivitis.
 - e. Inject some material into an anaerobic transport vial, and process specimens for anaerobes as described in section 4 of this handbook.
 5. Orbital cellulitis
 - a. Obtain aspirate or biopsy sample of the wound, and process as described above for preseptal cellulitis. Additionally, inoculate fungal media or submit to the laboratory for inoculation (Table 3.10–1).
 - b. Collect blood cultures.
 6. Dacryoadenitis
 - a. Collect a specimen of the purulent discharge by using a swab, as described above for conjunctivitis. Inoculate media (Table 3.10–1).
 - b. Do not perform a needle aspiration of the lacrimal gland.
 7. Dacryocystitis
 - a. Obtain conjunctival cultures.
 - b. Press the lacrimal sac to remove exudate material for culture and smear, or collect exudate in a needle and syringe.
 - c. Place aspirated material in a transport vial, and transport to the laboratory.
 8. Canaliculitis
 - a. Compress the inner aspect of the eyelid to express pus.
 - b. Follow procedure outlined above for conjunctivitis.
 - c. Inoculate media (Table 3.10–1), and prepare slides as described above for conjunctivitis.
 - d. Additionally, inoculate fungal media or submit to the laboratory for inoculation (Table 3.10–1).
 - e. Inject some material into an anaerobic transport vial, and process specimens for anaerobes as described in section 4 of this handbook.
- D. Rejection criteria
1. Request that a swabbed specimen of the conjunctiva accompany any specimen collected by invasive technique.
 2. Even in cases of suspected unilateral conjunctivitis, indicate that bilateral bacterial cultures are mandatory.
 3. When inoculated plates are delayed in transit, notify the physician that the culture may be compromised or contaminated.

III. MATERIALS

- | | |
|---|--|
| <p>A. Media</p> <ol style="list-style-type: none"> 1. BAP 2. CHOC 3. Anaerobic BAP (<i>see</i> section 4 for options) 4. THIO or other anaerobic broth for anaerobic culture 5. Media for fungal and mycobacterial cultures as listed in Table 3.10–1 (<i>see</i> sections 7 and 8) | <p>B. Gram stain reagents and slides</p> <p>C. Specimen collection devices</p> <ol style="list-style-type: none"> 1. Kimura platinum spatula 2. Cotton, polyester, or calcium alginate swab 3. Needle and syringe 4. Aerobic swab transport system 5. Anaerobic transport system 6. Topical anesthetic—proparacaine hydrochloride (0.5%) |
|---|--|

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. *See* procedures 14 and 3.3.1 for further procedures, especially for in-house-prepared media.
- B. Swabbed specimens from the conjunctiva are used as a control along with other specimens collected by more aggressive or invasive techniques.
- C. Conjunctival cultures are used to determine the presence of indigenous microbiota.

V. PROCEDURE

Observe standard precautions.

- A. **Direct smears**
 1. Gram stain
 - a. Prepare two or three smears from the clinical material if glass slides do not accompany the specimen. If cheesy concentrations are present, crush them onto a slide for Gram stain.
 - b. Place slides in 95 or 100% methanol for 5 to 10 min to fix material.
 - c. Perform a Gram stain (*see* procedure 3.2.1).
 - d. Examine the stained smear for the presence of somatic cells and extra- and intracellular organisms.
 - (1) The presence of PMNs suggests a bacterial infection.
 - (2) The presence of mononuclear cells may indicate viral conjunctivitis. Refer to section 10 of this handbook for detailed viral procedures.
 - (3) Refer to the Gram stain procedure (3.2.1) for details on interpretation of various morphologies observed on the smear.
 - (4) Refer to section 9 for examination for microsporidia.

▣ **NOTE:** Pigment granules that resemble gram-positive cocci may be present on the Gram-stained smear. They can be differentiated from cocci because they are large, oval, and brown.
 2. Giemsa stain
 - a. For suspected chlamydial infections, prepare smears and examine them for intracytoplasmic inclusions.
 - b. Alternatively, perform direct fluorescent-antibody test or culture for *Chlamydia* (procedures 10.6 and 10.7) or PACE 2 nucleic acid probe (Gen-Probe, Inc.) (procedure 12.2.2, part 1).
 3. Calcofluor white stain
 - a. Prepare a calcofluor white stain if fungi or *Acanthamoeba* cysts are suspected.
 - b. For details, refer to procedure 9.3.8.
- B. **Culture inoculation, examination, and interpretation**
 1. Inoculate culture media according to Table 3.10–1, if plates are not received. Streak in quadrants for isolation of colonies.
 - a. If a scant specimen of intraocular fluid is submitted in a syringe, use broth to wash out the syringe by drawing up a small amount of broth.

V. PROCEDURE (*continued*)

- b. Use the broth to inoculate plate media with 2 drops per plate.
 - c. Place the balance of the broth and specimen in broth culture tube. Avoid creating an aerosol.
 - d. For culture for *Acanthamoeba*, refer to procedure 9.9.2.
2. Incubate cultures at 35°C in 5 to 7% CO₂ for 72 h.
3. Refer to procedure 3.3.2 for instructions on incubation and examination of broth cultures. Hold broth cultures from invasively collected ocular specimens for 10 days (1, 3) to detect infections with *Propionibacterium acnes*.
4. Examine daily for the presence of microorganisms.
5. Estimate and report the number of each organism on each plate. The presence of moderate numbers of colonies or many colonies on one or more culture plates should indicate the bacterial etiology of the infection.
6. For quantitation of C streaks
 - a. 1 + : less than half of the C streaks are positive per plate
 - b. 2 + : more than half of the streaks, but not all, are positive
 - c. 3 + : all streaks are positive for bacteria
7. Identify the organisms by using the tests recommended in procedures 3.3.2, 3.18.1, and 3.18.2.
8. Consult the physician prior to identifying rare colonies of indigenous microbiota from noninvasively collected specimens, including the following.
 - a. Coagulase-negative staphylococci
 - b. Diphtheroids
 - c. Viridans group streptococci
 - d. *Moraxella catarrhalis*
 - e. *P. acnes*
 - f. *Peptostreptococcus* spp.
9. Correlate culture with the Gram stain of the direct smear.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. Telephone positive reports from invasively collected specimens to the physician as soon as possible.
- B. Report the relative number and morphology of all microorganisms seen, the presence and numbers of somatic cells (especially PMNs), and whether the organisms were observed intracellularly as well as extracellularly.
- C. Report the quantity and organism identity for each morphological type observed on culture media.
- D. If indigenous microorganisms are present and it has been determined that they may be contaminants, include a comment such as "Possible contamination" and/or "Presence of indigenous conjunctival microbiota."

VII. INTERPRETATION

- A. Generally if organisms are present in the direct smear and on the culture plates, they are considered significant.
- B. Use the following criteria to determine the significance of bacterial isolates that may otherwise be considered indigenous microbiota.
 1. Compare isolation of rare colonies of coagulase-negative staphylococci, diphtheroids, *P. acnes*, or viridans group streptococci with isolation from conjunctival cultures, if obtained.
 2. If growth occurs on more than one medium, results are generally considered significant in light of the clinical and Gram stain findings.
 - a. Determine if growth is present in the broth of either the aqueous or the vitreous fluid specimen or both.
 - b. If growth of one organism from the fluid occurs on only one medium, results may be considered equivocal.

VIII. LIMITATIONS

- A. False-positive cultures can result from contamination of the specimen or the inoculated plates with skin microbiota.
- B. Conversely, false-negative reports can result from considering corynebacteria as contaminating microbiota when they can be pathogens. For example, *Corynebacterium macginleyi* has been implicated in conjunctivitis and corneal ulcers (2).
- C. False-negative results can occur if antimicrobial agents are given prior to collection of the specimens.
- D. Even with the best techniques, culture often fails to yield the infecting organism. Currently, use of DNA probes is being investigated as a more sensitive alternative to culture.

APPENDIX 3.10-1

Descriptions of Clinical Syndromes Associated with Ocular Infections

A. Conjunctivitis

Conjunctivitis is an acute or chronic inflammation of the conjunctiva, the mucous membrane covering the anterior surface (sclera) of the eye. The symptoms, which may be unilateral or bilateral, include reddening of the surface, tearing, and a purulent discharge. The source of the involved bacterial organism is usually direct inoculation of exogenous organisms from fomites, hands, environment, etc., but hematogenous spread from another focus can occur.

B. Bacterial keratitis

Keratitis is defined as an inflammation of the cornea. It may present with a wide range of symptoms extending from a superficial infection of the corneal epithelium to deep stromal ulceration that may lead to perforation and/or loss of the eye. It is a serious condition requiring prompt and meticulous investigation. Predisposing factors for corneal ulceration include prior ocular disease, contact lens wear, and use of topical corticosteroids. In addition to persons with these factors, other individuals at risk include alcoholics, burn patients, and otherwise immunocompromised patients. Symptoms of keratitis include redness of the eye, inflammation of the conjunctiva, increased pain, decreased vision, and photophobia. Patients feel a foreign-body sensation in the eye that results in tearing and exudate formation.

C. Bacterial endophthalmitis

Endophthalmitis is the most serious and sight-threatening infection of the eye. It is an inflammation of the ocular cavities and intraocular tissue (uvea and retina) resulting from trauma to the eye, including surgery, injury, or corneal suppuration and perforation following keratitis. Endogenous endophthalmitis as a result of bacterial sepsis or from a contagious site, i.e., cellulitis, may also occur. The infection following surgery will often manifest within 72 h of surgery, presenting with decreased vision, pain, lid edema, conjunctival hyperemia, severe iridocyclitis (uveitis), and hypopyon (pus in the eye). Chronic endophthalmitis may follow.

D. Preseptal cellulitis

Preseptal cellulitis is an inflammation of the periorbital tissues resulting from traumatic injury, laceration, or a puncture wound. It may also result from an extension of impetigo or erysipelas. Symptoms are a warm erythematous eyelid with conjunctival edema. The condition needs to be differentiated from orbital cellulitis, a more systemic, severe infection of the orbit itself.

E. Orbital cellulitis

Orbital cellulitis is an infection of the orbital tissue resulting from trauma, surgery, or an extension of paranasal infection or panophthalmitis. It is a serious, systemic infection and may cause blindness, septic thrombosis of the cavernous sinus, or intracranial infections. Symptoms include fever, leukocytosis, lid edema, and limitation of ocular motility.

F. Miscellaneous ocular infections

1. Dacryoadenitis is an infection of the lacrimal glands. Symptoms include pain and tenderness in the upper lid.
2. Dacryocystitis is an infection of the lacrimal sac that usually follows obstruction of the nasolacrimal duct. Symptoms include pain, swelling, redness, and tenderness of the lacrimal gland. A fistula may form.
3. Canaliculitis is an inflammation of the canaliculus, the passage that connects the punctum to the lacrimal sac. Symptoms include swelling, pain, and tenderness at the corner of the eye. The infection may be accompanied by unilateral conjunctivitis and hyperemia of the eyelid.

3.11.1

Guidelines for Performance of Respiratory Tract Cultures

Specimens from the upper respiratory tract (throat specimens, nasopharyngeal swabs, nasal discharges) can be easily obtained but are contaminated with resident microbiota. In addition, many microorganisms present in the nares and throat are found in both the disease and the carrier states (1, 2, 3). It is estimated that 60% of children sporadically carry *Streptococcus pneumoniae* in their nasal passages by the age of 2 years (1). Because of this contamination, these specimens often do not provide accurate, clinically useful information for diagnosis of bacterial respiratory infection caused by organisms such as *S. pneumoniae*, *Haemophilus influenzae*, and *Moraxella catarrhalis*. On the other hand, these specimens are useful for the diagnosis of specific pathogens, whose presence in symptomatic patients most often indicates disease (i.e., *Streptococcus pyogenes*, *Bordetella pertussis*, *Corynebacterium diphtheriae*, and respiratory viruses). Nasal cultures are also performed

as a part of the infection control of hospitalized patients to detect carriage of oxacillin-resistant *Staphylococcus aureus* or as part of a staphylococcal outbreak. In the latter case, nasal carriage by hospital employees may also be important (procedure 13.17). Nasopharyngeal specimens are useful when it is important to determine if the patient is a carrier of a specific organism, such as *Neisseria meningitidis*, a yeast, or a mold, as part of the investigation of an exposure to these agents.

Thus, a request for “routine” bacterial culture of noninvasively collected nasal or throat specimens, usually submitted to the laboratory on swabs or as a wash, aspirate, or discharge, should *not* be processed by the laboratory (refer to cystic fibrosis procedure [3.11.3] for exception for deep pharyngeal cultures from these patients). It is important that these cultures be done only when detection of a specific pathogen is sought and not be performed routinely to detect any organism that is present.

When requests are received by the laboratory, the caregiver should be contacted to determine if the specimen was sent for detection of one of the specific pathogens (Table 3.11.1–1). If the specimen is being sent to diagnose a bacterial cause of lower respiratory disease, otitis media, or sinusitis, inform the caregiver that a more invasive specimen, such as endotracheal aspirate, maxillary sinus puncture, or tympanocentesis fluid, respectively, is needed to make the diagnosis (*see* Table 3.11.1–1 for specific specimens and procedural references). Procedures that follow in this portion present collection, processing, and interpretation to detect individual respiratory pathogens and procedures for bacterial etiology of upper and lower respiratory disease from specific anatomic sites. A procedure is also listed specifically for processing specimens from cystic fibrosis patients. Refer to Table 3.11.1–1 for the appropriate specimens and procedures.

Table 3.11.1–1 Appropriate specimens for diagnosis of bacterial and yeast upper and lower respiratory diseases

Disease(s) or condition	Common agent(s)	Specimen(s)	Procedure reference
Candidiasis (oral thrush)	<i>Candida albicans</i>	Swab of buccal mucosa, tongue, or oropharynx	8.3 (KOH, calcofluor white stain)
Cystic fibrosis	<i>Pseudomonas aeruginosa</i> <i>S. aureus</i> <i>Burkholderia cepacia</i> and others	Deep throat Lower respiratory ^a	3.11.3
Diphtheria	<i>C. diphtheriae</i>	Nasopharyngeal swab	3.11.7
Epiglottitis	<i>H. influenzae</i>	Blood culture	3.4.1
Esophagitis	<i>C. albicans</i>	Biopsy sample	8.3, 8.4
Gonococcal pharyngitis	<i>Neisseria gonorrhoeae</i>	Oropharyngeal swab	3.9.3
Laryngitis, bronchiolitis	<i>Mycoplasma pneumoniae</i>	Lower respiratory ^a	3.15
Lemierre's disease	<i>Fusobacterium necrophorum</i>	Blood culture	3.4.1
Meningococcal carriage	<i>N. meningitidis</i>	Oropharyngeal swab	3.9.3
Otitis externa	<i>P. aeruginosa</i>	Ear canal swab	3.11.5
Otitis media	<i>S. pneumoniae</i> <i>H. influenzae</i> <i>M. catarrhalis</i> <i>Alloiooccus otitis</i>	Tympanocentesis fluid	3.11.5
Pertussis	<i>B. pertussis</i>	Nasal wash, nasal aspirate, nasopharyngeal swab ^b	3.11.6
Pleural effusion	<i>S. aureus</i> <i>S. pyogenes</i> <i>S. pneumoniae</i>	Pleural fluid	3.5
Pneumonia, bronchitis	Many agents <i>M. pneumoniae</i> <i>Legionella</i> spp.	Lower respiratory ^a	3.11.2 3.15 3.11.4
Pneumonic, plague	<i>Yersinia pestis</i>	Oropharyngeal swab Lower respiratory ^a	3.11.2 and 16.7
Pneumonic tularemia	<i>Francisella tularensis</i>	Lower respiratory ^a	16.8
Sinusitis (acute)	<i>S. pneumoniae</i> <i>H. influenzae</i> <i>M. catarrhalis</i>	Maxillary sinus puncture and aspiration Rigid endoscopy, <i>not nasal washes or drainage</i>	3.11.9
Staphylococcal carriage	<i>S. aureus</i>	Nasal swab	13.11
Streptococcal pharyngitis	<i>S. pyogenes</i>	Nasopharyngeal swab	3.11.8
Vincent's angina	<i>Borrelia vincentii</i> (spirochetes) Anaerobes (fusiform rods)	Oropharyngeal swab	3.2.1 (Gram stain) or 7.2 (Ziehl-Neelsen stain but dilute 1:10 with water)

^a Lower respiratory includes sputa, endotracheal aspirates, lung biopsy samples, lung aspirates, and bronchoscopic specimens. Procedures for detection of respiratory viruses (section 10), *Mycobacterium tuberculosis* (section 7), aerobic *Actinomyces* (section 6), and fungi, such as *Histoplasma capsulatum* and *Coccidioides immitis* (section 8), should be included, depending on the symptoms and duration of illness.

^b Specimen is also useful to diagnose diseases caused by respiratory viruses (*see* section 10).

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Infections of the lower respiratory tract are the sixth leading cause of mortality in the United States, with 2,000,000 to 3,000,000 cases per year, resulting in 500,000 hospitalizations (1). For community-acquired pneumonia (CAP) in adults and the elderly, *Streptococcus pneumoniae* is the cause in 6 to 10% of all cases and 60% of the bacterial cases (6, 7, 12), hence the utility of the pneumococcal vaccine to prevent this disease.

Culture of lower respiratory secretions can be helpful, but in reality it is limited, with no agent isolated in 40 to 60% of cases (1). This lack of culture sensitivity may be due to the low sensitivity (50%) of sputum culture for *S. pneumoniae*, especially if specimens are not immediately processed. In addition, many agents of pneumonia are difficult to grow (e.g., *Legionella*, *Chlamydia pneumoniae*, and *Mycoplasma pneumoniae*). It is estimated that *C. pneumoniae* is the second most common cause of pneumonia and that *M. pneumoniae* accounts for most cases of ambulatory CAP identified by serologic methods (6, 15). *Haemophilus influenzae* and *Legionella* are the third and fourth most common bacterial causes of CAP requiring hospitalization. In addition to the difficulty in culturing the pathogens, specimens are easily contaminated with upper respiratory secretions, which may obscure the presence of lower respiratory pathogens.

Because of the difficulty in detection of the pathogen and the delay that is inherent

in culture, early guidelines for diagnosis and treatment of CAP suggested that culture was of very limited value. More recent guidelines of the Infectious Disease Society of America (IDSA) (1), the American Thoracic Society (ATS) (13), and the Canadian Infectious Disease Society (6) now recommend culture in limited situations, but each society has different criteria for culture. Many guidelines include a blood culture to detect pneumococcal pneumonia; 8 to 10% of patients with CAP will have positive blood cultures, with 60% of these containing *S. pneumoniae* (6). Generally respiratory culture and Gram stain can be helpful when the patient is ill enough to be admitted to the hospital, according to the IDSA. The ATS limits cultures to those where drug resistance is suspected or an unusual pathogen is being considered (e.g., areas where dimorphic fungi, mycobacteria, or *Legionella* is endemic). If pleural fluid is present, thoracentesis should also be performed. Appropriate antimicrobial therapy is necessary to decrease mortality; however, the overuse of antimicrobial agents is a cause for concern for the development of antimicrobial resistance (3). Each of the guidelines recommends specific empiric therapy based on the severity of illness and disease presentation.

The sputum Gram stain has variability in sensitivity and specificity, depending on

the specimen and the skill of the reader (6, 11, 13, 16). A great variability and a lack of reproducibility on repeat smear preparations were shown by Nagendra et al. (11); however, there was less variability for culture of the specimens. Generally smears are only of value if there are numerous inflammatory cells and a preponderance of gram-positive diplococci (57% sensitivity) or gram-negative rods suggestive of *Haemophilus* (82% sensitivity) (16). The specificity of the diagnosis by Gram stain can be increased if the Quellung test is performed on the direct specimen (6). The proper evaluation of the specimen by Gram stain is critical and is used to ensure that only appropriate specimens are processed. Refer to Appendix 3.2.1–2 of the Gram stain procedure for acceptability criteria.

Nosocomial pneumonia can be caused by a large number of pathogens, including anaerobes, as in aspiration pneumonia (7). Gram-negative rods are also common, especially in ventilator-associated pneumonia. The CDC has issued guidelines for prevention of nosocomial pneumonia (2). For ventilator-associated pneumonia, sputum is not as diagnostic a specimen as a specimen collected by bronchoscopy, which has an 82 to 91% sensitivity (8). This procedure presents processing and evaluation of specimens from patients with CAP and nosocomial pneumonia.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

■ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for physicians and caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

A. Specimen collection

1. Expectored sputum

- a. Do *not* have the patient rinse mouth and gargle with nonsterile water prior to sputum collection, since this can introduce contaminating microbiota.

■ **NOTE:** Commensal mycobacteria from tap water can contaminate mycobacterial cultures but are rarely an issue for routine bacteriology culturing. For specialized cultures (e.g., mycobacteria and legionellae), supply sterile saline or water to gargle prior to collection.

- b. Instruct the patient not to expectorate saliva or postnasal discharge into the container.
- c. Collect specimen resulting from deep cough in a leakproof cup or suitable other collection assembly.

2. Induced sputum

■ **NOTE:** “The utility of induced sputum for detecting pathogens other than *Pneumocystis carinii* or *Mycobacterium tuberculosis* is poorly established” (1).

- a. Using a wet toothbrush and *sterile* water or saline, brush the buccal mucosa, tongue, and gums for 5 to 10 min prior to the procedure. Do not use toothpaste.
- b. Rinse the patient’s mouth thoroughly with *sterile* water or saline.
- c. Using an ultrasonic nebulizer, have the patient inhale approximately 20 to 30 ml of 3% NaCl.
- d. Collect induced sputum in a leakproof cup or suitable other collection assembly.

3. Tracheostomy and endotracheal aspirates

- a. Aspirate the specimen into a sterile sputum trap (e.g., Luken trap) or leakproof cup.
- b. Do not culture tracheostomy aspirate unless clinical pneumonia is present (fever and infiltrates). Tracheostomy is followed by colonization within 24 h of insertion, and results may not correlate with disease.

4. Bronchoscopy specimens—collected by a pulmonologist or other trained physician

- a. Bronchoscopy specimens include bronchoalveolar lavage (BAL) samples, bronchial washings, protected specimen brushings (PSB), and transbronchial biopsy specimens.
- b. Culture BAL samples and PSB quantitatively or semiquantitatively for bacterial pathogens. (Refer to Appendix 3.11.2–1 for quantitative methods.)

c. Precautions

- (1) To avoid excess blood in the recovered fluid, obtain bronchial wash and BAL specimens before brushing or biopsy specimens. Blood may alter the concentration of cellular and noncellular components.
- (2) Avoid suctioning through the working channel before retrieval of specimens to avoid contamination of the specimens.
- (3) Avoid the injection of topical anesthetic agents as much as possible, as the injection method may lead to contamination of the specimen. Aerosol application of anesthetic agents is preferred.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- d. To obtain specimens, do the following.
 - (1) Bronchoalveolar washing or BAL sample
 - **NOTE:** The difference between a BAL sample and a bronchial washing is not apparent from the appearance of the specimen. The BAL sample is from the distal respiratory bronchioles and alveoli. Bronchial washings sample the major airways, which is the same area sampled by an endotracheal aspirate.
 - (a) Pass the bronchoscope transnasally or transorally in nonintubated patients or via the endotracheal tube in intubated patients.
 - (b) Inject sterile nonbacteriostatic 0.85% NaCl (generally 5- to 20-ml aliquots) from a syringe through a biopsy channel of the bronchoscope.
 - (c) Collect BAL sample by carefully wedging the tip of the bronchoscope into an airway lumen and instilling a large volume of sterile, nonbacteriostatic saline (greater than 140 ml). The sample returned contains secretions distal to the bronchioles and alveoli.
 - (d) Gently suction the recovered specimen into a sterile container before administering the next aliquot. (In general, 50 to 75% of the saline instilled is recovered in the lavage effluent.) Keep aliquots separate during collection.
 - (e) Discard the initial fluid as contaminated and submit the rest for culture and staining.
 - **NOTE:** In the laboratory, aliquots from the same site may be combined for microbiology cultures and smears, but aliquots from separate sites (for example, right upper lobe and right lower lobe) should be combined only after consultation with the physician of record.
 - (2) Bronchial brush specimens
 - (a) Instill a brush to collect cellular material from the airway wall. This is the best specimen for viral culture and cytology studies.
 - (b) Only PSB are acceptable for bacterial culture. Obtain by inserting a telescoping double catheter plugged with polyethylene glycol at the distal end (to prevent contamination of the bronchial brush) through the biopsy channel of the bronchoscope.
 - (c) Place specimen in 1 ml of nonbacteriostatic saline.
 - (3) Transbronchial biopsy samples
Obtain the biopsy sample through the biopsy channel of the bronchoscope, and transport it in a sterile container with a small amount of nonbacteriostatic sterile saline.
5. Lung aspirates—collected by trained physician
 - a. Use a computed tomography scan to obtain lung aspirates by inserting a needle through the chest wall into a pulmonary infiltrate.
 - b. Aspirate material from the lesion.
 - c. If the lesion is large or if there are multiple lesions, collect multiple specimens from representative sites.
 - d. Transport specimen without needle in syringe capped with Luer-Lok or transfer to sterile tube or Vacutainer.
6. Lung biopsy samples—collected by trained physician
 - a. Obtain a 1- to 3-cm-square piece of tissue, if possible.
 - b. If the lesion is large or if there are multiple lesions, collect multiple specimens from representative sites.
 - c. Submit in a sterile container(s) without formalin.
7. Pleural fluid—see procedure 3.5

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

B. Specimen transport

1. Submission to the laboratory
 - a. Collect specimens in leakproof cups or suitable other collection assembly (Luken trap) and label with source of material.
 - b. Submit aspirates in the original syringe with a Luer-Lok to prevent leakage, or transfer to a sterile tube.
2. Label specimens with demographic information, date and time of collection, and site of collection.
3. List the diagnosis or ICD-9 code for proper evaluation of the cultures.
4. Order the appropriate tests.

☑ **NOTE:** Anaerobic cultures should be limited to specimens that are not contaminated with upper respiratory microbiota (e.g., PSB and biopsy samples) and only when aspiration pneumonia or similar disease is being considered.
5. Store specimen at 2 to 8°C until cultures can be submitted or processed.

☑ **NOTE:** A delay in processing of more than 1 to 2 h may result in loss of recovery of fastidious pathogens, such as of *S. pneumoniae*, and overgrowth of oronasal microbiota (6).

C. Rejection criteria

1. Do not accept repeat cultures at intervals of less than every 48 h.
2. Reject the following specimens for diagnosis of lower respiratory tract disease.
 - a. 24-h sputum collection
 - b. Contaminated sputum and endotracheal specimens per Gram stain rejection criteria (Appendix 3.2.1–2)
 - c. Saliva
 - d. Induced sputum (1)
 - e. Nasal washes and aspirates or swabs of nares. See Table 3.11.1–1 and procedure 3.11.9 for appropriate specimens to diagnose sinusitis.
 - f. Throat specimens, since they are not indicative of the infection of the lower airways (5)
 - g. Specimens for anaerobic culture, except transtracheal aspirates, PSB, biopsy samples, pleural fluid, or other uncontaminated specimens
3. Culture bronchial brushings, if they are not collected with a protected catheter, only if the PSB is not available.
4. Bronchial washings are the secretions aspirated from the major airways and are less suitable for bacterial culture than BAL specimens collected from the bronchiolar and alveolar spaces. If both are received, culture only the BAL specimen quantitatively.
5. For specimens delayed in transit more than 2 h without refrigeration, indicate on the report that the delay in transit may compromise the culture results.

III. MATERIALS

A. Direct tests

1. Gram stain (procedure 3.2.1)
2. *S. pneumoniae* antisera (stored at 4°C). See Quellung procedure (3.17.42).
 - a. Methylene blue—0.3% in water
 - b. Normal rabbit serum
3. NOW urinary antigen assay (Binax, Inc., Portland, Maine)

B. Primary media

1. BAP
2. CHOC or horse blood agar (HBA), or HBA with 20,000 IU of bacitracin per liter (HBAB)
3. MAC or EMB

C. Identification methods

Refer to procedure 3.3.2 for supplies for identification of the common agents of pneumonia.

D. Other supplies

1. Incubator at 35°C with 5% CO₂ or other CO₂-generating system
2. Inoculating sticks and loops
3. Petri dishes and filter paper
4. Bacitracin (10-IU disk) and optochin disks (optional)

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
- B. Test each lot of CHOC according to procedure 3.3.1.
- C. QC HBA with bacitracin as indicated below; without bacitracin, test only with *H. influenzae*. Incubate at 35°C in 5% CO₂.

Test organism	Result
<i>Haemophilus influenzae</i> ATCC 10211	Growth
<i>Staphylococcus epidermidis</i> ATCC 12228	Partial to complete inhibition

- D. If used on direct specimen plates, perform QC on each lot or shipment of bacitracin (10-IU disk) and optochin disks. Use CHOC for bacitracin and BAP for optochin. See procedure 3.17.38 for optochin QC. For bacitracin QC, incubate CHOC at 35°C in CO₂.

■ **NOTE:** This is *not* the bacitracin disk historically used to detect group A beta-hemolytic streptococci.

Test organism	Bacitracin (10 IU) zone size
<i>Haemophilus influenzae</i> ATCC 10211	No zone
<i>Staphylococcus epidermidis</i> ATCC 12228	>12 mm

V. PROCEDURE

It is imperative that these cultures be handled in a biosafety hood.

A. Inoculation

Process specimens in biological safety cabinet, as aerosols can result in laboratory-acquired respiratory infections.

1. Process all specimens as rapidly as possible, especially specimens from the emergency department, from patients newly admitted to the hospital, and from invasive procedures (e.g., BAL and lung biopsy samples), to maintain viability of pathogens and avoid putting the patient at risk for repeat procedures.
2. Select the most purulent or most blood-tinged portion of the specimen.
3. In the case of bronchoscopy, perform quantitative cultures on BAL samples and/or PSB (Appendix 3.11.2–1). Do *not* centrifuge specimens for bacterial culture.
4. Prepare Gram stain. See procedure 3.2.1, including Appendix 3.2.1–2, for details on preparation and reading of smears.
 - a. Use a cytocentrifuge to prepare BAL specimens for Gram stain.
 - b. Prepare a touch prep for lung biopsy samples.
5. Using a sterile swab, stick or pipette, inoculate specimen to BAP, CHOC (or HBA or HBAB), and MAC (or EMB). Optionally, do one or more of the following.
 - a. Add a 10-IU bacitracin disk (not Taxo A) to CHOC or HBA to inhibit upper respiratory microbiota and improve detection of *H. influenzae*.
 - b. Add staphylococcal spots using *S. aureus* ATCC 25923 to BAP to demonstrate satelliting of *Haemophilus* on direct plates.

V. PROCEDURE (*continued*)

- c. Add optochin disk to the second quadrant of BAP, to demonstrate inhibition by *S. pneumoniae* for direct detection on primary plates.

☑ **NOTE:** Adding an optochin disk is not recommended routinely but may be helpful for laboratories with a large number of specimens from patients with community-acquired pneumonia.

B. Incubation

1. Incubate plates at 35 to 37°C in 5% CO₂ for a minimum of 48 h; 72 h is preferred.
2. For invasively collected lung cultures, extend incubation to 4 days.

C. Direct tests

1. Gram stain
 - a. Read Gram stain and note cells and bacteria according to procedure 3.2.1.
 - b. Reject specimens if they do not meet criteria of acceptability (*see* Appendix 3.2.1–2).
2. If there is a predominance of gram-positive diplococci, perform either of the following.
 - a. Direct bile test (procedure 3.17.6)
 - b. Direct Quellung test (procedure 3.17.42)
3. Perform NOW urinary antigen test, if desired, according to the manufacturer's instructions (Binax, Inc.).

☑ **NOTE:** This test had a sensitivity of 80% compared to pneumococcal bacteremia and 52% compared to sputum culture, with a very high specificity in one study (10). The sensitivity was 55% in a limited pediatric study (9).

D. Culture examination (*See* procedure 3.3.2 for identification tests and procedure 3.17 for biochemical procedures. Additional identification charts are in procedures 3.18.1 and 3.18.2.)

1. Observe plates at 24 h.
2. Incubate plates for an additional 24 to 48 h, which is useful to detect molds and slow-growing, fastidious gram-negative rods, such as *Bordetella* spp.
3. *Even if there was growth at 24 h, examine plates again at 48 h for morphologies not seen at 24 h.*
4. Use the Gram stain result as a guide to interpreting the culture.
 - a. Use the presence of inflammatory cells and bacteria in deciding on the extent of processing the culture.
 - b. If the culture does not match the smear results, review the smear a second time.
 - c. Follow Table 3.11.2–1 for processing and reporting significant microbiota.
5. Identify organisms present in *significant* amounts, defined as colony types that are not considered part of normal respiratory microbiota and are present in the following amounts:
 - a. Large numbers in the second or greater quadrant of the plate
 - b. >10³ in a PSB
 - c. >10⁴ in a BAL sample
 - d. Any amount of selected pathogens in a patient with cystic fibrosis. *See* procedure 3.11.3 for limitations on evaluation of cultures.
 - e. Small amounts of a bacterial species in the culture that are consistent with an etiologic agent seen in the Gram stain associated with inflammatory cells
 - f. Colonies in the first quadrant of the plate, only if there is little or no other microbiota on the plate (e.g., 90% pure) and the smear suggests inflammation
6. Subculture to BAP and/or CHOC to obtain isolated colonies for accurate identifications from mixed cultures.

Table 3.11.2–1 Guidelines for reporting pathogens in lower respiratory cultures

Action	Organism(s)
Examine for and always report.	<ol style="list-style-type: none"> 1. <i>Streptococcus pyogenes</i> 2. Group B streptococci in pediatric population 3. <i>Francisella tularensis</i> 4. <i>Bordetella</i> spp., especially <i>Bordetella bronchiseptica</i> 5. <i>Yersinia pestis</i> 6. <i>Neisseria gonorrhoeae</i> 7. <i>Nocardia</i> 8. <i>Bacillus anthracis</i> 9. <i>Cryptococcus neoformans</i> 10. Molds, not considered saprophytic contaminants
Always report, but do not make an effort to find low numbers, unless they are seen in the smear.	<ol style="list-style-type: none"> 1. <i>Streptococcus pneumoniae</i>; report AST 2. <i>Haemophilus influenzae</i>; report beta-lactamase
Report if present in <i>significant</i> ^a amounts, even if not predominant.	<ol style="list-style-type: none"> 1. <i>Moraxella catarrhalis</i> 2. <i>Neisseria meningitidis</i> Report the following for inpatients only: <ol style="list-style-type: none"> 3. <i>Pseudomonas aeruginosa</i>; report AST 4. <i>Stenotrophomonas maltophilia</i> 5. <i>Acinetobacter</i>; report AST 6. <i>Burkholderia</i>; report AST
Report if present in <i>significant</i> ^a amounts <i>and</i> if it is the predominant organism in the culture, particularly if smear suggests infection with morphology consistent with isolate.	<ol style="list-style-type: none"> 1. <i>Staphylococcus aureus</i>; report AST 2. Beta-hemolytic streptococcus B (adults), C, or G 3. Single morphotype of gram-negative rod (especially <i>Klebsiella pneumoniae</i>); report AST 4. Fastidious gram-negative rods; usually report beta-lactamase 5. <i>Corynebacterium</i> if urea positive or from intensive care unit 6. <i>Rhodococcus equi</i> in immunocompromised patients
Report as “Enteric gram-negative rods.”	More than one morphology of gram-negative rods that grow on MAC and are oxidase negative and are either indole positive, lactose positive, or spreading
Report as “Non-glucose fermenting, gram-negative rods.”	More than one morphology of gram-negative rods that either are oxidase positive and grow on MAC or are nonreactive on KIA or TSI. (See exceptions above.)
Report as “Isolates consistent with microorganisms encountered in the upper respiratory tract.” <i>Note:</i> If enterococci and coagulase-negative staphylococci (with or without yeasts) are the only organisms present, report as “Mixed gram-positive microorganisms,” or list individually with minimal identification if 90% pure culture.	Viridans group streptococci and/or nonpathogenic <i>Neisseria</i> ; diphtheroids; coagulase-negative staphylococci; <i>Rothia</i> ; group F streptococcus; anaerobes; <i>Haemophilus</i> species (not <i>H. influenzae</i>); <i>Eikenella</i> ; <i>Actinobacillus</i> ; <i>Capnocytophaga</i> ; <i>Moraxella</i> ; enterococci; yeasts; and insignificant numbers of <i>Staphylococcus aureus</i> organisms, ^b gram-negative rods, and <i>N. meningitidis</i>

^a Significant is defined as in large numbers in the second or greater quadrant of the plate, >10³ in a PSB, or >10⁴ in a BAL specimen; small amounts of a bacterial species in the culture that are consistent with an etiologic agent seen in the Gram stain associated with inflammatory cells; or colonies in the first quadrant of the plate, only if there is little or no other microbiota on the plate (i.e., 90% pure) and the smear suggests inflammation. See special criteria for a patient with cystic fibrosis in procedure 3.11.3.

^b Perform AST if requested based on infection control issues.

V. PROCEDURE (continued)

7. The following species are important respiratory pathogens. See Table 3.3.2–5 for rapid identification methods.

a. *Streptococcus* species

(1) Examine for beta-hemolytic colonies and identify catalase-negative cocci in chains and pairs.

(a) Use pyrrolidonyl-β-raphthylamide (PYR) test to identify *S. pyogenes*, which is reported in *any* amount.

V. PROCEDURE (continued)

- (b) Examine for colonies with a small zone of hemolysis and identify group B streptococcus in pediatric patients, if present, in any amount.
- (c) Identify other beta-hemolytic streptococci in significant amounts only if they are predominant. Do not report small colony types of beta-hemolytic streptococci or group F streptococci, as they are part of the upper respiratory microbiota.
- (2) Examine alpha-hemolytic colonies for morphology consistent with *S. pneumoniae*. These will be inhibited by optochin.
 - (a) Add a drop of 10% bile to colonies that resemble pneumococci.
 - (b) If colony dissolves, report *S. pneumoniae*.
 - (c) Quickly pick similar colonies. Perform antimicrobial susceptibility testing (AST) (see section 5). Confirm purity with optochin disk to detect contamination of AST results.
 - (d) If colonies are not dissolved by bile, but still resemble pneumococci, confirm identification with optochin susceptibility.
 - **NOTE:** Some pneumococci are bile resistant and others are resistant to optochin (14). No one test is 100% accurate, and the combination of these two tests will prevent erroneous reporting. The DNA probe (Gen-Probe) is another accurate method to confirm identification when the optochin zone is less than 14 mm.
- b. Fastidious gram-negative rods (these microorganisms grow slowly or not at all on MAC). Perform spot tests on significant numbers to differentiate them from normal respiratory microbiota.
 - (1) *H. influenzae* organisms are coccobacilli that grow on CHOC but not on BAP, except with staphylococci or other microorganisms to demonstrate satelliting. Perform ALA (aminolevulinic acid) test (procedure 3.17.3) to confirm identification and beta-lactamase test for penicillin susceptibility for *H. influenzae* isolates.
 - (2) *Francisella tularensis* organisms are coccobacilli that can grow on CHOC but do not grow on BAP, even with staphylococci for satelliting. They are weakly catalase positive and oxidase and urease negative. They are beta-lactamase positive.
 - (3) *Legionella* organisms are gram-negative rods that may grow on CHOC but will not grow on BAP, even with staphylococci for satelliting. They are motile and have a characteristic colony and Gram stain morphology (see procedure 3.11.4)
 - (4) The major significant *Bordetella* organisms which grow on BAP are catalase and urease positive. They may be visible only after 48 h. See Table 3.11.6–1.
 - (5) *Pasteurella* organisms are indole and oxidase positive and represent normal mouth microbiota of animals.
 - (6) Identify *Yersinia pestis* in any amount. It presents as a non-lactose-fermenting rod on MAC or EMB, but it may appear as pinpoint colonies on BAP at 24 h of incubation.
 - (7) Do not identify most other fastidious gram-negative rods, such as *Eikenella*, unless they are predominant and present in large amounts, since they are part of the normal upper respiratory microbiota and rarely cause respiratory disease.
- c. Gram-negative diplococci
 - (1) Examine colonies present in significant amounts that move when pushed. Confirm as *Moraxella catarrhalis*. Since more than 90% of *M. catarrhalis* organisms are beta-lactamase positive, testing is not helpful to treatment.

V. PROCEDURE (continued)

- (2) Examine CHOC for any oxidase-positive colonies that do not grow or grow poorly on BAP. Confirm identification of *Neisseria gonorrhoeae* and *N. meningitidis* (see Table 3.9.3–1). Do not perform AST.
- d. Gram-negative rods that grow well on either MAC or EMB
 - (1) Identify and perform AST on enteric gram-negative rods, particularly *Klebsiella pneumoniae*, if there is only one morphology in significant amounts with no other pathogens in greater amounts.
 - (2) For inpatients, regardless of the presence of other pathogens, examine for significant numbers of *Pseudomonas aeruginosa*, *Acinetobacter*, *Burkholderia*, and *Stenotrophomonas* organisms because they are typically resistant to multiple antimicrobials and can be implicated in nosocomial epidemics.
 - (3) If more than one type of other gram-negative rods are present in equal numbers, perform minimal testing to be able to describe the organisms (e.g., indole, oxidase, odor and morphology on MAC, colony pigment, and reaction on Kligler's iron agar [KIA] or triple sugar iron agar [TSI]).
 - (4) See procedure 3.11.3 for special requirements for cystic fibrosis patients.
- e. Staphylococci
 - (1) Identify *S. aureus* if present in significant amounts.
 - (a) Perform AST if the Gram stain shows predominant cocci in clusters associated with WBCs and no other pathogen in significant amounts.
 - (b) If the patient is an inpatient, based on infection control policy, check for resistance to oxacillin, even if organism is present in low numbers.
 - (2) Identify coagulase-negative staphylococci, without species identification or AST, only if they are in 90% pure culture. Otherwise include in respiratory microbiota.
- f. Do not report *Enterococcus* unless the culture is 90% pure and the identification is confirmed with extensive biochemical tests. See procedure 3.18.1. Many gram-positive cocci in the normal respiratory tract are PYR positive and even bile-esculin and LAP (leucine aminopeptidase) positive.
- g. Gram-positive rods
 - (1) Rule out *Nocardia* in any amount and *Rhodococcus equi* (mucoid and urease positive) from immunocompromised patients (see procedures 6.1 and 6.2 and Table 3.18.1–6).
 - (2) Examine for large, spore-forming, gram-positive rods. If present, identify *Bacillus anthracis* and *Bacillus cereus*.
 - (3) Limit identification of *Corynebacterium*, using a commercial kit for gram-positive rods, to those present in numerous and predominant amounts and when either of the following is true.
 - (a) The organism is rapid urea positive. (*Corynebacterium pseudodiphtheriticum* is urea positive.)
 - (b) The specimen is from an intubated patient from an intensive care unit.
 - (4) Generally, do not pursue other gram-positive rods, as they are unlikely to cause pneumonia.
- h. Identify molds (section 8), unless the organism is consistent with a laboratory or environmental contaminant (e.g., *Penicillium*).

■ **NOTE:** Biphasic fungi (*Histoplasma capsulatum* and *Coccidioides immitis*) can be isolated from plates held for >48 h, even as the yeast-phase colony morphology. Use caution in examination of older cultures.

It is imperative that these cultures be handled in a biosafety hood.

V. PROCEDURE (*continued*)

- i. Rule out *Cryptococcus* (section 8) and do not identify other yeasts further.
 ■ NOTE: *Candida* organisms are not a cause of pneumonia, except possibly in oncology (e.g., leukemia) or lung transplant patients or in neonates. Even in those cases, growth of *Candida* in lower respiratory specimens, regardless of species, does not correlate with disease (4). Yeasts are normal inhabitants of the mouth.
- j. If bacteria were seen on smear but did not grow on culture, extend the incubation and inoculate other media (e.g., for *Legionella*, *Bordetella pertussis*, and *Mycobacterium*).

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. Gram stain—report smear as indicated in procedure 3.2.1. Do not report rare (<1 in 20 fields) numbers of bacteria seen in the smear. If bacteria on smear were not isolated, make a notation on the report to indicate discrepancy.
- B. Report “No growth of pathogens or normal upper respiratory tract microorganisms” if there is no growth on any plates.
 ■ NOTE: This may be indicative of antimicrobial inhibition of normal microbiota.
- C. Positive reporting
 1. Report preliminary and final results as “Isolates consistent with microorganisms encountered in the upper respiratory tract” if no pathogens are isolated.
 2. Report all pathogens and susceptibility tests performed using Table 3.11.2–1 as a guide.
 3. Provide preliminary reports as indicated in procedure 3.3.2.
 4. Report AST in accordance with NCCLS guidelines (12) and section 5.

VII. INTERPRETATION

- A. A positive culture with *S. pneumoniae* or *H. influenzae* generally indicates infection with that organism, although carriage of these organisms may lead to false-positive results.
- B. A positive culture with a predominant gram-negative rod or *S. aureus* generally indicates infection with that agent if the smear suggests an infectious process involving the corresponding morphology.
- C. A negative culture cannot rule out infection. In fact, a pathogen is often not isolated.
- D. Controversy regarding the need for culture for CAP has been published by several medical groups (1, 6, 13), but most physicians agree on its benefits for ventilator-associated and nosocomial pneumonia.
- E. Generally CAP is treated with a penicillin-type agent, such as amoxicillin or amoxicillin-clavulanate; a fluoroquinolone; a macrolide; or combination therapy with these agents (1, 3, 6, 13).

VIII. LIMITATIONS

- A. Some agents do not grow in routine culture but can be a significant cause of disease.
- B. False-negative cultures can result from contamination of the specimen with normal oral microbiota or from prior antimicrobial therapy.
- C. False-positive results can be caused by overinterpretation of the culture results.

APPENDIX 3.11.2-1

Quantitative Culture of Protected Specimen Brush and Bronchoalveolar Lavage Fluid Specimens

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Quantitative cultures of BAL fluid are used in the diagnosis of ventilator-associated pneumonia, pneumonia in immunocompromised and cystic fibrosis patients, acute episodes in chronic obstructive pulmonary disease, and even in CAP. Quantitative cultures increase the specificity of the diagnosis, but the sensitivity is dependent on the threshold chosen for a positive result. Many authors report a colony count of $\geq 10^4$ CFU/ml to be consistent with bacterial pneumonia, whereas counts below 10^4 CFU/ml likely indicate contamination with oronasal microbiota (1, 2, 5, 6, 7). This theory has been validated in numerous clinical studies, and quantitative culture of BAL fluid specimens has become the reference method for the diagnosis of pneumonia by BAL (3). For PSB, a colony count of $\geq 10^3$ CFU/ml is consistent with bacterial pneumonia. Taking the dilution factor of both specimen effluents into consideration, this represents a count of bacteria in the secretions of the lung of 10^5 to 10^6 CFU/ml (2).

There are two methods of performing quantitative cultures: the serial dilution method and the calibrated-loop method (1, 2). After incubation the colonies are counted and multiplied by the appropriate dilution factor to determine the number of bacteria present in 1 ml of fluid.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection is performed by a trained physician. See procedure 3.11.2 for further details.

1. Collect BAL fluid by carefully wedging the tip of the bronchoscope into an airway lumen and instilling a large volume of sterile, nonbacteriostatic saline (greater than 140 ml). The sample returned contains secretions of distal bronchioles and alveoli. The initial fluid is discarded as contaminated, and the rest is submitted for culture and staining. Generally 10 to 100 ml is extracted containing 1 ml of secretions (2).
2. PSB are the least likely to be contaminated, since they are protected by two telescoping catheters, the outer of which is occluded with a Carbowax plug to prevent secretions from entering the catheters. Place the brush in 1 ml of diluent and submit for bacterial culture.

B. Specimen transport

1. Submit to laboratory in sterile, leakproof containers.
2. Label with specimen source and tests requested for each specimen type.
3. Deliver immediately to laboratory.

C. Rejection criteria

1. BAL fluid is preferred to bronchial washings for bacterial culture. Bronchial washings are acceptable for mycobacterial, *Legionella*, and fungal cultures.
 - ☑ **NOTE:** The difference between BAL fluid and bronchial washings is not apparent from the appearance of the specimen. The BAL sample is from the distal respiratory bronchioles and alveoli. Bronchial washings sample the major airways, which is the same area sampled by an endotracheal aspirate. They can be used for fungal, *Legionella*, or acid-fast bacillus (AFB) culture but are contaminated with upper airway secretions and are not appropriate for quantitative bacterial culture, if BAL fluid is also available.
2. Bronchial brush specimens not collected with catheter protection are best submitted for viral culture and not bacterial culture, since they contain cellular material.

III. MATERIALS

A. Primary media

1. BAP *or*
2. CHOC

B. Other supplies

1. Pipette method
 - a. One 100- μ l pipetter with sterile tips

Observe standard precautions.

APPENDIX 3.11.2-1 (continued)

- b. Two 16- by 125-mm snap-cap tubes containing 5 ml of sterile phosphate-buffered saline (PBS) or suitable broth
2. Loop method
 - a. 0.001-ml (1- μ l)
 - b. 0.01-ml (10- μ l) loop
 - c. Disposable loops are color coded according to volume delivery.
3. Sterile bent glass or plastic disposable sterile rods (hockey sticks) to spread inoculum (Excel Scientific, Wrightwood, Calif., [760] 249-6371).
4. Petri dish turntable to rotate plates (optional)
5. Incubator at 35°C with 5% CO₂ or other CO₂-generating system

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. For calibrated-pipette QC, refer to Appendix 3.12-4. If calibrated loops are used, verify that they are accurate by one of the methods in Appendix 3.12-3.

■ **NOTE:** Jacobs et al. (4) have indicated that actual BAL fluid should be used to validate the accuracy of the loops. Some, but not all, loops provide accurate results.

- B. Refer to procedure 3.11.2 for medium QC testing.

V. PROCEDURES

- A. Inoculation (*see* Fig. 3.11.2-A1).

1. Vortex specimen vial vigorously for 30 to 60 s.
2. Label a BAP or CHOC for each dilution. Do not use selective medium. If CHOC contains bacitracin, use BAP. Otherwise use CHOC for quantitative culture. Inoculate other media according to procedure 3.11.2 for other lower respiratory tract pathogens.
3. Pipette method
 - a. Transfer 100 μ l of PSB to each plate marked "× 10." Each colony from this plate = 10 CFU/ml.
 - b. Transfer 10 μ l of PSB or BAL specimen to each plate marked "× 100." Each colony from this plate = 100 CFU/ml.
 - c. For BAL (and PSB, optional), do the following.
 - (1) Label one tube of 5 ml of PBS "1:100."
 - (2) Transfer 50 μ l of "undiluted" fluid from the vial to the tube labeled "1:100." Vortex.
 - (3) Transfer 100 μ l of "1:100" dilution to each plate marked "× 10³." Each colony from this plate = 10³ CFU/ml.

It is imperative that these cultures be handled in a biosafety hood.

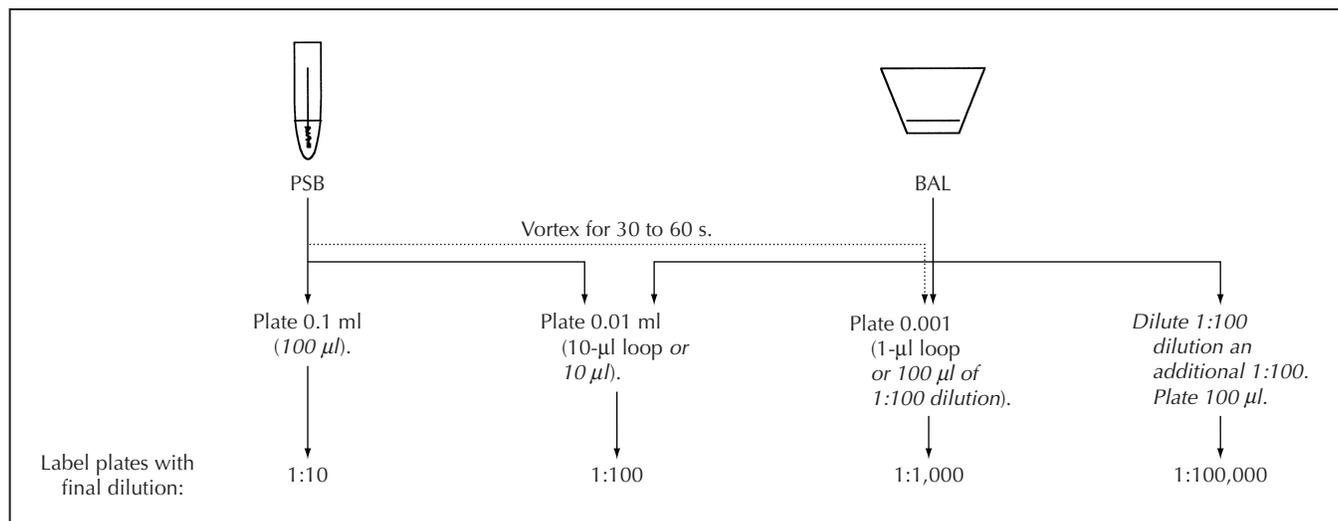

Figure 3.11.2-A1 Quantitative culture methods. Serial dilution method is in italics. Dashed line is optional. Adapted from reference 2.

APPENDIX 3.11.2-1 (continued)

- d. For BAL fluid only, do the following.
 - (1) Label one tube of 5 ml of PBS "1:10,000."
 - (2) Vortex.
 - (3) Transfer 50 μ l of "1:100" dilution to the tube labeled "1:10,000."
 - (4) Transfer 100 μ l of the "1:10,000" dilution to each plate marked " $\times 10^5$." Each colony from this plate = 10^5 CFU/ml.
 - e. *Spread the inoculum over the surface of each plate evenly by using a sterile glass or disposable plastic rod.*
 - (1) Place plate on spinning turntable for even greater distribution of colonies.
 - (2) Begin with the most dilute inoculum and proceed to the least dilute using the same sterile rod for each plate.
4. Loop method
- a. PSB
 - (1) Vortex for 30 to 60 s.
 - (2) Place 100 μ l (2 drops) of specimen onto each plate marked " $\times 10$." Each colony from this plate = 10 CFU/ml.
 - (3) Using a 1:100 loop, place 10 μ l on a plate labeled " $\times 100$." Each colony from this plate = 100 CFU/ml.
 - b. BAL fluid
 - (1) Vortex for 30 to 60 s.
 - (2) Using a 1:100 loop, place 10 μ l on a plate labeled " $\times 100$." Each colony from this plate = 100 CFU/ml.
 - (3) Using a 1:1,000 loop, place 1 μ l on a plate labeled " $\times 1,000$." Each colony from this plate = 1,000 CFU/ml.
 - c. *Spread the inoculum over the surface of each plate evenly by using a sterile glass or disposable plastic rod.*
 - (1) Place plate on spinning turntable for even greater distribution of colonies.
 - (2) Begin with the most dilute inoculum and proceed to the least dilute using the same sterile rod for each plate.
 - (3) Alternatively, spread the inoculum in only half the plate and use the second half to streak in two quadrants for isolation of large numbers of microorganisms.
- B. Incubate the aerobic plates in a 5 to 10% CO₂, 35°C incubator.
- C. Inoculate each additional medium with 100 μ l of specimen (2 drops) and streak for isolated colonies, according to procedure 3.11.2 or procedure 3.11.3.
- D. Prepare a Gram stain from the BAL sample, using the cytocentrifuge.
- E. Centrifuge the rest of the BAL specimen for culture for viruses, mycobacteria, *Legionella*, and fungi and for smears for viruses, *Pneumocystis*, AFB, and fungi, on request. Alternatively, use the unprotected brush as the best specimen for smears, if it is available.

POSTANALYTICAL CONSIDERATIONS

VI. INTERPRETATION

- A. Count the colonies from the dilution with the greatest number of colonies without confluence. Multiply by the dilution factor listed for each dilution (e.g., 40 colonies on the " $\times 1,000$ " plate is 40×10^3 CFU or 4×10^4 CFU).
- B. Count each morphotype individually.
- C. If growth is too numerous to count on the highest dilution, report the count as greater than that dilution.
- D. Counts for BAL fluid of less than 10^4 are considered to indicate contamination.
- E. Counts for PSB of less than 10^3 are considered to indicate contamination.

VII. REPORTING RESULTS

- A. Gram stain—report smear as indicated in procedure 3.2.1. Any organism seen in a cytocentrifuged smear of BAL fluid is considered indicative of bacterial pneumonia (6).
- B. Quantitative culture: report number of each pathogen found as CFU per milliliter of specimen. If culture count is lower than the threshold, identification and susceptibility testing are not generally indicated.

APPENDIX 3.11.2–1 (continued)

- C. *Candida* species are most often contaminants of the procedure and generally should not be identified to the species level.

VIII. LIMITATIONS

- A. Counts near the thresholds may be difficult to interpret accurately.
- B. Not all pathogens will grow on the media used and may result in a false negative culture.
- C. Anaerobes are implicated in disease, especially in the elderly or those obtunded with aspiration pneumonia. Cultures are generally not cost-effective or helpful because they vary in sensitivity from 20 to 60%, possibly due to aeration during collection and dilution of the specimen.
- D. Loop cultures are not as accurate as pipette cultures, but both are quite sensitive provided that a rod is used to spread the colonies on the plate. Spreading with the loop is *not* as sensitive a method and will underestimate the quantity of organisms present.
- E. Even a single dose of antimicrobial therapy prior to specimen collection can negate the ability to isolate the causative agent of disease from the specimen.

Dis.* **140**:306–310.

3.11.3

Respiratory Cultures from Cystic Fibrosis Patients

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Chronic lung infection is responsible for 75 to 85% of deaths in patients with cystic fibrosis (CF) (4, 6). Life expectancy has increased steadily over the past 50 years in large part because of improvements in management of lung disease in this patient population. The purpose of the CF culture is to provide a method for culturing respiratory secretions from patients with CF in order to isolate organisms associated with pulmonary disease in these patients. The number of microbial species associated with CF lung disease is relatively limited. Emphasis is placed on the recovery of those organisms, including mucoid and nonmucoid *Pseudomonas aeruginosa*, *Staphylococcus aureus*, *Burkholderia cepacia* complex (which includes *B. cepacia* genomovars I, III, and VI; *Burkholderia*

multivorans; *Burkholderia stabilis*; *Burkholderia vietnamiensis*; *Burkholderia ambifaria*; *Burkholderia anthina*; and *Burkholderia pyrrocinia*), *Stenotrophomonas maltophilia* and other non-glucose-fermenting, gram-negative rods, and *Haemophilus influenzae* and *Streptococcus pneumoniae*, (4, 6, 8, 11, 15). The vast majority of *B. cepacia* complex isolates that will be recovered from CF patients will be *B. cepacia* genomovar III, *B. multivorans*, and *B. vietnamiensis* (Table 3.11.3–1) (9). Nontuberculous mycobacteria and *Aspergillus* spp. may also play a role in CF lung disease and should be actively sought at the caregivers' request in these patients (6). Common respiratory viruses such as respiratory syncytial virus in children and

influenza virus in all patients may also cause respiratory symptoms and should be considered during periods of disease activity in the community (6). In selected centers, lung transplantation is performed in CF patients. Special culture needs of this patient population should be applied to specimens obtained from lung recipients with CF disease since they continue to harbor the same types of organisms as they did pretransplantation (16). Patients with CF may be colonized or chronically infected with microbiota which may change little over a long period of time; therefore, an approach is adopted which is designed to maximize service to the patient while minimizing duplication in the laboratory and assisting in cost containment.

Table 3.11.3–1 Characteristics of *B. cepacia* complex and related organisms^a

^d –(+), <20% of isolates gave a positive result.

3.11.3.1

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

- A. Specimen collection
1. Collect the following specimens for culture of respiratory secretions from CF patients.
 - a. Deep pharyngeal (also referred to as “cough or gagged” throat specimens)
 - (1) Place a plastic shaft, Dacron- or rayon-tipped swab in the back of the throat and induce coughing.
 - (2) Remove the swab when coughed secretions have been collected.
■ NOTE: This technique is used in children, usually <10 years of age, who are unable to produce sputum. *Do not use* this technique in children who are able to produce sputum.
 - b. Sputum
 - c. Endotracheal aspirates (on ventilated patients)
 - d. Bronchoscopically obtained specimens, including bronchoalveolar lavage (BAL) specimens, protected specimen brushings, and transbronchial biopsy specimens. See quantitative culture method (Appendix 3.11.2–1).
 2. Use the same transport devices for these specimens obtained from CF patients that would be used for non-CF patients.
 3. If the specimen cannot be transported and processed within 4 h, it may be held at 4°C for up to 24 h without affecting the recovery of the major pathogens of interest in CF patients.
- B. In addition to specimen labeling which meets good laboratory practices, identify the specimen as being obtained from a “cystic fibrosis patient” to allow appropriate specimen processing and workup.
- C. Rejection criteria
1. Since bronchoscopic specimens are obtained at significant expense and some degree of risk to the patient, all attempts should be made to process these specimens, even if they are compromised. However, on the final reports, note that specimen quality may have been compromised.
 2. Process no more than one specimen per month from nontransplant CF patients who are outpatients without physician or other caregiver consultation.
 3. Process no more than two specimens per admission for nontransplant CF patients who are inpatients without physician or caregiver consultation.
 4. If a swab is received labeled as a sputum, contact caregiver prior to processing, to determine source of specimen. It is likely a deep pharyngeal specimen.
■ NOTE: The microbiota responsible for chronic lung disease in CF patients is very stable, with patients being infected with organisms such as *S. aureus* or *P. aeruginosa* for months to years.
 5. No guidelines currently exist for frequency of culture from CF lung transplant recipients. Process specimens by request.
 6. Do not use culture rejection criteria for sputum or endotracheal aspirates based on Gram stain quality (Appendix 3.2.1–2), since they are of little value in CF patients. Specimens from CF patients will grow potential pathogens >90% of the time, although approximately 40% would be rejected based on the Gram stain evaluation (13).

III. MATERIALS

A. Media for culture

1. CHOC or horse blood agar with or without 20,000 U of bacitracin per liter (4) for recovery of *H. influenzae* (Remel, Inc.; BD Diagnostic Systems)

☑ **NOTE:** The addition of bacitracin will inhibit most strains of streptococci, staphylococci, and *Neisseria* and *Micrococcus* species, but *Escherichia coli*, some *Neisseria* species, and strains of *Candida*, *Klebsiella*, *Proteus*, and *Pseudomonas* spp. as well as other bacteria may grow on the medium.

2. Mannitol salt agar (MSA) for recovery of *S. aureus*
3. MAC
4. Columbia colistin-nalidixic acid agar (CNA)
5. *B. cepacia* selective agar (BCSA) (Remel, Inc.; Hardy Diagnostics) (10)

☑ **NOTE:** This medium contains lactose and sucrose with phenol red and crystal violet to differentiate colonies that oxidize these carbohydrates from those that do not, as well as polymyxin B, gentamicin, and vancomycin to inhibit most other bacteria.

B. Biochemical tests

1. See procedures 3.3.2 and 3.18.2 for standard laboratory tests and flowcharts helpful in identification of organisms recovered from CF patients.

2. For nonfermenting, gram-negative rods, use a commercial kit designed to identify them (e.g., Vitek GNI, GNI Plus, or API 20NE [bioMérieux, Inc.]; RapID NF Plus or N/F System [Remel, Inc.]; Microscan GNP [Dade-Behring Microscan]; Crystal E/NF [BD Diagnostic Systems]). Refer to procedure 3.1 for vendor contact information.

3. In addition, the following tests are helpful.

- a. Lysine and ornithine decarboxylase (procedure 3.17.15)
- b. *o*-Nitrophenyl- β -D-galactopyranoside (ONPG) (procedure 3.17.37)
- c. OF sugars (glucose, lactose, maltose, mannitol, adonitol, sucrose, and xylose [procedure 3.17.9])
- d. Colistin or polymyxin B disks (procedure 3.17.4)
- e. DNase (procedure 3.17.16)

4. Etests (AB Biodisk, Solna, Sweden) for trimethoprim-sulfamethoxazole, ticarcillin-clavulanic acid, and ceftazidime for susceptibility testing of *S. maltophilia*

5. Antimicrobial disks for susceptibility testing (procedure 5.1) or microdilution MIC method with overnight incubation (procedure 5.2)

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.

- B. QC the following media by lot when received.

1. *Haemophilus* media with bacitracin (see procedure 3.11.2 for details)
2. CHOC (see procedure 3.2.1 for details)
3. BCSA

Test organism	Incubation			Result
	Time (h)	Temp (°C)	Atmosphere	
<i>B. cepacia</i> ATCC 25416	24–72	35	Aerobic	Growth
<i>P. aeruginosa</i> ATCC 27853	24	35	Aerobic	Partial to complete inhibition
<i>S. aureus</i> ATCC 25923	24	35	Aerobic	Partial to complete inhibition

IV. QUALITY CONTROL (continued)

- C. Perform standard QC for reagents, commercial identification systems, and antimicrobial susceptibility testing according to package inserts and NCCLS documents (see sections 5 and 14).

V. PROCEDURE

Observe standard precautions.

A. Microscopic examination

1. Perform Gram stain on bronchoscopically obtained specimens and report results according to procedure 3.2.1.
2. Perform Gram stains on deep pharyngeal, sputum, and endotracheal aspirates by request only.
 - ▣ **NOTE:** Screening for specimen quality is inappropriate since limited organisms are associated with CF lung disease and their presence on culture is considered clinically significant regardless of Gram stain findings. See Table 3.11.3–2 for further details.
3. Perform acid-fast bacillus stains on request for sputum, endotracheal aspirates, and bronchoscopically obtained specimens from CF patients.

B. Culture methods

1. Inoculate each of the five media listed above and incubate CHOC or horse blood agar and CNA in 5% CO₂ at 35°C.
 - a. Incubate MAC, BCSA, and MSA without CO₂ at 35°C.
 - b. Inoculate the CHOC or horse blood agar quantitatively, if from bronchoscopy, according to Appendix 3.11.2–1.

Table 3.11.3–2 Processing of organisms

Organism	Oropharyngeal microbiota component	Identify	Special processing
Mold	NA ^a	Any amount	Identify to species level on annual basis.
<i>Enterobacteriaceae</i>	Not predominant or pharyngeal site	Predominant	Perform susceptibility testing.
<i>S. aureus</i>	NA	Any amount	Perform complete susceptibility testing yearly; perform oxacillin screening on each culture.
<i>H. influenzae</i>	Not predominant or pharyngeal site	Predominant	Perform beta-lactamase test. If colony is mucoid or wet, consult the lab director regarding possibly sending out for serotyping.
<i>S. pneumoniae</i>	Not predominant or pharyngeal site	Predominant	Screen for penicillin resistance with oxacillin disk. Perform penicillin Etest upon request.
<i>P. aeruginosa</i> , <i>B. cepacia</i> , other non-glucose-fermenting, gram-negative rods	NA	Any amount	Perform susceptibility testing.
Rapidly growing mycobacterium	NA	Any amount	Identify to species level.

^a NA, not applicable.

V. PROCEDURE (continued)

- c. For deep throat specimens, omit the CNA and CHOC or horse blood agar, since the specimen will only be examined for *P. aeruginosa*, *B. cepacia*, and *S. aureus*.
2. Because of the high rate of *P. aeruginosa* contamination, decontaminate all CF specimens in which the detection of acid-fast bacilli is requested using *N*-acetyl-L-cysteine–sodium hydroxide decontamination followed by 5% oxalic acid decontamination before inoculating standard mycobacterium isolation medium (17). See section 7 for general procedures.
3. Examine all plates at 24, 48, and 72 h of incubation. Examine BCSA plates also at 96 h for growth.
 - a. BCSA medium—*B. cepacia* complex will appear as small to large, pink, yellow, or metallic colonies. The medium surrounding the colonies will change from red to yellow. Proceed with identification from growth as indicated in Fig. 3.11.3–1.
 - b. MSA—for isolation of *S. aureus*, which will ferment the mannitol and produce a yellow zone around the colony
 - (1) Multiple strains of *S. aureus* may be present in one specimen; be alert to subtle differences in colonial morphology.
 - (2) In particular, thymidine-dependent strains of *S. aureus* may arise in patients treated with long-term trimethoprim-sulfamethoxazole; these strains frequently present with colonies which are somewhat smaller, flatter, and grayer than the parent strain (7).
 - (3) Pay close attention to colonial morphology of staphylococci on the CNA and horse blood agar or CHOC as well as the MSA. Strains of *S. aureus* which fail to ferment mannitol, or which do so only after many days of incubation, have been recovered from CF patients.
 - c. MAC—identify lactose-positive organisms according to the criteria in Table 3.11.3–2 and the methods in procedure 3.18.2. Subculture various morphotypes of non-lactose-fermenting, gram-negative rods from their primary plate to BAP. This will enable evaluation of their probable species morphology based on the following general guidelines.
 - (1) *P. aeruginosa*: beta-hemolytic, metallic, grape odor or mucoid colony morphology, oxidase positive, and indole negative. Both mucoid and nonmucoid phenotypes of *P. aeruginosa* should be identified using odor and colistin susceptibility. Perform further identification using commercial kits or biochemical tests, if odor is lacking. Refer to procedures 3.3.2 and 3.18.2.
 - (2) *S. maltophilia*: non-hemolytic, slight yellow pigment, and oxidase negative, at least initially.

■ **NOTE:** *S. maltophilia* isolates have been misidentified as *B. cepacia*, especially strains which are colistin resistant. *S. maltophilia* isolates growing on BCSA are colistin resistant. Key biochemical characteristics of *S. maltophilia* are an inability to oxidize mannitol, strong oxidation of maltose, and a positive reaction on DNase agar after a full 72 h of incubation. Unknown isolates should be considered DNase negative only after 72 h of incubation (5, 8).
 - (3) *Alcaligenes* and *Achromobacter* spp.: nonhemolytic, small colony type, oxidase positive, and not grapy or metallic smelling; may be sweet smelling.

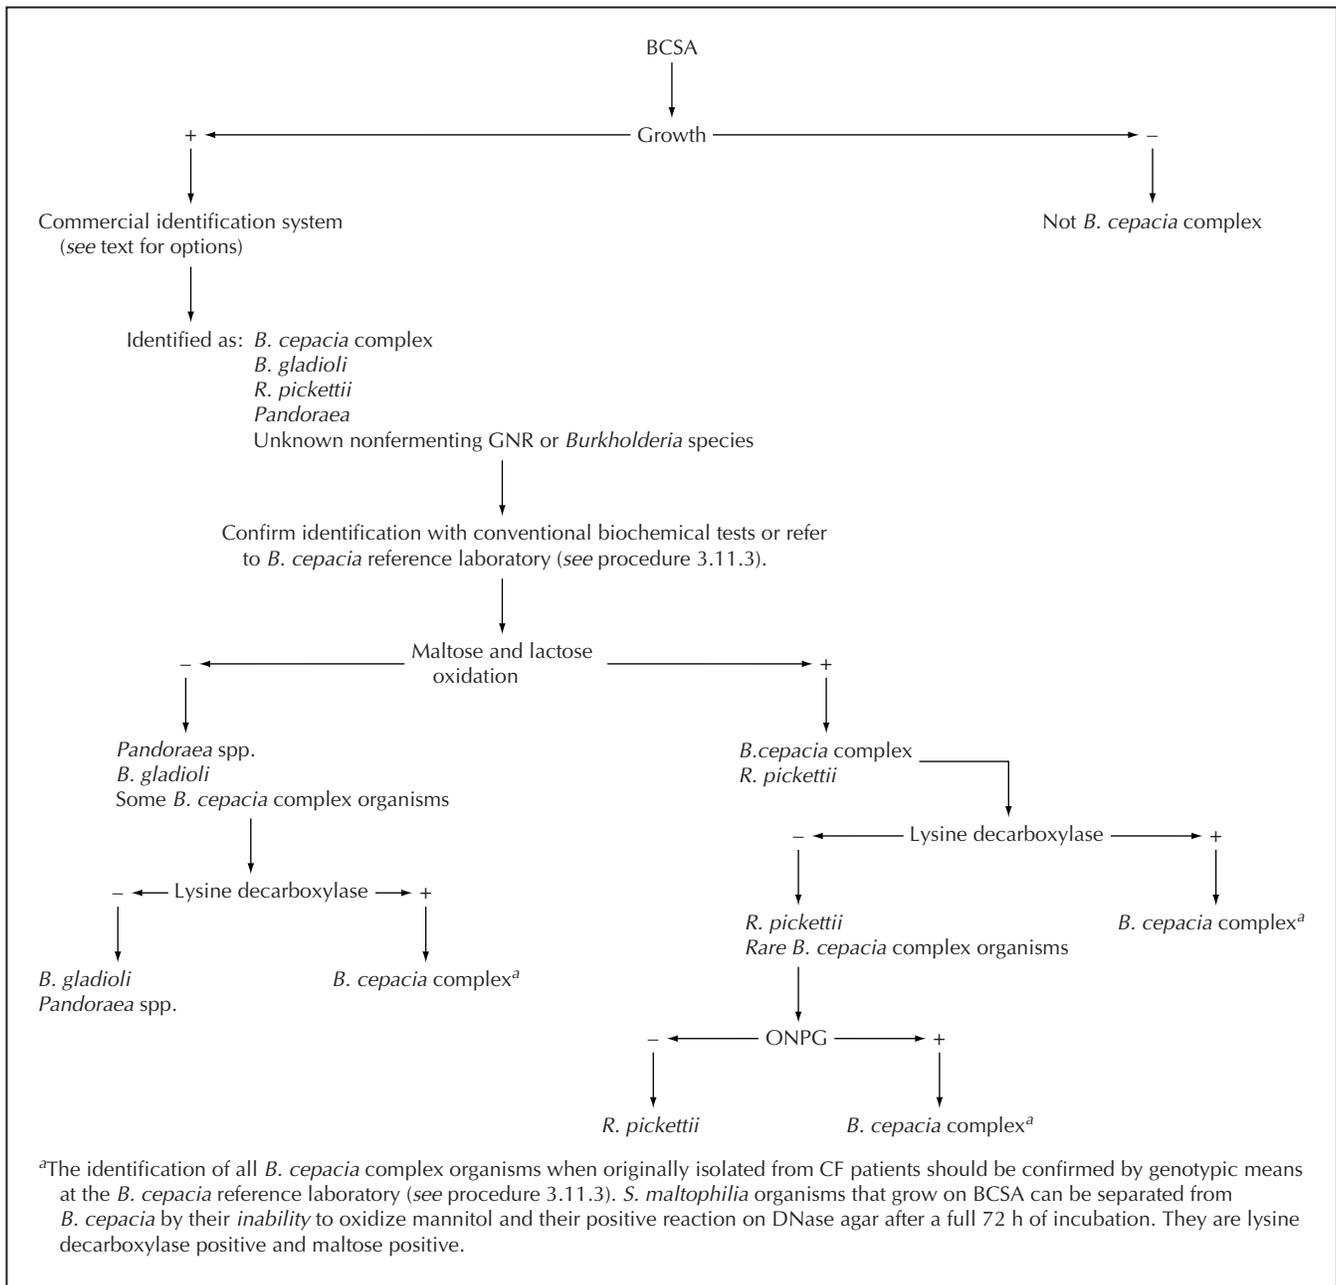

Figure 3.11.3–1 Flowchart for the identification of *B. cepacia* complex. GNR, gram-negative rod.

V. PROCEDURE (continued)

- (4) *B. cepacia* complex and related organisms: nonhemolytic, foul odor, oxidase variable. For details on identification of *B. cepacia* complex organisms to the species level by conventional methods, refer to Table 3.11.3–1.

■ **NOTE:** Confirm the identity of any organism from a CF patient identified by a commercial system as *B. cepacia*, as a *B. cepacia*-like organism, including a *Burkholderia* sp., *B. gladioli*, a *Pandoraea* sp., and *Ralstonia pickettii*, or as an unidentified gram-negative rod by genotypic means (1, 3, 11, 12). The United States Cystic Fibrosis

V. PROCEDURE (continued)

Foundation has established a reference laboratory at the University of Michigan for this purpose. Call (734) 936-9769 or e-mail Jlipuma@umich.edu for details on submission of isolates.

- d. Horse blood agar or CHOC—identify *Haemophilus*-like colonies from this medium by following criteria in Table 3.11.3–2 and methods in procedure 3.3.2.
 - e. CNA medium—identify *S. pneumoniae* isolates from this medium by following criteria in Table 3.11.3–2 and methods in procedure 3.3.2.
 - f. Molds may grow on BCSA, CNA medium, CHOC, or horse blood agar. Identify these organism by following criteria in Table 3.11.3–2 on an annual basis.
 - g. Rapidly growing mycobacteria may grow on CHOC/horse blood agar or CNA medium; identify if typical colony morphology is observed.
4. Further workup of positive cultures should follow guidelines in Table 3.11.3–2.
- a. For quantitative cultures, identify all organisms and do susceptibility testing for all organisms listed in Table 3.11.3–2 which are found at concentrations of $>10^3$ CFU/ml in protected specimen brushings and $>10^4$ CFU/ml in BAL samples. If multiple potential pathogens (≥ 3) are found above the quantitative cutoff, consult with the physician or caregiver concerning further workup of the specimen.
 - b. Susceptibility testing guidelines
 - (1) *S. aureus*: perform complete susceptibility testing of *S. aureus* once per year. Subsequent isolates from an individual patient should be screened for oxacillin resistance (procedure 13.17). Isolates should be confirmed as either oxacillin resistant or susceptible (procedure 5.4). Complete susceptibility testing on a more frequent basis is done only after consultation with the physician or caregiver.
 - (2) *H. influenzae*: perform beta-lactamase screening.
 - (3) *P. aeruginosa*: test each mucoid and nonmucoid morphotype separately by either disk diffusion, Etest, or microdilution MIC determination (2). Patient isolates should be tested no more than once per month for outpatients and twice during any admission for inpatients. Do not use rapid automated susceptibility test systems with less than 24 h of incubation for testing *P. aeruginosa*.
 - (4) *S. maltophilia*: test for MIC by either broth microdilution or Etest (4). The Etest panel can be limited to trimethoprim-sulfamethoxazole, ticarcillin-clavulanic acid, and ceftazidime.
NOTE: Reliable disk diffusion breakpoints to trimethoprim-sulfamethoxazole, minocycline, and levofloxacin will be available in NCCLS document M100-S14 in 2004.
 - (5) *B. cepacia* complex, *Alcaligenes*, and related organisms: test either by disk diffusion or by microdilution MIC testing. Report disk diffusion results using *P. aeruginosa* breakpoints with the disclaimer “nonstandardized susceptibility results (4).”
NOTE: Reliable disk diffusion breakpoints for *B. cepacia* to ceftazidime, minocycline, and meropenem will be available in NCCLS document M100-S14 in 2004.
5. Hold positive culture plates for 7 days at room temperature after laboratory results have been finalized.
6. Hold specimen for 7 days at 4°C to resolve any problem with the specimen.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. If no growth is observed, report “No growth.”
- B. If only normal microbiota is observed, report as such.
- C. Report all potential pathogens according to criteria listed in Table 3.11.3–2.
 - 1. For deep pharyngeal cultures, report the presence in any amount of *S. aureus*, *P. aeruginosa*, and *B. cepacia* only.
 - 2. For quantitative cultures, report all potential pathogens (Table 3.11.3–2) that are in concentrations of $>10^3$ CFU/ml for protected specimen brushings and $>10^4$ CFU/ml for BAL samples.
 - 3. For colistin-resistant gram-negative rods that are being referred to the CF reference laboratory, report as “probable XX,” where XX is the most likely identification from the flowchart. Add a note: “Sent to *B. cepacia* reference laboratory for definitive identification.” If the identification is truly in doubt, report the organism as “Unidentified gram-negative rod” and refer to the CF reference laboratory.
- D. Document all results either as hard copy or by computerized work card.

VII. INTERPRETATION

- A. The finding of *S. aureus*, *P. aeruginosa*, and *B. cepacia* complex regardless of quantity is always considered clinically significant (4, 6).
 - 1. Sputum cultures from CF patients have been shown to correlate well with the presence of these organisms in the lower airways (4, 6, 14).
 - 2. The presence of any of these three organisms in deep pharyngeal cultures should be reported. Other organisms in Table 3.11.3–2 should not be reported in pharyngeal cultures since they can be considered part of the oropharyngeal microbiota.
- B. The finding of *B. cepacia* complex organisms in particular is viewed as important in the CF community, since patients with these organisms are often segregated from *B. cepacia*-negative CF patients both socially and medically. In addition, infection with these organisms may be considered a contraindication for lung transplantation, an important life-saving option in the terminal phase of this disease. Therefore, accurate identification of this complex of bacteria is critical for patient care, especially in light of the fact that there is not convincing evidence that the organisms with which it most frequently confused, *B. gladioli*, *R. pickettii*, and *Pandoraea* spp., play a significant role in CF lung disease (1, 3, 12).
- C. *Aspergillus* spp., especially *Aspergillus fumigatus*, are associated with allergic bronchopulmonary aspergillosis (ABPA). ABPA is typically a clinical diagnosis with the finding of *Aspergillus* on culture supportive of the diagnosis of ABPA (6).
- D. Other agents listed in Table 3.11.3–2 have been associated with pulmonary exacerbation of CF and should be reported according to criteria in Table 3.11.3–2.

VIII. LIMITATIONS

- A. Patients with CF who are experiencing pulmonary exacerbation of their lung disease often respond to combinations of antimicrobials to which their organisms are resistant both individually and in combination by in vitro testing (4, 6).
- B. The interpretation of deep pharyngeal culture results is problematic. The absence of CF pathogens in these specimens is a good predictor of their absence in the lower airways. However, the presence of *S. aureus*, *P. aeruginosa*, and *B. cepacia* is not so strong a predictor of their presence in the lower airway. Nevertheless, caregivers of CF patients will treat the finding of these organisms in this specimen type as clinically significant (14). Other pathogens listed in Table 3.11.3–2 should not be reported from this specimen type.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Legionellosis is the collective name used to refer to (primarily pulmonary) infections caused by members of the genus *Legionella*. There are currently 45 named species in the genus, and several species contain more than one serotype. Many, but not all, species have caused human infection. Legionellae thrive in warm moist environments, both natural and artificial, and their multiplication is enhanced by the presence of free-living amoebae, in which the organisms multiply in these environments. Whether the few species which have not been isolated from humans are of lower virulence or simply live in environments with which humans do not come into contact is unknown. Transmission to humans typically occurs as aerosols. Legionellosis is not contagious.

Culture of respiratory secretions is among the most sensitive methods for the diagnosis of *Legionella* infection. The legionellae are intracellular pathogens, residing primarily in macrophages within

the alveoli. Like other intracellular pathogens, they may not be present in every sputum sample and, when present, their numbers may be low. Since many patients with legionellosis do not produce sputum, collection of multiple respiratory specimens may be beneficial.

Urinary antigen testing has supplanted direct immunofluorescence antibody (DFA) testing of sputum for rapid diagnosis of legionellosis (see Appendix 3.11.4–1). Although urine antigen testing is designed to detect infections due to *Legionella pneumophila* serogroup 1, patients with infections due to other species and serogroups may sometimes have a positive test (1, 3). While *L. pneumophila* serogroup 1 represents the most commonly recognized cause of legionellosis, it may account for as little as 50% of cases (6, 8); thus, a negative urinary antigen test is not sufficient to presume that a patient does not have legionellosis.

Testing for antibodies to *Legionella* is not useful in the care of critically ill patients and is not recommended for routine use. Most patients with culture-confirmed legionellosis do not develop detectable antibodies until >3 weeks after infection, and some highly immunosuppressed individuals never produce detectable antibodies (2). Likewise, high titers in acute-phase serum samples are not, in themselves, diagnostic. Many persons have preexisting antibody from prior (subclinical) *Legionella* infection. Antibody tests using paired serum samples may be useful, however, as a tool in tracking nosocomial and community outbreaks.

The procedures presented here include the detection of legionellae by culture of clinical specimens. Refer to procedure 13.5 for culture of environmental samples for legionellae.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection (see procedure 3.11.2 for details on collection of lower respiratory specimens)

■ **NOTE:** *L. pneumophila* survives in up to 3% salt solutions at temperatures below 30°C; in fact, small amounts of salt (0.1 to 0.5%) enhance survival (4). Saline is not toxic to the organism, as previously thought.

1. Respiratory secretions (sputum, bronchial and tracheal aspirates, bronchial washings)

- a. Place expectorated specimen in a sterile screw-cap cup.
- b. Specimens collected by bronchoscopy or aspiration may remain in the Luken trap for transport so long as the free ends of the tubing are securely joined together to prevent leakage of the specimen during transport.
- c. Collect at least 3 ml of specimen for *Legionella* culture.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

2. Bronchoalveolar lavage (BAL) fluid
Submit a minimum of 50 ml of fluid in a sterile container.
3. Sterile body fluids (pleural, pericardial, peritoneal)
 - a. Submit at least 5 ml in a sterile tube or in the syringe used for collection.
 - b. Remove the needle and cap the syringe with a Luer-Lok before transport.
4. Bronchial brushings
 - a. Cut the brush off at a point about 30 to 40 mm from the end.
 - b. Place the brush into a small tube containing no more than 0.5 ml of sterile saline or TSB.
5. Lung tissue
 - a. Place a piece of tissue approximating the size of a dime onto a gauze square moistened with sterile saline.
 - b. Place the gauze square and the tissue into a sterile specimen cup with a screw cap.
6. Other tissues and wound specimens (including prosthetic heart valves)
 - a. Perform culture for legionellae on such specimens, especially if routine bacterial cultures prove to be negative.
 - **NOTE:** Legionellae survive in the specimen when stored in the refrigerator for long periods of time. However, they may also be present in a backup broth used for culture but will not grow or be detected in the broth. If the routine culture is negative, and the specimen is no longer available, subculture the broth to selective medium for legionellae. Post-surgical wound infections due to use of contaminated water for wound care have been reported.
 - b. Collect tissues as for lung tissues.
 - c. Collect external wound specimens on swabs after cleansing the site with sterile saline.
7. Blood
There are no reliable methods for recovering legionellae from blood. "Blind subculture" of "negative" standard blood culture bottles sometimes results in recovery of the organism. The sensitivity of this method is not sufficient for routine use.

B. Timing and transport

1. Submit samples in the acute phase of infection, preferably before the beginning of antimicrobial therapy.
2. Transport to laboratory quickly. While legionellae may survive extended transport, their isolation may be compromised by overgrowth of commensal bacteria in the specimens.
3. If specimens are being transported to a remote laboratory, place samples on wet ice for transport.
4. For extended transport times (>1 day), freeze samples (-70°C) and transport on dry ice.

C. Rejection criteria

1. Respiratory secretions (sputum, etc.) submitted for routine bacterial culture are screened for adequacy by Gram stain; *do not* apply these criteria for specimens submitted for *Legionella* culture (5).
 - **NOTE:** Patients with Legionnaires' disease typically produce sputum which is thin and watery and may contain few WBCs. Additionally, only normal oral bacterial morphotypes may be seen in Gram stains because legionellae do not stain with Gram stain reagents in clinical specimens.
2. Reject BAL specimens with a volume of less than 30 ml. The procedure produces specimens which are very dilute and which must be concentrated by centrifugation before culture.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

3. Do not perform “quantitative BAL cultures” for legionellae; their concentration in such specimens is always low.
4. Pleural fluid specimens of less than 5 ml should be cultured only after alerting the physician that such specimens are unreliable for the recovery of *Legionella*.
5. Reject “test-of-cure” cultures, since they should not be used to monitor a patient’s response to therapy.

III. MATERIALS

Include QC information on reagent container and in QC records.

A. Media

1. Inoculate two media for each culture.
 - a. Buffered charcoal-yeast extract agar (BCYE- α)
 - ☑ **NOTE:** This nonselective medium contains ferric pyrophosphate, cysteine, α -ketoglutarate, and charcoal.
 - b. BCYE- α with polymyxin, anisomycin, cefamandole, and α -ketoglutarate (BMPA- α)
 - ☑ **NOTE:** While useful for specimens containing other microorganisms, this medium may be inhibitory to *Legionella* species (such as *Legionella micdadei*) which are susceptible to cefamandole. It should *never* be used alone.
2. Store at 4°C in sealed bags to keep it moist. Do not store for any period out of the bags.

B. Other supplies

1. Inoculating loop
2. Pasteur pipettes
3. Tissue homogenization apparatus (stomacher or other mechanical homogenizer) and TSB
4. Centrifuge to allow for 1,500 \times g and centrifuge tubes for BAL samples (50 ml) and body fluids (10 to 15 ml)

C. Reagents

1. KCl acid-wash solution, pH 2.2
 - a. Hydrochloric acid (0.2 M): add 2 ml of 1 M HCl to 8 ml of distilled water.
 - b. Potassium chloride (0.2 M): dissolve 1.5 g of KCl in 100 ml of distilled water.
 - c. Add 3.9 ml of 0.2 M HCl to 25 ml of 0.2 M KCl. Adjust pH to 2.2 \pm 0.1 at 25°C with HCl or KCl; filter sterilize.
 - d. Aseptically dispense 1-ml volumes into sterile screw-cap tubes containing a few glass beads. Store at room temperature. Shelf life is 1 year.
 - ☑ **NOTE:** KCl solution (pH 2.2, 0.2 M) may be purchased from Remel, Inc. (20 tubes/pack, catalog no. 062621; 100 tubes/case, catalog no. 062620)
Formula is HCl (0.2 M) at 135 ml plus potassium chloride (0.2 M) at 865 ml.
2. BCYE without cysteine (Remel, Inc.)
3. 5% Solution of powdered skim milk in sterile distilled water
4. Beta-lactamase test (procedure 5.3)
5. Hippurate test (procedure 3.17.21)
6. DFA reagents (see Appendix 3.11.4–2)

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media are within expiration period. Do not use if media appear to have dried, even if they have not passed the expiration date.
 - ☑ **NOTE:** In particular, the effectiveness of BMPA- α declines with age as the antimicrobial agents degrade. Media which are stored for extended periods may dry out, causing the concentrations of ingredients to rise and making the media inhibitory.
- B. Source of QC organisms
 - ☑ **NOTE:** True QC of *Legionella* media is difficult, since the organisms rapidly become adapted to growth on artificial media within one or two passages. Media which pass internal QC procedures may not be presumed always to be of adequate quality.

IV. QUALITY CONTROL

(continued)

1. Aliquot respiratory or tissue samples from a patient with Legionnaires' disease, for the best source of QC. Store at -70°C with approximately a 1-year expiration date. Lacking a clinical specimen, obtain a low-passage isolate of *L. pneumophila* from a reference laboratory.
 2. Suspend the isolate in a 5% solution of sterile skim milk and store in small aliquots at -70°C .
- C. Preparation of QC cultures. Use the methods outlined in NCCLS standard M22-A2 (7) and procedure 4.2.
1. Prepare a culture of the stored *Legionella* isolate on BCYE- α .
 2. Suspend colonies from this first stock culture in sterile TSB to match the turbidity of a no. 1.0 McFarland standard.
 3. Mix this adjusted culture with an equal volume of 10% (wt/vol) skim milk solution. Divide this final suspension into small aliquots and freeze at -70°C .
- D. QC testing
1. Remove one of the frozen aliquots from the freezer, thaw, and dilute 1/100 in TSB.
 2. Inoculate the volume of a 10- μl inoculating loop onto the surface of the media to be tested.
 3. Incubate for 48 h at 35°C and count the colonies. Depending on the exact concentration of the original suspension, there should be between 50 and 200 colonies on each inoculated plate.
 4. Keep detailed records of the colony counts for each lot of medium. Over time, the viability of the stored inoculum may decline, and a decrease in the number of colonies on the tested plates could be the result of decline in viability of the inoculum rather than a decrease in the quality of the media. In order to assess this possibility, test the lot in question again with a fresh inoculum which has not been frozen.
 5. Verify that BMPA- α is able to inhibit growth of similar suspensions containing *Staphylococcus aureus*, *Pseudomonas aeruginosa*, and *Candida albicans*.

V. PROCEDURES

It is imperative that these cultures be handled in a biosafety hood.

A. Culture inoculation

1. For all specimens, inoculate BCYE- α and BMPA- α plates.
 - a. Label plates with patient name and identifying number.
 - b. Record the date and time of inoculation.
 - c. Streak plates in several sectors to produce isolated colonies after incubation.
 - d. After initial processing, save a portion of specimen at 4°C for 7 days in case the specimen is contaminated and acid treatment is indicated.
2. Respiratory secretions
 - a. Touch a swab to the most purulent portions of the specimen containing blood or mucus, if present.
 - b. Use separate swabs to inoculate each plate.
 - c. If the specimen is from a patient with cystic fibrosis or a patient known to have colonization with gram-negative rods, acid treat the specimen and inoculate an additional BAP and BCYE- α plate.
 - (1) Place 0.1 ml of sputum sample into 0.9 ml of KCl solution, and vortex.
 - (2) Allow sample to incubate for 5 min at room temperature.
 - (3) Inoculate 0.1-ml portions of the treated specimen onto BCYE- α and BMPA- α .

V. PROCEDURES (continued)

3. BAL specimen
 - a. Centrifuge 30 to 50 ml or more of specimen at $1,500 \times g$ for 20 min.
 - b. Decant all but 0.3 to 0.5 ml of the supernatant. Vortex to resuspend sediment into the remaining supernatant.
 - c. Use a sterile Pasteur pipette to dispense 2 drops of the specimen onto each plate.
4. Sterile body fluids
 - a. Concentrate at least 10-fold, when possible, by centrifuging at least 5 ml at $1,500 \times g$ for 20 min.
 - b. Decant all but 0.5 ml of the supernatant. Resuspend any sediment in the remaining supernatant by vigorous shaking or vortexing.
 - c. Use a sterile Pasteur pipette to dispense 2 drops of the specimen onto each plate.
5. Bronchial brushings
 - a. Vigorously agitate the brush in the TSB to remove the cellular material adherent to it.
 - b. Use a sterile Pasteur pipette to dispense 2 drops of the specimen onto each plate.
6. Tissue
 - a. Place a piece of tissue no larger than a dime into 5 ml of TSB.
 - b. Homogenize the tissue using a mechanical tissue grinder or a stomaching device.
 - c. Use a sterile Pasteur pipette to dispense 2 drops of the specimen onto each plate.

B. Examination of cultures

1. Incubate cultures on buffered media in ambient air (*i.e.*, without increased CO_2) at 35 to 37°C for 7 days with adequate humidity (50 to 70% relative humidity) to prevent drying of media during incubation.
 - **NOTE:** Dried media are inhibitory to growth of *Legionella*. If low incubator humidity is a problem, place sterile gauze moistened with sterile water in bottom of jar and place plates on gauze in the jar.
2. Examine culture plates *daily* with the lids removed.
 - a. Examine plates early each morning so that suspicious colonies can be tested with FA reagents that day for early diagnosis of disease.
 - b. It is imperative to examine the plates using a dissecting microscope with a magnification of $\times 20$ to $\times 50$. Even colonies not yet visible to the naked eye will have the colony morphology typical of *Legionella*.
 - c. Use a focused light source aimed at a high oblique angle to illuminate the surface of the plate.
 - d. Avoid exposure to contaminating airborne molds during examination. Work in a biological safety hood, if possible.
3. At 24 h, if there is heavy growth of non-*Legionella* bacteria on the BCYE- α and BMPA- α plates, reprocess the original specimen using acid treatment, as described above for respiratory secretions containing gram-negative rods.
 - **NOTE:** Reprocessing of the culture may not be required if the “routine” culture of the sample yields organisms consistent with the patient’s diagnosis. Consultation with the patient’s physician regarding the likelihood of legionellosis may be appropriate prior to undertaking acid treatment of the specimen.

V. PROCEDURES (continued)

4. When viewed as described above, *Legionella* organisms appear as circular colonies with an entire edge, having a distinctive “ground-glass” appearance (see Fig. 3.11.4–1) and an iridescent blue, green, or pink hue. Only a few other bacteria of medical importance have this appearance. Older colonies are opaque, with a white center and opalescent perimeter.

■ **NOTE:** Colonies resembling *Legionella* may not be present on both media. *L. micdadei* and a few other species may be inhibited by the cefamandole in BMPA- α . On BCYE- α , growth of large amounts of other gram-negative bacteria and yeasts may inhibit the growth of *Legionella*.

Caution: Exercise caution when examining non-*Legionella* gram-negative bacteria present on BCYE- α . Some highly infectious organisms, such as *Francisella tularensis*, may grow preferentially on BCYE- α . Additionally, fungi such as *Coccidioides immitis* and *Histoplasma capsulatum* may also grow on BCYE- α .

C. Preliminary identification of isolates

1. Gram stain suspicious colonies. Legionellae will appear as small gram-negative rods, which may stain faintly. Typically they are about the size of *Haemophilus* spp.; however, it is not unusual for there to be long filamentous forms present as well.
2. Examine plates with presumptive legionella morphology immediately using a long-wave UV lamp (Wood’s lamp) in a darkened room, since some legionellae exhibit autofluorescence.
 - a. Bright blue-white fluorescence
 - (1) *Legionella bozemanii*
 - (2) *Legionella dumoffii*
 - (3) *Legionella gormanii*
 - (4) *Legionella anisa*
 - (5) *Legionella tucsonensis*
 - (6) *Legionella cherrii*
 - (7) *Legionella parisiensis*
 - (8) *Legionella steigerwaltii*
 - b. Yellow-green fluorescence
 - (1) *Legionella wadsworthii*
 - (2) *Legionella birminghamensis*
 - c. Red fluorescence
 - (1) *Legionella erythra*
 - (2) *Legionella rubrilucens*

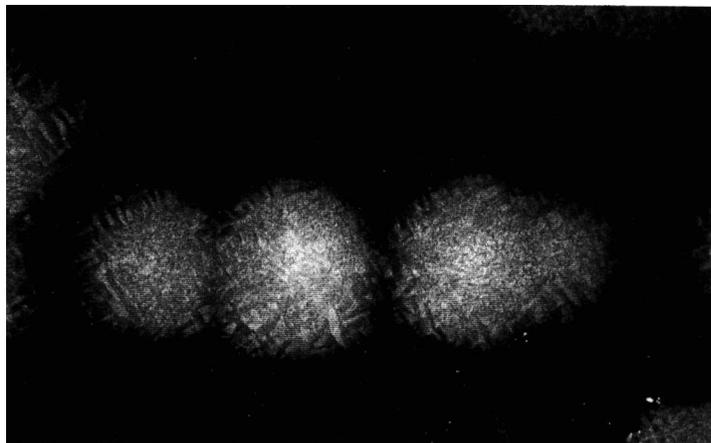

Figure 3.11.4–1 Colonies of *L. pneumophila* on BCYE- α showing ground-glass appearance.

V. PROCEDURES (*continued*)

3. Subculture suspicious colonies to BCYE- α and either a BAP or a plate of BCYE- α from which cysteine has been omitted. Do not use CHOC, since some *Legionella* isolates will grow on this medium.
 - a. Incubate plates at 35 to 37°C for 24 to 48 h.
 - b. Isolates which grow on BCYE- α but not on BAP or on the unsupplemented BCYE plate should be considered as presumptive *Legionella* spp. However, since rapid diagnosis is important to patient care, do not wait for these subculture results to perform confirmatory FA testing on typical colonies.
4. Perform rapid hippurate test and beta-lactamase test on suspicious colonies.
NOTE: There are few biochemical tests which can be used to identify legionellae. Testing for the ability to hydrolyze hippurate may be of routine value, especially for laboratories that do not perform DFA testing. All serotypes of *L. pneumophila* hydrolyze hippurate, but a few less common species (e.g., *Legionella spiritensis*, *Legionella waltersii*) may also. Nevertheless, since *L. pneumophila* is the predominant species isolated from human infections, the finding that an isolate hydrolyzes hippurate is reasonably powerful suggestive evidence of its identity.
5. Use the beta-lactamase test to separate *L. pneumophila* (positive) from other species, such as *L. micdadei* (negative), as an aid in choosing which antisera to test for identification.

D. Definitive identification of isolates

1. For definitive identification, refer isolates to the local or state health department laboratory or a reference laboratory.
NOTE: Definitive identification of *Legionella* to the species level requires testing not generally available in routine clinical microbiology laboratories, including the determination of the major branched-chain fatty acids contained in the cells and/or genetic analysis.
2. Identify the most prevalent species, *L. pneumophila* and *L. micdadei*, by testing the isolated colonies with DFA or indirect FA reagents, which are available commercially.
 - a. Perform FA tests as soon as suspicious colonies are isolated and preliminary rapid tests are performed.
 - b. Do not wait for subculture to confirm that the isolate does not grow on BAP, as delays may affect patient care.
 - c. See Appendix 3.11.4–2 for procedure.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS****A. Negative cultures**

1. Preliminary report: “No *Legionella* isolated to date.”
2. Final report: “No *Legionella* isolated after 7 days.”

B. Positive cultures

1. Report “Positive for *Legionella* spp.” if isolate has only been identified with polyvalent DFA reagents.
2. If serogroup or species has been determined, then report using the full species and/or serogroup designation, e.g., “Positive for *Legionella micdadei*.”
3. Notification
 - a. For hospitalized patients, notify the patient’s physician immediately. Notify infection control immediately also.
 - b. For outpatients or recently discharged patients, notify the patient’s physician immediately.

VI. REPORTING RESULTS

(continued)

- c. Report positive cultures and urinary antigen tests to local or state health departments using whatever means is customary, following local disease reporting guidelines.
- 4. Storage of isolates
Molecular methods for typing *Legionella* isolates are available from some reference laboratories. Since an individual patient may be a part of a developing outbreak, it is prudent to save clinical *Legionella* isolates in 5% sterile skim milk at -70°C for possible future typing studies.
- C. Contaminated cultures
If culture is overgrown with bacteria, yeast, or mold, report "Culture terminated due to growth of contaminating microbiota."

VII. LIMITATIONS

- A. Legionellae are reliably susceptible to macrolides (azithromycin, erythromycin), quinolones (e.g., levofloxacin), and rifampin. Acquisition of resistance during therapy does not occur. In vitro susceptibility testing is not useful for selecting the "best" antimicrobial agent or for any other therapeutic purpose and should not be performed.
- B. Legionellae are intracellular pathogens and may persist in sputum for several weeks after the institution of antimicrobial therapy. Test-of-cure cultures should not be used to monitor a patient's response to therapy, since patients who are recovering from Legionnaires' disease may continue to shed organisms. The patient's clinical response is the best indicator of a response to therapy.
- C. Culture may be the most sensitive indicator of disease, but a negative culture does not rule out infection. Inhibitors of growth, such as the presence of yeasts, sampling error in collection, and prior treatment with antimicrobial agents, can affect the sensitivity of culture.
- D. Legionellae have been isolated on CHOC in rare instances.
- E. *F. tularensis*, *Bordetella pertussis*, and *Afpia* will grow on BCYE- α and not on BAP. The former two species are not motile and the latter does not have the colony morphology of *Legionella* spp.
- F. Some species of *Legionella* will not react with current antisera. Suspicious colonies should be submitted to a reference laboratory for further identification.

APPENDIX 3.11.4–1

Legionella Urinary Antigen Test

I. PRINCIPLE

Urinary antigen testing has supplanted direct immunofluorescence testing of sputum for rapid diagnosis of legionellosis. While urinary antigen tests are generally of excellent specificity, the sensitivity (70 to 90%) is less than that of culture. These tests detect infections due to *Legionella pneumophila* serogroup 1 and perhaps some other serogroups as well (1, 2). When possible, antigen tests should be performed in conjunction with culture or respiratory secretions to enable the recovery of species and serotypes not detected by the urinary antigen test and also to provide organisms for molecular typing in the event that the patient is part of an outbreak of Legionnaires' disease. (*Also see procedure 11.4.*)

II. SPECIMEN

- Collect at least 5 ml of urine by clean catch or from a catheter.
- Submit in a sterile screw-cap container. Storage and transport in urine preservative tubes containing boric and formic acids are also acceptable.
- Store samples at 4°C until tested.
- Allow patient samples to come to room temperature before testing.

III. MATERIALS

- NOW *Legionella* urinary antigen test kit (Binax, Inc., Portland, Maine)
- For larger-volume laboratories, use similar tests available in EIA or ELISA format.
 - Legionella* urinary antigen EIA kit (Binax, Inc.)
 - Bartels *Legionella* urinary antigen ELISA (Intracel Corp., Rockville, Md.)
 - Urine *Legionella* antigen ELISA (Wampole Laboratories, Cranbury, N.J.)

IV. QUALITY CONTROL

- Remove control swabs (positive and negative) from pouch.
- Place each swab into a test card as described for patient specimens.
- Unlike for test specimens, add 6 drops of reagent A to the control specimens.
- Seal the test cards, as described for the assay, and incubate for 15 min.

V. ASSAY PROCEDURE

- Open test card pouch just before use. Label the test card with the sample accession number and other appropriate information.
- Dip a test swab (supplied as part of the test kit) into the urine sample, completely covering the head of the swab. Remove the swab from the urine.
- If the swab drips, touch the swab to the side of the container to remove the excess sample.
- Insert the swab through the bottom hole on the test card and push it forward until the top of the swab is visible in the top hole of the card.
- Hold the vial of reagent A vertically, 1 to 1.5 in. above the test card. Add 2 drops of reagent A to the bottom hole of the card.
- Peel off the adhesive tape from the right side of the card. Close and seal, pressing down on the edge of the test card. Incubate at room temperature.
- Start timer and read result after 15 min of incubation.

APPENDIX 3.11.4–1 (continued)

- VI. INTERPRETATION
- A. Determine results after 15 min of incubation. Reading results beyond this point may produce inaccurate results.
 - B. If no pink lines are seen in the test window, the assay is invalid and should be repeated.
 - C. A negative sample will produce a pink upper control line. The lower test line in the window will not be visible.
 - D. A positive sample will display two pink lines. Both the upper control line and the lower test line will be visible.
- VII. REPORTING RESULTS
- A. Positive urinary antigen
Report “Positive for urinary antigen of *Legionella pneumophila* serogroup 1.”
 - B. Negative urinary antigen
 1. Report “Negative for urinary antigen of *Legionella pneumophila* serogroup 1.”
 2. Also add the following comment: “Other serogroups and species of *Legionella* which may cause human disease are not detected by this test. Culture of respiratory secretions is recommended if infection with *Legionella* is still suspected.”
- VIII. LIMITATIONS
- A. This test detects primarily *L. pneumophila* serogroup 1 and should not be relied on solely for the diagnosis of legionellosis. A negative test does not rule out the possibility of legionellosis caused by other serogroups and species.
 - B. *Legionella* urinary antigen may persist in the urine of successfully treated patients for weeks to months following recovery. Sequential urinary antigen tests should not be performed to monitor response to therapy.
 - C. In one study comparing two EIAs and the NOW test, the sensitivities of the assays were 88 to 100% for severe cases of pneumonia but dropped to 40 to 53% for milder cases of the disease (3).

APPENDIX 3.11.4–2

Detection of *Legionella* by Fluorescent Antibody

I. PRINCIPLE

Rabbit antibodies prepared against *Legionella* species and serogroups are conjugated with fluorescein isothiocyanate (FITC). The antibodies will bind to the homologous *Legionella* species, making them visible when viewed under UV light. Direct immunofluorescence is most commonly used for the identification of *Legionella* isolates from cultures.

Direct immunofluorescence may also be used to detect legionellae in clinical specimens; however, the sensitivity of this procedure may be low, depending on the skill and experience of the operator (1). It should be used cautiously by inexperienced laboratorians for critical specimens such as lung tissue. Some laboratories use it as an adjunct to examination of highly contaminated sputum specimens in conjunction with acid decontamination and culture (J. Stout, personal communication). (Also see procedure 11.3.)

APPENDIX 3.11.4–2 (continued)

- II. SPECIMENS
- A. Tissue, fresh
1. Use a sterile scalpel to cut a fresh face on the surface of the tissue. Homogenize the tissue in sterile water to make an approximately 10% suspension.
 2. Alternatively, use a sterile scalpel to cut a fresh face on the surface of the tissue. Grasping the tissue with forceps, press the newly exposed face of the tissue to a clean slide.
 3. Make one slide for each antibody conjugate employed and one slide for a negative control conjugate.
 4. Air dry and heat fix.
 5. Fix smears in 1% formalin for 10 min. Drain and rinse off formalin with a gentle stream of filtered water.
- B. Tissue, formalin fixed
1. Use a scalpel to cut a fresh face on the tissue. Place the tissue in a petri dish and use the scalpel to scrape a fine puree of debris and tissue fluids from the newly cut surface of the tissue.
 2. Use the scalpel blade to transfer portions of the puree to clean microscope slides.
 3. Prepare one slide for each antibody conjugate employed and one slide for the negative control conjugate.
 4. Air dry and heat fix.
- C. Respiratory secretions
1. If present, select purulent-appearing portions of the sample. Use a swab to prepare thin smears of the sample on clean microscope slides. Prepare one slide for each antibody conjugate employed and one slide for the negative control conjugate.
 2. Air dry and heat fix.
 3. Fix in 1% formalin for 10 min. Drain and rinse with a gentle stream of filtered water.
- D. Any bacterial colony with morphology resembling *Legionella* spp.
1. Emulsify colonies into 1% formalin to match the turbidity of a no. 0.5 McFarland standard in saline or phosphate-buffered saline (PBS [Appendix 3.11.4–3]). Dilute the suspension 1/100 in PBS. *Note:* Making these suspensions too dense may quench the fluorescence.
 2. Use a separate slide for each antibody conjugate to be tested.
 3. Fix in 1% formalin for 10 min. Drain and rinse with a gentle stream of filtered water.
- III. MATERIALS
- A. Reagents
1. *Legionella* antisera, conjugated with FITC. Minimally, use conjugates reactive with *L. pneumophila* serogroups 1 to 6 and *L. micdadei*, except where local experience indicates an increased prevalence of other *Legionella* species. In these latter instances, antibody conjugates reactive with a broader range of species or serogroups are available.
 - a. SciMedx, Inc., Danville, N.J.
 - (1) Polyvalent *L. pneumophila* serogroup 1 to 6 reagent and monovalent *L. micdadei* reagent *or*
 - (2) Polyvalent *L. pneumophila* serogroups 1 to 6, *L. bozemanii*, *L. dumoffii*, *L. gormanii*, *Legionella longbeachae* serogroups 1 and 2, *L. micdadei*, *Legionella jordanis*
 - b. Zeuss Scientific, Raritan, N.J.
Polyvalent *L. pneumophila* serogroup 1 to 6 reagent
 2. FITC-conjugated negative control serum (normal rabbit globulins)
 3. PBS, pH 7.5, filtered (*see* Appendix 3.11.4–3)
 4. Buffered glycerol mounting fluid, pH 9.0
 5. Formalin (1%) in 0.85% saline (10% formalin diluted 1/10 with saline)
 6. Distilled water, filtered (*see* below)
 7. Low-fluorescence immersion oil
- ☑ **NOTE:** Filter all aqueous reagents made with locally produced deionized water through a 0.22- μ m-pore-size filter before use. Legionellae may colonize water-deionizing systems and produce false-positive tests.

APPENDIX 3.11.4–2 (continued)

- B. Alternative methods—indirect FA staining
- ☑ **NOTE:** Test kits employing indirect FA methods for staining of *Legionella* are also available and have performance similar to that of the DFA staining method described above. Contact the vendors for additional information, other supplies needed, and specific instructions for testing.
1. Remel, Inc. (Lenexa, Kans.)—Legionella Poly-ID test kit
L. pneumophila serogroups 1 to 6, *L. dumoffii*, *L. longbeachae* serogroups 1 and 2, *L. bozemanii*, *L. gormanii*, *L. micdadei*, *L. wadsworthii* serogroup 1, *Legionella oakridgensis*, *Legionella feeleeii* serogroup 1, *Legionella sainthelensi* serogroup 1, *L. jordanis* serogroup 1, *Legionella anisa* serogroup 1, *L. spiritensis* serogroup 1, *Legionella hackeliae*, *Legionella maceachernii*, *Legionella james-townensis*, *L. cherrii* serogroup 1, *L. steigerwaltii* serogroup 1, *L. parisiensis*, *L. rubrilucens* serogroup 1, *L. erythra* serogroup 1.
 2. Bio-Rad Laboratories (Hercules, Calif.)—MONOFLUO monoclonal immunofluorescence test kit contains monoclonal antibody reactive with all known serogroups of *L. pneumophila*.
 3. Zeuss Scientific—Legionella IFA test system
Legionella pneumophila serogroups 1 to 4
- C. Supplies
1. Clean plastic wash bottles
 2. Microscope slides suitable for FA testing. FA slides with delineated circles are recommended (Precision Laboratory Products, Middleton, Wis., <http://www.precisionslides.com>).
 3. Tuberculin syringes or 50- μ l pipettor to dispense antiserum
 4. Wooden applicator sticks
 5. Humidified staining chamber: a large covered petri dish lined with filter paper or covered glass baking dish lined with a paper towel. Chamber should contain a rack (e.g., glass rods) so that the slides do not sit directly on the moistened paper.
- IV. QUALITY CONTROL
- A. Prepare bacterial control slides containing *Legionella* for use with each test.
 1. *L. pneumophila* serogroup 1 may be used as a positive control for conjugates containing antibody against *L. pneumophila* and as a negative control for *L. micdadei* antibody conjugates.
 2. *L. micdadei* may be used as a positive control for conjugates containing *L. micdadei* antibody and as a negative control for conjugates containing *L. pneumophila* antibody.
 3. For polyvalent conjugates containing *L. micdadei* antibody conjugates, use another species of *Legionella* or *Escherichia coli* (e.g., ATCC 25922) as a negative control.
 4. Prepare suspensions of the control organisms as described above for cultures, or purchase formalin- or heat-killed suspensions of control organisms from vendor that supplies antibody reagents.
 - B. Place a drop of the diluted suspension of each control organism on one slide for each conjugate used and on one slide for the negative antibody conjugate. Thus, each control slide should contain both *L. pneumophila* and *L. micdadei* or another species if other species are being tested.
 - C. Prepare an extra slide for each specimen being tested, to use as a negative specimen control.
 - D. Do not report patient results if positive control slides do not produce a 3+ or greater fluorescence or the negative control slides produce more than 1+ fluorescence. See item VI for definitions of degree of fluorescence.
- V. PROCEDURE
- A. Place the slides in a humidified chamber on racks.
 - B. Add 25 to 50 μ l of the *L. pneumophila* polyvalent conjugate to each circle on one of the specimen slides and one of the bacterial control slides. Only one conjugate should be applied to any one slide, although one slide may contain several specimens.

APPENDIX 3.11.4–2 (continued)

- C. Use a wooden applicator stick to spread the conjugate drop over the entire area delineated by the circles on all of the slides. Use caution to avoid carrying over conjugate or bacteria between the circles. *Use a separate applicator stick for each circle or break off the end of the applicator before spreading the conjugate in the next circle.*
 - D. Similarly, add the *L. micdadei* conjugate to the specimen slides and a bacterial control slide.
 - E. Add 25 to 50 μl of the negative antibody conjugate to each circle on the control slide prepared from each of the specimens being tested and to a bacterial control slide. Spread within each circle, as described above.
 - F. Place the slides (test slides and control slides) into the humidified chamber, making certain that they do not touch each other. Cover the chamber to exclude light and allow the slides to incubate at room temperature for 20 to 30 min.
 - G. Rinse the antibody off of the slides with a gentle stream of PBS from a squirt bottle. While rinsing, hold the slide horizontally and allow the PBS to run across one circle at a time to minimize the chance that stained bacilli will be transferred between the circles.
 - H. Place the slides back onto the rack in the chamber or on a staining rack in a sink. Fill each circle with PBS and allow the slides to sit for 10 min. Do not allow the PBS to run between the circles, since stained bacilli from one sample may be carried to the next circle. Rinse with deionized water.
 - I. Wash and rinse the slides one more time with PBS and deionized water as described above. Allow slides to air dry.
 - J. Place a drop of buffered glycerol mounting fluid and a no. 1 coverslip on each slide. Examine immediately.
 - K. Examine slides using transmitted or incident UV light. Check with your microscope supplier for the proper combination of barrier and exciter filters needed for use with FITC.
- VI. INTERPRETATION
- A. Scan the slides with a 40 \times objective. Legionellae from cultures may appear as rods or as long filaments which stain apple-green on their periphery. Examine the bacterial control slides, where the bacteria will be easily visualized, first.
 - B. Examine positive areas of the slides with a 100 \times oil immersion objective to quantify the fluorescence.
 1. 4+ : cell wall appears as a brilliant yellow-green ring around a less bright central area of the bacilli.
 2. 3+ : cell wall stains bright yellow-green.
 3. 2+ : cell wall is dull yellow-green, barely discernible from central area of cell.
 4. 1+ : diffuse faint staining of cells; cell center is indistinguishable from cell wall.
 - C. Fluorescence in the “test” conjugate of $\geq 3+$ and no fluorescence in the control conjugate is a positive test as long as there is $\geq 3+$ fluorescence of the appropriate bacterial control suspension.
 - D. Similarly examine the negative control slides containing the negative conjugate. They should display no more than 1+ fluorescence.
 - E. Examine slides made from clinical specimens (especially respiratory secretions) for at least 5 min, since they may contain few bacilli. Bacteria in clinical specimens may appear either intra- or extracellular.
- VII. REPORTING RESULTS
- A. Report positive or negative results on direct tests as “Positive (or negative) for *Legionella* (add the antiserum name that produced the positive result) by direct fluorescent-antibody test.”
 - B. For cultures, use the positive results of the species-specific antiserum to definitively identify the species present.
- VIII. LIMITATIONS
- A. Dim fluorescence ($\leq 2+$) of the test conjugate and dim fluorescence of the control conjugate indicate probable cross-reaction with a non-*Legionella* bacterium.
 - B. Dim fluorescence of the test conjugate and no fluorescence in the control conjugate indicate possible cross-reaction with a species or serotype of *Legionella* other than the ones against which the test conjugate was produced. This result may also be

APPENDIX 3.11.4–2 (continued)

produced by some cross-reacting non-*Legionella* organisms, such as *P. aeruginosa*, *Pseudomonas fluorescens*, *B. pertussis*, and *Bacteroides* spp. These cross-reacting bacteria can be recognized because the size and shape of the fluorescent cells will be different from those of the fluorescent cells of *Legionella* spp. Compare the morphologies of bacteria in these slides to those of the positive bacterial control slides.

- C. The sensitivity of direct immunofluorescence testing on clinical samples may range from <50% to about 75%, depending on the skill and experience of the operator.

Reference

1. **Edelstein, P. H., R. D. Meyer, and S. M. Finegold.** 1980. Laboratory diagnosis of Legionnaire's disease. *Am. Rev. Respir. Dis.* **121**:317–332.

APPENDIX 3.11.4–3

Phosphate-Buffered Saline, pH 7.5 ± 0.1

- A. Stock buffer (pH will not be 7.5)

Na ₂ HPO ₄ (anhydrous reagent grade)	13.8 g
NaH ₂ PO ₄ ·H ₂ O (reagent grade)	1.8 g
NaCl (reagent grade)	85.0 g
Distilled water to make final volume of	1,000.0 ml

- B. Working solution (pH 7.5 ± 0.1; 0.01 M buffer; 0.85% NaCl)

concentrated stock solution	100.0 ml
distilled water to make final volume of	1,000.0 ml

- C. When commercially available reagent packets are used

1. Add one envelope of the powdered mixture to a 1-liter volumetric flask, and fill the flask to 1 liter with freshly deionized water.
2. Mix until all powder is dissolved. Buffer should be clear and colorless.
3. Measure the pH. Adjust to pH 7.5 ± 0.1 with HCl or NaOH.
4. Assign a 1-month expiration date. Store at 2 to 8°C.

- D. Filter buffer if made with locally produced deionized water through a 0.22-μm-pore-size filter before use.

3.11.5

Otitis Cultures

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Otitis media is an infection of the middle ear and accounts for more than 30 million office visits per year for a cost of over \$2 billion in the United States (1). More than 80% of children have one or more episodes of otitis media by age 6 years, with the highest number of cases between 2 and 6 years of age (17). Hearing loss and deficits in learning are a few of the complications (13). The most common agents of otitis media are *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Moraxella catarrhalis*, and *Alloicoccus otitis* (2, 3, 8, 13), although *Streptococcus pyogenes* is found on a seasonal basis (11, 13). (*Note:* Although the name *Alloicoccus otitidis* is in common usage (5), that name has not been officially adopted; *Alloicoccus otitis* is the official name.) Amoxicillin and amoxicillin-clavulanate are the drugs of choice for initial treatment (15). Although *S. pneumoniae* organisms are becoming increasingly more resistant, the concentrations of amoxicillin that can be achieved in the middle ear fluid are sufficient to eliminate all but the most resistant strains

(11). Treatment generally resolves the infection, but treatment failures occur and surgical intervention can be necessary (4, 10, 11, 15). Tympanocentesis and culture of the middle ear fluid constitute a valuable tool for definitive diagnosis, to guide therapy, to evaluate treatment failures, and for research studies to determine the efficacy of antimicrobials against the most common agents. However, the diagnosis is usually made on clinical grounds, because of the invasive nature of tympanocentesis. Culture is usually reserved for persistent infections. Recently, multiplex PCR methods for the detection of common agents have been used to improve sensitivity in the diagnosis (7, 16). Historically pediatricians cultured the nasopharynx to predict the pathogens in the middle ear fluid. This practice is no longer recommended, since the presence of pathogens in the nasopharynx does not predict the pathogens present in the middle ear (6). However, lack of isolation of any pathogen has a 96% negative predictive value for lack of a pathogen in the middle ear fluid (6).

Otitis externa is an infection of the external auditory canal. Unique problems occur with this infection because of the narrow and tortuous nature of the canal and its tendency to trap foreign objects, wax, and water. Infections are classified as acute and chronic. Acute infections are often referred to as “swimmer’s ear.” *Pseudomonas aeruginosa* is a frequent cause of freshwater otitis, and *Vibrio alginolyticus* is a cause in oceanic swimmers, although other aerobic bacteria can be involved. Localized infections with *Staphylococcus aureus* or *S. pyogenes* can also occur. Contaminating skin bacterial microbiota (corynebacteria and staphylococci) can be present, which are not significant. More invasive infections are caused by the extension of the bacteria into the adjacent soft tissue and bone. *P. aeruginosa* is generally the causative agent, and treatment with systemic agents is required. Chronic infections are usually caused by fungi, mycobacteria, *Nocardia*, and underlying diseases, such as syphilis (11).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

■ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for physicians and other caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

A. Specimen collection

1. External ear
 - a. Insert sterile swab into ear canal until resistance is met.
 - b. Rotate swab and allow fluid to collect on swab.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

2. Tympanocentesis fluid
 - ☑ **NOTE:** Because of the invasive nature of the collection process, these specimens are usually submitted primarily to diagnose middle ear infections only if previous therapy has failed.
 - a. Clean the external canal with mild detergent.
 - b. Using a syringe aspiration technique, the physician will obtain the fluid from the ear drum.
 - c. Send the specimen in a sterile container or in the syringe capped with a Luer-Lok and with the needle removed.
 - d. If the eardrum is ruptured, collect exudate by inserting a sterile swab through an auditory speculum.

B. Specimen transport

1. Submit to laboratory
 - a. Submit swabs in tube of transport medium or in BD Culturette EZ.
 - b. Submit aspirates in a sterile container or in the original syringe capped with a Luer-Lok to prevent leakage.
2. Label specimens with demographic information, date and time of collection, and site of collection.
3. List the diagnosis of otitis media, chronic otitis, or otitis externa.

III. MATERIALS

A. Primary media

1. BAP
2. CHOC
3. MAC or EMB
4. BHI agar prepared with 5% rabbit blood for detection of *A. otitis* (The following companies supply defibrinated rabbit blood and dehydrated BHI agar for preparation of media: Remel, Inc.; BD Diagnostic Systems; and Hardy, Inc.)
 - ☑ **NOTE:** *A. otitis* occasionally grows on BAP with 5% sheep blood in 5 days but does not grow on CHOC, Mueller-Hinton agar (MH) with lysed horse blood, buffered charcoal-yeast extract agar, brucella agar, or Columbia colistin-

nalidixic acid agar (3). Growth generally takes 72 h on rabbit blood agar (3). Routine testing for this organism is beyond the capabilities of most laboratories, but awareness of the species may be important to communicate to the physician.

B. Identification methods

1. Gram stain (procedure 3.2.1)
2. Refer to procedure 3.3.2 for identification of the common agents of otitis.

C. Other supplies

1. Incubator at 35°C with 5% CO₂ or a CO₂-generating system
2. Inoculating sticks and loops
3. Petri dishes and filter paper

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that plate media meet expiration date and QC parameters per current NCCLS document M22. See procedures 14.2 and 3.3.1 for further procedures.
- B. Test each lot of CHOC per procedure 3.3.1.

V. PROCEDURE

Observe standard precautions.

A. Inoculation

1. Inoculate specimen to BAP, CHOC, and MAC.
2. Firmly roll swab over one-sixth (no more) of the agar surface, or aspirate 3 or 4 drops of fluid onto agar. Streak carefully for isolation in four quadrants to minimize overgrowth by other microorganisms.

B. Incubation

1. Incubate plate at 35 to 37°C in 5% CO₂ for a minimum of 48 h.
2. For cultures of invasively collected ear fluid samples, incubation may be extended to 4 days, if results are negative. Anaerobic cultures may be indicated (*see* section 4).

V. PROCEDURE (*continued*)**C. Gram stain**

1. Perform a Gram stain from the swab or fluid (procedure 3.2.1).
2. Note the presence of WBCs and bacteria.

D. Culture examination

1. External otitis: observe plates at 24 and 48 h for growth of enteric gram-negative rods, pseudomonads, vibrios, streptococci, coryneforms, and *S. aureus*.
 - a. Since only one pathogen is generally responsible for otitis externa, mixed cultures of gram-negative rods should be minimally identified.
 - b. For gram-negative rods, perform spot oxidase and indole tests to avoid misidentifications.
 - (1) *V. alginolyticus* is an oxidase- and indole-positive, gram-negative rod that grows well on MAC. It will grow on MH with 4% salt (9). Place a colistin or polymyxin B disk on MH. It is further identified by most kit systems, although the reactions are improved if the inoculum is made in saline rather than water (*see* Table 3.18.2–8).
 - (2) *P. aeruginosa* is oxidase positive and indole negative and often has a characteristic odor or blue-green or brown pigment, for definitive identification. If the characteristic odor or these pigments are lacking, it can be definitively identified by positive growth at 42°C and production of a fluorescent pigment on agar media (procedure 3.17.17).
 - (3) Other gram-negative rods are less common and are usually identified by commercial kits. Exception: swarming *Proteus* spp. are identified by indole, ampicillin susceptibility, and ornithine (*see* Table 3.3.2–5).
 - (4) Perform antimicrobial susceptibility testing (AST) on the predominant microorganism. Evaluate swarming *Proteus* organisms on MAC or EMB, where they generally do not swarm, to be sure they are the predominant microorganism before performing AST; they can be an important pathogen from a patient with diabetes mellitus.
 - c. Examine cultures for predominant gram-positive cocci. Generally *S. aureus* and *S. pyogenes* are the most common gram-positive cocci involved in otitis externa.
 - (1) Identify *S. pyogenes* and other beta-hemolytic streptococci (Table 3.3.2–5).
 - (2) Identify and perform AST on *S. aureus* (Table 3.3.2–5 and section 5, respectively)
 - d. Identify yeasts and molds, if present. *Aspergillus* and *Candida albicans* have been implicated in chronic infections.
 - e. Since resident cutaneous microbiota (coagulase-negative staphylococci and coryneforms) are normal in the external ear canal, they should not be further evaluated.
2. Otitis media: observe plates at 24 h and up to 4 days for cultures of middle ear fluid. Pursue all organisms present, since the specimen is collected by an invasive procedure and any microorganism can be considered the agent of disease.
 - a. Fastidious gram-negative rods and diplococci
 - (1) Identify *H. influenzae* and *M. catarrhalis* according to Table 3.3.2–5 and perform beta-lactamase test on *H. influenzae*. Since more than 90% of *M. catarrhalis* organisms are beta-lactamase positive, testing is not helpful to treatment.
 - (2) *Bordetella trematum* is an oxidase-negative, catalase-positive, gram-negative rod that has been implicated in ear infections (18). It is motile, frequently reduces nitrate, and may or may not grow on MAC (*see* Table 3.11.6–1).

V. PROCEDURE (continued)

- b. Observe for growth of gram-positive cocci. Refer to Table 3.3.2–5 for rapid identification tests to identify the following.
 - (1) *S. pyogenes* and other beta-hemolytic streptococci
 - (2) *S. pneumoniae*
 - (a) Confirm negative bile solubility test with optochin disk.
 - (b) Perform AST, using standardized methods (reference 14 and section 5), per laboratory protocol and physician policy.
- c. Normal skin microbiota (coagulase-negative staphylococci and corynebacteria) are not generally identified to the species level unless they are the only predominant species in the culture and are present in large numbers.
 - (1) Identify *Turicella otitidis*, a long coryneform rod implicated in otitis media (5). It is catalase positive, asaccharolytic, and CAMP test positive.
 - (2) Examine for *Nocardia* in chronic infections (*see* procedure 6.1).
3. Examine, on request, for *A. otitis* from middle ear fluid. Prepare BHI agar with 5% rabbit blood and inoculate with specimen. Incubate plates for 5 days; increased CO₂ is not required.
 - A few strains have been reported to grow on sheep blood agar, but it is not optimal (3).
 - a. *A. otitis* is slow growing and produces pinpoint colonies that are moist and slightly yellow (3). No hemolysis is observed. Eventually the colonies adhere to the agar.
 - b. No growth is seen on CHOC (3).
 - c. On Gram stain, *A. otitis* organisms are gram positive cocci in clusters and tetrads without chains and cannot be distinguished from staphylococci.
 - d. Perform the following tests to confirm the identification. Note the expected reactions (12).
 - (1) Catalase negative or weak
 - (2) Pyrrolidonyl-β-naphthylamide (PYR) positive
 - (3) Leucine aminopeptidase (LAP) positive
 - (4) Vancomycin susceptible

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. Gram stain—report smear as indicated in procedure 3.2.1.
- B. Negative results
 1. Report preliminary and final results as “No growth.”
 2. Indicate the number of days the culture was incubated.
 3. If bacteria were seen on smear but did not grow on culture, extend the incubation and make a notation on the report to indicate the discrepancy.
- C. Positive reporting
 1. Indicate the presence of skin microbiota, without identification.
 2. If the culture is mixed but with no predominating pathogen, indicate the genera and do not report further: e.g., “Mixed microbiota present, consisting of three morphologies of gram-negative rods, molds, and skin microorganisms; contact laboratory if further testing is clinically indicated.”
 3. Report all pathogens and susceptibility tests performed, using preliminary reports as indicated in procedure 3.3.2 and NCCLS guidelines (14). Also refer to section 5.
 4. For *Vibrio*, report that the organism is resistant to colistin or polymyxin B if there was no zone around the disk, since ear drops often contain this antimicrobial.

VII. INTERPRETATION

- A. A positive external ear culture with a predominant gram-negative rod, beta-hemolytic streptococci, or *S. aureus* generally indicates infection with that agent.
- B. A positive middle ear culture with *S. pneumoniae*, *H. influenzae*, *M. catarrhalis*, and *A. otitis* generally indicates infection with that organism.
- C. A negative culture cannot rule out otitis media. In fact, in chronic infections, a pathogen is often not isolated.
- D. Controversy regarding the need for treatment of otitis media has been found in recent literature, but most physicians agree on its benefits (15). *A. otitis* is resistant to sulfamethoxazole-trimethoprim and often to erythromycin (3), but it does not have a beta-lactamase.
- E. Otitis externa is usually treated with ear drops containing a variety of agents, including 2% acetic acid, hydrocortisone, and antimicrobial agents, such as quinolones, neomycin, and either gentamicin or polymyxin B.

VIII. LIMITATIONS

- A. Methods that employ PCR for the detection of pathogens responsible for otitis media are more sensitive than culture techniques and increase the rate of detection of a pathogen to 75% (16).
- B. False-negative cultures can result from overgrowth of the culture with normal cutaneous microbiota.
- C. False-positive results can be caused by overinterpretation of the culture results.
- D. *T. otitidis*, a coryneform rod, has been infrequently isolated from ear fluid and may be a cause of otitis media (5).
- E. *A. otitis* is difficult to culture and may not be detected.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

A resurgence of cases of pertussis (whooping cough) and outbreaks in North America in the last decade created a renewed interest in establishing a laboratory diagnosis of the disease. Compared to the period from 1990 to 1993, the period from 1994 to 1996 had average incidences of pertussis among age groups 5 to 9, 10 to 19, and ≥ 20 years that increased 40, 106, and 93%, respectively, in the United States (6). Clinical diagnosis may be elusive, since the typical cough with whoop occurs late in the illness (weeks 3 to 6) and symptoms are often nonspecific and virus-like, especially in older children and adults. In young children, the disease may be severe, with choking, apnea, or cyanosis, and with significant morbidity and mortality. Adults can serve as a reservoir for transmission of the disease to unvaccinated infants or may suffer from the disease themselves.

Treatment in the early stages of infection reduces the severity of illness and further spread of the disease. Thus, an accurate early laboratory diagnosis remains a key tool in control and prevention. Pertus-

sis is caused primarily by *Bordetella pertussis* and occasionally by *B. parapertussis*. Other species of *Bordetella*, such as *B. holmesii*, *B. hinzii*, and *B. bronchiseptica*, can cause respiratory infections in humans but not specifically “whooping cough.”

Bordetella spp. are small, faintly staining, gram-negative coccobacilli. They are nonmotile obligate aerobes that do *not* utilize carbohydrates, and they grow slowly in vitro; some can be recovered from the respiratory tracts of animals. *B. pertussis*, in particular, is very fastidious and must be cultured initially on special media. *B. parapertussis* is less fastidious. *B. parapertussis*, *B. bronchiseptica*, *B. holmesii*, and *B. hinzii* grow on blood agar within 2 to 3 days.

Laboratory confirmation of pertussis is subject to many constraints, and the primary method used, culture, is considered no more than 50% sensitive. Unfortunately, prior to 1996, culture was the only acceptable laboratory criterion for confirming a case of pertussis. Diagnosis by culture is insensitive because of issues re-

lated to specimen collection and transport, the fastidious nature of the organism, and interference from other bacterial microbiota. In June 1996, the Council for State and Territorial Epidemiologists revised the laboratory criteria to include positive PCR assays for *B. pertussis* as official laboratory confirmation of pertussis (1). Therefore, PCR has become the test of choice for the diagnosis of pertussis (3, 12, 18). For PCR testing protocol, see procedure 12.2.3, part 11. Reagents (polyclonal and monoclonal) are available for direct fluorescent-antibody (DFA) testing, but a positive DFA result without culture or PCR confirmation is *not* considered suitable confirmation of pertussis in any state in the United States. Culture still has a role in isolation of *B. pertussis* and related species, especially for antimicrobial susceptibility testing (AST) in cases of treatment failure (8). This procedure describes the processing and culturing of specimens for *Bordetella* spp. Refer to Appendix 3.11.6–1 for the DFA procedure and procedure 12.2.3.11, part 11, for PCR.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

■ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for physicians and caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

A. Specimen collection

■ **NOTE:** Cough plates and nasal swabs, previously thought to be ideal specimens, are no longer recommended for culture of *Bordetella*.

1. Timing

- a. Collect as soon as possible after symptoms develop.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- b. Collect specimens up to 4 weeks after onset, provided that antimicrobial therapy has not been started.
 - **NOTE:** The organism is rarely found by culture after the fourth week of illness, and the percentage of positive culture results decreases with time. Positive results have been reported using PCR with specimens collected as late as 60 days after onset of symptoms.
2. Collection of nasopharyngeal specimen
 - **NOTE:** *B. pertussis* exhibits a tropism and binds specifically to ciliated respiratory epithelial cells. Since the nasopharynx is lined with these cells, it is a far superior site for detection of the bacterium.
 - a. Nasopharyngeal swabs (refer to Fig. 3.11.6–1A)
 - **NOTE:** Nasopharyngeal swabs *cannot* be used for PCR since both the alginate component and the aluminum shaft inhibit PCR-based assays (17).
 - (1) Use a *calcium alginate or Dacron fiber tip swab* on a fine flexible wire. Bend the wire so that it mimics the curve of the nasal airway and gently pass the swab through the nostril to the posterior nasopharynx. Do not force the swab; resistance will be felt when the posterior nasopharynx is reached.
 - (2) Rotate the swab and leave it in place for up to 30 s or until the patient coughs. Withdraw as quickly as possible.
 - (3) Repeat procedure through the second nostril.
 - (4) Submit both swabs for culture and DFA testing.
 - b. Nasal wash: syringe method (refer to Fig. 3.11.6–1B)
 - (1) Use a 3- to 5-ml syringe with a 2-in 18-gauge tubing attachment. Fill the syringe with saline.
 - (2) Instruct the patient not to swallow during the procedure.

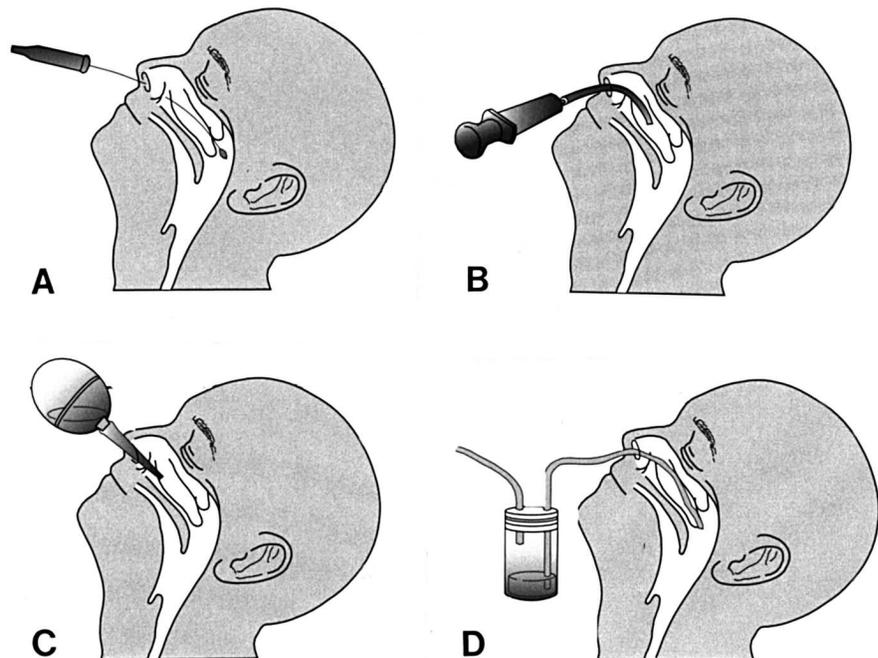

Figure 3.11.6–1 Collection of nasal pharyngeal swab(s) (A), nasal wash specimen(s) by syringe method (B), nasal wash specimen(s) by bulb method (C), and nasal aspirate specimen(s), assisted by vacuum (D). Diagrams courtesy of BD Diagnostic Systems, Sparks, Md., with permission.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- (3) With the patient's head hyperextended (approximately 70° angle), quickly instill approximately 5 ml of sterile 0.85% NaCl into one nostril.
 - (4) Immediately aspirate the saline solution back into the syringe, *or*
 - (5) Tilt the head forward and allow the fluid to run out of the nares into a sterile container, *or*
 - (6) Aspirate the fluid by inserting a rubber bulb syringe into each nostril.
 - (7) Place the specimen in a sterile container.
- c.** Nasal wash: bulb method (refer to Fig. 3.11.6–1C)
- (1) Suction 3 to 5 ml of sterile 0.85% NaCl into a 1- to 2-oz tapered rubber bulb.
 - (2) Instruct the patient not to swallow during the procedure.
 - (3) With the patient's head hyperextended (approximately 70° angle), insert the bulb into one nostril until the nostril is occluded.
 - (4) Quickly instill the sterile saline into the nostril with one squeeze of the bulb.
 - (5) Immediately release the bulb to collect the nasal wash specimen.
 - (6) Empty the bulb contents into a sterile container and transport.
- d.** Nasal aspirate: vacuum assisted (refer to Fig. 3.11.6–1D)
- (1) Connect a mucus trap (i.e., Luken's tube) to a suction pump and catheter, turn on suction, and adjust to suggested suction pressure (*see* chart below).
 - (2) Insert the end of the catheter through the external nares to the posterior pharynx.
 - (3) Apply suction while slowly withdrawing the catheter, allowing the catheter to remain in the nasopharynx no longer than 10 s.
 - (4) After aspiration, flush material out of the catheter with a small volume (1 to 1.5 ml) of sterile saline.

Patient age	Catheter size (French) ^a	Suction pressure (mm Hg)
Premature infant	6	80–100
Infant	8	80–100
Toddler	10	100–120
School age	12	100–120
Adolescent/adult	14	120–150

^a To determine length of catheter tubing, measure distance from tip of nose to external opening of ear.

■ **NOTE:** Nasopharyngeal aspiration or wash yields sufficient material for numerous diagnostic procedures and gives a 11% higher yield on culture than nasopharyngeal swabs (7). Aspirate specimens are easily divided and saved, are suitable for all testing methodologies, and can be frozen for long periods (2 years at –70°C).

■ **NOTE:** Nasopharyngeal specimen collection directions are taken in part with permission from BD Diagnostic Systems, Sparks, Md.

B. Specimen transport

1. Inoculate plates at bedside.

■ **NOTE:** The best culture results are achieved when specimens are plated directly onto culture media at the bedside; unfortunately, for many this is not possible or practical to establish as a routine. Bedside plating results in a higher positive culture rate than that obtained with nasopharyngeal aspirates taken at the same time and cultured the same day in the laboratory.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

2. Alternatively, submit in transport tube; choose a transport medium based on the length of time the specimen will be in transit.
 - a. Transport tubes
 - (1) 0.5 to 1% casein hydrolysate (Casamino Acid; Remel, Inc.)
 - (2) Amies transport medium
 - (3) Half-strength charcoal blood agar stab, also called Regan-Lowe transport medium (14) (prepared media available from Hardy Diagnostics)
 - (a) Weigh 25.5 g of CM119 charcoal agar (Oxoid, Inc., Ogdenburg, N.Y.) into 900 ml of water, autoclave, and cool.
 - (b) Add 100 ml of sterile defibrinated horse blood (available from most medium vendors) and 40 mg of cephalixin.
 - (c) Dispense into screw-cap vials to fill half full, seal, and store for up to 2 months at 4°C. Label containers with the expiration date.
 - b. If delay is brief (≤ 2 h), use 0.5 to 1% casein hydrolysate (Casamino Acid) solution (Remel, Inc.) as a transport medium. With nasopharyngeal aspirates, add the solution to the specimen container and mix well.
 - c. If specimens will be plated within 24 h of collection, use Amies medium *with* charcoal.
 - d. If delay is prolonged (>24 h but ≤ 3 days), use Regan-Lowe transport medium.
 - (1) Incubate at 35°C for 2 days.
 - (2) Then hold at *room temperature* during transport.
 - (3) For this choice, transit time should not exceed 3 days.
 - e. If transit time will exceed 3 days, use Regan-Lowe transport medium.
 - (1) Incubate at 35°C for 2 days.
 - (2) Then hold at 4°C during transport.
 - (3) Organisms can remain viable for as long as 8 days with this choice.

C. Rejection criteria

1. Do not perform culture if transport conditions are not followed.
2. Throat specimens, nares swabs, and sputum are unacceptable specimens.
3. Do not perform cultures from specimens collected on rayon or cotton swabs, as they contain fatty acids that inhibit growth.

III. MATERIALS

A. Primary tests

See Appendix 3.11.6–1 for DFA reagents.

B. Media

1. Regan-Lowe agar media containing Oxoid CM119 charcoal agar (51 g/liter), 10% defibrinated horse blood, and 0.04 g of cephalixin per liter (BD Diagnostic Systems; Hardy Diagnostics; Remel, Inc.). Some formulas use cyclodextrin in place of charcoal.
 - a. Store commercially prepared plates at 4°C for 4 to 8 weeks in sealed container.
 - b. Prepare in-house from Regan-Lowe base dehydrated medium (CM119).
 - (1) Dehydrated base has a 4-year shelf life.
 - (2) Dehydrated media can be purchased with or without 40 mg of cephalixin per liter.

(3) Add 10% horse blood to autoclaved and cooled medium prior to use.

(4) Plates are good for 4 to 8 weeks from date of preparation (10).

■ **NOTE:** Bordet-Gengou agar has been supplanted by Regan-Lowe agar, which has a longer shelf life and greater ability to isolate the organism and is easier to prepare (10). Some *Bordetella* spp. are inhibited by cephalixin, and some investigators recommend using media with and without antimicrobial agents (9). Unfortunately, medium without antimicrobial agents becomes overgrown by contaminants very quickly, and this practice does not appear to increase the positivity rate. As a result, most laboratories do not follow this recommendation.

III. MATERIALS (continued)

2. BAP
3. MAC—used to verify growth requirements
- C. Identification methods
 1. Gram stain (procedure 3.2.1)
 2. Catalase test (procedure 3.17.10)
 3. Oxidase test (procedure 3.17.39)
 4. Rapid urea test (procedure 3.17.48)
 5. Nitrate medium (procedure 3.17.35)
 6. Mueller-Hinton agar for pigment
7. Serologic reagents
 - a. *B. pertussis* agglutination anti-serum (BD Diagnostic Systems no. 210590, formerly Difco 2310-50-0) (*B. parapertussis* agglutination reagent is not available.)
 - b. DFA antisera (see Appendix 3.11.6–1).
- D. Other supplies
 1. Incubator at 35°C
 2. Fluorescent microscope

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. See Appendix 3.11.6–1 for QC of DFA reagents.
- B. Test each lot of serologic agglutination reagents prior to use and, additionally, at least every six months with a positively (*B. pertussis* ATCC 9797) and negatively (*Escherichia coli* ATCC 25922) reacting control.
- C. For biochemical tests, see each biochemical procedure for QC requirements.
- D. Perform QC on each lot of Regan-Lowe agar. Incubate aerobically overnight at 35°C.
 1. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further details.
 2. For controls, it is better to freeze aliquots of clinical specimens that have not been cultivated through several passages.
 - a. Freeze in sheep blood, skim milk, or 15% glycerol at –70°C (see item V in procedure 14.2).
 - b. Use these isolates or ATCC strains for control of media, by following inoculum preparation described in procedure 14.2.

Test organism	Result
<i>Bordetella pertussis</i> ATCC 9797 or in-house strain	Growth
<i>Bordetella parapertussis</i> ATCC 15311	Growth
<i>Staphylococcus aureus</i> ATCC 25923	Partial to complete inhibition

V. PROCEDURE

Observe standard precautions.

- A. See Appendix 3.11.6–1 for DFA tests.
 - **NOTE:** Always perform culture with DFA because of the insensitivity of DFA and the subjectivity of interpretation of DFA tests.
- B. Culture inoculation
 1. Firmly roll swab over one-third of the Regan-Lowe agar surface, and streak carefully for isolation in four quadrants to minimize overcrowding by breakthrough microorganisms that may release inhibitory substances to suppress growth of *Bordetella*.
 2. Inoculate a BAP and incubate with the Regan-Lowe agar for comparison of growth.
- C. Incubation
 1. Place plates in a plastic bag or moist chamber with a sterile moistened filter paper to avoid drying. *B. pertussis* is very susceptible to drying.
 2. Place at 35°C in an aerobic atmosphere (without 5% CO₂).
 - **NOTE:** An incubation temperature of 37°C will not support the growth of many strains of *B. pertussis*; maintaining 35°C is critical.

V. PROCEDURE (continued)

3. Incubate plates for 5 to 12 days.

☑ **NOTE:** While most colonies of *B. pertussis* and *B. parapertussis* are detected in 5 to 7 days, maximum recovery can take as long as 12 days. Katzko et al. (11) showed that 16% of *B. pertussis* organisms and 50% of *B. parapertussis* organisms were recovered only after extended incubation.

D. Culture examination

1. Observe BAP at 24 h and daily thereafter for a total of 72 h.
 - a. *B. pertussis* does not grow on BAP, but other species do (Table 3.11.6–1).
 - b. *B. parapertussis* colonies are smooth and opaque and usually hemolytic.
 - c. *B. bronchiseptica* colonies are gray-white, somewhat flat, and dull and may have hazy hemolysis.
2. Observe Regan-Lowe plates at 48 h and daily thereafter with the use of a magnifying lens.
 - a. *B. pertussis* colonies appear at a minimum of 72 h as small, convex, gray, smooth, and very shiny, like drops of mercury. They may vary in size and run together.
 - b. *B. parapertussis* colonies appear similar to those of *B. pertussis* but are grayer and less domed, and they grow more rapidly.
 - c. *Legionella* may grow on Regan-Lowe plates and will appear as ground-glass colonies.
3. Gram stain colonies suggestive of *Bordetella*, especially those growing on Regan-Lowe plates and not on BAP.
 - a. Apply the counterstain (carbol fuchsin or basic fuchsin preferred) for 1 to 2 min to enhance staining intensity.
 - b. Observe for Gram-negative coccobacilli or short rods consistent with *Bordetella* spp.
4. Perform catalase and oxidase tests. *B. pertussis* is positive for both. *B. parapertussis* is catalase positive and oxidase negative.
5. Immediately confirm suspicious colonies.
 - a. Perform DFA for *B. pertussis* and *B. parapertussis* (Appendix 3.11.6–1).
 - b. For *B. pertussis*, perform slide agglutination test.
 - (1) Add a drop of a turbid saline suspension (no. 3 McFarland standard) from a colony suspension to a drop of the working dilution (1:10) of the *B. pertussis* antiserum on a slide.

Table 3.11.6–1 Biochemical differentiation of *Bordetella* species of importance in respiratory cultures^a

Test	<i>B. pertussis</i>	<i>B. parapertussis</i>	<i>B. holmesii</i> (CDC NO-2)	<i>B. trematum</i>	<i>B. bronchiseptica</i> ^b	<i>B. avium</i> ^c	<i>B. hinzii</i> ^c
Motility	–	–	–	+	+	+	+
Urease	–	+	–	–	+	–	–
Oxidase	+	–	–	–	+	+	+
Catalase	+	+	V (W)	+	+	+	+
Growth on MAC	–	+ (D)	+ (D)	+	+	+	+
Soluble pigment (on peptone agar, e.g., MH)	NA	Brown	Brown	–	–	W, amber	–
Nitrate/with gas ^d	NA	–/–	–/–	V	+/–	–/–	–/–
Growth on BAP (hemolysis)	– (NA)	+ (beta)	+ (V green)	+ (–)	+ (rare beta)	+ (V beta)	+ (–)

^a Table extrapolated from references 4, 15, 16, and 19. NA, not applicable; W, weak; V, variable; D, delayed.

^b *B. bronchiseptica* grows on salmonella-shigella agar and is tartrate negative, unlike other closely related organisms (*Oligella ureolytica* and *Ralstonia paucula* [IVc-2]). Also see Table 3.18.2–12 for other tests to separate these genera. *Brucella* spp. are similar to *B. bronchiseptica*, but the former are not motile and generally do not grow on MAC.

^c *B. avium* is malonate negative, and *B. hinzii* is malonate positive; *B. avium* is not a human pathogen (4).

^d The nitrate reaction is first; if the gas reaction is known, it is listed second, preceded by a slash.

V. PROCEDURE (continued)

- (2) Also add a drop of suspension without antiserum for comparison.
- (3) Observe for agglutination under $\times 30$ magnification.
- (4) A 4+ rapid and complete reaction (large clumps and clear background) is considered a positive result.
- (5) No agglutination should be visible in the saline control. If agglutination in the control does occur, the culture is rough and not suitable for serologic techniques.
- c. Additional testing is not necessary unless results are equivocal.
6. If DFA or agglutination is negative, confirm species with biochemical tests.
 - a. Perform rapid urea test.
 - (1) Both *B. parapertussis* and *B. bronchiseptica* are urea positive.
 - (2) *B. pertussis* is negative.
 - *Brucella spp.* are oxidase, catalase, and urea positive. Work in a biological safety cabinet until this genus has been eliminated from consideration. *Brucella spp.* grow on blood agar, generally not on MAC, and are not motile.
 - b. If isolate grows on BAP, inoculate Mueller-Hinton agar for pigment production.
 - c. See additional tests for identification of *Bordetella* spp. in Table 3.11.6-1 or submit to reference laboratory for confirmation.
7. Do not perform AST routinely. Seal positive culture plates and hold for at least 7 days at 4°C, should AST be needed for determination of erythromycin resistance.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

A. Negative results

1. If the culture is negative, report "No *Bordetella pertussis* or *Bordetella parapertussis* isolated."
2. Report the number of days the culture was incubated.

B. Positive results

1. If the culture is positive, report the appropriate species identified, such as "*Bordetella pertussis* isolated."
2. Report the presence of *B. pertussis* or *B. parapertussis* as soon as preliminary tests are completed.

■ **NOTE:** The report of *Bordetella* is of critical value because patients with pertussis are placed in isolation rooms.

Call positive results to the attending physician(s) or caregiver and to infection control for inpatients. Document notification.

3. Pertussis is a reportable disease in most states; however, a positive DFA result without culture or PCR confirmation (procedure 12.2.3, part 11) is *not* considered suitable confirmation of pertussis in any state in the United States.

VII. INTERPRETATION

- A. The isolation of *B. pertussis* is always significant. Patients who are symptomatic by definition have pertussis; those who do not have symptoms are carriers and represent a public health risk. Both should be treated.
- B. Virtually all *B. pertussis* organisms are susceptible to erythromycin (the drug of choice to treat colonization), negating the need for AST (5). However, erythromycin resistance has been recently reported, and AST may be indicated in cases of treatment failure. Testing is nonstandard, since it has to be performed on Regan-Lowe media. Both disk diffusion and the Etest method have been used (8).

VII. INTERPRETATION (continued)

- C. *B. bronchiseptica* has been isolated from lower respiratory tract specimens, usually after 48 h of incubation. Rule out this pathogen, using Table 3.11.6–1, when examining such specimens.

VIII. LIMITATIONS

- A. Methods that employ PCR are more rapid and sensitive than culture or DFA techniques.
- B. *Legionella* spp. cross-react with *B. pertussis* antiserum (13).
- C. Some *B. pertussis* organisms can grow on buffered charcoal-yeast extract medium with α -ketoglutarate, used for recovery of *Legionella*.
- D. False-positive results can be caused by misinterpretation of the confirmatory tests.
- E. The polyclonal antibody reagents used for DFA are capable of cross-reacting with several non-*B. pertussis* bacteria, resulting in false-positive results (2).
- F. The monoclonal DFA reagent may produce a positive result with some strains of *B. bronchiseptica* (package insert, Altachem Pharma Inc.)
- G. Treatment with antimicrobial agents can affect both DFA and culture, resulting in false negatives.

APPENDIX 3.11.6–1

Detection of *Bordetella pertussis* by Direct Fluorescent Antibody

I. PRINCIPLE

The DFA test performed on nasopharyngeal specimens is an important adjunct to culture for early presumptive diagnosis of pertussis. DFA tests are rapid but are too insensitive and subjective to be done in lieu of culture. Success in interpreting DFA examinations of clinical material is directly proportional to the experience of the reader. A positive DFA result without culture or PCR confirmation is *not* considered suitable confirmation of pertussis in any state in the United States.

Reagents (polyclonal and monoclonal) are available for testing, but the polyclonal reagent has variable sensitivity and low specificity. The monoclonal reagent contains fluorescein-conjugated anti-*B. pertussis* monoclonal antibody and rhodamine-conjugated anti-*B. parapertussis* monoclonal antibody. Limited information is available at this time concerning the sensitivity and specificity of the monoclonal reagent (2).

DFA is performed directly on the patient specimen but can also be used to confirm an isolate grown in culture as *B. pertussis* or *B. parapertussis*.

II. SPECIMENS

- A. Nasopharyngeal specimen (*see* procedure 3.11.6 for collection)
- B. Smears prepared from presumptive *B. pertussis* or *B. parapertussis* cultures, to confirm identification

III. MATERIALS

A. DFA reagents

1. Polyclonal reagents: BD Diagnostic Systems (formerly Difco reagents)
 - a. Bacto chicken anti-*B. pertussis* fluorescein isothiocyanate (FITC) conjugate (formerly Difco no. 2359-56; BD Diagnostic Systems catalog no. 223591).
 - b. Bacto chicken anti-*B. parapertussis* FITC conjugate (formerly Difco no. 2378-56; BD Diagnostic Systems catalog no. 223781).
 - c. Reagent preparation
 - (1) Bring lyophilized reagents to room temperature.
 - (2) To rehydrate, add 5 ml of sterile distilled or deionized water to each vial and rotate gently to completely dissolve contents.
 - (3) Determine the working dilution of each FITC conjugate immediately after rehydration, since it varies with each lot of reagent, the fluorescent microscope and filters used, and the age of the bulb.

APPENDIX 3.11.6–1 (continued)

- (a) Prepare twofold dilutions of each FITC conjugate ranging from 1:5 to 1:80 in phosphate-buffered saline (PBS) buffer and test using stock strains.
 - (b) Choose the working dilution as one dilution less than the highest dilution yielding a 4+ fluorescence. For example, if the last dilution yielding a 4+ fluorescence is 1:40, then 1:20 (one less dilution) is the working dilution for that reagent.
 - (4) Aliquot the working dilution of each conjugate and store at -20°C until the expiration date of original vial.
 - (5) Label with reagent name, lot number, dilution, and preparation and expiration date.
 2. Monoclonal reagents
 - a. Accu-Mab Plus *B. pertussis/parapertussis* DFA (Altachem Pharma Inc., Edmonton, Alberta, Canada)
 - (1) Catalogue no. BP002-01 (one-vial, 40-test kit)
 - (2) Catalog no. BP002-04 (four-vial, 160-test kit).
 - b. Supplied ready for use in PBS, pH 7.2, in an amber glass serum vial
 - c. Store at 2 to 8°C .
 - B. Supplies
 1. Wash buffer: PBS, 0.01 M phosphate, 0.15 M sodium chloride (pH 7.2 to 7.4)
 - a. Stock solution
 - (1) Dissolve 2.56 g of $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ (or 2.89 g of $\text{NaH}_2\text{PO}_4 \cdot 2\text{H}_2\text{O}$) and 11.94 g of Na_2HPO_4 in 500 ml of distilled H_2O .
 - (2) Add 97.66 g of NaCl, and bring to a total volume of 1,000 ml.
 - (3) Sterilize by autoclaving or filtration and adjust pH to 7.2.
 - (4) Store at 4°C for up to 6 months.
 - b. Working solution
 - (1) Dilute stock 1:10 in sterile distilled H_2O .
 - (2) Store at 4°C for up to 2 weeks.
 2. McFarland standard no. 3 (Appendix 3.16–1)
 3. 0.5 to 1% Casamino Acids (catalog no. 060462; Remel, Inc.)
 4. 95% Ethanol
 5. Staining tray and moisture chamber
 6. FA mounting fluid, pH 7.2; (9 parts reagent-grade glycerin to 1 part PBS)
 7. 25- μl pipette for monoclonal reagents
 8. Miscellaneous: microscope slides, immersion oil, wooden applicator sticks, staining jar, coverslips
 - C. Fluorescent microscope with excitation and emission filters for FITC conjugate (and rhodamine conjugate for monoclonal reagent). Check with your microscope supplier for the proper combination of barrier and excitation filters needed for use with conjugates.
- IV. QUALITY CONTROL
 - A. Keep both the reagent and stained slides in reduced light to minimize photobleaching of the fluorescent dyes.
 - B. Always use aseptic technique when opening reagents for use.
 1. Perform a visual inspection of the vial for turbidity and/or mold growth prior to each use.
 2. Do not use reagents if any signs of contamination (turbidity or growth) are present.
 - C. Prior to use of new lots and each time a fluorescent antigen test is performed, test a positively and negatively reacting control with *each antiserum*.
 1. Positive controls must fluoresce brilliant apple-green with the fluorescein filters and bright orange-red with the rhodamine filters, as indicated in the chart below.
 2. For positive controls, coccobacilli must be brightly fluorescent at the edges and have dark centers.
 3. A positive control should show a 4+ reaction and the negative control should not exceed a 1+ reaction according to the chart below. See grading system in item VI below.

APPENDIX 3.11.6–1 (continued)

4. If a positive control is less than 3+, or if a negative control exceeds 1+, the test should be repeated and patient specimen slides should not be read and/or reported.

Test organism	Polyclonal reagent (apple-green)		Monoclonal reagent	
	<i>B. pertussis</i> conjugate	<i>B. parapertussis</i> conjugate	Fluorescein filter (apple-green)	Rhodamine filter (orange-red)
<i>B. pertussis</i> ATCC 9797	Positive, 3–4+	Negative or 1+	Positive, 3–4+	Negative or 1+
<i>B. parapertussis</i> ATCC 15311	Negative or 1+	Positive, 3–4+	Negative or 1+	Positive, 3–4+
<i>Bordetella</i> (not <i>B. pertussis</i> , <i>B. parapertussis</i> , or <i>B. bronchiseptica</i>)—optional			Negative or 1+	Negative or 1+

D. Preparation of positive and negative control slides

1. Store stock strains of QC organisms frozen at -70°C indefinitely (see item V in procedure 14.2) or on sealed plates at 4°C for 1 month.
2. Pick appropriate colonies from Regan-Lowe agar and emulsify in 2 ml of sterile distilled or deionized water (use PBS wash buffer for monoclonal reagents) until a cell density equal to a no. 3 McFarland standard is achieved. (An ideal smear will contain 10 to 100 organisms/oil immersion field.)
3. From the cell suspension smear a drop or large loopful of specimen on two areas of each clean glass microscope slide. Each area should be 10 to 15 mm in diameter. Do this for each control organism used. Only one area per slide is needed for monoclonal reagent.
4. Allow the smears to air dry and then fix the slide by a 1-min immersion in 95% ethanol. Remove slides, and allow them to air dry (or for monoclonal reagents, flood with 95% ethanol and allow the ethanol to evaporate at room temperature).
5. Place in a slide storage box, and keep at -20°C for up to 1 year. However, condensation and frost buildup can cause problems over time. Fixed control slides may also be kept in a desiccator in the dark at room temperature for up to 1 year.
6. Each time the test is performed, remove one *B. pertussis* and one *B. parapertussis* control slide from the freezer and allow them to come to room temperature.
7. Test each control slide in the same manner as each patient or culture specimen is tested.

☑ **NOTE:** *B. pertussis* ATCC 12742 and *B. parapertussis* ATCC 15237 are both mutant strains lacking lipopolysaccharide structures that are required for the monoclonal reagent to attach. They must *not* be used as positive controls in this procedure.

V. PROCEDURE

A. Preparation of slides

1. Specimens

- a. If swab is received, place in a tube containing 0.5 ml of sterile 0.1% casein hydrolysate, and vortex for 20 s.

☑ **NOTE:** This step is very important, as smears made directly from the specimen swabs often have so much background fluorescence from nasal secretions that interpretation becomes difficult if not impossible.

- b. For aspirate specimens, vortex the aspirate for 20 s and then use the aspirate directly.

2. Cultures

- a. Pick appropriate colonies from Regan-Lowe agar and emulsify in 2 ml of sterile distilled or deionized water (use PBS wash buffer for monoclonal reagents) until a cell density equal to a no. 3 McFarland standard is achieved.
- b. An ideal smear will contain 10 to 100 organisms/microscopic field.

APPENDIX 3.11.6–1 (continued)

- B. DFA procedure (polyclonal reagents)
1. Process patient specimen, culture, and control slides in the same manner.
 2. Smear a drop or large loopfull of emulsified specimen or culture in two separate areas on a glass slide. Each area should be 10 to 15 mm in diameter.
 3. Draw a line with a wax pencil to separate sides or, preferably, use Teflon-coated slides with wells (Precision Laboratory Products, Middleton, Wis., <http://www.precisionslides.com>).
 4. Fix slides.
 - a. Heat fix gently using either a flame or hot plate until warm to the touch *or*
 - b. Immerse for 1 min in 95% ethanol.
 5. Add several drops (1 drop = 35 μ l) of the appropriate FA working conjugate to the fixed smears.
 - a. Use FITC-conjugated *B. pertussis* antiserum on one half of each slide and FITC-conjugated *B. paraptussis* antiserum on the other half.
 - b. Keep the same antiserum location on each slide (i.e., *B. pertussis* antiserum on left side of each slide).
 6. Spread the conjugate over the entire area using a wooden applicator stick.
 7. Place the slide(s) in a staining tray or moisture chamber.
 8. Incubate at room temperature for 30 min.
 9. Remove excess conjugate.
 10. Place slide(s) in a staining jar containing PBS wash buffer for 10 min; change buffer two times during wash step.
 11. Rinse for 2 min in distilled water.
 12. Remove the slide(s), allow to drain, and air dry or blot with bibulous paper.
 13. Add a small drop of mounting fluid (pH 7.2) to the center of each stained area, and mount each with a coverslip.
 14. Examine slides using a fluorescent microscope with filters for fluorescein conjugate.
 15. Examine control slides with 100 \times objective before proceeding to specimen slides.
 16. Screen specimen slides with 40 \times objective and confirm with 100 \times objective.
- C. DFA procedure (monoclonal reagents)
1. Process patient specimen, culture, and control slides in the same manner.
 2. Smear a drop or large loopful of emulsified specimen or culture on a glass slide approximately 10 to 15 mm in diameter.
 3. Fix slides immediately.
 - a. Flood the smear with 95% ethanol and allow the ethanol to evaporate at room temperature.
 - b. In addition, if specimen was transported or mixed in casein hydrolysate, dip the slide several times in PBS wash buffer to remove casein and allow slide(s) to dry.
 4. Add 25 μ l of the DFA reagent to each fixed smear.
 5. Spread the reagent over the entire area using a wooden applicator stick.
 6. Place the slide(s) in a moisture chamber for 30 min at room temperature. Do not allow the reagent to dry on the slide(s) or results will not be accurate.
 7. Place slide(s) in a staining jar containing PBS wash buffer for 5 min.
 8. Place positive control slides in a separate staining jar.
 9. Repeat wash with fresh wash buffer for an additional 5 min. (If background fluorescence is found to be too high, increase wash steps to 10 min each.)
 10. Dip slide(s) for 1 min in distilled water.
 11. Blot excess water from slide(s) with lint-free tissue or bibulous paper and allow to air dry.
 12. Add a small drop of mounting fluid (pH 7.2) to the center of each stained area, and mount each with a coverslip.
 13. Examine slides with fluorescent microscope with filters for both fluorescein and rhodamine.
 - a. Since fluorescein fades more rapidly than rhodamine after light exposure, examine each slide with fluorescein filters before proceeding to rhodamine filters.

APPENDIX 3.11.6–1 (continued)

- b. Examine control slides with 100× objective before proceeding to specimen slides.
- c. Screen specimen slides with 40× objective and confirm with 100× objective.

VI. INTERPRETATION

- A. Score fluorescence from 1+ to 4+.
 1. Score immediately when each field is first viewed since the dyes, especially fluorescein, may fade rapidly after exposure to the excitation beam of the microscope.
 2. Use the following grading for controls and specimens with fluorescein conjugate and filters.
 - a. 4+ : brilliant apple-green fluorescence with clear-cut cell outline and sharply defined center
 - b. 3+ : bright apple-green peripheral fluorescence with clear-cut cell outline and sharply defined center.
 - c. 2+ : definite but dull apple-green peripheral fluorescence with cell outline less well defined
 - d. 1+ : very dim, barely visible apple-green fluorescence with cell outline indistinguishable from center
 3. Use the following grading for controls and specimens with rhodamine conjugate and filters.
 - a. 4+ : brilliant orange-red fluorescence with clear-cut cell outline and sharply defined center
 - b. 3+ : bright orange-red peripheral fluorescence with clear-cut cell outline and sharply defined center
 - c. 2+ : definite but dull orange-red peripheral fluorescence with cell outline less well defined
 - d. 1+ : very dim, barely visible orange-red fluorescence with cell outline indistinguishable from center
- B. A positive cell must appear as a small oval-shaped or coccobacillary cell with an intense (3+ to 4+) fluorescence surrounding a *dark cell center*.
 1. Ignore occasional nonspecifically staining diplococci, or diphtheroid-like rods.
 2. Consider typical morphology as well as fluorescence in the interpretation.
- C. For a positive result
 1. Polyclonal reagents
 - a. Slide positive for *B. pertussis* must show *four or more cells* with the characteristic morphology and 3 to 4+ apple-green fluorescence on the area stained with *B. pertussis* antiserum, with no or 1+ fluorescence on the area stained with *B. parapertussis* antiserum.
 - b. Slide positive for *B. parapertussis* must show *four or more cells* with the characteristic morphology and 3 to 4+ apple-green fluorescence on the area stained with *B. parapertussis* antiserum, with no or 1+ fluorescence on the area stained with *B. pertussis* antiserum.
 2. Monoclonal reagents
 - a. Slide positive for *B. pertussis* must show one cell with the characteristic morphology and 3 to 4+ yellow-green fluorescence with fluorescein filters and no or 1+ fluorescence with rhodamine filters.
 - b. Slide positive for *B. parapertussis* must show one cell with the characteristic morphology and 3 to 4+ orange-red fluorescence with rhodamine filters and no or 1+ fluorescence with fluorescein filters.
 - c. Depending on your microscope filters, positive *B. parapertussis* cells may give a faint orange fluorescence (maximum, 1+) when viewed using the fluorescein filter. This faint orange fluorescence should not be confused with the expected bright green fluorescence of positive *B. pertussis* cells.

APPENDIX 3.11.6–1 (continued)

d. Depending on your microscope filters, positive *B. pertussis* cells may give a pale yellow fluorescence (maximum, 1+) when viewed using the rhodamine filter. This pale yellow fluorescence should not be confused with the expected bright orange-red fluorescence of positive *B. parapertussis* cells.

■ **NOTE:** The manufacturer claims that the monoclonal reagents are so specific that a slide should be considered positive for *B. pertussis* or *B. parapertussis* if a single cell with the characteristic morphology and appropriate fluorescence is observed. The single evaluation of the monoclonal reagent published to date used the stringent criterion of a minimum of four fluorescing organisms with typical morphology to qualify as a positive, but it was felt that the manufacturer's recommendation of a single cell was valid (2).

VII. REPORTING RESULTS

A. Negative results

1. Report the DFA test result as "Negative for *Bordetella pertussis* and *Bordetella parapertussis* by direct fluorescent-antibody testing."
2. If an isolate from a culture does not fluoresce with reagents, report "No *Bordetella pertussis* or *Bordetella parapertussis* isolated."

B. Positive results

1. For positive DFA test, report "Positive for *Bordetella pertussis* or *Bordetella parapertussis* by DFA."
2. For positive DFA test from culture, report "Positive for *Bordetella pertussis* or *Bordetella parapertussis*" depending on which conjugate gave a positive result.

VIII. LIMITATIONS

- A. Methods that employ PCR are more rapid and sensitive than culture or DFA techniques.
- B. Polyclonal reagent for DFA has variable sensitivity and low specificity.
- C. False-positive results can be caused by misinterpretation of the confirmatory tests.
- D. The polyclonal antibody reagents used for DFA are capable of cross-reacting with several non-*B. pertussis* bacteria, resulting in false-positive results (1).
- E. The monoclonal DFA reagent may produce a positive result with some strains of *B. bronchiseptica* (package insert, Altachem Pharma Inc.)
- F. *Legionella* spp. cross-react with *B. pertussis* antiserum (3).
- G. Treatment with antimicrobial agents can affect both DFA and culture, resulting in false negatives.

3.11.7

Corynebacterium diphtheriae Cultures

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Diphtheria is an acute, toxin-mediated, communicable infectious disease primarily of the upper respiratory tract (throat, larynx) and occasionally of the skin. It is caused by toxigenic lysogenized strains of *Corynebacterium diphtheriae*, of which there are four biotypes: mitis, intermedius, belfani, and gravis. Diphtheria exacts a high mortality rate, approximating 10%. A less severe diphtheria-like disease (pharyngitis and atypical symptoms, such as endocarditis, septic arthritis, and other forms of systemic disease) caused by nontoxigenic strains has been reported. The classic pseudomembrane of the pharynx may be lacking in mild cases, which usually mimic streptococcal pharyngitis.

Although the number of cases reported in the United States has significantly declined, studies of diphtheria immunity levels among adults in the United States have shown that from 20 to 90% do not possess adequate immunity against the disease (10). In 1996, isolation of toxigenic *C. diphtheriae* from the blood of an American Indian woman living in the Northern Plains region of the United States prompted public health officials to conduct diphtheria surveillance in the patient's community, resulting in the recovery of 10 *C. diphtheriae* isolates (2, 8, 10). There is currently no geographic concentration of cases in the United States. An-

timicrobial agents have little or no effect on the clinical outcome, and laboratory confirmation of diphtheria often requires several days, yet diagnosis and antimicrobial treatment are essential in limiting further spread (3, 11).

This procedure presents proper specimen collection and transport and culture for *C. diphtheriae*. Some laboratories may not be able to store the culture medium because of few requests and may elect to submit specimens to a reference laboratory for culture. It is a CAP requirement that the laboratory have available a mechanism to provide culture for *C. diphtheriae*, when requested.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

☑ **NOTE:** Refer to procedure 3.3.1 for additional details on specimen collection. The following can be copied for preparation of a specimen collection instruction manual for physicians and other caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

Observe standard precautions.

A. Specimen collection

1. Contact the clinical microbiology laboratory prior to specimen collection for diphtheria, because special techniques and/or media are required for the isolation of these agents.
2. In case of respiratory diphtheria, obtain material for culture on a swab (either a cotton- or a polyester-tipped swab) from the inflamed areas in the nasopharynx (3).
 - a. If membranes are present and can be removed, swab from beneath the membrane.
 - b. Collect from several areas to increase sensitivity.
 - c. Collect nasopharyngeal swabs from suspected carriers.
 - d. For details, see Specimen Collection, Transport, and Handling for culture of beta-hemolytic streptococci, procedure 3.11.8.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- If cutaneous diphtheria is suspected, collect skin (aspirate/swab), throat (swab), and nasopharynx (swab) specimens (1, 11).

B. Specimen transport

- Use any routine swab collection systems, such as Amies or BD Culturette EZ, because the organism is not fastidious.
 - ☑ **NOTE:** BD Culturette EZ is preferred because the polyurethane adsorbs and releases >95% of the organisms, unlike other swabs that absorb the organisms, making release inefficient.
- If inoculation of media is anticipated to exceed 24 h, use silica gel transport packages or sterile, desiccated silica gel crystals in tubes (3). However, it is best to avoid delays in culture inoculation to provide speed and accuracy in the diagnosis.
- Follow the guidelines for the packaging and shipping of infectious substances as outlined in the respective Department of Transportation (DOT) or International Air Transport Association (IATA) regulations for shipping of specimens and/or cultures suspected of containing *C. diphtheriae* (see procedure 15.5).
- Include patient demographics on the culture request form (age, sex, and name), including vaccination and travel history. Record collection time and source of specimen.

C. Rejection criteria

- Specimens not representative of the anatomic site from which *C. diphtheriae* is commonly found
- Specimens not accompanied by appropriate information (patient name, age, and vaccination history; source of specimen)
- Specimens submitted in unapproved packaging and shipping containers
- Specimen transport time exceeds 24 h and specimen is not contained in silica gel transport medium.

III. MATERIALS

A. Media

- BAP inoculated for the detection of hemolytic streptococci and *C. diphtheriae* present in large numbers. Addition of a 50- μ g disk of fosfomycin (BD Diagnostic Systems) to the initial inoculum will inhibit most contaminating oral microbiota and allow coryneforms to grow (3).
- Selective media (see Appendix 3.11.7-1 for details)
 - Cystine tellurite blood agar (CTBA) (Remel, Inc.) or serum tellurite agar with lamb serum (BD Diagnostic Systems)
 - ☑ **NOTE:** This medium inhibits oronasal microbiota and turns colonies of corynebacteria, staphylococci, and yeasts black.
 - Tinsdale (TIN) agar base medium (Remel, Inc.)
 - ☑ **NOTE:** This medium contains cysteine and forms a halo around colonies that produce cystinase.

3. Slants (optional)

- Loeffler agar slant (LAS) (Remel, Inc.) or Loeffler blood serum with beef serum (BD Diagnostic Systems) *or*
 - Pai agar slant (formula in Appendix 3.11.7-1)
- Todd-Hewitt broth with 3% sterile rabbit blood (optional). Defibrinated rabbit blood is available from most medium vendors and from Hemostat (Los Angeles, Calif., [800] 572-6888) or Quad-5 (Ryegate, Mont., [406] 568-2911).

B. Reagents

- Gram stain reagents (see procedure 3.2.1)
- Alkaline Loeffler methylene blue stain (LMBS) (optional)
 - Dissolve 0.3 g of methylene blue in 30 ml of 95% ethanol.
 - Then add 100 ml of 0.01% potassium hydroxide.
- 3% Hydrogen peroxide for catalase (see procedure 3.17.10)

III. MATERIALS (continued)

4. Conventional biochemical media: see procedures 3.17 and 3.18.1.
- a. Sugar fermentation media (procedure 3.17.9)
 - (1) Preferably cysteine Trypticase agar for determining oxidation (found at surface of the tube) and fermentation (acid or alkali production in entire tube) for acid production from glucose, maltose, sucrose, mannitol, and xylose, *or*
 - (2) Rapid sugar fermentation tubes (Remel, Inc.)
 - b. Nitrate broth (procedure 3.17.35)
 - c. Motility media (procedure 3.17.31)
 - d. Urea hydrolysis (procedure 3.17.48)
 - e. Esculin hydrolysis (procedure 3.17.5)
 - f. A beta-hemolysin-producing strain (e.g., *Staphylococcus aureus* ATCC 25923) for CAMP reaction (procedure 3.17.8)
5. Commercial identification systems: RapID CB Plus system (Remel, Inc.), API (RAPID) Coryne system (bioMérieux), Biolog GP plate (Biolog, Hayward, Calif.), BBL CRYSTAL GP system (BD Diagnostic Systems)
- ▣ **NOTE:** Publications related to the performance of these systems are limited to the first three systems (4, 5, 6, 7). It is recommended that the use of any of the above-listed commercial identification systems be supplemented with macroscopic morphology and Gram stain characteristics. Any isolate that is unidentifiable and deemed to be clinically significant should be sent to a creditable reference laboratory with expertise in identification of corynebacteria, especially for identification of toxin-producing *C. diphtheriae*.
- C. Other supplies**
1. Incubator at 35°C
 2. Microscope

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures.
- B. QC checks need not be performed in-house on commercially purchased BAP. However, each new lot number and each new shipment of CTBA, LAS, Pai, and TIN must be tested with stock strains of *C. diphtheriae* (preferably biotype intermedius) for characteristic growth (11). Incubate aerobically overnight at 35°C.

Test organism	Result
<i>Corynebacterium diphtheriae</i> bv. intermedius ATCC 9675 or ATCC 51696	CTBA: growth, gray to black colonies, some with dark centers LAS: growth Pai: growth TIN: black colony with halo
<i>Streptococcus pyogenes</i> ATCC 19615	TIN: black, pinpoint without halos
<i>Staphylococcus aureus</i> ATCC 25923	CTBA: inhibition (partial to complete)

- C. Test each lot of reagents and kits used for identification with organisms known to produce reliable positive and negative reactions.
- D. Test methylene blue stain with a characteristic *Corynebacterium* and another gram-positive microorganism with each use of the test.

V. PROCEDURE

Observe standard precautions.

❑ **NOTE:** Refer to Fig. 3.11.7–1 for a flowchart of steps in the isolation, detection, and identification of *C. diphtheriae*.

A. Inoculation

❑ **NOTE:** Use of biosafety cabinet will avoid contamination of the culture or specimen as well as protect laboratory processing personnel.

1. If the swab appears desiccated, was collected several days prior to receipt, or is received in silica gel, place it into Todd-Hewitt broth supplemented with 3% sterile rabbit blood, incubate it overnight, and then inoculate isolation media.
2. Inoculate the specimen to CTBA and BAP; streak for isolation. Incubate media at 35°C aerobically.

Figure 3.11.7–1 Flowchart for evaluation of culture for *C. diphtheriae*.

V. PROCEDURE (continued)

3. Optionally, inoculate an LAS or a Pai agar slant, and leave the swab on the slant during incubation.
 - a. Incubate media at 35°C aerobically.
 - b. After 18 to 24 h of incubation, subculture the agar slant to a second plate of CTBA.

B. Culture evaluation

1. Examine all agar plates at 24 and 48 h for colonies typical of *C. diphtheriae* (see descriptions below). Pursue any beta-hemolytic colonies on BAP and dark colonies on CTBA.
2. Subculture colonies that are catalase positive and exhibit typical morphology on Gram stain (Fig. 3.11.7-2) to the following.
 - a. BAP to provide growth for identification procedures
 - b. Modified TIN plate. Stab the agar in several places for halos.
3. Incubate plates aerobically at 35°C and examine at 24 and 48 h. Do not incubate in CO₂.

C. Morphology of *C. diphtheriae*

1. Cellular morphology (Fig. 3.11.7-2)
 - a. Gram stain: pleomorphic gram-positive rods that occur in angular arrangements (commonly referred to as palisades or Chinese letters); possibly coccobacillary forms, most notably in older cultures

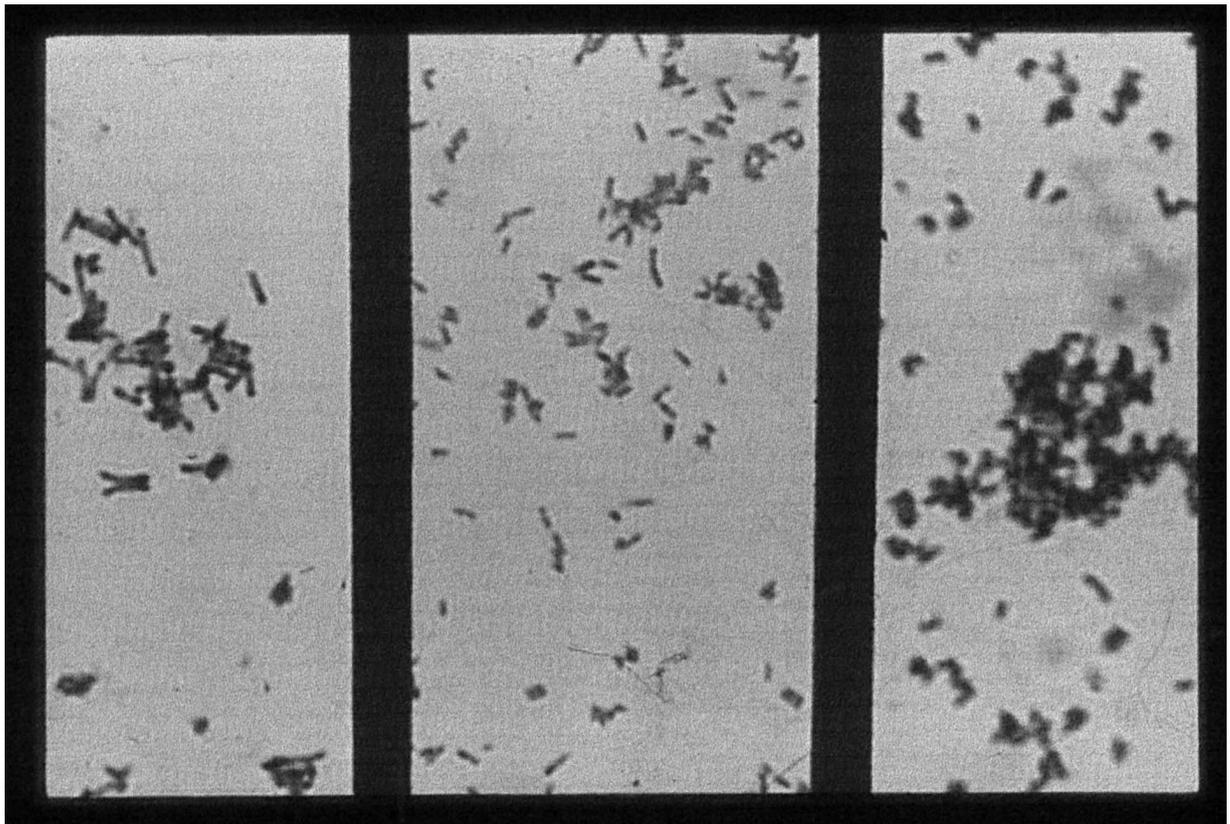

Figure 3.11.7-2 Microscopic morphology of three types of *C. diphtheriae* grown on Loeffler media and stained with Loeffler methylene blue: from right to left they are biotypes *gravis*, *mitis*, and *intermedius*. Photos reproduced from Clinical Microbiology, ASM Committee on Educational Materials, 1985.

V. PROCEDURE (continued)

- b. LMBS: pleomorphic beaded rods whose ends may be swollen, producing a club shape; angular arrangements; reddish purple metachromatic granules or bars apparent
- 2. Colonial morphology
 - a. CTBA: grayish black (gunmetal gray) and 1 to 3 mm in size, with a garlic-like odor
 - (1) Biotype intermedius: smallest, flat
 - (2) Biotypes mitis and gravis: larger, convex, smooth or wrinkled
 - b. BAP (Fig. 3.11.7-3)
 - (1) Biotype intermedius: smaller, flat, creamy, transparent, nonhemolytic
 - (2) Biotypes mitis and gravis: larger, convex, with weak beta-hemolysis
 - (3) *Streptococcus pyogenes*: gram-positive cocci in chains; production of beta-hemolysis
 - c. TIN: brownish black zone (halo) around the colony darkens with age.
- D. Identification procedures
 - 1. Examine TIN at 24 and 48 h for brownish black halos.
 - 2. Make a suspension of suspected colony on any of the agars in Todd-Hewitt broth. Use this suspension to do the following.
 - a. Prepare stains
 - (1) Examine LMBS or Gram stain black colonies to confirm characteristic cellular morphology. *Staphylococcus* spp. may produce a characteristic halo on TIN.
 - (2) Perform wet mount motility to eliminate *Bacillus* spp.

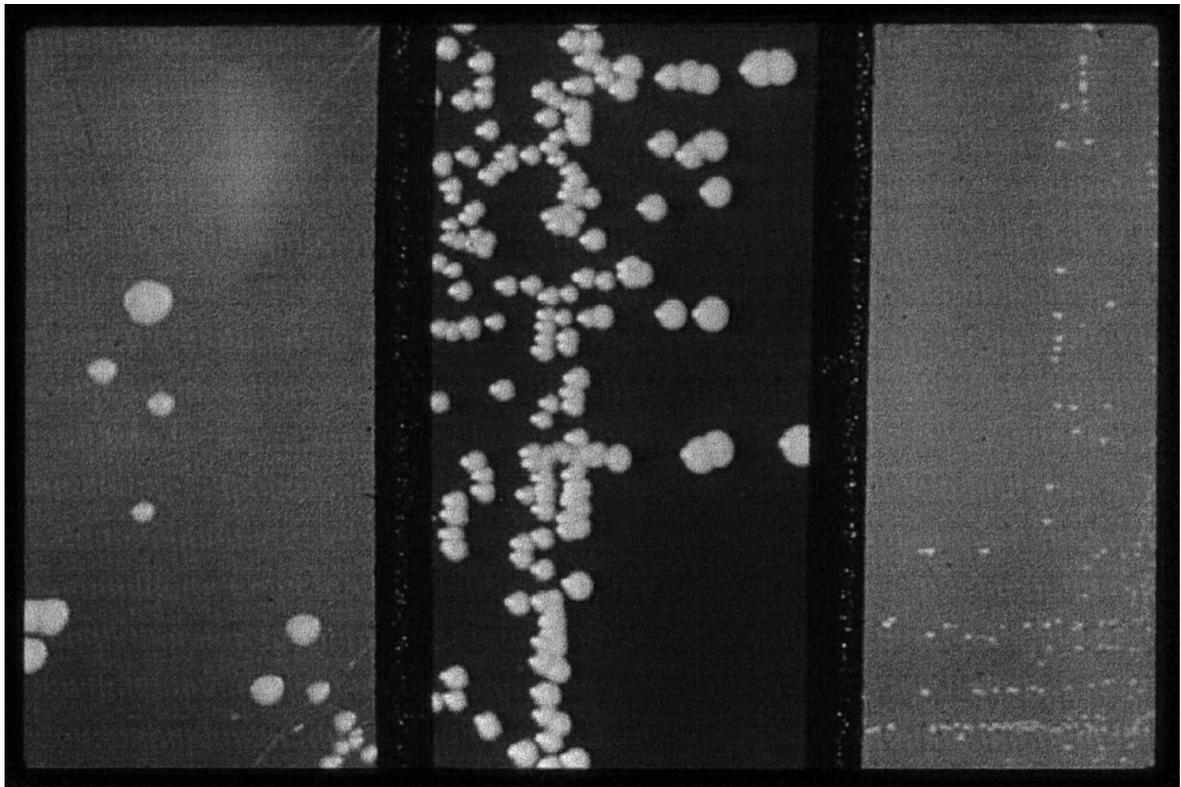

Figure 3.11.7-3 Colonial morphology of *C. diphtheriae* grown on BAP for 48 h; from right to left they are biotypes gravis, mitis, and intermedius. Photos reproduced from Clinical Microbiology, ASM Committee on Educational Materials, 1985.

V. PROCEDURE (continued)

- b. Inoculate CAMP test.
- c. Inoculate biochemical tests.
 - (1) Conventional
 - (a) Urea
 - i. For agar slant, overlay urea slant with sterile mineral oil.
 - ii. Or use rapid disk test (preferred) (procedure 3.17.48)
 - a. *Corynebacterium ulcerans* and *Corynebacterium pseudotuberculosis* produce a characteristic halo on TIN and are urea positive (Table 3.11.7–1).
 - **NOTE:** *C. ulcerans* has been known to cause diphtheria-like disease and can elaborate diphtheria toxin. *C. pseudotuberculosis* can also produce the toxin.
 - b. *C. diphtheriae* is urea negative.
 - (b) Nitrate
 - (c) Sugar fermentation
 - i. Conventional media may be supplemented with a drop or two of sterile rabbit serum to enhance growth (see procedure 3.17.9). Incubate aerobically at 35°C and examine daily for 3 days, or
 - ii. Inoculate 1 drop of each rapid sugar identification medium heavily with a loopful of colony, making an even suspension. Incubate for 1 h in a 37°C water bath. Interpret as for conventional tests.
 - (2) As an alternative to the above-mentioned biochemical tests, inoculate a commercial identification test kit and read according to the manufacturer's instructions.
- E. If identification procedures indicate *C. diphtheriae*, *C. ulcerans*, or *C. pseudotuberculosis*, ship (per DOT or IATA packaging and shipping guidelines) LAS or Pai or other slant to a public health laboratory for toxigenicity testing. The isolate must be toxigenic to confirm a clinical diagnosis of diphtheria (11). Contact the local public health laboratory to determine where it wishes the isolate to be sent. The CDC Diphtheria Laboratory performs toxin testing 7 days a week.
- F. Antimicrobial susceptibility testing

In the absence of published NCCLS guidelines for susceptibility testing of corynebacteria (9), it is recommended that if testing is requested, tests be performed on Mueller-Hinton agar with sheep blood using the Etest method (procedure 5.8). Report the MIC without an interpretive breakpoint, unless it is obviously resistant.

Table 3.11.7–1 Key biochemical reactions to identify toxic *Corynebacterium* species^a

Species	Halos on TIN	Motility	Nitrate	Urea	Hemolysis	Can have diphtheria toxin	Reverse CAMP
<i>C. diphtheriae</i>	+	–	+ ^b	–	V	+	–
<i>C. ulcerans</i>	+	–	–	+	+	+	+
<i>C. pseudotuberculosis</i>	+	–	V	+	+	+	+
<i>C. pseudodiphtheriticum</i>	Unknown	–	+	+	–	–	–

^a Table extrapolated from text and tables in reference 3. +, positive; –, negative; V, variable. *C. ulcerans* is trehalose and glycogen positive; *C. pseudotuberculosis* is not. Many commercial kits do an excellent job of identification of these species. *C. diphtheriae*, *C. ulcerans*, and *C. pseudotuberculosis* are pyrazinamidase negative; *C. pseudodiphtheriticum* and many common corynebacteria are positive. For laboratories that must screen numerous isolates for *C. diphtheriae*, tablets to rapidly test for pyrazinamidase activity are available from Key Scientific.

^b *C. diphtheriae* biotype belfani is nitrate reductase negative.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. If the culture is negative, report “No *Corynebacterium diphtheriae* isolated after 3 days.”
- B. Positive culture results
 1. If biochemical results are consistent with *C. diphtheriae*, report “Presumptive for *Corynebacterium diphtheriae*; sent to public health laboratory for confirmation and toxigenicity testing.” Do not report any enumeration.
 2. Notify physician and infection control of positive results. Diphtheria is a reportable disease in most states.
 3. Document notification.

VII. INTERPRETATION

- A. Pleomorphic gram-positive rods that usually grow well on BAP and are catalase positive, nonmotile, CAMP negative, and urea negative and form halos on TIN are presumptively *C. diphtheriae*.
- B. Confirm such results with further biochemical kit or sugar tests.
- C. Phenotypic identification of *C. diphtheriae* does not mean that the organism is a toxin producer. Toxin genes are carried on plasmids which can be lost. Toxin production must be demonstrated.

VIII. LIMITATIONS

- A. Smears made directly from clinical specimens are not reliable for diagnostic purposes, since metachromatic granules are found in other bacteria as well (11). Methylene blue stain (Loeffler) smears from media incubated for a short time are no longer recommended, for the same reason.
- B. *C. diphtheriae* must be a toxigenic strain to be diagnostic of diphtheria.
- C. TIN is not suitable as a primary plating medium, since it may not support the growth of some strains of *C. diphtheriae*.
- D. Do not read TIN too soon, since several organisms may give some slight browning on this medium in 18 h.
- E. Incubation at 5 to 10% CO₂ retards the development of halos on TIN.
- F. Black colonies on CTBA can be due to other organisms capable of reducing tellurite to tellurium. Other *Corynebacterium* spp., staphylococci, and some streptococci possess this ability.
- G. *C. diphtheriae* rapidly loses viability in saline. Use broth for suspensions of the organism or to moisten specimen swabs.
- H. Sterile rabbit serum will enhance growth of *C. diphtheriae*, in particular biotype intermedius, and is especially advised in biochemical media.
- I. Toxigenicity testing (modified Elek test) requires skill and experience in the preparation of reagents and interpretation of results and is therefore best left to public health laboratories or other reference laboratories that perform these procedures with some regularity.

APPENDIX 3.11.7–1

Media for Detection of *Corynebacterium diphtheriae*

Refer to manufacturers' package inserts for additional information.

- A. TIN agar: a peptone agar base enriched with bovine serum, cysteine hydrochloride, potassium tellurite, and sodium thiosulfate
 1. The TIN kit (Remel) includes one tube of TIN agar base along with one bottle of desiccated TIN enrichment containing tellurite and serum. One tube and one bottle make one plate. Prepare a sufficient number of plates for QC testing and patient specimens.
 2. Melt the agar in the bottle by boiling.
 3. Rehydrate the enrichment by adding 3.3 ml of sterile distilled water aseptically to the bottle. Allow to sit until completely hydrated.
 4. Cool the base to 47 to 50°C. Add the enrichment and pour one plate. Plate is good for 5 days after pouring. Perform QC.
- B. CTBA is a heart infusion agar supplemented with 5% rabbit blood, tellurite, and L-cystine; shelf life is 1 month. Deeps with a longer shelf life are available.
- C. Loeffler blood serum medium contains eggs and beef serum, rather than agar, to coagulate to produce a solid medium. It is best purchased commercially.
- D. Pai agar slant
 1. 666 ml of fresh eggs, 333 ml of distilled water, and 80 ml of glycerin
 2. Filter eggs and water through gauze and add glycerin.
 3. Tube in 3-ml amounts, slant, and autoclave for 1 h at 110°C.
 4. Tightly cap; shelf life is 1 year (1).

3.11.8

Group A Streptococcus Culture and Direct Antigen Detection

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Group A beta-hemolytic streptococcus (GABHS) is an important pathogen that causes pharyngitis, cellulitis, and bacteremia. Serious sequelae, including scarlet fever, acute glomerulonephritis, toxic shock syndrome, and acute rheumatic fever, can result from infections with this microorganism.

The primary reason this microorganism is an effective pathogen is the variety of virulence factors it can produce. Numbering among them are somatic constituents like M protein and capsule, enzymes like streptolysin O, DNase B, and streptokinase, and toxins like erythrogenic toxins A to C.

GABHS accounts for 30% of pharyngitis cases in children aged 5 to 15 years but only 10% of adult cases. Other bacterial causes of pharyngitis include group C and G beta-hemolytic streptococci, *Neisseria gonorrhoeae*, *Corynebacterium diphtheriae*, and *Arcanobacterium haemolyticum*. However, most cases of pharyngitis have a viral etiology. In children, the most worrisome complications of GABHS infection are acute rheumatic fever, acute glomerulonephritis, and peritonsillar abscess. Antimicrobial therapy alleviates pharyngeal symptoms and prevents some of the sequelae of infection.

Since Breese et al. (5) first described throat culturing for GABHS, numerous methods of detection have been published. It is important to select diagnostic tests

that are highly sensitive for use in children, since low numbers of GABHS in specimens may still indicate infection. That is because collecting high-quality pharyngeal specimens from uncooperative children can be difficult. For this reason, the American Academy of Pediatrics continues to recommend that negative rapid antigen detection tests be confirmed by culture (1).

Guidelines were published recently for testing adults with pharyngitis who lacked the complications of heart disease, chronic lung disease, or a history of acute rheumatic fever (9). They state that these patients should be screened for presence of the Centor criteria (8): history of fever, tonsillar exudates, absence of cough, and tender anterior cervical lymphadenopathy (lymphadenitis). Patients with two or more criteria should have rapid GABHS antigen detection performed, with antimicrobial therapy prescribed only for patients with positive results. Alternatively, antimicrobial therapy can be administered to patients who meet three or four of the criteria without a need for diagnostic testing.

The Infectious Diseases Society of America (IDSA) does not support diagnosing GABHS pharyngitis on clinical grounds alone, which it feels could result in the unnecessary use of antimicrobial agents in uninfected patients. It recommends instead that adult patients suspected of being infected have their diag-

nosis confirmed by at least a positive antigen detection test prior to antimicrobial therapy (4).

Both sets of guidelines discourage pharyngeal cultures during the routine evaluation of pharyngitis in adults or for confirming negative antigen test results when test sensitivities exceed 80%. However, the IDSA guidelines leave the decision to the physician as to whether cultures should be performed instead of or in addition to antigen detection assays. Additional indications for pharyngeal cultures in adults are (i) investigations of outbreaks of GABHS disease, (ii) monitoring the appearance and spread of antimicrobial resistance, and (iii) examination for pathogens other than GABHS.

GABHS are important causes of bacteremia and skin and soft tissue infections as well. Recently appreciated is the role of GABHS as an etiologic agent of perianal dermatitis in children following swallowing or direct inoculation of infectious respiratory secretions (2, 15). Two other highly publicized GABHS diseases in recent years have been necrotizing fasciitis (“flesh-eating” bacterial disease) and streptococcal toxic shock syndrome.

This procedure describes laboratory options for detection and identification of GABHS by direct methods and by culture. The emphasis is on pharyngeal specimens, since they are often submitted specifically for culture of this organism.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

▣ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for physicians and caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

A. Specimen collection

1. Pharynx (6)
 - a. Place gentle pressure on the tongue with a tongue depressor.
 - b. Extend one or two sterile swabs (one for the antigen test and one for culture if necessary) between the tonsillar pillars and behind the uvula, avoiding the tongue, buccal mucosa, and uvula.
 - c. Sweep the swabs back and forth across the posterior pharynx, tonsillar areas, and any inflamed or exudative areas.
 - d. Do not obtain specimens if the epiglottis is inflamed, since sampling may trigger life-threatening respiratory obstruction.
2. Perianal dermatitis (cellulitis)
 - a. Cleanse the sampling area with saline, followed by two applications of 70% alcohol.
 - b. Collect an aspirate from the leading edge of the inflamed area.
 - c. Order an aerobic (routine) wound culture (*see* procedure 3.13.1)
3. Blood culture (*see* procedure 3.4.1)
4. Wound culture (*see* procedure 3.13.1)

B. Specimen transport

1. Submit swabs for GABHS culture to the laboratory as follows.
 - a. Dry in a paper envelope *or*
 - b. Moistened or immersed in transport medium
2. Label specimens with the patient's demographic information, name of person requesting the test, date of specimen collection, the specimen collection site, and the test to be performed.

C. Rejection criteria

1. Pharyngeal cultures for GABHS are not recommended for confirmation of negative antigen detection results for adults when the antigen test sensitivity exceeds 80%.
2. Do not perform Gram stains of pharyngeal specimens for diagnosis of GABHS pharyngitis, since the results are not helpful.

III. MATERIALS

A. Primary tests: antigen detection tests for GABHS

▣ **NOTE:** Many kits for detection of GABHS antigen are commercially available (10). Some of these products are Clinical Laboratory Improvement Amendments (CLIA) waived and are readily performed in physician offices. For an up-to-date list of CLIA-waived tests, please refer to the website <http://www.cms.hhs.gov/clia/waivetbl.pdf>. Almost all of the assays are based on nitrous acid extraction of group A streptococcal antigen from specimens followed by particle agglutination, staphylococcal coagglutination, EIA, immunochromatography, or optical immunoassay techniques for detection of antigen. Kits vary in their sensitiv-

ities in detection of GABHS, and reports of the same kit can differ depending on the culture media and conditions used for the comparison (11).

B. Culture

1. Inoculate one of the following.
 - a. BAP
 - b. NNA: BAP with 30 µg of neomycin per ml and 15 µg of nalidixic acid per ml (BD Diagnostic Systems, Sparks, Md.)
 - c. Selective streptococcal agar: BAP with neomycin and polymyxin B (Remel, Inc.; Hardy Diagnostics) or colistin and oxolinic acid (Remel, Inc.).
 - d. Selective group A streptococcus agar containing trimethoprim-

III. MATERIALS (continued)

sulfamethoxazole with or without colistin or crystal violet (available from most vendors)

☑ **NOTE:** Media with trimethoprim-sulfamethoxazole can be used for growth of GABHS and group B beta-hemolytic streptococci but not for group C, F, or G beta-hemolytic streptococci. Contact the vendor for information on the antimicrobial agents in their selective media, as they vary from vendor to vendor.

2. Identification methods

- a. Gram stain (procedure 3.2.1)
- b. Catalase test (procedure 3.17.10)
- c. One or more of the following
 - (1) Pyrrolidonyl- β -naphthylamide (PYR) (procedure 3.17.41)
 - (2) AccuProbe STREP A DNA probe assay for RNA (Gen-Probe Inc.)
 - (3) Latex particle agglutination or staphylococcal protein A coagglutination tests for streptococcal grouping
 - (a) Directigen (BD Diagnostic Systems)

- (b) Meritec Strep (Meridian Diagnostics)
- (c) Oxoid Strep Grouping (Oxoid)
- (d) PathoDx (Diagnostic Products Corp., Los Angeles, Calif.)
- (e) Prolex (Pro-Lab Diagnostics, Austin, Tex.)
- (f) Slidex Strep (bio-Mérieux Vitek, Hazelwood, Mo.)
- (g) Streptex (Abbott Diagnostics, Abbott Park, Ill.)

3. Other supplies needed

- a. Incubator maintained at 35°C with provision for ambient, 5 to 10% CO₂, or anaerobic incubation
- b. Disposable cards for latex particle agglutination or staphylococcal protein A coagglutination identification tests

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

A. Antigen detection tests

1. Test a positive and negative control antigen with each new lot and at the start of each work shift.

☑ **NOTE:** Use of some commercial kits, having an internal patient control, does not necessitate other daily QC. Consult the package insert.
2. Determine whether the antigen detection test is at least 80% sensitive compared to culture as a QA check.

B. Immunological identification tests

1. Test each new lot of antiserum with a corresponding positively and negatively reacting control organism prior to use and every 6 months thereafter.
2. Test each lot of extraction reagent with a known culture of GABHS to verify its ability to extract the antigen.

C. Culture media

1. Verify that culture media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
2. Perform growth checks on each new lot of selective blood agar that contains antimicrobial agents (*see below*).

Test organism	Result
<i>Proteus mirabilis</i> ATCC 12453	Partial to complete inhibition
<i>Streptococcus pyogenes</i> ATCC 19615	Growth of beta-hemolytic colonies

V. QUALITY CONTROL

(continued)

■ **NOTE:** Recently published NCCLS QC standards (19) propose the elimination of user QC for commercially prepared group A selective agars. Consult with local regulatory agencies and NCCLS documents prior to discontinuation of user QC.

V. PROCEDURE

Observe standard precautions.

A. GABHS antigen detection tests

1. Perform antigen detection tests on pharyngeal specimens to provide rapid results.
 - a. Follow each step of the manufacturer's instructions carefully.
 - b. Include control steps, as indicated by the manufacturer.
2. Confirm negative results from pediatric patients with culture, because current tests are unable to detect low numbers of GABHS in poorly collected specimens.

■ **NOTE:** Confirmation of negative test results for adult patients is generally unnecessary, unless the sensitivity of the test is less than 80%.
3. Do not confirm positive results for any patients, except during validation testing, to determine the test specificity, or to recover isolates for antimicrobial susceptibility testing (AST) (14).

B. Culture

1. Inoculation of culture media
 - a. Choose either BAP and/or one of the selective sheep blood agars

■ **NOTE:** Inoculating two swabs with both nonselective and selective media adds to the expense but will increase the sensitivity of culture (16).
 - b. Firmly roll a pharyngeal swab over one-sixth (no more) of the agar surface, and streak carefully for isolation in four quadrants to minimize overgrowth by other microorganisms. Carefully stab the agar several times with the same loop both in an area that has been streaked and in an area that has not been streaked, so as not to leave gaps, in order to improve detection of beta-hemolysis when plates are incubated aerobically (Fig. 3.11.8–1).
2. Incubate culture plates at 35 to 37°C for 48 h under one of the following conditions.
 - a. Aerobic with ambient air for BAP with agar stabs
 - b. Aerobic with 5 to 10% CO₂ for selective streptococcal agar with agar stabs (*This method is not acceptable for BAP without antimicrobials.*)
 - c. Anaerobic for either BAP or selective agars (3)

■ **NOTE:** Each of the methods described above has good sensitivity; in comparative studies no one method was consistently better for detection of GABHS (14, 16). However, aerobic incubation in CO₂ is helpful for isolating pathogens other than GABHS, such as group C and G streptococci. Incubation for 48 h consistently increases the yield of positive cultures by 5 to 46% depending on the study (14). Prolonged incubation is most important if selective media, which may somewhat inhibit the growth of GABHS, or if anaerobic incubation is used.
3. Examination of culture media (Fig. 3.11.8–2)
 - a. Observe culture media after 24 (and 48) h for small translucent or transparent colonies that are dome shaped, have an entire edge, and are surrounded by a relatively wide zone of complete (beta-) hemolysis.
 - b. Perform a catalase test on one or two colonies. Catalase-positive colonies are not streptococci.
 - c. Perform a Gram stain on catalase-negative colonies. Organisms other than gram-positive cocci in pairs or chains are not streptococci.

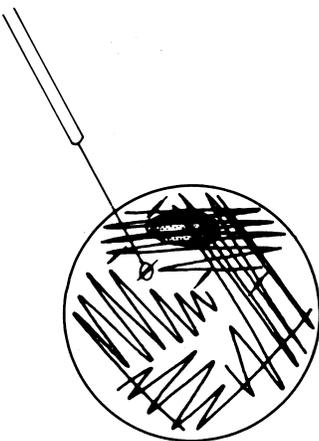

Figure 3.11.8–1 Method of streaking plate for throat culture with stabs in agar.

Figure 3.11.8-2 Algorithm for laboratory diagnosis of streptococcal pharyngitis.

V. PROCEDURE *(continued)*

4. Confirmatory tests

a. Confirm beta-hemolytic, catalase-negative, gram-positive cocci in pairs and chains as *Streptococcus pyogenes* by *one* of the following.

- (1) Positive PYR test (18). For specimens from nonpharyngeal sites, confirm with a negative bile-esculin or esculin test (procedure 3.17.5).
- (2) Positive result for group A streptococcal antigen with an immunological grouping test
- (3) Positive DNA probe result

▣ **NOTE:** The presence of a zone of growth inhibition around a bacitracin (Taxo A) disk to identify streptococci as GABHS is not reliable (20).

b. If a catalase-negative, beta-hemolytic isolate is PYR negative, test it with immunological grouping reagents to identify it as group B, C, F, or G. Do not report GABHS that are PYR negative as *S. pyogenes* because they belong to the *Streptococcus anginosus* group of normal respiratory microbiota.

V. PROCEDURE (*continued*)

- c. If a colony Gram stain reveals gram-positive bacilli, perform the CAMP test (procedure 3.17.8). *A. haemolyticum* is catalase negative and reverse-CAMP test positive and forms slowly growing beta-hemolytic colonies on nonselective or selective sheep blood agar.
5. Do not perform AST as a routine, since all GABHS continue to exhibit penicillin susceptibility. Save positive culture plates (preferably for 7 days) in case AST is needed for determination of erythromycin or clindamycin resistance. See section 5 and reference 17 for methods.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS****A. Negative results from pharyngeal specimens**

1. Report the antigen detection result as “Negative for group A streptococci by antigen detection assay.”
2. Report the culture result as “No pathogenic streptococci isolated” if there are no beta-hemolytic colonies or if beta-hemolytic colonies are identified as group A (PYR negative), B, D, or F.

B. Positive results from pharyngeal specimens

1. Report the antigen detection result as “Positive for group A streptococcus by direct antigen test.”
2. Report the culture result as “Group A beta-hemolytic streptococcus (or *S. pyogenes*) isolated,” including enumeration (*see* procedure 3.3.2 for reporting enumeration) if *S. pyogenes* is identified.
3. If *A. haemolyticum* is identified, report the culture as positive for this microorganism.
4. If group C or G beta-hemolytic streptococci are identified, report or do not report according to the preferences of the ordering physician.

VII. INTERPRETATION

- A. A positive pharyngeal culture for GABHS indicates the presence of *S. pyogenes* but does not distinguish between infection and colonization (12, 13).
- B. All *S. pyogenes* organisms are susceptible to penicillin (the antimicrobial agent of choice for treating infection), negating the need for susceptibility testing. If testing is performed, penicillin resistance must be confirmed by a reference laboratory (17). For penicillin-allergic patients, erythromycin is the therapeutic agent of choice. Recurrent tonsillitis may require surgery and treatment with clindamycin (7).
- C. GABHS can be resistant to erythromycin and clindamycin; in some geographic areas the incidence is high (20), and testing may be indicated when penicillin therapy is contraindicated.

VIII. LIMITATIONS

- A. Falsely negative pharyngeal cultures can result from overgrowth of cultures by normal oral microorganisms or from the lack of beta-hemolysis in cultures incubated aerobically.
- B. Falsely positive pharyngeal culture reports can result from misinterpretation of identification tests. PYR-positive colonies may be enterococci, which are rarely beta-hemolytic and uncommonly found in the pharynx. Isolates from rectal swabs should be identified by immunological methods or the combination of PYR and esculin hydrolysis tests.
- C. PYR-negative GABHS are not *S. pyogenes* but members of the *S. anginosus* group, which is not a cause of pharyngitis.
- D. Group C and G beta-hemolytic streptococci can cause pharyngitis and fever, but they do not place patients at risk of acute rheumatic fever.

3.11.9

Nasal Sinus Cultures

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Acute rhinosinusitis, an infection of one or both of the paranasal sinuses, is among the most common health problems (6). It is manifest by an inflammatory response of the mucous membranes of the nasal cavity, seen as edema and hypersecretion of mucus following a common upper respiratory viral infection (5, 8). The disease is mild but results in considerable medical cost to relieve facial pain and swelling, nasal discharge, fatigue, and symptoms related to the inflammatory process (8). Therapies to alleviate the symptoms of congestion and improve nasal drainage are recommended early in the viral infection and can prevent progression to bacterial infection (7). Antimicrobial agents are important, if the disease progresses beyond 7 to 10 days, to reduce time to recovery, aid

in symptom resolution, and prevent complications from progression of the disease (3, 7). Antimicrobial therapy is usually targeted to the most common agents, *Streptococcus pneumoniae*, *Haemophilus influenzae*, *Moraxella catarrhalis*, and *Streptococcus pyogenes* (2, 3). Some authors include anaerobes and *Staphylococcus aureus* as possible agents of disease, but these bacteria are less often associated with acute inflammation (11). In 40% of cases, no agent is cultured, which has suggested that *Mycoplasma pneumoniae* or *Chlamydia pneumoniae* is involved (5). Sinus infections can become chronic, although the etiology of this presentation has been controversial. For chronic infections, particularly in diabetic patients and

in tropical countries, fungi can invade the sinuses and cause progressive, life-threatening infections. Anaerobes have also been implicated, and therapy usually includes agents, such as metronidazole or clindamycin, which are active against anaerobes (1).

This procedure deals only with invasively collected specimens for diagnosis of acute sinusitis. Refer to other procedures in this handbook for culture for viruses, fungi, and mycobacteria and for nasal carriage of contagious pathogens or *Bordetella pertussis* (see Table 3.11.1–1). Collection of specimens from patients with sinusitis is performed by otolaryngologists who perform nasal endoscopy or sinus puncture and aspiration.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

▣ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for physicians and caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

- A. Specimen collection is performed by an otolaryngologist.
 1. Rigid endoscopy (11)
 - a. Provide patient with an intranasal decongestant and then a topical anesthetic.
 - b. Identify the middle meatus adjacent to the maxillary sinus ostium ipsilateral to the side to be aspirated.
 - c. Collect drainage from the middle meatus with a small swab on a wire.
 2. Maxillary sinus puncture and aspiration
 - a. Clean the anterior nares with antiseptic solution.
 - b. Apply topical anesthetic.
 - c. Puncture the maxillary antrum and aspirate secretions with a needle and syringe.
 - d. If no material is aspirated, irrigate with 2 ml of nonbacteriostatic saline.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- B. Specimen transport
 1. Submission to the laboratory
 - a. Submit swabs in tube of transport medium or in BD Culturette EZ.
 - b. Submit aspirates in the original syringe with a Luer-Lok to prevent leakage.
 2. Label specimens with demographic information, date and time of collection, and site of collection.
 3. List the diagnosis and whether it is chronic or acute.
 4. Order anaerobic culture if appropriate to the diagnosis.
- C. Rejection criteria
 1. Reject requests for routine bacterial culture of nasal washes and nasal aspirates not collected by otolaryngologists as inappropriate and lacking specificity to diagnose either sinusitis or lower respiratory disease (4, 10). These specimens are acceptable for *B. pertussis* and for viral culture.
 2. Nasal swabs not collected by otolaryngologists are acceptable only for specific culture (e.g., *B. pertussis* or *Corynebacterium diphtheriae*) or staphylococcal carriage, which should be indicated along with the culture request. They are unacceptable to diagnose acute sinusitis (4, 10). They may, however, be acceptable for diagnosis of fungal invasion of the sinuses (see section 8).

III. MATERIALS

- | | |
|---|--|
| <ul style="list-style-type: none"> A. Primary media <ol style="list-style-type: none"> 1. BAP 2. CHOC 3. Anaerobic plate media (on request). See section 4. B. Identification methods <ol style="list-style-type: none"> 1. Gram stain (procedure 3.2.1) 2. Refer to procedure 3.3.2 for identification of the common agents of sinusitis. | <ul style="list-style-type: none"> C. Other supplies <ol style="list-style-type: none"> 1. Incubator at 35°C with 5% CO₂ or a CO₂-generating system 2. Inoculating sticks or loops 3. Petri dishes and filter paper |
|---|--|

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
- B. Test each lot of CHOC per procedure 3.3.1.

V. PROCEDURE

Observe standard precautions.

- A. Inoculation
 1. Inoculate specimen to BAP and CHOC.
 2. Firmly roll swab over one-sixth (no more) of the agar surface, or deposit 3 or 4 drops of fluid onto agar. Streak carefully for isolation in four quadrants to minimize overgrowth by other microorganisms.
- B. Incubation
 1. Incubate plate at 35 to 37°C in 5% CO₂ for a minimum of 48 h.
 2. For special requests in cases of chronic infections, extend incubation to 4 days.
- C. Gram stain
 1. Perform a gram stain from the swab or fluid (procedure 3.2.1)
 2. Note the presence of inflammatory cells and bacteria.

V. PROCEDURE (*continued*)**D. Culture examination**

1. Observe for growth of *S. pneumoniae*, *H. influenzae*, *M. catarrhalis*, and *S. pyogenes*.
 - a. Refer to Table 3.3.2–5 for rapid identification tests.
 - b. *S. pneumoniae*
 - (1) Confirm bile solubility with optochin disk, if questionable or resistant.
 - (2) Perform antimicrobial susceptibility testing (AST), using standardized methods (9), per laboratory protocol and physician policy.
 - c. Perform beta-lactamase test on *H. influenzae*.
 - d. Since greater than 90% of *M. catarrhalis* organisms are beta-lactamase positive, testing is not helpful for treatment.
2. Observe plates at 24 and 48 h for growth of enteric gram-negative rods and *S. aureus*.
 - a. These organisms are usually considered contaminants in sinus specimens and are not identified unless they are the predominant species in the culture.
 - b. Perform AST only if the Gram stain suggests that they are involved in an inflammatory process and no other pathogens are isolated.
 - **NOTE:** Normal skin microbiota (coagulase-negative staphylococci and corynebacteria) are not identified to the species level.
3. Identify any molds that are present. Yeasts need not be identified to the species level, as they have not been implicated in sinusitis.
4. Identify any other predominant organism that is not part of the normal respiratory microbiota.
5. If anaerobic cultures were ordered, refer to section 4 for identification; gram-positive anaerobes are more likely to be present in sinus infections than gram-negative rods.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. Gram stain: report smear as indicated in procedure 3.2.1.
- B. Negative culture results
 1. Report preliminary and final reports as “No growth.”
 2. Indicate the number of days the culture was incubated.
- C. Positive results
 1. Report all pathogens and susceptibility tests performed, using preliminary reports as indicated in procedure 3.3.2 and NCCLS guidelines (9).
 2. Indicate presence of aerobic skin microbiota, without species identification.
 3. If the culture is mixed, with no predominating pathogen, indicate the genera and do not report further, e.g., “Mixed microbiota present, consisting of three morphologies of gram-negative rods and skin bacteria.”
 - **NOTE:** Mixed microbiota without a predominant pathogen generally indicates that the specimen was not collected appropriately. Exception is made if the Gram stain demonstrates inflammation by the presence of PMNs.

VII. INTERPRETATION

- A. A positive culture with *S. pneumoniae*, *H. influenzae*, *M. catarrhalis*, and *S. pyogenes* generally indicates infection with that organism.
- B. A positive culture with a predominant gram-negative rod or *S. aureus* may or may not indicate infection with that agent.
- C. A negative culture cannot rule out sinusitis. In fact, often a pathogen is not isolated.

VII. INTERPRETATION

(continued)

- D.** Most physicians agree on the benefits of antimicrobial therapy for acute sinus infections. Generally a beta-lactam agent, such as amoxicillin, amoxicillin-clavulanate, or a cephalosporin, is used, negating the need for culture (3). However, for persistent chronic infection in the face of therapy, cultural evaluation and antimicrobial profiling are indicated.

VIII. LIMITATIONS

- A.** Inaccurate culture reporting can result from contamination of the specimen with normal oral microbiota.
- B.** False-negative cultures can be caused by delays in processing.
- C.** False-positive cultures can be caused by overinterpretation of the culture results.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Urinary tract infections (UTI) account for seven million visits to physicians' offices and over one million hospital admissions per year. Epidemiologic studies by E. H. Kass (8) have shown that bacterial counts of $\geq 10^5$ CFU/ml for a pure culture of gram-negative bacilli were found to be associated with acute bacterial infections of the urinary tract. In females with dysuria and acute UTI, other investigators reported that $>10^2$ CFU/ml can be significant (6, 7, 15). For infants and catheterized patients, low counts also have been shown to be significant (4, 16, 17). Because of the importance of colony counts for infection, urine cultures are always performed with an accompanying colony count (2).

Urine is normally a sterile body fluid. However, it is easily contaminated with

microbiota from the perineum, prostate, urethra, or vagina. The microbiologist must provide detailed instructions to ensure proper specimen collection, preservation, labeling, and transport of urine for culture.

The etiologic agents of urinary tract infection are generally limited to the patient's own intestinal microbiota, with *Escherichia coli*, *Enterococcus* spp., *Klebsiella-Enterobacter* spp., and *Proteus* spp. representing a majority of isolates from both hospitalized patients and outpatients. Refer to Table 3.12-1 for a list of usual microbiota of contaminated and infected urine.

Several terms may be encountered with the submission of specimens for culture. These are defined in Table 3.12-2. Since the significance of bacterial counts depends on the disease presentation, different criteria are often used to determine if the count of bacteria in the urine is significant and requires treatment. Because the laboratory rarely knows details other than patient age and sex and type of specimen, the significance of bacteria in the urine is usually based only on these criteria. Pyuria, in addition to bacteriuria, is also an important factor in establishing the presence of a UTI (see procedure 3.2.3 and Appendix 3.12-1).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

▣ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for physicians and other caregivers. It is the responsibility of the laboratory director or designee to educate physicians and other caregivers on proper specimen collection.

Observe standard precautions.

A. Specimen collection

1. Clean-voided midstream urine collection

a. Preparation

▣ **NOTE:** Several studies with both symptomatic and asymptomatic women found that cleansing did not decrease contamination of specimens (9). Cleansing of the male genitalia also has not been shown to improve the detection of bacteriuria (11). No difference in contamination rates was seen when nonsterile containers are used. Should it be necessary to provide collection instructions for hospitalized patients, the following instructions are helpful.

Table 3.12–1 Urinary microbiota^a

Microbiota	Organism	Extent of workup if count is appropriate per Table 3.12–4
Urogenital	Viridans group streptococci, <i>Neisseria</i> spp., diphtheroids, <i>Lactobacillus</i> spp., anaerobes	Report as urogenital microbiota.
Skin	Diphtheroids, <i>Staphylococcus</i> spp.	Report as skin or with urogenital microbiota unless present in amounts >10-fold more than other microbiota. Then treat as uropathogen.
Uropathogens	Gram-negative bacilli <i>Staphylococcus</i>	ID to species level and AST ID and AST of <i>S. aureus</i> ; ID of <i>Staphylococcus saprophyticus</i> with novobiocin disk for females of childbearing age; AST generally not needed for <i>S. saprophyticus</i> or other coagulase-negative staphylococci.
	Yeasts	ID of <i>C. albicans</i> and <i>Candida glabrata</i> ; ID of others to species level only on request
	Beta-hemolytic <i>Streptococcus</i> <i>Enterococcus</i> spp.	ID, especially of group B in women in childbearing years Check for VRE on inpatients; ID to species level and AST only if VRE and on request
	<i>G. vaginalis</i>	ID only if number is 10 times greater than that of all other microbiota
	<i>Aerococcus urinae</i>	ID only if number is 10 times greater than that of all other microbiota (20) (see Table 3.18.1–4b for tests to identify)
	<i>Corynebacterium</i> (urease positive)	ID and AST, if number is 10 times greater than that of all other microbiota and $\geq 100,000$ CFU.

^a Abbreviations: AST, antimicrobial susceptibility testing; ID, identification; VRE, vancomycin-resistant enterococcus.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- (1) Females
 - ▣ **NOTE:** Collection of midstream urine specimens should be avoided during menses.
 - (a) While the labia are held apart with the aid of a pair of sponges, wash the vulva thoroughly from front to back with two successive cotton pledgets or sponges soaked in soap. Special attention should be paid to the urethral meatus (benzalkonium or hexachlorophene should not be used, as a single drop of residual can sterilize the urine before the specimen reaches the laboratory).
 - (b) Then with two additional sponges and sterile water or saline, rinse the vulva.
- (2) Circumcised males: no preparation for midstream specimen.
- (3) Uncircumcised males: the process is similar to that described above for females.
 - (a) Retract the foreskin, and wash the glans penis thoroughly with two successive cotton pledgets or sponges soaked in soap, paying special attention to the urethral meatus.
 - (b) Then rinse the glans with additional successive pledgets with sterile water or saline.

Table 3.12–2 Definitions

Term	Definition
Bacteriuria	Presence of uropathogenic bacteria in the urine
Cystitis	Inflammation of the bladder
Cystostomy	Surgical procedure of inserting tube directly in the bladder through the suprapubic area to drain urine
Dysuria	Pain or burning on urination, a common complaint on presentation of UTI
Nephrostomy	Surgical procedure leaving tubing directly in the kidney
Prostatitis	Infection of the prostate gland; patient may present with fever or be asymptomatic
Pyelonephritis	Acute infection of the kidney and renal pelvis usually with fever, chills, and flank pain; chronic; may be without symptoms
Pyuria	Urine WBC count of 8–10/μl (or >5/high-power field in a conventional urinalysis), which correlates with WBC excretion rate of >400,000 WBC/h)
Urethritis	Inflammation of the urethra; may be caused by sexually transmitted diseases or uropathogens
Urosepsis	UTI with accompanying bacteremia
Urostomy	Surgical procedure leaving an external opening in the abdominal wall, usually made of intestine, for the egress of urine
Suprapubic aspirate	Specimen of urine collected with a syringe and needle inserted directly through the skin into the bladder
Straight catheter urine	Specimen collected by the insertion of a catheter into the urethra
Uncomplicated UTI	Infection in a patient with structurally and functionally normal urinary tract
Complicated UTI	Infection in a patient with functional abnormalities or other disease that reduces the efficacy of antimicrobial therapy
Asymptomatic UTI	Infection with >10 ⁵ bacteria/ml with no symptoms of infection

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- b. Have the patient collect voided urine directly into a disposable leakproof container, instructing the patient to not halt and restart the urinary stream for a “midstream” collection but preferably move the container into the path of the already voiding urine.

☑ **NOTE:** Never collect urine from a bedpan or urinal.

2. Catheter urine

- a. Using a needle and syringe, collect urine through the catheter port, after cleaning with alcohol. Alternatively, collect the sample directly into a Vacutainer tube without anticoagulant, using a Vacutainer holder and needle. *Do not send urine obtained from a catheter bag.*
- b. A straight catheter (in and out) is used by a physician or trained health care worker (HCW) to obtain urine directly from the bladder.
 - (1) This procedure must be carried out with aseptic technique, to avoid the risk of introducing microorganisms into the bladder.
 - (2) Discard the initial 15 to 30 ml of urine and submit the next flow of urine for culture.

3. Ileal conduit

- a. Remove the external device.
- b. Cleanse the stoma with 70% alcohol followed by iodine.
- c. Remove the iodine with alcohol.
- d. Insert a double catheter into the cleansed stoma, to a depth beyond the fascial level, and collect the urine.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

4. Urine collection by suprapubic needle aspiration directly into the bladder is performed by a physician or trained HCW. This method is the preferred method for infants, for patients for whom the interpretation of results of voided urine is difficult, and when anaerobic bacteria are suspected as the cause of infection.
 - a. Bladder should be full and palpable before aspiration.
 - b. Shave and disinfect the skin over the bladder.
 - c. Make a small lance wound through the epidermis above the symphysis pubis.
 - d. Aspirate using a needle and syringe. Submit in syringe or cup.
 5. Prostatic massage is used primarily to diagnose acute or chronic prostatitis. For both diseases, gram-negative enteric organisms are the most frequently isolated pathogens. *Neisseria gonorrhoeae* is found infrequently but is sometimes implicated in acute prostatitis. Fluid can also be used to demonstrate *Trichomonas* in males who act as vectors.
 - a. Perform a digital massage through the rectum.
 - b. Collect the specimen in a sterile tube or on a sterile swab.
 - c. Label clearly (e.g., “EPS” [for expressed prostatic secretions] or “VB3” [for voided bladder—third urine collection]) for proper culturing.
 6. Cystoscopy is a bilateral ureteral catheterization to determine the site of infection in the urinary tract. This procedure is usually performed in specially designated areas such as operating rooms or specialty clinics.
 - a. Clean the urethral area (and vaginal vestibule in females) with soapy water, and rinse the area well with water.
 - b. Insert a cystoscope (obturator in place) into the bladder.
 - c. With sterile technique, collect approximately 5 to 10 ml of urine from open stopcock into a sterile container.
 - d. Label this sample “CB,” for catheterized bladder urine, and refrigerate it. Then irrigate the bladder. (Use sterile nonbacteriostatic 0.85% NaCl to irrigate the bladder.)
 - e. After irrigation of the bladder and insertion of the ureteral catheters, collect irrigating fluid passing from the bladder through the ureteral catheters by holding the ends of both catheters over an opened sterile container.
 - f. Label this sample “WB,” for washed bladder urine, and refrigerate it.
 - g. Pass the ureteral catheters to each midureter or renal pelvis without introducing additional irrigating fluid. Open both stopcocks of the cystoscope to empty the bladder.
 - h. Discard the first 5 to 10 ml of urine from each ureteral catheter.
 - i. Collect four consecutive paired cultures (5 to 10 ml each) directly into opened sterile containers.
 - j. Label these specimens “LK-1,” “RK-1,” “LK-2,” and “RK-2” (LK for left kidney and RK for right kidney). Submit all samples for culture.
- B. Timing of specimen collection**
1. Obtain early-morning specimens whenever possible. Allowing urine to remain in the bladder overnight or for at least 4 h will decrease the number of false-negative results.
 2. Do not force fluids in order to have the patient void urine. Excessive fluid intake will dilute the urine and may decrease the colony count to $<10^5$ CFU/ml.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

C. Specimen transport

1. Transport urine to the laboratory after collection or, if urine cannot be delivered to the laboratory within 2 h after collection, refrigerate for up to 24 h both during the holding period and during transport. *Do not freeze.*
2. If refrigeration is not possible and specimens are delayed in transport, collect in transport tubes with preservatives.
 - a. Examples: 0.5 ml of freeze-dried boric acid-glycerol or boric acid-sodium formate (B-D urine tubes, Becton Dickinson, Rutherford, N.J.).
 - b. Place at least 3 ml of urine into the transport tube to avoid an inhibiting or diluting effect on the microorganisms.

D. Specimen labeling and request submission

1. Label the urine container with demographic information of the patient and the time of collection. Using the laboratory's protocol, ensure that the collection method is communicated to the laboratory.
2. Be alert to the fact that the person ordering the test may desire a Gram stain, may request only a colony count screen without preliminary identification, or may request omission of antimicrobial susceptibility testing (AST) in cases of uncomplicated UTI. Perform only those tests ordered.

■ **NOTE:** Fungal cultures of urine usually are requests to detect the presence of yeasts. It is rarely necessary to inoculate these to selective fungal media with centrifugation and prolonged incubation. Notify the physician that yeast cultures are included as part of the routine urine culture and yeasts will be cultured and reported if found. However, when yeast cultures are requested, culture at least 0.01 ml per plate and hold cultures for 48 to 72 h to detect yeasts in low numbers.

E. Rejection criteria:

1. Request a repeat urine specimen when there is no evidence of refrigeration and the specimen is >2 h old.
2. Request a repeat specimen or obtain the information when the collection time and method of collection have not been provided.
3. Reject 24-h urine collections.
4. Reject urine specimens obtained with the same collection method within 48 h of receipt of first specimen. Call this a duplicate specimen.
5. For infants, a voided specimen provides misleading information; a catheterized specimen should be collected. Institute a policy to discourage submission of voided or bagged specimens for culture.
6. Reject Foley catheter tips as unacceptable for culture; they are unsuitable for the diagnosis of urinary infection (3).
7. Reject urine from the bag of a catheterized patient.
8. Reject specimens that arrive in leaky containers.
9. Except for suprapubic bladder aspirates, reject specimen requests for anaerobic culture.
10. If an improperly collected, transported, or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised and who was notified. Generally, voided urine from inpatients is easily recollected.
11. For rapid urine screens for voided urine specimens from outpatients to eliminate those that do not warrant culture, see Appendix 3.12-2 and reference 12.

III. MATERIALS

A. Media

1. BAP
2. MAC or EMB
3. Columbia colistin-nalidixic acid agar (CNA) or phenylethyl alcohol agar (PEA) (optional)
 - ☑ **NOTE:** The advantage of adding CNA to the culture is that it allows detection of gram-positive microbiota when overgrown with gram-negative microbiota. In addition, the Columbia base allows growth of some bacteria that are inhibited on tryptic soy-based agars. The added expense may allow more accurate and often less time-consuming evaluation of cultures.
4. CHOC: use for surgically collected kidney urine or specimens collected by cystoscopy or after prostatic massage. These can be labeled "EPS" or "VB3."
5. Other media: see Table 3.12-3 for commercial systems. These systems work best for specimens from outpatients or those likely to have only one pathogen. When mixed microbiota are expected (e.g., specimens from patients with indwelling catheters or from geriatric pa-

tients), these systems are contraindicated.

B. Stain reagents

See Gram stain procedure (procedure 3.2.1).

C. Supplies

1. Loop method
 - a. Use either platinum or sterile plastic disposable loops.
 - b. Sizes
 - (1) 0.001-ml (1- μ l) loop to detect colony counts greater than 1,000 CFU/ml
 - (2) 0.01-ml (10- μ l) loop to detect colony counts between 100 and 1,000 CFU/ml.
 - (3) Disposable loops are color coded, according to volume delivery.
2. Pipettor method: Sterile pipette tips and pipettor to deliver 10 or 1 μ l.
3. Sterile bent glass or plastic disposable sterile rod or "spreader," if desired, to spread inoculum (Excel Scientific, Wrightwood, Calif., [760] 249-6371).
4. For commercial systems in Table 3.12-3, follow manufacturers instructions.

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Unless calibrated pipettors are used for the inoculum and spreaders are used to spread the inoculum, colony counts are only approximations and can be off by as much as a hundredfold (1). Especially at higher counts, one colony does not represent 1 CFU, nor is this accuracy necessary for urine culturing. Choose the method from Fig. 3.12-1 that is most efficient, depending on the number of specimens received and the expertise of the staff. When the method of colony count has been decided, validate the method with the following protocol.
 1. Make a 0.5 McFarland suspension of *E. coli* ATCC 25922, *Pseudomonas aeruginosa* ATCC 27853, and *Enterococcus faecalis* ATCC 29212 in broth or saline.
 2. Using a sterile pipette tip and calibrated pipettor, dilute each 1:100 by placing 0.05 ml (50 μ l) of culture into 5 ml of saline. Vortex. This should represent 10^6 CFU/ml.
 3. Prepare a 1:10 dilution from the 1:100 dilution by inoculating 0.5 ml of suspension to 4.5 ml of saline (equals 10^5 CFU/ml). Vortex and repeat to prepare two more 1:10 dilutions.
 4. Label the dilutions "10⁶," "10⁵," "10⁴," and "10³," respectively, beginning with the 1:100 dilution (the labeling may have to be adjusted after the final counts are calculated from the growth).
 5. Inoculate each dilution to a BAP by the chosen colony count method for use in the laboratory, using both the 0.01- and 0.001-ml loops or pipettes. Label the plates with organism name, the expected CFU per milliliter (10^6 , 10^5 , 10^4 , and 10^3), and the dilution used (10^{-2} and 10^{-3} for 0.01 and 0.001 ml, respectively).

Table 3.12–3 Summary of bacteriological culture systems^a

Culture system	Principle	Comment(s)
Bactercult (Carter-Wallace/Wampole Division, Cranbury, N.J.)	Sterile, disposable tube coated with culture medium; contains phenol red indicator for presumptive ID of common uropathogens	Colonies counted
Bullseye Urine Plate (HealthLink Diagnostics, Jacksonville, Fla.)	Five-chambered plate containing media for isolation and identification of common uropathogens and their AST patterns	Colonies counted; direct AST
CPS ID 2 (bioMérieux Vitek, Inc., Hazelwood, Mo.)	Enumeration and presumptive ID of common urinary pathogens	Identifies <i>E. coli</i> , <i>Proteus mirabilis</i> , <i>Enterococcus</i> spp., and indole-positive <i>Proteus</i> ; presumptive ID of <i>Klebsiella pneumoniae</i> , <i>P. aeruginosa</i> , <i>S. aureus</i> , <i>S. agalactiae</i> , and <i>Candida</i> spp.
Diaslide (Diatech Diagnostics Inc., Boston, Mass.)	Transparent hinged plastic casing contains CLED and MAC for detection and presumptive identification of common UTI pathogens	Growth is compared to reference photographs for quantitation; morphology and color determine presumptive ID.
DIP N COUNT (Starplex Scientific, Etobicoke, Ontario, Canada)	Paddle contains CLED and MAC or EMB	Colonies are compared to a color density chart; color chart is used for ID.
Rainbow (Biolog, Inc., Hayward, Calif.)	Rainbow agar CP-8 used with eight confirmation spot tests for ID of eight microorganisms causing UTI; medium contains chromogenic substrates which color microorganisms	Interpretation may occur within 3 to 6 h for rapidly growing organisms.
URI-CHECK (Troy Biologicals, Inc., Troy, Mich.)	Dipslide culture for the enumeration and ID of uropathogens; dipslide contains CLED and MAC or EMB; similar to DIP N COUNT	Growth density is compared to chart.
Uri-Kit/Uri-Three (Culture Kits Inc., Norwich, N.Y.)	Agar plate systems used to detect common uropathogens: Uri-Kit is plastic hinged case containing CLED medium; Uri-Three triplate contains BAP and MAC and CLED	Growth density is compared to a colony density chart.
Uricult Trio (Orion Diagnostica, Espoo, Finland)	Three-medium dipslide containing CLED, MAC, and a β -glucuronidase substrate for enumeration of microorganisms and presumptive ID of <i>E. coli</i>	<i>E. coli</i> appears as brown colonies.

^a From reference 2. Abbreviations: ID, identification; CLED, cystine lactose electrolyte-deficient agar.

IV. QUALITY CONTROL (continued)

- Also inoculate 0.05 ml (50 μ l) of each of the last three 1:10 dilutions to a BAP, using a sterile pipette tip and calibrated pipettor. Spread these plates with a spreader for accurate colony counting. Label these plates with the organism names, “10⁵,” “10⁴,” or “10³,” and the words “1:20 dil.” Do this in duplicate.

■ **NOTE:** Spreading with a loop will not give an accurate count.

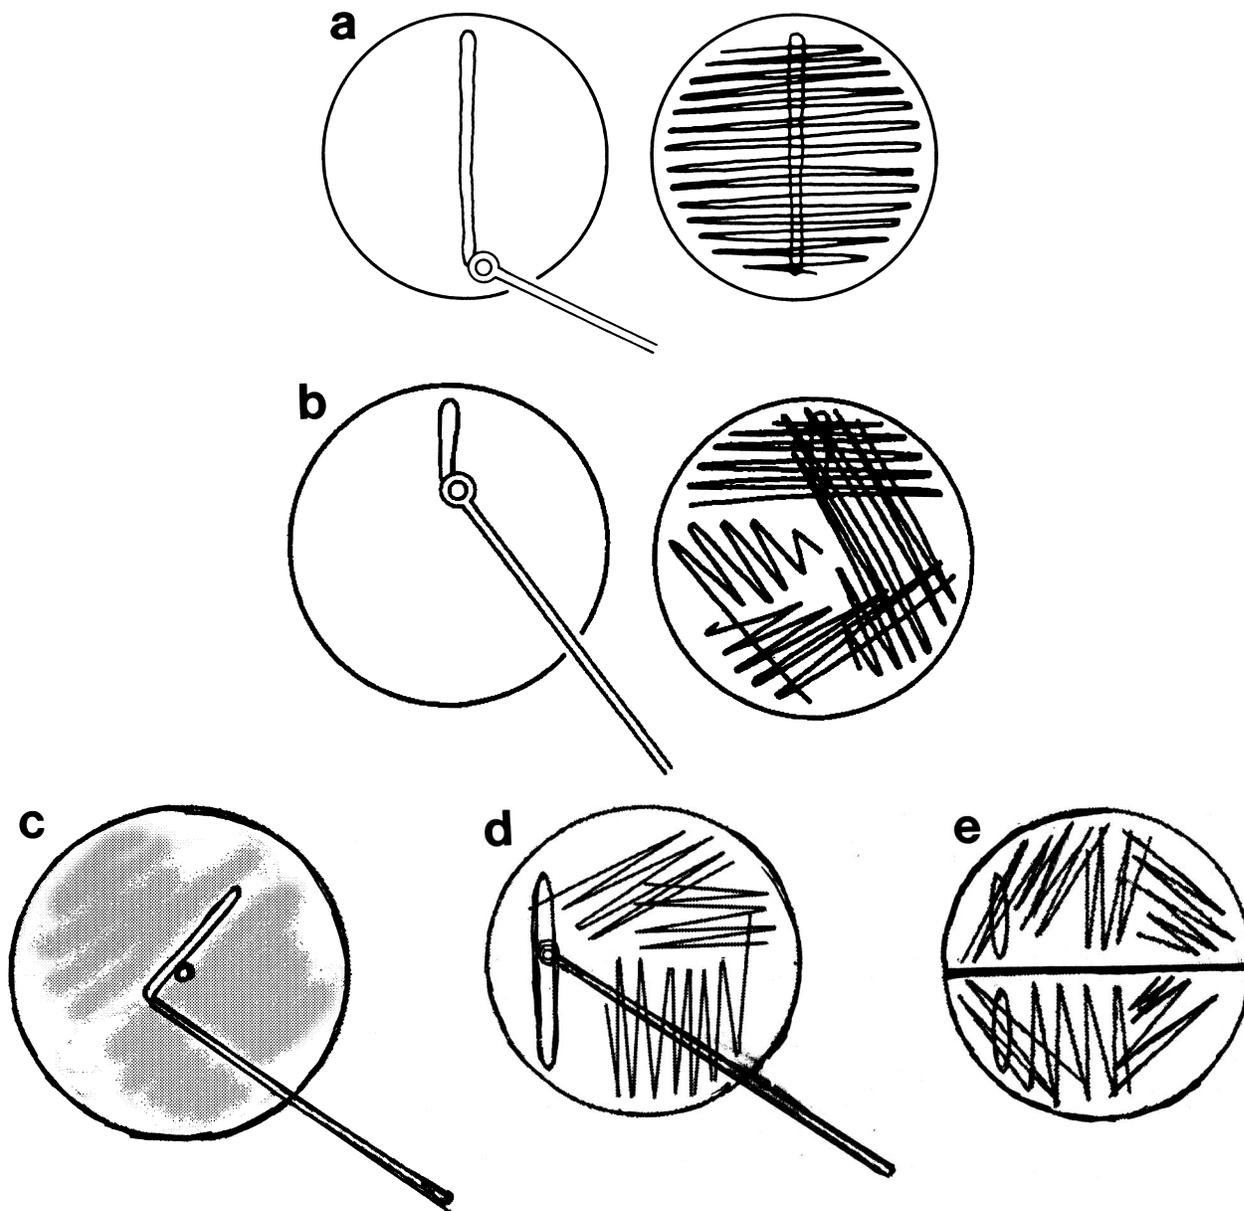

Figure 3.12-1 (a) Method of streaking urine for colony count using a 0.001-ml loop; (b) method of streaking urine for colony count using either a 0.01- or 0.001-ml loop; (c) spreader method of streaking urine for colony count after inoculation with either a 0.01- or 0.001-ml volume; (d) method of streaking 0.01 ml of urine using drip method for count and quadrant streaking for isolation; (e) MAC-CNA biplate with 0.01 ml of urine streaked in quadrants (EMB and PEA are other options).

IV. QUALITY CONTROL (continued)

7. Incubate plates for 18 h, and find the lowest dilution made with the 50- μ l pipette (1:20 dilution) that has 30 to 300 colonies. Multiply the count by 20 to determine the CFU per milliliter in that dilution of the culture. Repeat with the duplicate plate of that dilution and determine the average count of the two plates. Use this accurate count to adjust the final counts for each of the four dilutions (10^6 , 10^5 , 10^4 , and 10^3) based on this calculation.

IV. QUALITY CONTROL (continued)

- Example:** If the 1:20 dilution of the 10^4 plates has an average of 50 colonies, the true count is 50×20 , or 10^3 . All plates counts should then be reduced by a factor of 10 (e.g., the 10^4 is 10^3 , the 10^3 is 10^2).
8. Relabel each of the plates inoculated by the urine count method, to match the actual counts determined by the calibrated method.
 9. Display plates for the laboratory staff to educate them on the appearance of each colony count. Photographs can be helpful. Prepare definitions of colony counts, using the appearance of each plate and enter as part of this procedure.

Example: “ 10^5 CFU/ml shows confluent growth in the initial drop of urine with the 0.01-ml inoculum but shows approximately 50 colonies with the 0.001- μ l loop.”
 - B. Inspect nondisposable calibrated loops regularly to confirm that they remain round and are free of bends, dents, corrosion, or incinerated material. Refer to Appendix 3.12–3 for procedures to QC microbiological loops.
 - C. For disposable loops, check for certificate of count validation from the manufacturer with each lot. Verify calibration for each of the first few lots when changing manufacturers, by following Appendix 3.12–3.
 - D. Calibrate pipettors at regular intervals, if used (*see* Appendix 3.12–4).
 - E. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.

V. PROCEDURE

Observe standard precautions.

A. Microscopic and other direct methods

■ **NOTE:** The Gram stain is useful in rapidly determining the type and count of bacteria and cells in urine and should be performed on request (14, 19). It is particularly helpful if results can be made available while the patient is in the clinic. For inpatients, the urine Gram stain can help diagnose the cause of sepsis before blood cultures are positive.

1. Gram stain: refer to procedure 3.2.1.
 - a. Place 10 μ l of well-mixed, *uncentrifuged* urine onto a glass slide, and allow it to air dry without spreading. Fix with methanol.
 - b. Determine the number of organisms per oil immersion field. Each bacterium seen corresponds to a count of 10^5 /ml of urine (2).
 - c. The presence of many squamous epithelial cells and different microbial morphotypes suggests contamination.
2. Detection of pyuria

■ **NOTE:** Pyuria with a WBC count of $>10/\mu$ l (or >5 per high-power field [HPF] in a conventional urinalysis) has a specificity of 90% for predicting catheter-associated UTI with greater than 10^5 CFU/ml but a sensitivity of only 37% (18).

 - a. Detect by either Gram stain or urinalysis (procedure 3.2.3), from examination of freshly collected uncentrifuged urine.
 - b. Use enhanced urinalysis for pediatric patients less than 2 years old. Place uncentrifuged urine in a hemacytometer and count WBCs (5, 13, 14). This method is reported to have a sensitivity of 84% and specificity of 90% for infants (10).
 - c. For commercial methods, see Appendix 3.12–1 and reference 13.

V. PROCEDURE (*continued*)**B. Culture methods**

1. For voided urine specimens and those from indwelling catheters, culture at least 0.001 ml. For other urine specimens, culture 0.01 ml. See Table 3.12–4.
■ NOTE: Only streak the blood plate for colony count. Other plates should be streaked in quadrants for isolation of colonies (Fig. 3.12–1b and e), rather than for colony count, to minimize delays in obtaining isolated colonies and false-negative culture results due to antimicrobial inhibition. If colony count cannot be performed due to overwhelming spreading *Proteus*, an estimate of the count can be made from the isolation plates.
2. Inoculation methods for colony count (*choose one method*)
 - a. Calibrated-loop method
 - (1) Using the disposable or flamed and cooled calibrated loop, hold the loop vertically, and immerse it just below the surface of a well-mixed, uncentrifuged urine specimen.
 - (2) Deliver a loopful of well-mixed urine onto the blood agar plate and spread using one of the three methods below.
 - (a) Using the loop, make a straight line down the center of the plate and streak the urine by making a series of passes at 90° angles through the inoculum (method for 0.001 ml only). See Fig. 3.12–1a.
 - (b) Deliver the loopful onto one quadrant of plate by making a straight line or a V-shaped line. Streak urine onto the first quadrant, and proceed by streaking onto all four quadrants. See Fig. 3.12–1b.
 - (c) Spread the loopful of urine over the surface of the entire plate, using the loop in three directions or a sterile spreader or bent rod (“hockey stick”). See Fig. 3.12–1c.
 - b. Pipette inoculation methods
 - (1) With a sterile pipette tip and calibrated pipettor, aspirate 0.01 ml of well-mixed urine onto one side of plate and allow to drip down plate. Streak urine in quadrants on rest of plate with sterile loop. See Fig. 3.12–1d.
 - (2) Alternatively, drop onto plate and spread by one of the methods described above.
 - c. For bacteriological culture systems, see Table 3.12–3. For each method, a measured amount of urine is placed on agar surfaces, and after incubation, colonies are counted. The sensitivities of these systems vary and are high when only one pathogen is likely.
3. Take an additional loopful or pipette full of well-mixed urine for selective agar plates to be inoculated and streak in quadrants for isolation as indicated in Fig. 3.12–1e and Fig. 3.3.1–1 and 3.3.1–2 in procedure 3.3.1.
4. Incubate in ambient air overnight at 35 to 37°C.
 - a. Perform anaerobic cultures only on anaerobically collected suprapubic bladder aspirates (received in a syringe) on special request or when bacteria suggestive of anaerobes are seen in the direct smear but fail to grow on culture.
 - b. If convenient, incubate BAP and CNA in 5% CO₂ to enhance growth of gram-positive organisms.
5. Examination of culture media
 - a. Examine cultures that have been incubated overnight but make final reading at 18 h unless the specimen fits the criteria below.
 - b. Reincubate until culture has incubated for 48 h if one of the following is true.

Table 3.12-4 Protocol for workup of urine cultures

Type of urine	Inoculation	No. of isolates		Time to final report
		1 isolate ^a	2 uropathogens ^a ≥3 uropathogens	
Voided midstream: obtained in outpatient clinics and doctors' offices from patients <65 yr old	Streak 0.001 ml to BAP for count. Streak MAC (or EMB) in quadrants (CNA or PEA optional).	<10,000 CFU/ml, minimal ID ^b ≥10,000 CFU/ml (or ≥1,000 CFU of uropathogen/ml in females 14-30 yr old), ^c definitive ID ^d and AST	For each <100,000 CFU/ml, minimal ID For each that is ≥100,000 CFU/ml, definitive ID and AST	Report count plus "Multiple bacterial morphotypes present. Suggest appropriate recollection with timely delivery to the laboratory, if clinically indicated." Day 1 or 2 (minimum incubation, 18 h) ^e
Indwelling catheter; voided from geriatric (≥65 yr old) and all inpatients	Streak 0.001 ml to BAP for count. Streak CNA (or PEA) and MAC (or EMB) in quadrants.	<10,000 CFU/ml, minimal ID ≥10,000 CFU/ml, definitive ID and AST	For each <100,000 CFU/ml, minimal ID For each that is ≥100,000 CFU/ml, definitive ID and AST	If voided urine, or if catheter collected and urinalysis WBCs or leukocyte esterase is available and normal, report as for voided outpatient urine. Day 2 or 3 (minimum incubation, 36 h)
Straight catheter; pediatric catheterized, suprapubic, kidney, cystoscopy yeast cultures	Streak 0.01 ml to BAP for count. Streak CNA (or PEA) and MAC (or EMB) in quadrants. Add CHOC for surgically collected or prostate specimens.	100 to 1,000 CFU/ml with normal urogenital or skin microbiota, minimal ID ≥1,000 CFU/ml or any pure culture of lower count of uropathogen, definitive ID and AST	For each <1,000 CFU/ml, minimal ID For each uropathogen that is ≥1,000 CFU/ml, definitive ID and AST	Minimal ID of each uropathogen, with note: "Contact laboratory if definitive identifications are clinically indicated." For each <10,000 CFU/ml, minimal ID For each that is ≥10,000 CFU/ml, definitive ID and AST Day 2 or 3 (minimum incubation, 48 h)

^a Urogenital or skin microbiota that is at least 10 times less than the uropathogens is ignored for purposes of workup. If this microbiota is equal to the uropathogens, report "Multiple bacterial morphotypes present. Suggest appropriate recollection with timely delivery to the laboratory, if clinically indicated." For list of uropathogens and urogenital and skin microbiota, see Table 3.12-1.

^b For minimal identification (ID), see Table 3.12-5.

^c Report any amount of group B streptococci (*S. agalactiae*) in this age group. Check staphylococci with novobiocin disk for *Staphylococcus saprophyticus*, a uropathogen in this age group.

^d For definitive ID, see Table 3.12-1.

^e See text (item V.B.5.b) for exceptions.

V. PROCEDURE (continued)

- (1) The specimen was collected by an invasive technique, such as suprapubic bladder aspiration or straight catheter method.
 - (2) Tiny or scant colonies are present that are barely discernible.
 - (3) Culture results do not correlate with Gram stain findings or clinical conditions (e.g., the patient has sterile pyuria or symptoms without a positive culture).
 - (4) The patient is immunocompromised, including patients who have transplanted organs.
 - (5) Yeast or fungal culture is requested or appropriate (e.g., neonatal intensive care unit cultures).
- **NOTE:** Incubation may need to be up to 72 h if CNA or EMB is not used. Many yeasts grow well on EMB.
- c. For positive cultures, examine culture media for the quantity and morphological type of organisms present.
 - (1) With a 0.001-ml loop, one colony equals 1,000 CFU/ml.
 - (2) With a 0.01-ml loop, one colony equals 100 CFU/ml.
 - (3) When the colonies are too numerous to count
 - (a) The maximum readable using the 0.001-ml loop is $>10^5$ CFU/ml.
 - (b) The maximum readable on the 0.01-ml loop is $>10^4$ CFU/ml.
 - (4) Use the procedure in item IV to estimate counts between the maximum and minimum.
 6. Further workup of positive cultures
 - a. Determine the colony count of each morphotype in the culture separately by examining BAP.
 - b. Using Tables 3.12–1 and 3.12–4, determine the extent of workup of each organism.
 - c. For testing for minimal identification guidelines, refer to Table 3.12–5.
 - d. Do not identify normal urogenital microbiota to the genus or species level.
 - e. *Streptococcus agalactiae* should be reported from women in childbearing years and from known diabetics, regardless of the count.
 - f. Because *E. coli* represents 80% of the pathogens in voided urine cultures, use rapid identification methods to identify this species. See Table 3.3.2–5.
 - g. For definitive identifications, refer to Table 3.3.2–5 and procedures 3.18.1 and 3.18.2.
 - h. Perform AST as indicated in the tables and described in section 5.
 - i. Always identify to the species level if oxidase positive and indole positive, since such organisms are pathogens regardless of count (e.g., *Aeromonas* and *Vibrio* spp.).
 7. Hold positive culture plates at room temperature for at least 2 to 3 days for possible further workup if requested by the patient's physician.
 8. Hold urine specimens at refrigeration temperatures for 24 h to resolve any problems with the specimen or culture results.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. Report Gram stain results for bacteria and cells per Gram stain procedure (3.2.1).
- B. Negative results
 1. If no growth is observed on all media and 0.01 ml was cultured, report "No growth of $\geq 10^2$ CFU/ml at xx," where xx is either 1 day, 24 h, or 48 h.
 2. If 0.001 ml was cultured, report "No growth of $\geq 10^3$ CFU/ml at xx."

Table 3.12–5 Reporting of isolates with minimal testing^a

Report	Minimal testing
Enteric gram-negative rod	Grows typically on MAC or EMB and appears lactose positive or spreading on any medium or is indole positive and oxidase negative.
Non-glucose-fermenting, gram-negative rod	Appears lactose negative on MAC or EMB and is oxidase positive and indole negative or has odor of <i>Pseudomonas</i> or <i>Alcaligenes</i> . If desired, inoculation and incubation of KIA or TSI can be used to distinguish from enteric rods.
Gram-negative rod or non-lactose-fermenting, gram-negative rod	Grows well on EMB or MAC but does not fit either of the above criteria for gram-negative rods.
Yeast	Morphology consistent with yeast in wet mount or “feet” present on plate.
<i>S. aureus</i>	Catalase-positive, gram-positive cocci and slide coagulase positive. <i>Caution: S. saprophyticus</i> can be positive in latex or coagglutination serologic coagulase tests.
Coagulase-negative staphylococci	Catalase-positive, gram-positive cocci and slide coagulase negative
<i>Enterococcus</i>	Catalase-negative, PYR-positive, nonhemolytic, and gram-positive cocci
Viridans group streptococci	Gram-positive cocci in pairs and chains, catalase negative, alpha-hemolytic, or PYR negative. Rule out <i>A. urinae</i> (differs by a Gram stain showing tetrads and clusters) prior to reporting, if numbers are significant (20).
<i>Lactobacillus</i> spp.	Gram-positive rods, catalase negative, alpha-hemolytic
<i>Corynebacterium</i> spp.	Gram-positive rods, catalase positive. Rule out uropathogenic <i>Corynebacterium</i> with rapid urease test (procedure 3.17.48), if numbers are significant.

^a See Table 3.12–4 for indications. Abbreviations: KIA, Kligler’s iron agar; TSI, triple sugar iron agar; PYR, pyrrolidonyl-β-naphthylamide.

VI. REPORTING RESULTS (continued)

C. Positive results

1. If only urogenital or skin microbiota is observed, report as such.

Example: “10,000 CFU/ml normal urogenital microbiota.”

2. As specified in Table 3.12–4, mixed cultures are reported with the count in CFU per milliliter, followed by “Multiple bacterial morphotypes present; possible contamination; suggest appropriate recollection, with timely delivery to the laboratory, if clinically indicated.”
3. Otherwise, report the colony count of each pathogen separately, followed by the presumptive, minimal, or definitive identification and susceptibility test results, as indicated in Tables 3.12–4 and 3.12–5.
 - **NOTE:** For general principles of reporting preliminary and final results, refer to procedure 3.3.2.
4. When antimicrobial inhibition is observed (i.e., no growth in the primary area of the plate but growth in the area where the inoculum is diluted), do not report the count but report “Colony count unreliable due to antimicrobial inhibition.”
5. Notify physician of unusual positive findings (e.g., *Salmonella typhi* or *Burkholderia pseudomallei*).

- D. Document all testing in a hard copy or computerized work card.

VII. INTERPRETATION

- A. The criterion of $\geq 10^5$ CFU/ml for significance can be applied to a majority of specimens submitted for culture. However, the following are true.
 1. A mixed culture in an uncomplicated outpatient population likely indicates contamination.

VII. INTERPRETATION

(continued)

2. Low levels ($<10^4$ /ml) of organisms commonly found on the skin and external and internal genitalia are considered to be contaminants, but in selected circumstances, a count of *Enterobacteriaceae* of 10^2 CFU/ml or more, especially for *Salmonella*, can be considered significant.
 3. Colony counts of $<10^5$ CFU/ml in voided specimens in the presence of dysuria and symptoms of UTI may be significant.
- B.** Performance of AST directly from the urine specimen is not recommended. However, by special request, AST can be performed directly from a urine specimen if the direct Gram stain suggests that the specimen is monomicrobial. Results should be read by experienced microbiologists, who can detect mixed cultures. These methods are not Food and Drug Administration cleared and are not standardized, but may provide rapid information to physicians. They should be followed up with standard susceptibility testing. Refer to *Cumitech 2B* for further discussion (2).

VIII. LIMITATIONS

- A.** For uncomplicated UTI, culture is usually not indicated and a 3-day course of therapy is sufficient for cure. Culture and AST are useful in evaluating recurrent infections.
- B.** In cases of sterile pyuria, the Gram stain is important. If organisms are seen but not cultured and findings persist, an anaerobic culture may be indicated.
- C.** False-negative results are due, in part, to interfering substances, diluted urine, low urine pH, and subjective interpretation of the criteria for further workup of the culture.
- D.** The presentation of UTI can be similar to that of genital infections. Genital culture for *N. gonorrhoeae*, *Chlamydia*, and other agents of sexually transmitted diseases should be considered. In addition, agents of vaginitis and vaginosis should also be included, such as *Gardnerella vaginalis*, mycoplasmas, *Candida albicans*, other yeasts, and *Trichomonas*.
- E.** For sterile pyuria, mycobacterial infection should be considered (*see* section 7). The specimen for culture should be the first voided urine of the day, three days in a row.

APPENDIX 3.12–1

Commercial Systems for Evaluation of Pyuria Prior to Culture

- A. The KOVA Glasstic Slide 10 (Hycor Biomedical, Inc.) is an optically clear, plastic, disposable slide chamber with grids that holds up to 10 specimens and allows the user to perform quantitative microscopic counts of somatic and bacterial cells. Each of the 10 chambers will hold a standardized 6.6 μ l of sample and has a depth of 0.1 mm.
 1. Add 6.6 μ l of uncentrifuged urine to one grid of the KOVA Slide.
 2. Allow grid to fill by capillary action.
 3. Quantitate cells under $\times 400$ magnification.
 4. A positive urine sample contains >10 WBCs/ μ l.
- B. Yellow IRIS (International Remote Imaging Systems) is an automated urinalysis instrument for use on midstream urine specimens from immunocompetent adults. It incorporates a flow microscope, video camera, and digitalized picture image-processing computer.
- C. Dipstick method for detection of bacteria and WBCs
 1. Specimen: fresh voided urine from immunocompetent patient
 2. Materials: Chemstrip LN (Bio-Dynamics, Division of Boehringer Mannheim Diagnostics, Indianapolis, Ind.)
 3. Procedure
 - a. Dip the strip into the urine specimen for 1 s.
 - b. Withdraw the strip over the specimen container rim to remove excess urine.
 - c. Read results within 2 min.
 - d. Compare the color intensity with the color guide provided by the manufacturer.
 4. Interpretation
 - a. Nitrate reductase
 - (1) Many, but not all, gram-negative bacilli reduce nitrate to nitrite.
 - (2) Low urine pH (<6) may yield false-negative test results.
 - b. WBC esterase in WBCs produces a positive reaction.
 5. Limitations
 - a. Vitamin C, phenazopyridine, and high protein levels may interfere with test results.
 - b. The leukocyte esterase is a sensitive test to determine pyuria, but the sensitivity of test results is higher when both parameters are used.
 - c. Some non-glucose-fermenting gram-negative bacilli, e.g., *Acinetobacter*, are nitrate negative. All gram-positive microorganisms are nitrate negative. False-negative results will occur with infections with these organisms, which may be common in nosocomial UTI.
 - d. Neutropenic immunocompromised patients, having very few if any WBCs in urine, have false-negative leukocyte esterase tests.

APPENDIX 3.12-2

Rapid Urine Screens Used To Reject Voided Urine from Outpatients

- A. Enzyme tube test: URISCREEN (Bard Patient Care Division, Murray Hill, N.J.) (1)
1. Add 1.5 to 2.0 ml of well-mixed urine to a tube containing dehydrated reagent.
 2. Add 4 drops of 10% hydrogen peroxide.
 3. Gently mix the contents of the tube, avoiding formation of bubbles.
 4. Observe the tube for the formation of foam above the surface of the liquid.
 5. A positive reaction is indicated by the release of catalase and occurs within 2 min.
- B. Nonautomated filtration device: FiltraCheck-UTI (Meridian Diagnostics, Cincinnati, Ohio)
1. Add 2 drops of well-mixed urine and 6 drops of diluted hydrochloric acid to a capsule.
 2. Gently mix, and pour into a disposable filter disk with a conical well.
 3. Add safranin O dye, and wash twice with decolorizer.
 4. Compare residual pink with a color guide.
- C. Cellenium automated urine screening system (Trek Diagnostic Systems, Westlake, Ohio)
- The Cellenium is the first fully automated urine screening system. Using proprietary robotic operation, aliquots of urine are dispensed into a Cellenium cassette and fluorescent nucleic acid stains are added. The cassette is automatically coupled with the Cellenium membrane. Vacuum filtration results in a monolayer of stained microorganisms on the membrane which is examined using computerized fluorescent microscopy imaging (CFMI). Results are equal to the CFU per milliliter of the standard culture method. For specimens with $>10^4$ CFU/ml, the reported information includes Gram and morphology classification, including bacteria, yeasts, and WBCs.
1. Inoculate 1.5 ml of urine into two tubes.
 2. Place tube into the Cellenium instrument.
 3. The system automatically processes the specimen as follows.
 - a. The instrument automatically dispenses aliquots into the cassettes.
 - b. Fluorescent probes are added automatically.
 - c. A vacuum step results in a monolayer of stained microorganisms on the membrane.
 - d. The membrane is examined at high magnification using CFMI.
 - e. Interpretation is based on the quantitative measurement of optical properties of single cells using staining methods, CFMI, and algorithms.

1. Pezzlo, M. T., D. Amsterdam, J. P. Anhalt, T. Lawrence, N. J. Stratton, E. A. Vetter, E. M. Peterson, and L. M. de la Maza. 1992. Detection of bacteriuria and pyuria by URISCREEN, a rapid enzymatic screening test. *J. Clin. Microbiol.* **30**:680-684.

APPENDIX 3.12-3

Use and Calibration of Microbiological Loops

I. PRINCIPLE

The volume of fluid picked up by a calibrated loop depends on the volume and shape of the container holding the liquid and the direction and depth the loop is immersed. Variability results from surface tension and wetted surface of the loop. Liquids in containers with small diameters (<1 cm) have high surface tensions, which result in less loop pickup since glass-liquid and plastic-liquid (adhesive) forces are greater than liquid-liquid (cohesive) forces. When the wire above the loop is wetted by deep immersion into the fluid, excess liquid drains down the wire and enlarges the volume transferred (1).

Quantitative loops are commonly used to set up quantitative cultures and check inocula for antimicrobial tests. Quantitative loops are less accurate than pipettors yet are an excellent way to set up a semiquantitative culture or dilution. Quantitative loops are used when $\leq 20\%$ error is acceptable.

Loops are calibrated either by the dye method or by the drill bit method. Another method, the pour plate method, is rarely used because it is cumbersome.

II. TYPES OF LOOPS

- A. Volume is either 1 or 10 μ l.
- B. Reusable loops are made of wire, usually platinum or nichrome.
- C. Disposable loops are made of plastic.

APPENDIX 3.12–3 (continued)

III. MATERIALS

- A. Drill bit method (drill bits can be purchased at a hardware store)
 - 1. Twist drill bits (no. 53 and 54) for 0.001-ml loop
 - 2. Twist drill bits (no. 21 and 22) for 0.01-ml loop
 - 3. For disposable loops, some manufacturers supply a “go-no go” bar to calibrate their loops. Drill bits do not work for these loops.
- B. Dye method
 - 1. Distilled water, either type I or type II
 - 2. Evans blue dye solution (EBD)
 - a. Stock
 - (1) Add 0.75 g of EBD to 100 ml of distilled water.
 - (2) Filter solution through no. 40 Whatman filter paper.
 - (3) Store at room temperature in a dark bottle for 6 months. Label bottle with contents, expiration date, and initials of preparer. Note lot number and expiration date in the work record.
 - b. Working solutions
 - (1) Prepare dilutions of the EBD stock solution in distilled water to equal to 1:500, 1:1,000, 1:2,000, and 1:4,000 by diluting 1 ml of stock dye in 49 ml of distilled water.
 - (2) Dilute 1 ml of this 1:50 dilution in 9 ml of distilled water. This is a 1:500 dilution.
 - (3) Perform twofold serial dilutions, starting with 5 ml of the 1:500 solution and 5 ml of distilled water, to prepare the remaining dilutions.
 - (4) Store the four dilutions for up to 6 months, but prepare new dilutions if the reading of any one dilution differs by 3% from previous readings.
 - 3. Supplies
 - a. Square glass cuvettes with a 1-cm light path. Use the same cuvette for all measurements.
 - b. Glassware: several clean 15-ml test tubes, several class A 1- and 10-ml pipettes
 - c. Good-quality spectrophotometer with the following specifications: linear through 2.0 absorbance units at 350 nm; spectral band width, ≤ 2 nm (348 to 352 nm); precision (drift) of ≤ 0.001 Å/h; accuracy of wavelength selected, ≤ 1 nm

IV. QUALITY CONTROL

- A. General considerations
 - 1. Reusable loops
 - a. Inspect calibrated loops regularly to confirm that they remain round and are free of bends, dents, corrosion, or incinerated material.
 - b. Check the loops to ensure that the delivery volume is accurate on a monthly basis (2).
 - 2. Check delivery volumes of disposable loops upon receipt of a new lot number. Satisfactory performance of multiple lots and manufacturer’s certificate of in-house QC eliminate the need for routine calibration.
- B. Methods for calibration of loops
 - 1. Food and Drug Administration (FDA) drill bit method
 - **NOTE:** The FDA uses the standard 0.001-ml platinum-rhodium loop in plate counts on milk. The drill bit method of QC is simple and does not require a spectrophotometer.
 - a. Calibration of 0.001-ml loop (inside diameter of 1.45 ± 0.06 mm)
 - (1) Obtain two twist drill bits (no. 53 and 54).
 - (2) Carefully slip the 0.001-ml loop over the end of the no. 54 bit. If the loop is calibrated, it will fit over the bit.
 - (3) Repeat the procedure with the no. 53 bit. If the loop is calibrated, it will not fit over the end.
 - (4) If the loop fits over the no. 53 bit, it is inaccurate. Follow corrective action.
 - b. Calibration of 0.01-ml loop
 - (1) Obtain two twist drill bits (no. 21 and 22).
 - (2) Repeat the procedure described above for the 0.001-ml loop.
 - (3) A calibrated 0.01-ml loop will fit over the end of a no. 22 drill bit and will not fit over a no. 21 bit.

APPENDIX 3.12-3 (continued)

- c. For disposable loops, the drill bits will not work but the manufacturer may supply a calibration bar that is similar to the drill bits.
2. Colorimetric dye calibration procedure
 - a. Set spectrophotometer to absorbance mode, using a wavelength of 600 nm.
 - b. Zero spectrophotometer with distilled water.
 - c. Measure and record the absorbance of each dye dilution (1:500, 1:1,000, 1:2,000, 1:4,000).
 - d. Plot the optical density (vertical axis) against each of the concentrations of the dilutions (horizontal axis) on worksheet 1 (see p. 3.12.28). Draw a single line that most closely fits all four points to construct the calibration curve.
 - e. Using the 0.001-ml loop, transfer 10 loopfuls of the EBD stock dye solution to 10 ml of distilled water. After thorough mixing, measure and record the absorbance of this solution. The absorbance should correspond to that of the 1:1,000 dilution on the calibration curve.
 - f. Prepare and evaluate three additional test solutions for a total of four readings. Record the readings on the worksheet and determine the average. Then calculate the percent inaccuracy by following the instructions on the worksheet.
 - g. If the average reading is more than $\pm 20\%$ of the 1:1,000 stock solution dilution, the loop is inaccurate. Follow with corrective action.
 - h. To calibrate the 0.01-ml loop, transfer 10 loopfuls of the EBD stock solution to 100 ml of distilled water using the 0.01-ml loop. After thorough mixing, measure and record the absorbance of this solution. Prepare and evaluate three additional test solutions for a total of four readings. Then calculate the percent inaccuracy by following the instructions on the worksheet. The final reading should be the same as that of the 0.001 loop, i.e., $\pm 20\%$ of the 1:1,000 stock solution dilution.
- C. Corrective action
 1. If delivery of loop does not fall within the specified tolerance limit, the loop can be discarded and replaced or repaired and retested.
 2. Repair by dipping in sand to remove deposits, and clean by wetting with alcohol and igniting.
 3. Loops can be returned to their calibrated diameter by using standard, circular gauges (Remel, Inc.). Reconditioned loops must be calibrated before being put back in service.
 4. For inaccurate disposable loops, contact manufacturer for replacement.
- V. PROCEDURE FOR LOOP USE
 - A. For reusable loops, flame and cool before the first and after each transfer. Use a new, unwetted disposable loop for each transfer.
 - B. Fluid should be in a widemouthed container (diameter, >1 cm).
 - C. Swirl the specimen to mix the bacterial suspension evenly.
 - D. Hold the loop vertically, and immerse it to just below the surface of the liquid. Avoid any bubbles on the meniscus of the liquid.
 - E. Check to ensure that no bubbles are within the loop.
 - F. Move loop straight up and down only.
 - G. Transfer contents of loop to the plate by pressing liquid to the plate until the liquid is no longer visible in the loop. Spread with loop or, for greater accuracy, spread with a bent rod.
- VI. LIMITATIONS

Quantitative loops, both disposable and reusable, will be grossly inaccurate if bubbles are present in the film of fluid transferred. Avoid bubbles by not shaking liquid. Inspect loopful carefully for bubbles. Remove bubbles by flaming (reusable loop), replacing (disposable loop), or redipping (either loop).

APPENDIX 3.12–4**Use and Calibration of Pipettors****I. PRINCIPLE AND DESCRIPTION****A. Principle**

Pipettors aspirate and expel by an air or positive-displacement mechanism. The former mechanism uses air to push out the liquid, and the latter uses a plunger. Positive-displacement pipettors are generally thought to be more accurate for smaller volumes and, in theory, do not need the pipettor tip replaced between samples. Air displacement pipettors are more commonly used in microbiology.

B. Description

The term “pipettor” describes dispensing, diluting, and pipetting equipment. The pipettor may be manual or automated. There are repeater, adjustable-volume, and multichannel models.

Manual pipettors are lightweight cylindrical tools consisting of a handheld mechanical handle for volume adjustment and calibration and a delivery shaft that fits to disposable tips. Pipettors are approximately 10 in. long and deliver microliter to milliliter volumes. On automated pipettors, the mechanical handle is replaced with instrumentation.

C. Pipetting technique**1. Forward pipetting**

- a. Refer to Fig. 3.12–A1.
- b. When prerinsing by forward pipetting, follow procedure for forward pipetting but dispense aliquot back into original container or discard. Proceed with deliveries for calibration.
- c. Top and bottom stop positions do not include eject stroke position for ejecting pipettor tips.

2. Reverse pipetting

- a. Refer to Fig. 3.12–A2.
- b. When prerinsing by reverse pipetting, follow procedure for reverse pipetting. Dispense liquid back into original vessel or discard. Proceed with deliveries for calibration.
- c. Top and bottom stop positions do not include eject stroke position for ejecting pipettor tips.

D. Accuracy and precision**1. Definition of accuracy**

“Accuracy” is the closeness of agreement between the stated volume of the pipettor and the mean volume obtained during repeated, controlled deliveries. Accuracy is numerically expressed as inaccuracy, given as a percentage. Inaccuracy can be thought of as the difference between the expected or theoretical result and the calculated result.

2. Definition of precision

“Precision” is the agreement between replicate measurements. Precision is numerically expressed as imprecision, given as the coefficient of variation. Imprecision can be thought of as the range of values in which 95% of the replicate measurements fall.

3. Use of inaccuracy and imprecision as they relate to calibration of liquid delivery instruments

- a. Proper calibration of pipettors requires calculation of both inaccuracy and imprecision.
- b. Inaccuracy and imprecision must be calculated for each volume of an adjustable pipettor and each channel of a multichannel pipettor unless the manufacturer’s procedure instructs otherwise.

E. Uses for liquid delivery systems in microbiology

Pipettors are used to dilute sera, set up quantitative cultures, prepare inocula for antimicrobial tests, add ingredients to media and reagents, and add exact amounts of reagents or specimen during a test procedure. Pipettors are used because of their excellent accuracy and precision and because they expeditiously dispense small volumes repeatedly.

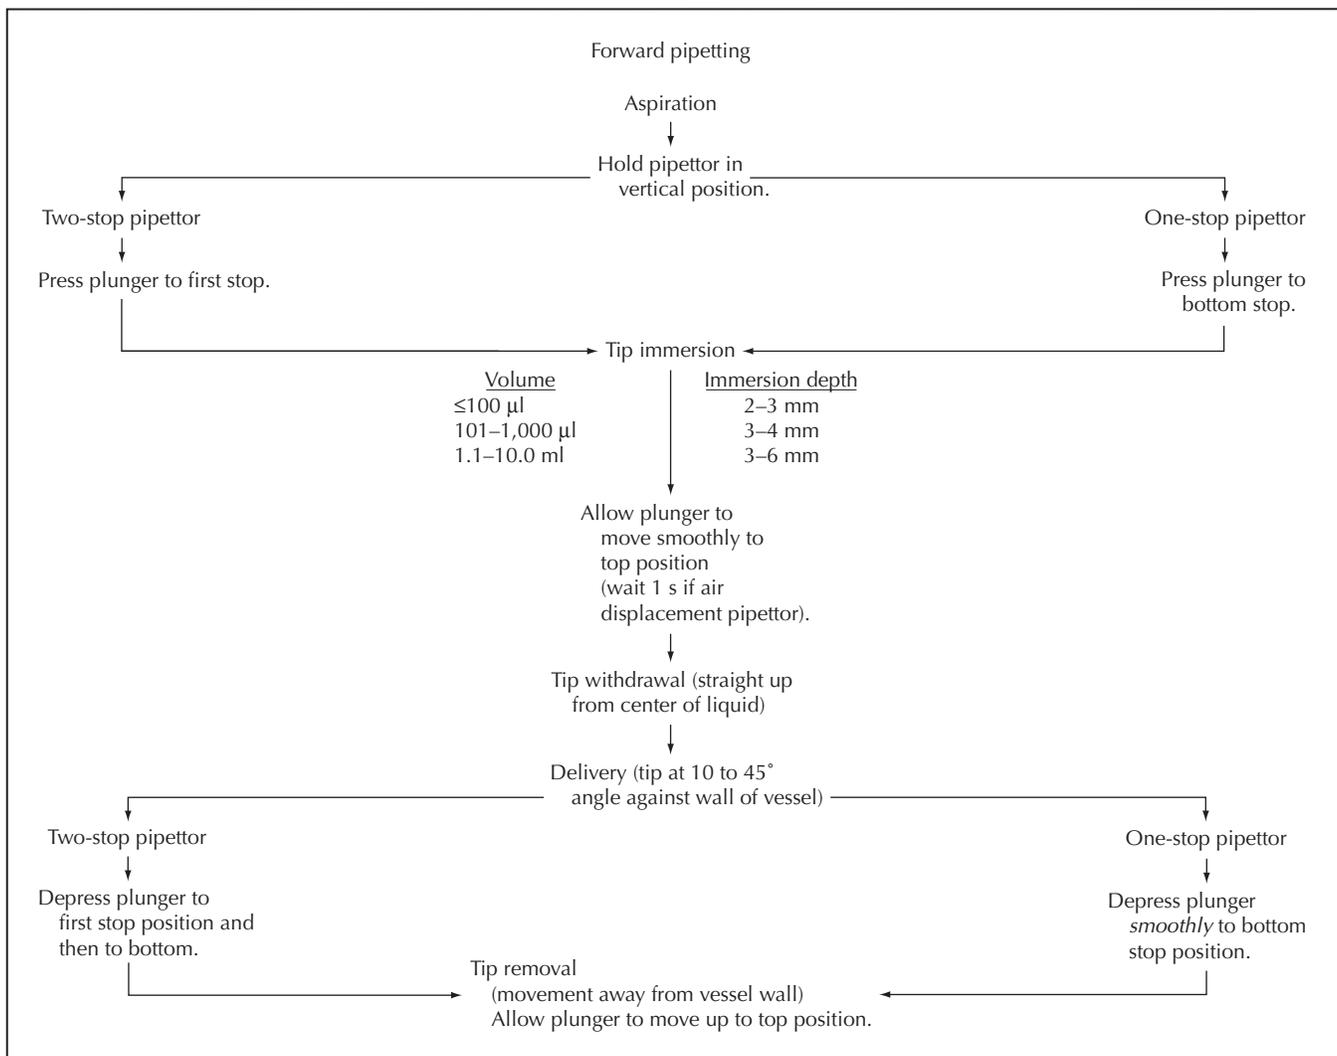

Figure 3.12–A1 Flowchart for forward pipetting (adapted from reference 7 with permission).

APPENDIX 3.12–4 (continued)

F. Calibration factors

1. Importance of calibration

Volumetric measurement using pipettors is a potential source of error in the clinical laboratory. A small error in pipetting can cause a large error in the final result.

2. Requirement for pipettor calibration

Laboratory inspecting agencies such as the CAP and the JCAHO require periodic testing of pipetting equipment to ensure accurate delivery.

3. Proposed standard for pipettor calibration

Guidelines for calibration of volumetric pipettors are found in many sources (1–10).

4. Calibration methods available (Table 3.12–A1)

Numerous methods for calibration are available. The gravimetric, spectrophotometric, and colorimetric methods are the most convenient and commonly used. Radioisotopic, enzymatic, and acid-base titration methods are less commonly recommended and are not discussed further. Commercially available pipettor calibration kits designed for in-house or send-out measurement and calculation are available (*see* Table 3.12–A2).

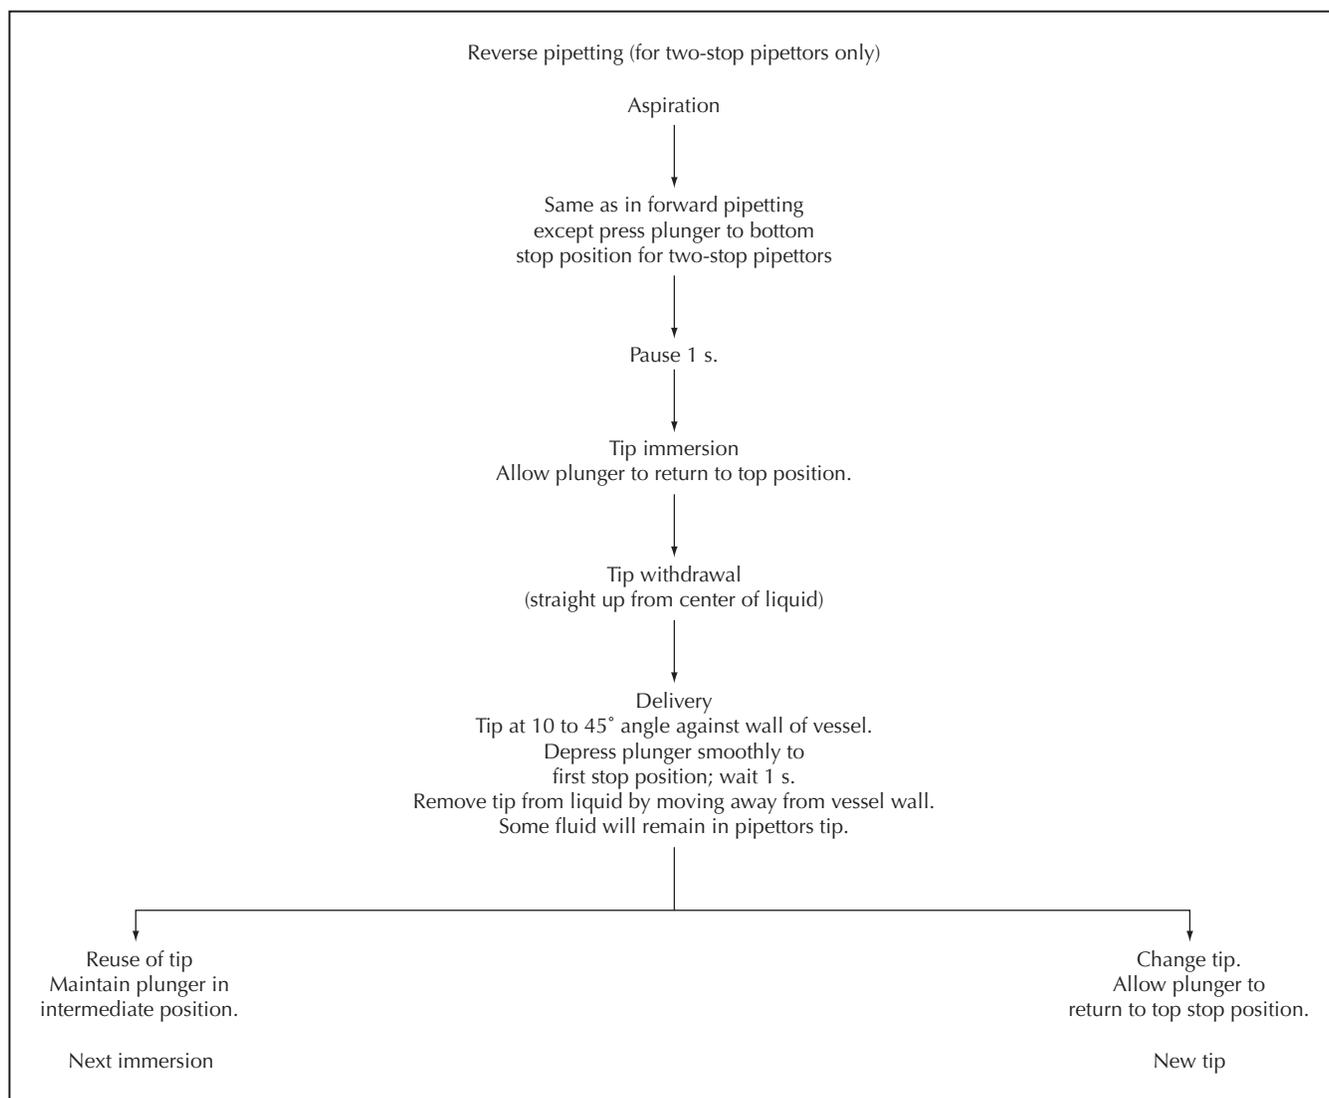

Figure 3.12–A2 Flowchart for reverse pipetting (adapted from reference 7 with permission).

APPENDIX 3.12–4 (continued)

II. SPECIAL PRECAUTIONS AND ENVIRONMENTAL CONCERNS

A. Special precautions for pipettor calibration

1. Changing pipettor tips during calibration procedure

Use the same pipettor tip for all deliveries during the calibration procedure, whether the pipettor is used for repetitive dispensing of several aliquots of the same liquid (e.g., buffers, reagents) or for transferring single aliquots of different liquids (e.g., serum). *Note:* During actual pipetting for routine use, a different tip must be used for each different liquid.

2. Prerinsing pipettor tips

“Prerinsing” is the precoating of the inside of the tip with the liquid being dispensed. Prerinse by aspirating an aliquot of the liquid into the tip and then dispensing it back into the original container or discarding it. Prerinse improves uniformity and precision by providing identical contact surfaces for all aliquots.

- a. If the pipettor is normally used for repetitive dispensing of several aliquots of the same liquid, prerinse pipettor tip *at the beginning*, before dispensing the first aliquot.

APPENDIX 3.12-4 (continued)

Table 3.12-A1 Calibration methods for volume-dispensing instruments

Method	Basis of system	Limitation
Gravimetric	1 ml of water = 1 g (adjusted for temp and pressure)	Vol dispensed must be >0.002 ml
Spectrophotometric	Absorbances of potassium dichromate used to create calibration curve	Vol dispensed must be >0.01 ml

Table 3.12-A2 Commercial pipettor calibration systems and related products

Supplier	Product(s)
Brinkman Instruments, Inc.	Autoclavable pipettors
Calibrite Corp.	Pipette calibration service
Laboratory Equipment Support Service, Inc.	Audit systems, reference service for pipettor calibration
Medical Laboratory Automation, Inc.	Automatic pipettors, pipette calibration kits
SMI Scientific Manufacturing Industries, Inc.	Positive-displacement pipettors
Streck Laboratories	VC-100, automated acid-base titration system

b. If the pipettor is normally used for transferring single aliquots of different liquids, prerinsing may not be necessary.

B. Environmental concerns for pipettor calibration

1. Temperature control

- Temperatures of pipettors to be calibrated, room air, test liquid (water), and other equipment should be identical ($\pm 0.5^\circ\text{C}$).
- Temperature should be as close as possible to temperature at which pipettor is used.
- Keep temperature stable throughout procedure.

2. Miscellaneous environmental concerns

- Maintain relative humidity at 45 to 75%. This reduces evaporation and limits buildup of static electricity.
- Prepare aqueous test liquids from NCCLS type I or II water (*see* procedure 14.4), which prevents impurities from affecting water density.
- Use water with no visible bubbles. Air bubbles alter measured volume.
- Complete weighing steps quickly. Use a lid on the weighing vessel to decrease evaporation. These precautions obviate an evaporation factor in the calculations.

III. CALIBRATION OF PIPETTORS

A. Frequency of calibration

Microbiology laboratory guidelines for frequency of pipettor calibration (Table 3.12-A3)

In general, pipettors used in microbiology and serology laboratories are not used for critical-volume delivery and may not require a rigorous calibration schedule. Guidelines for testing frequency do not exist for pipettors that are used less frequently or that are not used for critical delivery.

- Determine frequency of calibration for each pipettor on the basis of its use. Pipettors used daily require more frequent calibration than those used weekly or monthly.
- Pipettors used for critical-volume delivery need more frequent testing than those used to deliver approximate volumes.
- Carefully label pipettors for approximate delivery so that they are not used for more exact purposes.

APPENDIX 3.12–4 (continued)

Table 3.12–A3 Suggested calibration schedule for microbiology laboratory pipettors

Pipettor use	Calibration schedule ^a			
	New or after maintenance	Monthly	Quarterly	Annually
Critical-vol delivery required ^b				
Weekly or monthly use	A, P		A	P
Daily use	A, P	A		P
Critical-vol delivery not required ^c				
Weekly or monthly use	A, P			A, P
Daily use	A, P		A	P

^a A, test for accuracy; P, test for precision.

^b Critical-volume delivery may be required for reagent delivery in some assays.

^c Critical-volume delivery generally not required for serum dilutions (including Venereal Disease Research Laboratory and rapid plasma reagin tests), quantitative culture, inocula for antimicrobial tests, adding ingredients to media and reagents, adding reagents to test procedure, or adding specimen to slide for fluorescent staining.

B. Calibration procedures: gravimetric method

1. Materials and supplies

a. Reagent

Distilled water: NCCLS type I or II (*see* procedure 14.4)

b. Equipment

(1) Analytic balance: balance capable of measuring to 0.001 mg (1.0 µg)

(2) Thermometer: NBS calibrated to 0.1°C

(3) Weighing vessel: nonporous glass, plastic, or metal weighing container

Open surface area should be as small as possible to control evaporation.

Use a loose-fitting lid to prevent evaporation of the small volumes of distilled water that will be weighed. Handle weighing vessel with forceps or washed gloves.

2. Procedure

a. Record temperature (rounded to the closest 0.5°C) before test procedure.

b. Tare the weighing vessel.

c. Prerinse the pipettor tip, if necessary, with distilled water.

d. Deliver one aliquot of distilled water into weighing vessel by using standard operating procedure for that pipettor (i.e., forward or reverse pipetting). The emphasis throughout is on smoothness, uniform timing, and uniform motion.

e. Replace lid of weighing vessel.

f. Record results of weighings on worksheet 2 (*see* p. 3.12.29).

g. Deliver additional aliquots (4 for inaccuracy determination or 10 for imprecision determination) with uniform timing. Record weight of each aliquot. After all weighings are completed, calculate the net weight of each aliquot.

3. Calculations

a. Use worksheet 2 (*see* p. 3.12.29).

b. Calculate the mean weight (\bar{W}) by using the individual weights (W_i) and the number of weighings (n).

$$\bar{W} = \frac{\sum W_i}{n}$$

c. Calculate the mean volume (\bar{V}) by using the mean weight (\bar{W}) and factor Z, which controls for water density variation resulting from temperature, atmospheric pressure, and relative humidity changes.

$$\bar{V} = (\bar{W})(Z)$$

Factor Z is calculated by using Table 3.12–A4. A standard Z value, using an average room temperature and barometric pressure, can be used in calculations

APPENDIX 3.12-4 (continued)

to calibrate pipettors that are not used to deliver critical volumes. Calculate the actual Z value (by using current temperature and atmospheric pressure) when calibrating pipettors used to deliver critical volumes.

- d. Calculate inaccuracy ($\bar{E}\%$) by using mean volume (\bar{V}) and nominal volume (V_0). Use four weighings generally.

$$\bar{E}\% = \frac{\bar{V} - V_0}{V_0} \times 100$$

- e. Calculate imprecision (CV%) by using individual weights (W_i), mean weight (\bar{W}), and number of weighings (n). Use 10 weighings generally.

$$CV\% = 100 \times \frac{\sqrt{\frac{\sum(W_i - \bar{W})^2}{n - 1}}}{\bar{W}}$$

APPENDIX 3.12–4 (continued)

C. Calibration procedures: spectrophotometric method

1. Materials

a. Reagents

- (1) Potassium dichromate: $K_2Cr_2O_7$, analytical reagent grade
- (2) Perchloric acid diluent: $HClO_4$, analytical reagent grade (0.001 N)
- (3) Distilled water: NCCLS type I or II (*see* procedure 14.4)
- (4) Stock solutions

Stock solutions are stable for 1 year if protected from evaporation.

(a) Stock solution I

Weigh approximately 10 g of $K_2Cr_2O_7$, and record weight to nearest 0.001 g. Transfer chemical to clean, 1,000-ml volumetric flask. Dilute to 1,000 ml with 0.001 N $HClO_4$.

(b) Stock solution II

Using a volumetric pipettor, transfer 100 ml of stock solution I to another clean, 1,000-ml volumetric flask. Again, dilute to 1,000 ml with 0.001 N $HClO_4$.

b. Equipment

(1) Spectrophotometer

Good-quality instrument is needed. Specifications include the following: linear through 2.0 absorbance units at 350 nm; spectral band width, ≤ 2 nm (348 to 352 nm); precision (drift) of $\leq 0.001 \text{ \AA/h}$ ($\leq 0.0001 \text{ nm/h}$); accuracy of selected wavelength, ≤ 1 nm.

(2) Cuvettes: square glass cuvettes with a 1-cm light path

Use the same cuvette for all measurements.

(3) Volumetric glassware: two class A 1,000-ml volumetric flasks; one class A 100-ml volumetric pipette; several each class A 1-, 2-, and 10-ml pipettes

(4) Analytic balance: balance capable of measuring to 1.0 mg (0.001 g)

2. Procedure

- a. Set spectrophotometer to absorbance mode, using a wavelength of 350 nm.
- b. Zero spectrophotometer with diluent (0.001 N $HClO_4$).
- c. Consult Table 3.12–A5 to determine appropriate stock solution and diluent to use based on sample volume and cuvette size.
- d. Record absorbance values on worksheet 3 (*see* p. 3.12.30).
- e. Prerinse the pipettor tip if necessary with distilled water.
- f. Aspirate sample by using standard operating procedure for that pipettor (*i.e.*, forward or reverse pipetting). The emphasis throughout is on smoothness, uniform timing, and uniform motion.
- g. Deliver appropriate volume of sample (stock solution) into cuvette.
- h. Deliver the specified volume of diluent (0.001 N $HClO_4$) into cuvette.
- i. Cap the cuvette with Parafilm. Mix solution by inverting cuvette at least three times.
- j. Place cuvette in spectrophotometer. Close door.
- k. Read absorbance value, and record on worksheet 3 (*see* p. 3.12.30).

Table 3.12–A5 Theoretical absorbance values for test solutions

Vol (μ l) of pipettor to be tested	Stock solution to use	Vol (ml) of diluent to use	Theoretical absorbance of test solution ^a
10	I	2	0.532
20	I	10	0.213
50	II	2	0.261
100	II	2	0.510
200	II	10	0.210
250	II	10	0.261
500	II	10	0.509
1,000	II	10	0.972

^a Adapted from reference 7 (with permission).

APPENDIX 3.12-4 (continued)

Table 3.12-A6 Suggested tolerance limits for microbiology pipettors

Pipettor use ^a	Inaccuracy (%)	Imprecision (%)
Critical-vol delivery required		
Delivers <50 µl	± 2	± 2
Delivers >50 µl	± 1.5	± 1
Critical-vol delivery not required		
Delivering specimen to slide for FA staining	± 10	Not necessary
Other uses ^b	± 2	± 2

^a See Table 3.12-A3, footnotes *b* and *c*. FA, fluorescent antibody.

^b Includes Venereal Disease Research Laboratory and rapid plasma reagin tests.

- l. Discard test solution from cuvette.
 - m. Repeat steps III.C.2.f through 1 until 4 (inaccuracy determination) or 10 (imprecision determination) samples have been measured.
 - n. Rezero spectrophotometer with diluent (0.001 N HClO₄). Difference should be <0.001 Å.
3. Calculations
- a. Use worksheet 3 (see p. 3.12.30).
 - b. Calculate the mean absorbance (\bar{A}) by using the individual absorbances (A_i) and the number of absorbance measurements made (n).

$$\bar{A} = \frac{\sum A_i}{n}$$

- c. Calculate inaccuracy ($\bar{E}\%$) by using the mean absorbance (\bar{A}) and the theoretical absorbance (A_0).

$$\bar{E}\% = \frac{\bar{A} - A_0}{A_0} \times 100$$

- d. Calculate imprecision (CV%) by using the individual absorbance (A_i), the mean absorbance (\bar{A}), and the number of absorbance measurements (n).

$$CV\% = 100 \times \frac{\sqrt{\frac{\sum(A_i - \bar{A})^2}{n - 1}}}{\bar{A}}$$

D. Tolerance

1. Tolerance
 - a. Different tolerance limits for inaccuracy and imprecision are used for various laboratory applications. Most recommended tolerance limits are designed for pipettors that must deliver critical volumes, such as those used in clinical chemistry laboratories.
 - b. Tolerance limits for pipettors and quantitative loops tailored to specific laboratory uses can be determined by each user. Table 3.12-A6 is a list of suggested tolerance limits for common microbiology laboratory uses.
2. Corrective action
 - a. If delivery of pipettor does not fall within the specified tolerance limits, the pipettor must be adjusted (either in-house or by manufacturer), used for less critical delivery, or discarded.
 - b. Following pipettor adjustment, 10 weighings must be performed to evaluate both accuracy and precision.

IV. TROUBLESHOOTING

Pipettors that do not deliver volumes within the acceptable tolerance levels even after adjustment may have been calibrated incorrectly or may have the wrong pipettor tips.

APPENDIX 3.12-4 (continued)

- A. To verify calibration procedure, review carefully, and if necessary, calibrate by a second procedure (in-house or sent out).
- B. Different brands of micropipettor tips vary in quality and may contribute to pipetting error. Poorly fitting tips can affect volume of sample aspirated or dispensed. Different brands of tips can be tested for accuracy and precision.

Calculations for worksheet 2

W_i = individual weights
 \bar{W} = mean weight
 n = number of weighings
 \bar{V} = mean volume
 V_0 = nominal volume

Mean weight (\bar{W})

$$\bar{W} = \frac{\sum W_i}{n}$$

Mean volume (\bar{V})

$$\bar{V} = (\bar{W})(Z)$$

Inaccuracy ($\bar{E}\%$): use four weighings.

$$\bar{E}\% = \frac{\bar{V} - V_0}{V_0} \times 100$$

Imprecision (CV%): use 10 weighings.

$$CV\% = 100 \times \frac{\sqrt{\frac{\sum (W_i - \bar{W})^2}{n - 1}}}{\bar{W}}$$

Calculations for worksheet 3

A_i = individual absorbance
 n = number of absorbance measurements
 \bar{A} = mean absorbance
 A_0 = theoretical absorbance

Mean absorbance (\bar{A})

$$\bar{A} = \frac{\sum A_i}{n}$$

Inaccuracy ($\bar{E}\%$): use four readings.

$$\bar{E}\% = \frac{\bar{A} - A_0}{A_0} \times 100$$

Imprecision (CV%): use 10 readings.

$$CV\% = 100 \times \frac{\sqrt{\frac{\sum (A_i - \bar{A})^2}{n - 1}}}{\bar{A}}$$

3.13.1

Wound and Soft Tissue Cultures

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

A wide variety of microorganisms that reside on the skin and mucous membranes of the body, as well as those found in the environment, can cause skin and soft tissue infections. These organisms enter the body through breaks in the skin or mucous membranes, through wounds made by trauma or bites (exogenous) or as a complication of surgery or foreign-body implants (endogenous), or they can be spread through the vascular system (hematogenous).

Acute wound infections are normally caused by external damage to intact skin, such as those produced during surgery or by trauma and bites. Conversely, chronic infections, such as decubiti or foot and leg ulcers, are normally due to complications related to impaired vascular flow or metabolic disease (e.g., diabetes mellitus). Wound colonization and/or infection is often polymicrobial, with both aerobes and anaerobes (*see* section 4) involved.

Tissues collected during surgery or aspirates obtained through intact skin by needle and syringe or by fine-needle biopsy are the best types of specimen to obtain for microbiology culture. If the skin surface and surgical areas are properly disinfected prior to specimen collection, the organisms present can be assumed to be the cause of infection. Interpretation of microbial cultures taken from open skin or abscesses may be compromised, due to the fact that these lesions are often colonized with a large number of indigenous microbiota. Such cultures are indicated only if

there are clear signs of infection or if a wound is failing to heal. Proper preparation of the wound prior to specimen collection can minimize contamination. After appropriate debridement and cleansing of the wound, the specimen should be obtained by biopsy from the leading edge of the lesion, where pathogens should be present and colonizing organisms are less likely to occur. Bacterial cultures of purulent material obtained by needle and syringe aspiration can also provide meaningful results. If an aspirate or tissue sample cannot be obtained, swab collections of exudate from the deep portion of lesions can be submitted. Swabs are the least appropriate specimen for microbiology analysis, as the organisms isolated may only be colonizing the area and not involved in the infective process.

The primary agents of skin and tissue infections are *Staphylococcus aureus*, *Pseudomonas aeruginosa*, members of the *Enterobacteriaceae*, beta-hemolytic streptococci, and a variety of anaerobes. In appropriately collected specimens, the presence of one of these organisms may indicate the need for antimicrobial therapy. Since wound infections can be polymicrobial, treatment may initially need to be broad in spectrum, and there is little need to identify and perform antimicrobial susceptibility testing (AST) on all isolates. Tissues and aspirates are acceptable for anaerobic culture, as anaerobes can account for 38 to 48% of the total number of microbial isolates in wound specimens

(Table 3.13.1–1 and reference 1). It must be emphasized that wound specimens collected on swabs will be less appropriate than tissues or aspirates for anaerobic culture, provided that the tissues and aspirates are submitted under anaerobic transport conditions.

The accumulation of inflammatory cells and the resultant collection of pus within an abscess or a sinus tract is a hallmark of local infection. Evidence of this process can be documented by the presence of PMNs in the Gram-stained smear. Therefore, the quality of a wound specimen can be assessed by Gram stain, which should be used to guide the extent of microbiology testing. The presence of epithelial cells indicates contamination of the specimen with skin or mucous membrane microbiota and may compromise the significance of the culture results. Quantitative cultures of tissue specimens have been shown to be useful in evaluation of wound healing related to skin grafting (procedure 3.13.2); however, the presence of organisms in the Gram stain of an appropriately collected specimen from an infected wound correlates with a clinically significant count of bacteria (2). In addition, many publications have shown that for acute wounds, a swab culture with enumeration of the organisms present correlates well with quantitative tissue cultures (*see* review by Bowler et al. [1] and refer to procedure 3.13.2 for quantitative methods).

Table 3.13.1–1 Aerobic and anaerobic isolates from acute and chronic infections^a

Aerobic and facultative microorganisms	Anaerobic bacteria	Aerobic microorganisms from unusual, specialized, and zoonotic infections	Yeasts
Coagulase-negative staphylococci <i>Staphylococcus aureus</i>	<i>Peptostreptococcus</i> spp. <i>Streptococcus anginosus</i>	<i>Actinobacillus actinomycetemcomitans</i> <i>Aeromonas</i> spp.	<i>Candida albicans</i> <i>Candida krusei</i>
Beta-hemolytic streptococci <i>Enterococcus</i> spp. <i>Streptococcus</i> spp. (viridans group)	<i>Clostridium</i> spp. <i>Eubacterium limosum</i> <i>Propionibacterium acnes</i> <i>Bacteroides fragilis</i> group <i>Prevotella</i> spp.	<i>Bacillus anthracis</i> <i>Bergeyella zoohelcum</i> <i>Capnocytophaga</i> spp. and EF-4 <i>Chromobacterium violaceum</i> <i>Eikenella corrodens</i>	<i>Candida parapsilosis</i>
<i>Corynebacterium</i> spp. <i>Bacillus cereus</i>	<i>Porphyromonas asaccharolytica</i> <i>Fusobacterium necrophorum</i> <i>Veillonella</i> spp.	<i>Erysipelothrix rhusiopathiae</i> <i>Francisella tularensis</i> <i>Haemophilus</i> spp. <i>Kingella kingae</i> NO-1	
<i>Escherichia coli</i> <i>Serratia</i> spp. <i>Klebsiella</i> spp. <i>Enterobacter</i> spp. <i>Citrobacter</i> spp. <i>Morganella morganii</i> <i>Providencia stuartii</i> <i>Proteus</i> spp. <i>Acinetobacter baumannii</i> <i>Pseudomonas aeruginosa</i> <i>Stenotrophomonas maltophilia</i> <i>Sphingobacterium multivorum</i>		<i>Pasteurella multocida</i> <i>Streptobacillus moniliformis</i> <i>Vibrio vulnificus</i>	

^a Data revised from Bowler et al. (1). Wounds include cutaneous abscesses, postsurgical wounds, bites, ulcers, and pressure sores.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

■ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for caregivers. It is the responsibility of the laboratory director or designee to educate physicians and other caregivers on proper wound specimen collection.

A. General considerations

1. Preferably collect specimen prior to initiation of therapy and only from wounds that are clinically infected or deteriorating or that fail to heal over a long period.
2. Cleanse skin or mucosal surfaces.
 - a. For closed wounds and aspirates, disinfect as for a blood culture collection with 2% chlorhexidine or 70% alcohol followed by an iodine solution (1 to 2% tincture of iodine or a 10% solution of povidone-iodine [1% free iodine]). Remove iodine with alcohol prior to specimen collection.
 - b. For open wounds, debride, if appropriate, and thoroughly rinse with sterile saline prior to collection.
3. Sample viable infected tissue, rather than superficial debris.
4. Avoid swab collection if aspirates or biopsy samples can be obtained.
5. Containers
 - a. Anaerobe transport vial for small tissues
 - b. Sterile cup for large tissues with nonbacteriostatic saline on a gauze pad to keep moist
 - c. Syringes with safety devices to protect from needle exposure
 - (1) Expel the air from the syringe, remove the needle after activating the safety apparatus, and cap the syringe with a sterile Luer-Lok.
 - (2) Alternatively, place the aspirated contents in a sterile blood collection tube without anticoagulant (e.g., Vacutainer or similar type).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- d. Broth culture medium in small sterile snap-top microcentrifuge tubes for fine-needle aspirates (FNA). These tubes are ideal for this type of specimen, because the specimen is easily visible and can be minced with a sterile glass rod in the laboratory, if necessary.
 - e. Swabs (*ideally, submit two, one for Gram stain and one for culture*) in either the CultureSwab EZ II system (BD Diagnostic Systems) or a swab transport system with Stuart's or Amies medium to preserve specimen and to neutralize inhibitory effects of swabs. EZ II and synthetic swab systems are best for anaerobic preservation (6).
- B. Specimen collection after proper disinfection**
- NOTE:** Refer to procedure 3.13.2 for quantitative culture methods.
1. Closed abscesses
 - a. Aspirate infected material with needle and syringe.
 - b. If the initial aspiration fails to obtain material, inject sterile, nonbacteriostatic saline subcutaneously. Repeat the aspiration attempt.
 - c. Remove needle and submit with Luer-Lok on the syringe or place contents in a sterile blood collection tube without anticoagulant.
 2. FNA
 - a. Insert the needle into the tissue, using various directions, if possible.
 - b. If the volume of aspirate is large, remove the needle and submit with Luer-Lok on the syringe.
 - c. If the volume is small, aspirate the specimen into the sterile locking microcentrifuge tube containing broth by drawing up and down to release the specimen from the syringe.

NOTE: Always use a safety device on the needle. Do not submit needle to the laboratory.
 3. Open wounds
 - a. Cleanse the superficial area thoroughly with sterile saline, changing sponges with each application. Remove all superficial exudates.
 - b. Remove overlying debris with scalpel and swabs or sponges.
 - c. Collect biopsy or curette sample *from base or advancing margin of lesion*.
 4. Pus
 - a. Aspirate the deepest portion of the lesion or exudate with a syringe and needle.
 - b. Collect a biopsy sample of the advancing margin or base of the infected lesion after excision and drainage.
 - c. For bite wounds, aspirate pus from the wound, or obtain it at the time of incision, drainage, or debridement of infected wound. (Do not culture fresh bite wounds, as there is generally not yet evidence of infection. These wounds will harbor the resident respiratory microbiota introduced from the bite, but cultures cannot predict if they will cause infection.)
 - d. Submit as for closed abscesses.
 5. Tissues and biopsy samples
 - a. Collect sufficient tissue, avoiding necrotic areas. Collect 3- to 4-mm biopsy samples.
 - b. Place small pieces of tissue in anaerobic transport vial; place larger pieces of tissue in a sterile container.
 6. Collect swabs only when tissue or aspirate cannot be obtained.
 - a. Limit swab sampling to wounds that are clinically infected or those that are chronic and not healing.
 - b. Remove superficial debris by thorough irrigation and cleansing with nonbacteriostatic sterile saline. If wound is relatively dry, collect with two cotton-tipped swabs moistened with sterile saline.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

- c. Gently roll swab over the surface of the wound approximately five times, focusing on area where there is evidence of pus or inflamed tissue.
 - d. If anaerobic and aerobic culture is indicated, transfer swabs immediately to an anaerobic transport tube or submit in CultureSwab EZ II system. For aerobic culture, submit in aerobic transport tube or CultureSwab EZ II system.
 - **NOTE:** Organisms may not be distributed evenly in a burn wound, so sampling different areas of the burn is recommended. Blood cultures should be used to monitor patient status.
- C. Label specimen and requisition.
 1. List demographic information on the patient.
 2. Describe the type of specimen (deep tissue, superficial tissue, decubitus, catheter site, boil, abscess, cellulitis, aspirate, pus, drainage, surgical incision site, etc.)
 3. State anatomic location (arm, leg, etc.)
 4. Record collection time and date.
 5. List diagnosis or ICD9 code, including cause and clinical signs of infection.
 6. List antimicrobial therapy prior to specimen collection.
 7. Choose tests requested, including anaerobic culture, if appropriate.
 - **NOTE:** To avoid the overuse of full fungal cultures that require incubation periods of greater than 1 week, the laboratory can offer a fungal culture with a shorter (2- to 4-day) incubation period. Such cultures are useful and cost-effective for the diagnosis of nosocomial, foreign-body, and postoperative infections, where the likely pathogen is either bacteria, *Candida* species, or *Aspergillus* species. *Candida* or *Aspergillus* species will grow on routine bacterial culture media within 1 week; however a selective fungal medium may be indicated for cultures expected to contain mixed microbiota. Full fungal cultures should be reserved for diagnosis of chronic infections, particularly those caused by dematiaceous and biphasic molds, and should be performed only from specimens not submitted on swabs.
- D. Deliver aspirates and tissues to the laboratory within 30 min for best recovery.
 1. Keep tissues moist to preserve organism viability.
 2. Do not refrigerate or incubate before or during transport. If there is a delay, keep sample at room temperature, because at lower temperature there is likely to be more dissolved oxygen, which could be detrimental to anaerobes.
- E. Rejection criteria
 1. Do not accept specimens for microbiological analysis in container with formalin.
 2. If numerous squamous epithelial cells are present on the Gram stain, especially from swab specimens, request a recollection if there is evidence of infection.
 3. Discourage submission of specimens to determine *if* an infection is present.
 4. Reject swabs that have been delayed in transit more than 1 h if they are not in some transport system (either CultureSwab EZ II system or one with preservative).
 5. For multiple requests (acid-fast bacilli, fungal, bacterial, and viral) but little specimen, contact the physician to determine which assays are most important and reject the others as “Quantity not sufficient.”

III. MATERIALS

A. Media

1. BAP
2. CHOC for surgical tissues, closed aspirates, biopsy samples, and FNA specimens or specimens from genital sites to culture for *Neisseria* or *Haemophilus* spp.
3. MAC or EMB, except for clean surgical specimens (e.g., orthopedic cultures). When in doubt, examine Gram stain to determine the likelihood of a mixed culture.
4. Phenylethyl alcohol agar (PEA) or Columbia colistin-nalidixic acid agar (CNA), if source (e.g., gastrointestinal) or *Gram stain indicates that the culture contains gram-negative rods*, which may inhibit gram-positive organisms.
5. Thayer-Martin or similar selective media for genital specimens or for other specimens if *Neisseria gonorrhoeae* is suspected.
6. Anaerobic culture media, if appropriate for site of collection and transport conditions. See section 4.
7. Special media for recovery of certain fastidious or unusual organisms. Refer to the table of contents of this section for procedures listed by specific microorganism names.
8. Broth for culture of tissues in order to detect small numbers of organisms, if appropriate. Specimens suitable for enrichment broths might include biopsy samples, surgically collected tissues, FNA, and other invasively collected specimens. Common broth media are as follows.
 - a. Anaerobic BHI or TSB with 0.1% agar with or without yeast extract

- b. Fastidious anaerobe broth (Que-lab Laboratories, Inc., Montreal, Quebec, Canada; Remel, Inc.)
- c. Brucella broth
- d. THIO: least desirable broth medium to grow low numbers of aerobic organisms and yeasts (5); however, it is excellent for anaerobic organism recovery.

■ **NOTE:** Morris et al. (4) concluded that THIO, inoculated as an adjunct to direct plating of wound, soft tissue, and fluid specimens, seldom yielded results that would alter patient management and could be omitted for most specimens without compromising patient care (with the exception of tissue specimens). Silletti et al. (7) reported that broths are not helpful for culture of swabs obtained from open wounds.

B. Tissue-homogenizing apparatus

1. Scalpels and petri dishes (Fig. 3.13.1-1)
2. Mortars and pestles. Use only in an anaerobic chamber if anaerobes are suspected, as these devices aerate the specimen (Fig. 3.13.1-2).
3. Automated pummeling instrument (stomacher [Tekmar Co., Cincinnati, Ohio]; MiniMix [Interscience Laboratories, Inc., Hingham, Mass.]) (Fig. 3.13.1-3)
4. Commercially available disposable plastic grinding devices (BD Diagnostic Systems; Sage Products Inc., Crystal Lake, Ill.). These are safer than glass handheld grinders (Fig. 3.13.1-4)

C. Gram stain reagents

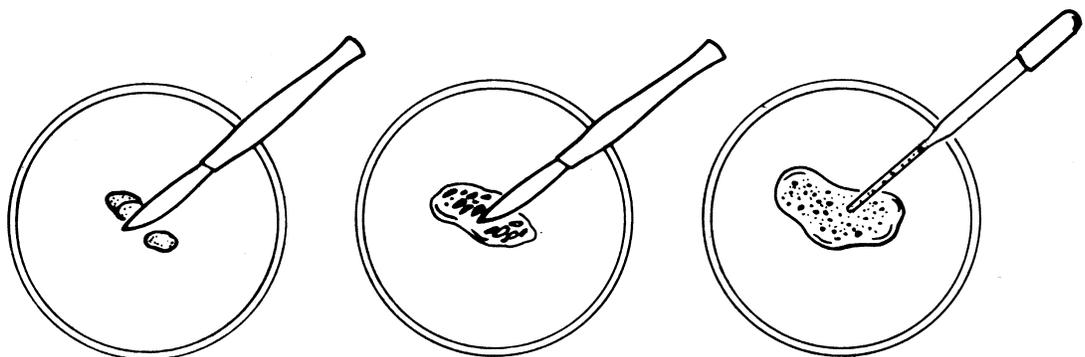

Figure 3.13.1-1 Illustration of sterile-scalpel method of homogenization of tissue.

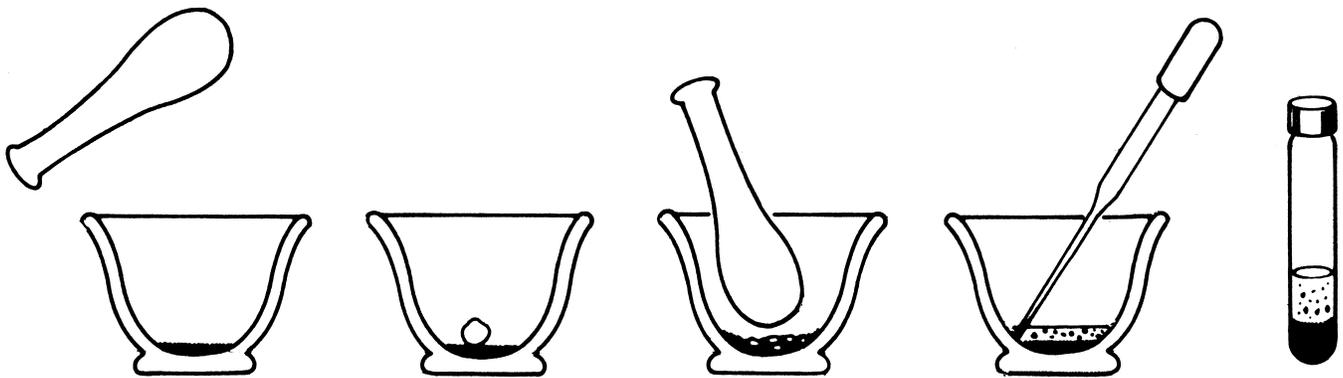

Figure 3.13.1-2 Illustration of mortar-and-pestle method of homogenization of tissue.

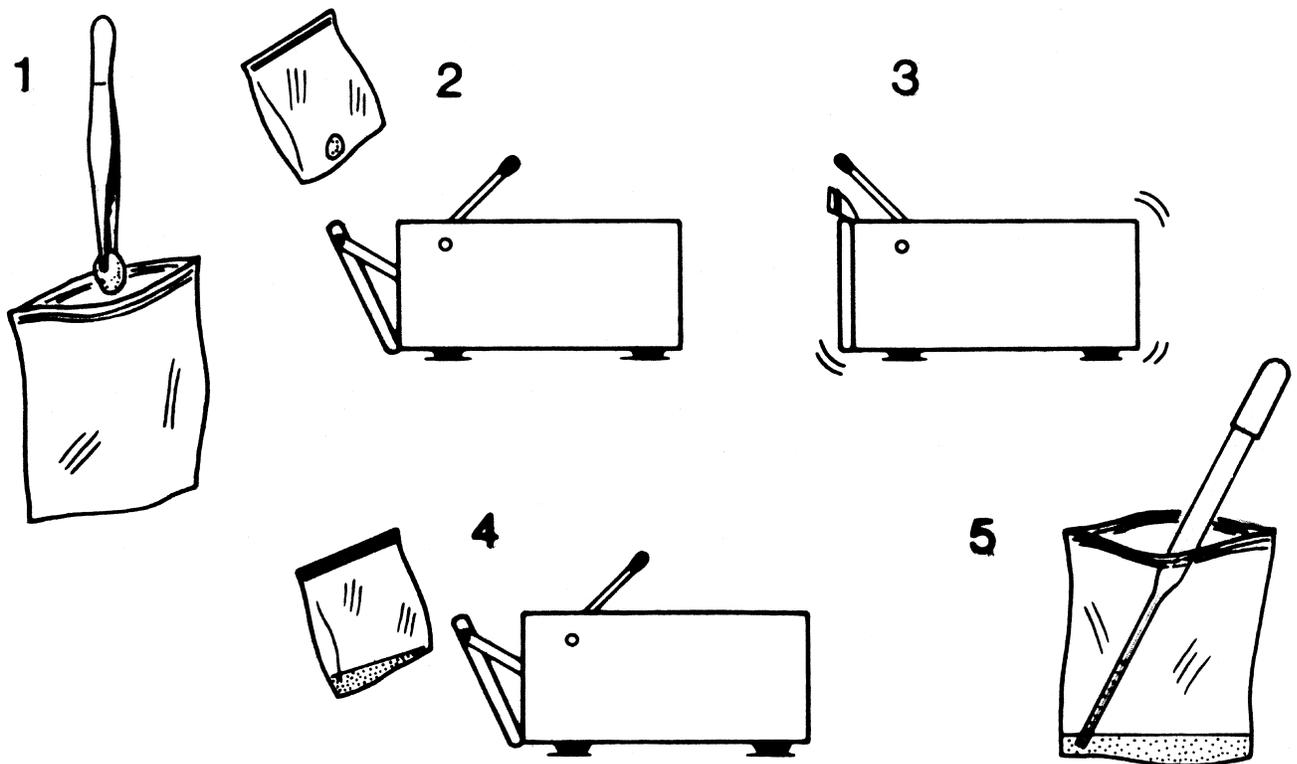

Figure 3.13.1-3 Illustration of stomacher method of homogenization of tissue.

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
- B. QC each lot of CHOC (procedure 3.3.1) and *N. gonorrhoeae* selective agar (procedure 3.9.3) using appropriate microorganisms listed in these procedures.
- C. Perform other user QC per current NCCLS document M22 and section 14 of this handbook.

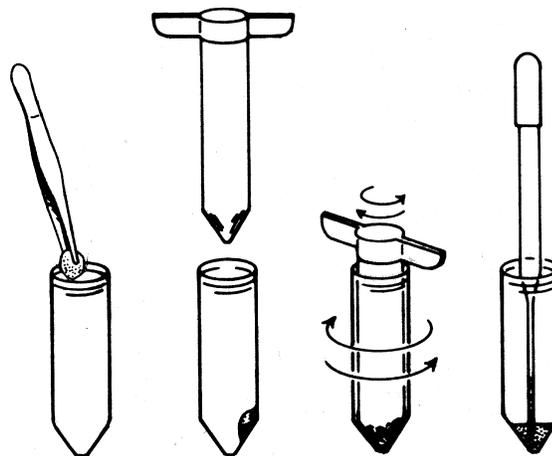

Figure 3.13.1-4 Illustration of tissue-grinding kit method of homogenization of tissue.

V. PROCEDURE

Observe standard precautions.

- A. For safety reasons, as with all microbiological specimens, and to protect the specimen from environmental contamination, place specimen and media in a biological safety cabinet or anaerobic chamber to perform specimen preparation and inoculations.
 - B. Inoculation
 1. Tissues
 - a. Select the area of the specimen that is bordering and including necrotic tissue.
 - b. Perform anaerobic culture first, preferably in an anaerobic chamber.
 - (1) If the tissue is large enough to be safely handled, place the tissue in a petri dish or specimen cup and cut it in half with a knife. Cut a smaller piece from the half and immediately touch the cut surface to the inoculum area of the anaerobe plates, place the tissue into broth culture medium, and streak the anaerobe plates for isolation.
 - (2) Alternatively, and for smaller tissue specimens, grind or homogenize tissues in THIO or other reduced broth (Fig. 3.13.1-1 to 3.13.1-4).
 - (3) Incubate immediately.
 - c. If the tissue can be easily teased apart (e.g., lung, kidney, brain tissue), cut a portion of the tissue into several pieces (use a sterile blade and stick or scissors) or gently tease it apart with sterile sticks (Fig. 3.13.1-1). (Save one piece of cut tissue without teasing for the smears.) Inoculate a piece of tissue onto each of the culture plates.
 - d. If the tissue is hard (e.g., bone, skin)
 - (1) Using a sterile scalpel, carefully chip bone into small pieces.
 - (2) Alternatively, place some of the tissue in the grinding apparatus (Fig. 3.13.1-2 and 3.13.1-4) and grind with about 0.5 ml of fluid from broth culture medium.
 - (3) After homogenization, remove the homogenized specimen using a sterile pipette. Inoculate plates and place the rest into broth culture medium.
- **NOTE:** Always examine these specimens for the presence of any soft tissue. If you find any such material, carefully remove it with a sterile surgical scalpel. This tissue may be processed separately.

V. PROCEDURE (continued)

- e. Use an automated pummeling instrument to grind tissues that cannot be easily teased, if available (Fig. 3.13.1–3).
 - (1) Place a portion of specimen into sterile bag.
 - (2) Insert sample bag between door and paddles in blender, allowing 4 cm of bag to project above top of door.
 - (3) Pull handle forward to firmly close door, and switch machine on for 1 to 5 min.
 - (4) Switch machine off, hold bag, open door by lifting handle, and remove bag.
 - (5) Remove sample from bag by using sterile pipette, and inoculate media.
 - f. For Gram stain
 - (1) *Always prepare the smear after the culture has been inoculated. Never touch the slide with a pipette or swab that will then be used for culture.*
 - (2) Make a fresh cut of tissue and prepare the smear by touching the tissue to the slide. If the tissue is hard and does not stick to the slide, place the tissue between the two slides and press the slides together. Then separate by drawing the slides against each other (*see* Fig. 3.2.1–1 and 3.2.1–2).
 - g. If the tissue is large enough, save an intact piece in the refrigerator for up to 7 days, or in the freezer for extended storage.
2. Aspirates and pus
 - a. Mix the specimen thoroughly. Place a drop of the specimen onto each piece of the medium.
 - b. If sufficient specimen is submitted, inoculate invasively collected aspirates to broth culture medium to make a 1:10 dilution. If the volume is small, omit broth culture.
 - c. Prepare smear for Gram stain by placing a drop of specimen on a slide and spreading it to make a thin preparation. If the aspirate fluid is clear, use the cytocentrifuge to concentrate the specimen for the smear.
 - d. If sufficient specimen is available, save a portion in the refrigerator for up to 7 days for further testing, if indicated.
 3. Swabs
 - a. If an anaerobic culture is to be performed, inoculate anaerobic plates first.
 - b. Then place swab in 1 to 2 ml of broth and vortex.
 - c. Squeeze the swab against the side of the broth tube to express remaining fluid and then discard.
 - d. Inoculate aerobic plates and prepare smear for Gram stain as described for aspirates and pus.
 - e. Alternatively, the swab can be used for direct specimen plating. Always inoculate media from the least inhibitory to the most inhibitory.
 - f. Save broth in the refrigerator for up to 7 days for further testing, if indicated.

☑ **NOTE:** Do not culture swabs from superficial wounds or abscesses in broth medium.
- C. Aerobic incubation conditions (*see* section 4 for anaerobic incubation conditions and workup of anaerobic culture)
 1. Incubate BAP, CNA or PEA, and CHOC in humidified incubator at 35 to 37°C with 5% CO₂. Incubate for a minimum of 48 h for open wound cultures and for 3 to 4 days for invasively collected specimens with no initial growth. For negative cultures from critical sources (e.g., brain aspirates, corneal tissue) or, possibly, for specimens with PMNs and no organisms isolated in culture, extend incubation time longer, even up to 7 days, especially if a shortened fungal culture was requested.

V. PROCEDURE (continued)

2. Incubate MAC or EMB plates in ambient air at 35 to 37°C, unless it is inconvenient to keep them separate from the rest of the culture in 5% CO₂.
 3. Incubate broth in ambient air at 35 to 37°C for 3 to 4 days. If possible, hold for 1 week at room temperature to ensure that some specimen is available if further testing is indicated.
- D.** Perform a Gram stain on all specimens and use in the evaluation of culture.
1. Refer to procedure 3.2.1 for details on smear preparation and staining.
 2. Record the relative numbers of WBCs, epithelial cells, and bacterial and fungal morphotypes.
 - a. If clinically important organisms are recognized or suspected (e.g., from a normally sterile site) based on the Gram stain interpretation, telephone or report results to the appropriate caregiver immediately. Report any bacteria seen in a surgically collected specimen from a normally sterile site. Some examples of significant bacteria include the following.
 - (1) Clostridium-like gram-positive rods seen on specimens from soft tissue infections or aspirates even in the absence of numerous intact PMNs.

NOTE: Clostridia most often produce a variety of phospholipases and lipases, which destroy host cells; thus, cells are not characteristically seen on smear.
 - (2) Numerous PMNs and gram-positive cocci in clusters resembling *Staphylococcus* in an abscess or tissue.
 - (3) Bacteria seen from brain abscess specimens.
 - (4) Gram-positive, lancet-shaped diplococci suggestive of *Streptococcus pneumoniae* from endometrial tissue.
 - b. If multiple morphologies are seen on the smear and the culture was not inoculated onto selective agar, go back to the specimen and inoculate it to CNA or PEA and EMB or MAC.
- E.** Culture workup
1. Read plates and broth daily. Refer to procedure 3.3.2 for description of colony types, initial reading, testing, and reporting preliminary and final cultures. For identifications refer to Table 3.3.2–5 and procedures 3.18.1 and 3.18.2.
 2. For cultures of lymph nodes, work in a biological safety cabinet, since pathogens can be found in these specimens that are hazardous, e.g., *Francisella*, *Mycobacterium*, and *Brucella*.
 3. Refer to Table 3.13.1–1 for the list of the most common pathogenic organisms associated with wound infections and Fig. 3.13.1–5 for algorithm for extent of workup of cultures. Follow Fig. 3.13.1–6 and identify any number of the organisms listed.
 4. Generally identify up to three microorganisms listed in Table 3.13.1–1 if any of the following is true.
 - a. PMNs were present on direct smear.
 - b. The specimen was collected from a normally sterile site.
 - c. The specimen was of good quality (e.g., no or few epithelial cells present).
 - d. The organism was seen on the direct smear.
 5. Perform only minimal testing to indicate the type of microbiota present for noninvasively collected specimens with any of the following.
 - a. Moderate or numerous epithelial cells present on the smear
 - b. No evidence of infection on the smear (no PMNs) and no clinical information accompanying the specimen to indicate an infection

It is imperative that these cultures be handled in a biosafety hood.

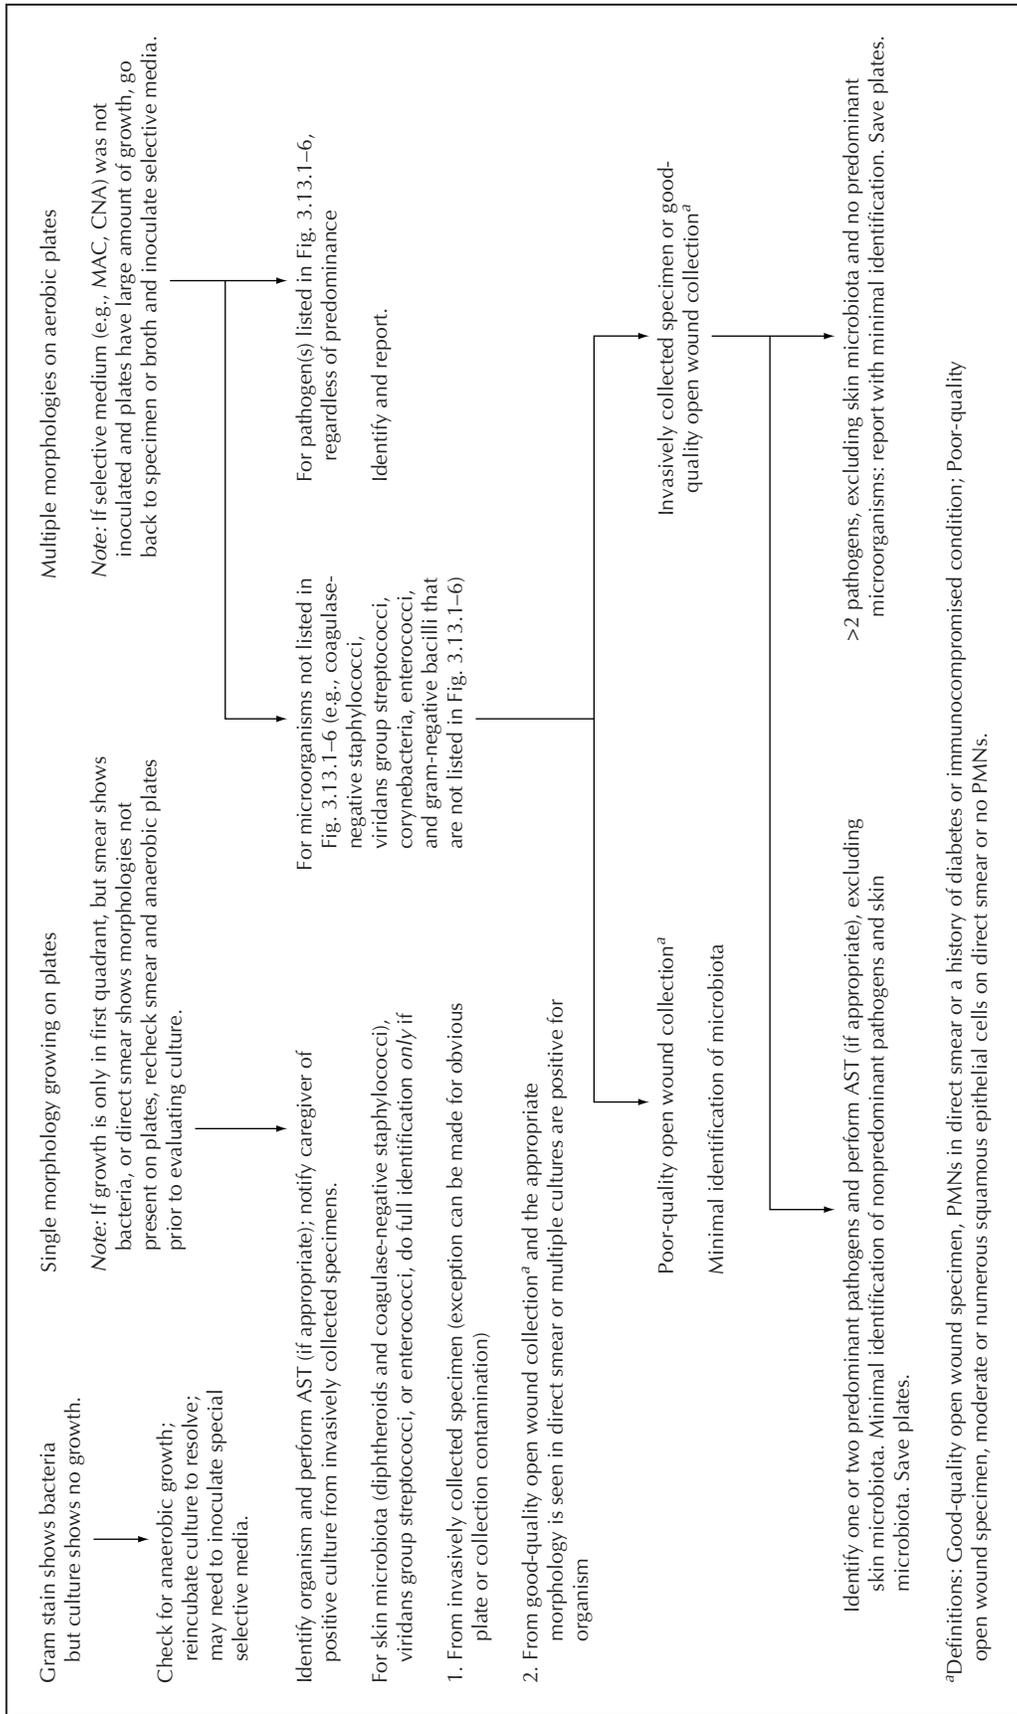

Figure 3.13.1-5 Initial evaluation of positive wound cultures for organisms growing aerobically. *Note:* For lymph nodes, perform all work using biological safety cabinet.

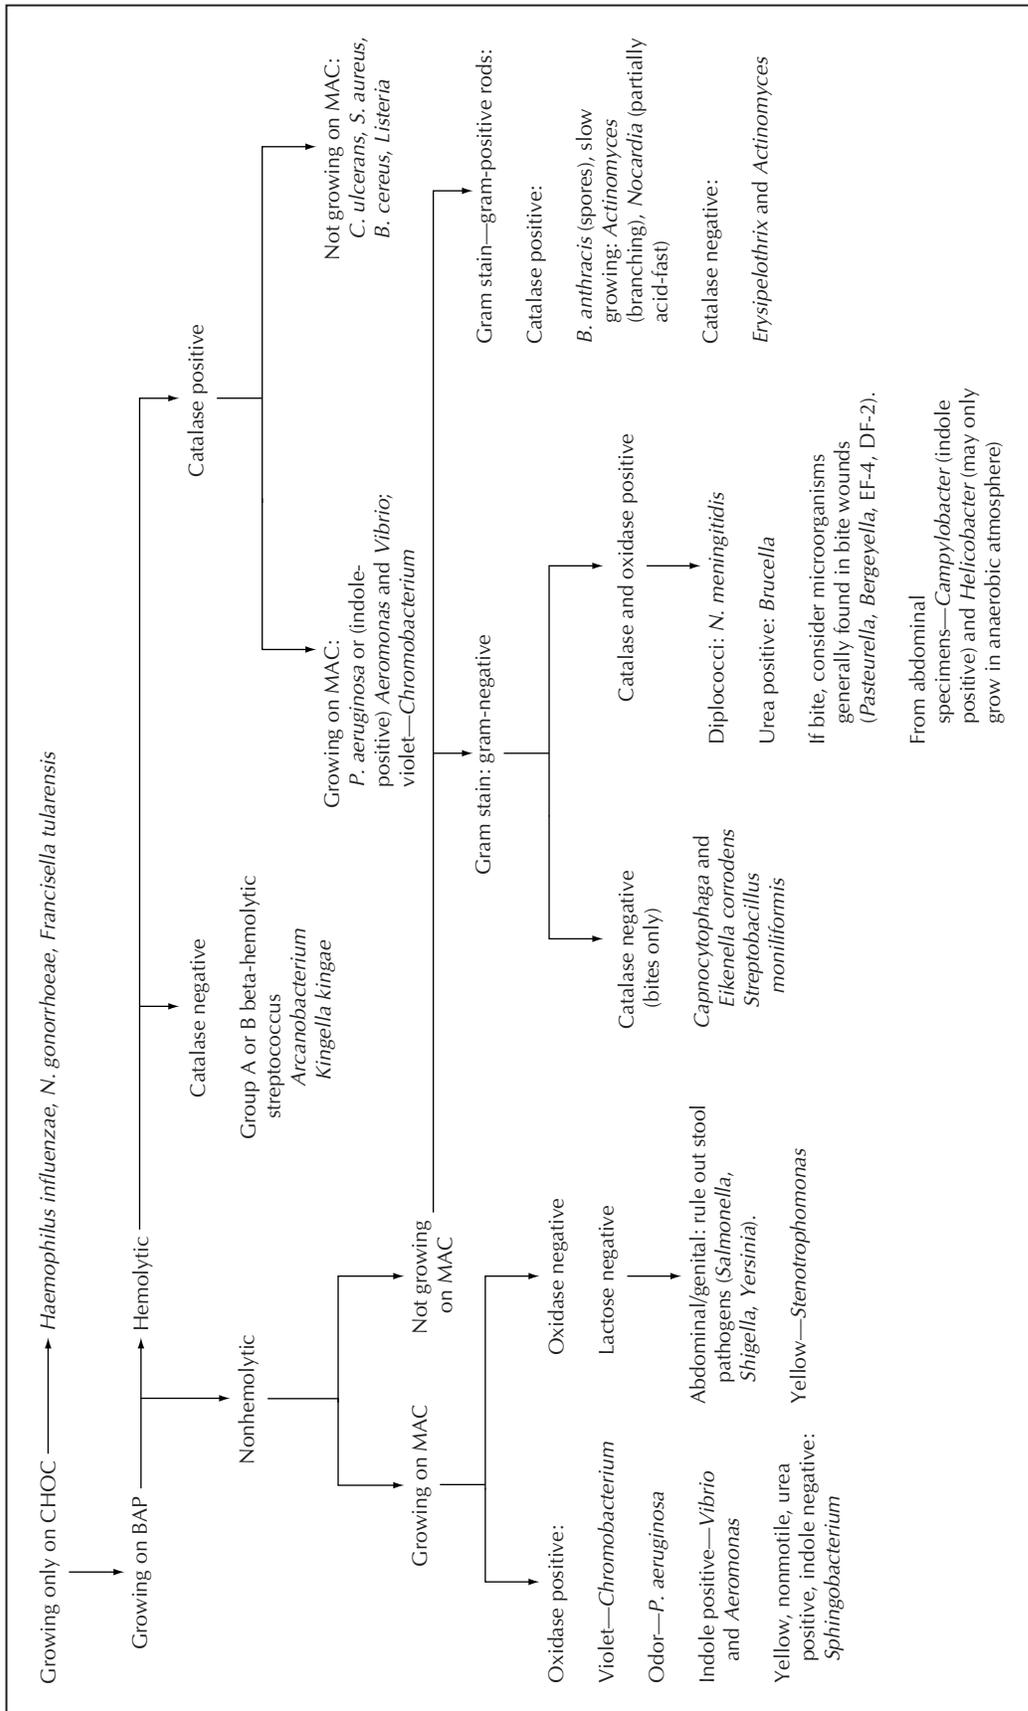

Figure 3.13.1–6 Algorithm to rapidly detect aerobic and facultatively aerobic microorganisms usually considered significant, even in low numbers or in mixed cultures. See procedures 3.18.1 and 3.18.2 for other tests needed to confirm suspected identifications.

V. PROCEDURE (continued)

- c. ≥ 3 Organisms growing in the culture. See exceptions for specific organisms in Fig. 3.13.1–6, which are generally always reported.
 - **NOTE:** Save all culture plates with growth for several days in case further work is requested by the physician. Seven days is usually sufficient, but if space is a problem, transfer isolates to culture tubes for storage or save for a shorter period.
- 6. Identify any number of microorganisms that only grow on CHOC, and not on BAP (*N. gonorrhoeae*, *Haemophilus*, and *Francisella*). Identify *Neisseria meningitidis*.
- 7. Identify *Streptococcus pyogenes* or *Streptococcus agalactiae*.
 - **NOTE:** Notify the physician of the isolation of *S. pyogenes*, as it may represent a life-threatening case of necrotizing fasciitis.
- 8. *Staphylococcus*
 - a. *S. aureus*
 - (1) Perform AST from invasively collected specimens and from others, if the Gram stain indicates a good-quality specimen and an infectious process with this organism (e.g., PMNs with few or no squamous epithelial cells and staphylococci seen on specimen Gram stain).
 - (2) If an infectious process is not apparent but it is the hospital policy to track nosocomial methicillin-resistant *S. aureus* (MRSA) infections, rule out MRSA on inpatient specimens, unless the patient has a prior positive culture with MRSA. Notify infection control practitioner if MRSA is present, per hospital policy.
 - b. When *coagulase-negative staphylococci* are present, perform AST only if they are the only organisms isolated from invasively collected specimens, if they are associated with PMNs in the direct smear, or if they are isolated from multiple cultures. Report as normal cutaneous microbiota if found in mixed cultures in any amount from superficial wound specimens or if numerous epithelial cells are present in the specimen.
- 9. For *viridans group streptococci* or *enterococci*
 - a. Identify at least to the genus level from surgically, invasively collected specimens where the organism is the single or predominant pathogen and the Gram stain indicates infection (the presence of PMNs).
 - b. Include in normal microbiota if found in mixed cultures and not predominant.
 - c. If determined to be a significant isolate or if indicated by infection control policies, perform a vancomycin screen on enterococci from inpatients and from transplant and oncology outpatients. Perform AST only if isolate is from normally sterile site (e.g., bone, brain) in pure or almost pure culture.
- 10. For *gram-positive rods*, if specimen is from a normally sterile site or biopsy sample, rule out *Listeria*, *Erysipelothrix*, *Bacillus cereus*, *Bacillus anthracis*, *Arcanobacterium*, *Corynebacterium ulcerans*, *Nocardia*, and *Actinomyces*. Identify other gram-positive rods if numerous or seen as predominant in smear. Otherwise include these in skin microbiota.
- 11. Include *yeasts* as part of normal microbiota unless predominant or numerous. Except for specimens from normally sterile sites, generally identify only *Candida albicans* to the species level.
- 12. For predominant or moderate to numerous amounts of *enteric gram-negative rods*
 - a. If only one or two species are present or predominant and *an indication of infection is seen on smear*, identify and perform AST. For specimens from the abdominal cavity, the aerobic plates may contain only a few

V. PROCEDURE (continued)

Escherichia coli organisms but the smear appears to represent mixed morphologies. In such cases, do not set up AST on the *E. coli* until the results of the anaerobic culture can be evaluated. Potentially the anaerobic microbiota may be the significant, predominant pathogen(s).

- b. If enteric bacilli are few in amount or not predominant, or if >2 species are present with no predominant strain, report as “mixed GI [for gastrointestinal] microbiota.”
 - (1) Rule out fecal pathogens (*Salmonella*, *Shigella*, *Campylobacter*, and *Yersinia* spp.) for specimens from abdominal abscesses.
 - (2) Generally save a representative plate for up to 7 days in case further work is requested.
 - c. Identify and perform susceptibility tests on multiple morphologies of enteric gram-negative rods only on special request after consultation with the laboratory director, designee, or physician.
 - **NOTE:** When cultures contain a variety of enteric rods, treatment must include a combination of antimicrobial agents which are known to eradicate normal intestinal microbiota. Examination of a culture with fecal contamination to detect and separate each species is futile and not helpful for overall treatment decisions.
13. For gram-negative rods that are not of the *Enterobacteriaceae* family
- a. Rule out organisms which are always considered pathogenic (e.g., *Bruceella*, *Haemophilus*, *Pasteurella*, *Francisella*). Generally these organisms are recognized because they do not grow on MAC or EMB. These organisms are not uncommon in dog and cat bite wounds. Work in a biological safety cabinet, and see procedure 3.18.2 for identification flowcharts and tables.
 - *Francisella can be found in lymph node biopsy samples and is extremely infectious. It is a tiny coccobacillus that grows slowly and is catalase positive or weak and oxidase negative. It can ferment glucose, but it is negative for other biochemical tests. It is beta-lactamase positive. Refer to procedure 16.8 on bioterrorism for other details.*
 - b. Identify obvious *P. aeruginosa* (characteristic odor and beta-hemolytic colonies) and *Stenotrophomonas maltophilia* (yellow and oxidase negative). If in pure culture or significant amounts and the Gram stain suggests an infective process, perform AST.
 - c. Identify oxidase-positive, indole-positive organisms (Table 3.18.2–8) which are likely to be *Aeromonas* or *Vibrio*. Also examine for the pigmented gram-negative rods *Chromobacterium violaceum* and *Sphingobacterium*.
 - d. Identify and perform AST on other gram-negative rods (*Pseudomonaceae*, *Acinetobacter*, and related non-glucose-fermenting rods) by following the algorithm in Fig. 3.13.1–5.
14. Refer to procedure 3.3.2 for details on handling of broth cultures.
- F. Hold positive culture plates at room temperature or in the refrigerator for several days (generally 7 days) after the culture is completed for additional work if requested by the physician.

It is imperative that these cultures be handled in a biosafety hood.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. Report Gram stain results as soon as possible, generally within 1 h for specimens from critical sites.
- B. Report all negative cultures as “No growth in _____ days.”
- C. Report individually those organisms that are always considered pathogenic (Fig. 3.13.1–6) with enumeration, using a preliminary identification initially and the genus and species (if applicable) as the final identification, if applicable.
- D. Due to their known virulence factors, indicate the presence of the following species.
 1. Beta-hemolytic streptococci
 2. *S. aureus*
 3. *P. aeruginosa*
 4. *Clostridium perfringens*
 5. Report “Pigmented anaerobes,” *Bacteroides* spp., and “Mixed anaerobes” without further identification. (See section 4 for identification methods.)
- E. Report other pathogens, as indicated in Fig. 3.13.1–5, with either definitive or minimal identification, depending on quantitation, number of species present, and Gram stain results. (See Table 3.13.1–2 for examples of reports.)

Table 3.13.1–2 Examples of mixed wound culture reporting^a

Microbiological observation	Examples of specimen submissions			
	Example 1	Example 2	Example 3	Example 4
PMNs in Gram stain	–	2+	3+	1+
Bacteria in Gram stain	3+ gram-negative rods	3+ gram-negative rods	3+ gram-positive and -negative rods	No organisms seen
Bacteria in culture				
<i>S. aureus</i>	1+	2+	1+	–
<i>P. aeruginosa</i>	–	3+	–	–
Beta-hemolytic streptococci	–	–	–	1+ group A
<i>Enterobacteriaceae</i> (agents of gastroenteritis ruled out)	3+ pure	1+	2+	1+
<i>Peptostreptococcus</i> spp.	–	1+	1+	1+
<i>Clostridium</i> spp.	1+	–	3+	–
Pigmented gram-negative anaerobes	–	–	3+	–
Nonpigmented gram-negative anaerobes	1+	–	1+	–
Information provided on microbiology report	3+ <i>E. coli</i> ; 1+ anaerobic GI microbiota; 1+ <i>S. aureus</i>	2+ <i>S. aureus</i> (AST); 3+ <i>P. aeruginosa</i> (AST); 1+ mixed skin and enteric microbiota	4+ mixed aerobic and anaerobic GI microbiota; 1+ <i>S. aureus</i>	1+ <i>S. pyogenes</i> ; 1+ mixed skin and enteric microbiota
Notes	May rule out MRSA for infection control purposes. Save plates; may need to do AST on <i>E. coli</i> if diabetic, etc.		May rule out MRSA for infection control purposes.	

^a Revised from Bowler et al. (1).

VI. REPORTING RESULTS

(continued)

- F. Report AST on gram-negative rods, enterococci, or *S. aureus*, using the flow-chart in Fig. 3.13.1–5. Generally do not perform AST on microorganisms that are not predominant, are in mixed cultures, or are skin microbiota or if culture does not show evidence of an infectious process. Make exceptions to this general policy if requested to do so by physician caring for the patient or for infection control purposes.
- G. When multiple morphologies are present, report with minimal identification.
Example: “Culture yields growth of >3 colony types of enteric gram-negative bacilli. Consult microbiology laboratory if more definitive studies are clinically indicated.”
See Table 3.13.1–2 for other examples.
- H. Additionally, if mixed microbiota are cultured with no predominant microorganism, report as GI, oronasal, skin, or genital microbiota. Use of selective media is helpful in evaluation of polymicrobial nature of culture.
- I. For further details on reporting, refer to procedure 3.3.2.

VII. INTERPRETATION

- A. Continuous dialogue between the clinician or nurse and the microbiology laboratory should be encouraged for proper interpretation of results.
- B. The results of wound cultures will only be as valuable as the quality of the specimen submitted, its transport, and expedient processing.
- C. Reporting selected organisms in mixed cultures can lead to erroneous interpretation of the number and variety of infecting pathogens.
- D. Performance of AST is not indicated in cases of mixed microbiota indicative of infection of the abdominal cavity with bowel contents. Treatment should include broad-spectrum coverage for normal intestinal microbiota.
- E. *Use of the Gram stain can improve the accuracy of evaluating the importance of each potential pathogen. Organisms present in the Gram stain of an appropriately collected specimen correlate with $\geq 10^5$ organisms per g of tissue (2, 3).*
- F. Clinical studies have demonstrated that the microbial load in an acute wound can predict delayed healing or infection. The more numerous the organisms, the more likely they are to be indicative of infection (1).
- G. Many wound infections are polymicrobial, and the isolation of an organism in culture may or may not correlate with infection of the wound.

VIII. LIMITATIONS

- A. The microbiologist plays a critical role in the treatment of wound infections because practitioners often consider the report from the laboratory as definitive proof of infection. Providing inappropriate identifications and susceptibility results can prompt unnecessary treatment.
- B. The presence of PMNs is an indication of an inflammatory or infectious process, while the presence of epithelial cells indicates surface contamination of the specimen. Specimens containing numerous epithelial cells yield culture results of questionable accuracy in the diagnosis of the infectious process, and one can consider rejection of these specimens for culture.
- C. If a patient is immunocompromised or has poor vascular supply, inflammatory cells may not be present in the specimen as a guide to the extent of workup of the culture.
- D. Low levels of organisms or fastidious organisms that grow poorly on the direct plates may be missed in culture.
- E. Unusual treatment considerations may alter the usual policies of the laboratory in reporting AST.

VIII. LIMITATIONS (continued)

- F. The lack of isolation of a pathogen does not necessarily mean that the laboratory was unable to detect the agent. Other inflammatory diseases can have the same presentations as infectious diseases, including the presence of PMNs on the Gram stain.

3.13.2

Quantitative Cultures of Wound Tissues

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Quantitative culturing is a patient management tool that can be used with a limited variety of specimen types. However, as indicated in the review by Bowler et al. (2), several publications have demonstrated a correlation between quantitative tissue biopsy cultures and the semiquantitative method of enumeration of organism growth (*see* Table 3.3.2–2) in a qualitative swab culture. Tissues from acute wounds, such as those from trauma and burn patients, and duodenal aspirates are the specimen types that may be used for quantitative microbiological analysis. This pro-

cedure describes collection and processing of tissue specimens and determination of bacterial counts. The presence of bacteria in tissue in significant amounts is one of a number of factors which have been associated with delayed healing and has also been correlated with infection. When tissue is not readily available, a swab sample may be a convenient substitute for a tissue biopsy sample, and in a quantitative culture, it may similarly be an indicator of an infectious process. However, semiquantitative swab culture is generally sufficient for patient management.

Quantitative cultures for anaerobic bacteria are problematic and thus less meaningful. Anaerobic microorganisms tend to live in microbial synergy with other organisms in the culture and do not grow well when diluted.

Quantitation of bacteria in duodenal aspirates can predict defects in mobility of the intestines. See procedure 13.15 for details. For quantitative culture of specimens from bronchoscopy, refer to the respiratory procedure (Appendix 3.11.2–1).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. Tissues

- a. Submit 2- by 1-cm or larger tissue sample collected after cleansing and/or surgical debridement to yield the most useful information. (Refer to procedure 3.13.1 for collection details). This will yield approximately 500 mg of tissue, depending on the density (3).
- b. Submit as soon as possible without transport medium, but keep moist in a sealed, sterile container.

2. Swab collection

- a. Refer to procedure 3.13.1 for collection.
- b. *Use only alginate swabs for quantitative culture.*

B. Rejection criteria

1. If insufficient specimen is received for quantitation, process the specimen for qualitative culture only.
2. Do not process dry swabs.

III. MATERIALS

- | | |
|---|--|
| <p>A. Media</p> <ol style="list-style-type: none"> 1. BAP or CHOC 2. EMB or MAC 3. THIO or saline for dilutions <p>B. Reagents</p> <ol style="list-style-type: none"> 1. Stain reagents for Gram stain 2. 0.85% sterile NaCl 3. Sterile Ringer's solution (available from suppliers of intravenous solutions) containing the following per liter <ol style="list-style-type: none"> a. 8.5 g of NaCl b. 0.3 g of KCl c. 0.33 g of CaCl₂ <p>C. Other supplies</p> <ol style="list-style-type: none"> 1. Loop method: use either platinum or sterile plastic disposable loops to deliver 0.001 ml (1 µl) or 0.01 ml (10 µl). | <ol style="list-style-type: none"> 2. Pipettor method: sterile pipette tips and pipettor to deliver 10 or 1 µl 3. Sterile bent glass or plastic disposable sterile rods to spread inoculum (Excel Scientific, Wrightwood, Calif.; [760] 249-6371) 4. Sterile pipettes 5. Analytical balance 6. Polytron omnimixer (Brinkman Instruments, Westburg, N.Y.) or automated pummeling instrument (stomacher; Tekmar Co., Cincinnati, Ohio) 7. CO₂ incubator at 35 to 37°C 8. Anaerobic atmosphere (optional) |
|---|--|

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that media meet expiration date and QC parameters per current NCCLS M22 document. See procedures 14.2 and 3.3.1 for further procedures, especially for in-house-prepared media.
- B. Validate the method of quantitation using known cultures of various colony counts. Refer to Appendixes 3.12–3 and 3.12–4 for QC for loops and pipettors, respectively.

V. PROCEDURE

Observe standard precautions.

- A. **Specimen processing**
 1. **Tissues**
 - a. Weigh the tube containing the tissue on an analytical balance.
 - b. Remove the tissue by using aseptic technique, and place it in 5 ml of sterile 0.85% NaCl or THIO (4, 5, 7). Use THIO only if anaerobic culture is performed. This is a 1:5 dilution of tissue.
 - c. Reweigh the now empty original specimen tube, and subtract to determine the weight of the tissue in grams or milligrams.
 - d. Homogenize the tissue for 15 to 30 s. Keep the homogenate cool during processing. See procedure 3.13.1 for detailed tissue homogenization methods.
 - e. Plate 0.1 ml of the original homogenate. Label plate “10⁻¹” for amount of dilution of original homogenate (which is a 1:5 dilution of the specimen).
 - f. Make one to three serial 1:10 dilutions of the homogenate with 0.5-ml aliquots and 4.5 ml of sterile 0.85% NaCl per aliquot.
 - g. Plate 0.1 ml of each dilution onto BAP or CHOC and EMB or MAC. Evenly distribute the inoculum with a sterile bent rod. Label plates “10⁻²,” “10⁻³,” and “10⁻⁴.” Alternatively, for the 10⁻³ and 10⁻⁴ dilutions, inoculate 0.01 and 0.001 ml of the first dilution with 10- and 1-µl loops, respectively.
 - h. Repeat inoculations onto anaerobic BAP, if desired.
 - i. Incubate aerobic plates at 35°C in 5% CO₂ for 18 to 24 h. Use an anaerobic atmosphere for anaerobic plates.

V. PROCEDURE (*continued*)**2. Swabs**

- a. Place swab in 5 ml of Ringer's solution. Vortex and remove remaining swab material. (Swab should dissolve.)
- b. Beginning with item V.A.1.e above, serially make 10-fold dilutions in 0.85% NaCl and process as for tissue.

B. Gram stains

1. Prepare Gram stain of tissue specimens by spreading a 0.01-ml aliquot of the homogenate on a 1- by 1-cm area of a glass slide (6).
2. Allow the slide to dry, fix with methanol, and Gram stain.
3. Examine 10 fields under a 100× oil immersion objective (*see* procedure 3.2.1 for reporting guidelines).
4. Organisms are visible in Gram stains when at least 10⁵ organisms per g of tissue are present in the specimen (6).

C. Examination of cultures: tissue and swabs

1. Determine the number of organisms per gram of tissue by counting the colonies on the plate that grew between 30 and 300 colonies.
 NOTE: Only use MAC or EMB if overgrowth on BAP or CHOC precludes accurate counting of gram-negative bacilli.
2. Calculate the total number of organisms by using the colony count times the dilution factor (use 5 as the factor for the homogenate dilution and the dilutions labeled on the plates for subsequent dilutions) divided by the original weight of the tissue. There is no weight of the tissue for swab specimens. Use only dilution factors.

Example: Tissue weighed 0.3 g.

Count was 50 on plate labeled "10⁻³."

$$\frac{50 \text{ CFU} \times 5 \text{ (homogenate dilution)} \times 10^3 \text{ (plate dilution)}}{0.3 \text{ g}} = \frac{2.5 \times 10^5 \text{ organisms}}{0.3 \text{ g}} = 8.3 \times 10^5 \text{ CFU/g}$$

3. Report total count "per gram of tissue" or "per swab."
4. Work up pathogenic organisms for identification and antimicrobial susceptibility testing (AST) according to procedure 3.13.1 when count is >10⁵ organisms per g. Special consideration must be made case by case for counts of <10⁵ organisms per g, depending especially on the identity of the isolate(s) and the type of disease of the patient.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. Report direct results of smear of tissues with enumeration of each morphotype.
- B. Report wound cultures as total number of organisms per gram of tissue.
- C. See procedure 3.13.1 for reporting predominant species and AST.

VII. INTERPRETATION

- A. The probability that tissue from a traumatic wound or burn is infected or will fail to heal can be predicted from cultures showing >10⁵ organisms per g (2–5).
- B. Colony counts of approximately 10⁵ CFU/g of tissue were found to be equivalent to colony counts of 10³ bacteria/ml of specimen obtained on a moist *alginate* swab (1).

VIII. LIMITATIONS

- A. These tests should be used only under certain circumstances and after consultation with the physician or clinical service.
- B. Loops are not as accurate as pipettes to deliver the inoculum.
- C. Spreading with a loop is not as accurate as spreading with a bent rod.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Leptospirosis is a spirochetal zoonosis caused by the genus *Leptospira*. Human-pathogenic *Leptospira* infects about 160 wild and domesticated mammalian species worldwide, which excrete the organism in their urine. The human disease is more commonly associated with occupations or recreational activities associated with direct skin or mucous membrane contact either with the animal reservoir or with water, soil, or sewage contaminated with the animal urine. Although most reports consider human infections to be caused by the species *Leptospira interrogans*, DNA relatedness studies have demonstrated that *L. interrogans* probably consists of at least seven species, including *L. interrogans*, *Leptospira noguchii*, *Leptospira weilii*, *Leptospira santarosai*, *Leptospira borgpetersenii*, *Leptospira kirschneri*, and *Leptospira inadai* (9). Serologic studies indicate that there are more than 218 serovars of pathogenic *Leptospira*, but the serovar cannot be used to predict an isolate's molecular identification. Species identification is thus limited to special reference laboratories, such as the CDC.

The disease can present as a febrile illness with or without meningitis or as

Weil's syndrome, a potentially fatal illness that presents as hemorrhage, renal failure, and jaundice. Symptoms in milder disease include fever, malaise, muscle aches, and headache. Clinical recognition of leptospirosis is difficult because leptospires can affect many different organ systems, resulting in a nonspecific clinical presentation. Consequently, leptospirosis is often misdiagnosed as influenza, aseptic meningitis, encephalitis, dengue fever, hepatitis, or gastroenteritis. Effective treatment and preventive measures are available, if the disease is diagnosed in a timely manner.

Diagnosis is generally made by serologic testing, which is available from specialized reference laboratories, such as the CDC. The microscopic agglutination test (MAT) is the "gold standard" serologic test to which others are compared. Because a fourfold rise in titer between acute- and convalescent-phase samples is necessary for serologic confirmation, the MAT is not useful for guiding clinical management early in the course of the patient's illness.

Several serologic tests have recently been evaluated by the CDC, including a

microplate immunoglobulin M (IgM) ELISA (PanBio, Windsor, Brisbane, Australia; 61-7-3357-1177), an indirect hemagglutination assay (MRL Diagnostics, Cypress, Calif.), and an IgM dot ELISA dipstick test (DST; Integrated Diagnostics Inc., Baltimore, Md.), as rapid alternatives to the MAT (1). The CDC conclude that the ease of use and significantly high sensitivity and specificity of DST and ELISA make these good choices for diagnostic testing.

Leptospires are thin, spiral-shaped bacteria requiring special techniques for isolation. They are aerobic bacteria that can be cultivated at 30°C in media containing either rabbit serum (Fletcher's medium) or bovine serum albumin and fatty acids (leptospira or Ellinghausen-McCullough-Johnson-Harris [EMJH] medium [4, 7]). See Appendix 3.14–1 for further descriptions of media. Growth is observed in broth in a few days to 4 weeks. Culture of spinal fluid and blood during the first week of illness and of urine after the first week can be helpful in confirming the diagnosis. However, rapid methods, such as PCR, are more helpful since culture is not timely for treatment of serious infections.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. CSF (collect during first week of illness)
2. Urine (collect during second week of illness)
 - a. Inoculate into culture medium within 1 h of collection *or*
 - b. Dilute 1:10 in 1% bovine serum albumin and store at 5 to 20°C for longer (a few days) stability (9).
3. Dialysis fluid

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

4. Blood
 - a. Collect with sodium polyamethol sulfonate (SPS) or inoculate directly into culture medium.
 - b. In SPS, leptospire are stable for at least 6 days (9).
 - c. Protect from excessive heat or cold (5).

B. Specimen timing

1. Alert laboratory that specimen is being submitted for *Leptospira* culture, so that media can be available prior to collection and/or arrangements for PCR testing can be made.
2. Collect blood and CSF only in the first week of illness, prior to initiation of treatment.
3. Collect urine during the second week of illness or later. Organisms can be present for up to several months.
4. Culture multiple specimens taken at least 1 day apart to increase likelihood of a positive result (6).

C. Rejection criteria

1. Urine received greater than 1 h after collection unless it has been diluted in albumin
2. Blood or CSF from patients who have been symptomatic for greater than 10 days
3. Direct dark-field smears are not recommended since protoplasmic extrusions are too easily mistaken for spirochetes (6).

III. MATERIALS

A. Media

1. *Leptospira* EMJH base and enrichment medium
 - a. Purchase dehydrated powdered media from BD Diagnostic Systems (3). Follow manufacturer's instructions.
 - b. Other manufacturers may refer to medium as bovine serum albumin-Tween 80 medium.
 - c. EMJH medium can be prepared in-house; see Appendix 3.14–1 (4, 7).

☑ **NOTE:** Bovine serum albumin-Tween 80 medium is recommended (6).
2. Fletcher's medium (3) (beef extract and peptone with rabbit serum and 1.5% agar) with and without 5-fluorouracil can be purchased in prepared tubes from Remel, Inc., or BD Diagnostic Systems.
3. Dispense medium in 5-ml amounts into sterile screw-cap tubes.
4. For urine specimens, add 5-fluorouracil to the medium to inhibit contaminants (2, 8).
 - a. Preparation of 5-fluorouracil
 - (1) Add 1.0 g of 5-fluorouracil to 50 ml of sterile distilled water.

(2) Add 1 to 2 ml of 2 N NaOH, and heat gently (less than 56°C) for 1 to 2 h to dissolve.

(3) Adjust to pH 7.4 with 1 N HCl, and bring volume to 100 ml with sterile distilled water.

(4) Filter sterilize, and store at 2 to 8°C.

b. Descriptions of this reagent do not give a shelf life (8). Keep for no longer than 1 year. Write expiration date on the label.

c. Add 0.1 ml of solution described above to 5 ml of medium for a final concentration of 200 µg/ml.

5. Store medium at 2 to 8°C, or add 1.5 g of agar per liter to the base to make medium semisolid. Then store at room temperature.

6. Shelf life is as long as 36 months for EMJH medium (5).

B. Other supplies

1. Fluorescent antiserum to *Leptospira* (Animal and Plant Health Inspection Service, U.S. Department of Agriculture, Ames, Iowa)
2. Dark-field microscope
3. Fluorescent microscope
4. Incubator at 28 to 30°C

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL****A. Organisms needed**

1. *Leptospira interrogans* subsp. *canicola* (ATCC 23470)
2. *Leptospira interrogans* subsp. *grippityphosa* (ATCC 23604)

B. Procedure

1. Inoculate *L. interrogans* subsp. *canicola* into one tube of medium and *L. interrogans* subsp. *grippityphosa* into another tube of medium.
2. Incubate at 28 to 30°C (or at room temperature). Medium should give good growth with typical microscopic morphology by 7 days (3).
3. Check the performance of the medium every 6 months, or keep strains viable by subculturing 0.5 ml monthly to new media.

V. PROCEDURE

Observe standard precautions.

A. Inoculation

1. Process specimen as soon as received.
 - **NOTE:** Use of biosafety cabinet will avoid contamination of the culture or specimen as well as protect laboratory processing personnel.
 2. Inoculate media.
 - a. Blood
 - (1) Inoculate four tubes of bovine serum albumin-Tween 80 medium with 1 or 2 drops of fluid per tube (two tubes with 1 drop and two tubes with 2 drops).
 - (2) If it is not possible to inoculate with freshly drawn blood, the blood sample can be taken with sodium oxalate or heparin as well as with SPS. Citrate may be inhibitory (10).
 - b. CSF or dialysis fluid
 - (1) Inoculate up to 0.5 ml per 5-ml tube.
 - (2) Inoculate several tubes if enough specimen is available, using various amounts of inoculum per tube.
 - c. Urine
 - (1) Prepare 1:10 and 1:100 dilutions of urine with bovine serum albumin-Tween 80 medium. This will dilute out growth-inhibiting substances that may be present in the urine (9). It may also dilute out contaminating organisms.
 - (2) For each of the following dilutions, inoculate two tubes of bovine serum albumin-Tween 80 medium.
 - (a) Urine undiluted, 1 drop per tube
 - (b) Urine diluted 1:10, 1 drop per tube
 - (c) Urine diluted 1:100, 1 drop per tube
 - (3) Duplicate these inoculations with medium containing 5-fluorouracil.
 - (4) Using this protocol, inoculate a total of 12 tubes for one urine specimen.
- B. Incubate the tubes in the dark at 28 to 30°C (or at room temperature).
 - C. Using a fluorescent microscope, directly examine specimen with specific fluorescent antiserum, if available (Animal and Plant Health Inspection Service, U.S. Department of Agriculture).
 - D. Examination of cultures
 1. Examine all culture tubes weekly for signs of growth (turbidity, haze, or a ring of growth).

V. PROCEDURE (continued)

2. Examine all tubes microscopically each week.
 - a. Take a small drop from 1 cm below the surface, and examine it with dark-field illumination. Use $\times 400$ magnification. Leptospire will be seen as tightly coiled spirochetes about 1 μm wide and 6 to 20 μm long. They rotate rapidly on their long axes and usually have hooked ends.
 - b. Positive culture tubes generally have a ring of growth (Dinger's ring) several centimeters below the surface of the semisolid medium.
3. If the specimen is positive, subculture one of the tubes to two tubes of fresh medium. Transfer about 0.5 ml taken from the area of growth.
 - a. Cultures can remain viable for at least 8 weeks in semisolid medium (9).
 - b. Submit positive cultures to a reference laboratory for confirmation and possible serologic typing.
 - c. Securely seal in tube of bovine serum albumin-Tween 80 medium for submission of culture.
4. Incubate cultures for 6 weeks before reporting them as negative.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. Report negative cultures as "No *Leptospira* isolated after 6 weeks."
- B. If all tubes inoculated with a specimen become contaminated before 6 weeks, report as "Culture contaminated; no further examination possible."
- C. Report positive cultures as "Leptospire isolated."
- D. Document notification of physician of positive findings.

VII. INTERPRETATION

- A. A positive culture indicates infection with the organism.
- B. A negative result does not rule out leptospirosis.
- C. Susceptibility testing is rarely performed. The treatments of choice are penicillin and doxycycline.

VIII. LIMITATIONS

- A. False-negative cultures can result from contamination of the urine with other microbiota.
- B. Culture is the definitive test but has a low sensitivity and may take up to 6 weeks for a positive result.

APPENDIX 3.14–1

***Leptospira* Ellinghausen-McCullough-Johnson-Harris Base and Enrichment Medium (1, 2)**

A. Basal medium

1. Ingredients

Na ₂ HPO ₄ , anhydrous	1.0 g
KH ₂ PO ₄ , anhydrous	0.3 g
NaCl	1.0 g
NH ₄ Cl, 25% aqueous	1.0 ml
thiamine hydrochloride, 0.5% aqueous	1.0 ml
sodium pyruvate, 10% aqueous	1.0 ml
glycerol, 10% aqueous	1.0 ml
distilled water	996.0 ml

2. Procedure

- Dissolve salts in 996 ml of distilled water, add stock solutions (ammonium chloride, thiamine hydrochloride, sodium pyruvate, and glycerol), and adjust to pH 7.4.
- Autoclave at 121°C for 20 min.

B. Albumin-fatty acid supplement

1. Ingredients

bovine albumin fraction V	20.0 g
CaCl ₂ ·2H ₂ O, 1.0% aqueous	2.0 ml
MgCl ₂ ·6H ₂ O, 1.0% aqueous	2.0 ml
ZnSO ₄ ·7H ₂ O, 0.4% aqueous	2.0 ml
CuSO ₄ ·5H ₂ O, 0.3% aqueous	0.2 ml
FeSO ₄ ·7H ₂ O, 0.5% aqueous	20.0 ml
vitamin B ₁₂ , 0.2% aqueous	2.0 ml
Polysorbate (Tween) 80, 10% aqueous	25.0 ml
distilled water	to 200.0 ml

2. Procedure

- **NOTE:** Aqueous stock solutions must be prepared prior to formulation of medium.
- Add the bovine albumin slowly, with careful stirring to avoid foaming, to 100 ml of water.
 - Slowly add the remaining ingredients, stirring constantly.
 - Adjust the pH to 7.4, and add water to make a 200-ml final volume.
 - Filter sterilize through a Seitz or membrane filter (0.2- to 0.3- μ m porosity).

C. Prepare the complete medium by combining 1 part supplement with 9 parts basal medium.

Mycoplasma pneumoniae, *Mycoplasma hominis*, and *Ureaplasma* Cultures from Clinical Specimens

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Mycoplasma pneumoniae is a common cause of upper and lower respiratory infections in persons of all ages. Tracheo-bronchitis is the most common clinical syndrome, but pneumonia commonly occurs and extragenital infections have been described. A review of human disease caused by *M. pneumoniae* (1) contains more detailed information about clinical aspects of infections due to this organism.

Specimens obtained from the upper and lower respiratory tract are appropriate to culture for the presence of *M. pneumoniae*. Since the organism has also been known to cause invasive disease in other body sites, it may also be appropriate in some circumstances to culture sterile body fluids such as CSF, synovial fluid, or other types of clinical specimen, depending on the type of infection suspected. Growth and presumptive identification of *M. pneumoniae* can be accomplished by demonstration of glucose hydrolysis in SP-4 broth and development of spherical 10- to 100- μm colonies on SP-4 agar media after 4 to 20 days or more of incubation. Definitive organism identification has been accomplished using a variety of tests such as hemadsorption, tetrazolium reduction, or growth inhibition in the presence of specific antiserum. More recently, the PCR assay has been used to distinguish *M. pneumoniae* from several species of commensal mycoplasmas that often inhabit the human respiratory tract. Since culture may not detect *M. pneumoniae* in some specimens, alternative methods such as the

PCR assay and serologic testing should be considered for optimum detection, even if culture is attempted.

Mycoplasma hominis and *Ureaplasma* species are the predominant mycoplasmal species recoverable by culture from the human urogenital tract. Even though these organisms may occur as commensals, they have been associated with a number of human urogenital infections in adults and can also cause extragenital infections involving the lungs and sterile body sites such as synovial fluid or CSF, most commonly in immunosuppressed children or adults or in preterm neonates. Refer to recent reviews (2) and reference texts (3) for more detailed descriptions of specific diseases that may be caused by these organisms. Although other potentially pathogenic species such as *Mycoplasma fermentans* and *Mycoplasma genitalium* may occur in some settings, their cultivation conditions are not well established and their detection is more readily achieved by non-culture-based methods such as the PCR assay. Therefore, cultivation techniques for them are not described in this handbook. The species *Ureaplasma urealyticum* (the only pathogenic *Ureaplasma* of humans) was recently divided into two separate species, *Ureaplasma urealyticum* and *Ureaplasma parvum* sp. nov. However, it is not practical or necessary to distinguish between them for diagnostic purposes.

A single liquid growth medium such as 10B broth can be used for cultivation of

M. hominis and *Ureaplasma* species. Evidence of growth in liquid medium is based on an alkaline shift due to arginine hydrolysis by *M. hominis* or urea by *Ureaplasma* species. Definitive identification of *Ureaplasma* spp. can be established based on characteristic 15- to 60- μm brown granular colonies that develop in 1 to 3 days. Presumptive identification of *M. hominis* can be determined by typical 200- to 300- μm "fried-egg" colonies that develop in 2 to 4 days, but definitive species identification requires additional tests such as growth inhibition with homologous antiserum or the PCR assay (see procedure 12.2.3, part 10).

A variety of serologic assays are commercially available to test for the presence of antibodies against *M. pneumoniae*. Due to the organism's slow growth in culture and the limited availability of PCR in diagnostic laboratories, demonstration of seroconversion (fourfold change in titer) using quantitative assays for immunoglobulin M (IgM) and IgG antibodies has been the primary means for diagnosis of *M. pneumoniae* respiratory infections. Commercially available serologic tests for *M. pneumoniae* include both qualitative and quantitative assays and utilize EIA, immunofluorescence, and particle agglutination technologies. These products are discussed in greater detail elsewhere (4, 5). Evaluation of commercial diagnostic kits and media can be found in *Cumitech* 34 (4).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

■ **NOTE:** Refer to procedure 3.3.1 for additional details. The following can be copied for preparation of a specimen collection instruction manual for physicians and caregivers. It is the responsibility of the laboratory director or designee to educate physicians and caregivers on proper specimen collection.

A. Specimen collection

1. Fluid specimens (e.g., pleural fluid, bronchoalveolar lavage fluid, sputum, endotracheal aspirates, CSF, synovial fluid, amniotic fluid, pouch of Douglas fluid, semen, prostatic secretions, urine)

■ **NOTE:** Urethral swabs from men and vaginal or cervical swabs from women are preferred over urine specimens for detection of genital mycoplasmas.

- a. Collect in a sterile container.
 - b. If greater than a 1-h delay in inoculation is anticipated, and/or volume of fluid obtained is very small and susceptible to drying, as in the case of neonatal endotracheal aspirates, place fluid in 0.3 to 1.5 ml of transport medium, described below and in Appendix 3.15–1.
 - c. Collect urine specimens from women by urethral catheterization, for more meaningful result.
2. Blood
 - a. Collect in a vial of mycoplasma broth culture medium without anticoagulant in at least a 1:5 or 1:10 ratio.
 - b. Collect at least 10 ml for adults, but smaller volumes comparable to those obtained for conventional bacterial blood cultures are acceptable for neonates and children.
 - c. Do not use any medium containing sodium polyanethol sulfonate (SPS) anticoagulant, which is present in most commercial blood culture bottles, since it is inhibitory to mycoplasmas and ureaplasmas.
 3. Tissues (e.g., lung, placenta, endometrium, fallopian tube, bone chips, and urinary calculi)

Collect in a sterile container with sufficient transport medium to prevent drying.

4. Swab specimens (e.g., nasopharynx, throat, urethra, vagina, cervix, wound)

- a. Use only Dacron or polyester swabs with aluminum or plastic shafts.
 - (1) Do not use cotton swabs because the fibers and wooden sticks are inhibitory to mycoplasmas.
 - (2) Do not use vaginal lubricants or antiseptics prior to collection of urogenital specimens, as they are inhibitory to mycoplasmas.

- b. Collect throat, nasopharyngeal, vaginal, or wound specimens by swabbing back and forth over the mucosa or surface of wound to maximize recovery of cells.

■ **NOTE:** Vaginal swabs are somewhat more likely to contain genital mycoplasmas and ureaplasmas than cervical or urethral swabs from women.

- c. Collect specimens from the male or female urethra or female cervix by inserting a urethral swab at least 1 cm into the urethra and rotating it 360°.
- d. After collection of swab specimen, swirl swab in a vial containing transport medium, express excess fluid by pressing the swab against the inside of the vial, and then discard swab.

B. Timing of specimen collection

1. Collect early-morning specimens of expectorated sputum.
2. Obtain all specimens prior to initiation of antimicrobial therapy when possible.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

C. Specimen transport

1. Transport specimens to the laboratory as soon as possible because of the fastidious nature of mycoplasmas and potential loss of mycoplasmal viability if specimens are allowed to dry out.
 - a. Add 0.3 to 1.5 ml of transport medium to original fluid specimens if more than 1 h is likely to elapse before a specimen can be transported to the laboratory. Always collect swab specimens, blood, and tissues in transport medium.
 - b. Refrigerate specimen in transport medium at 4°C if delay in transportation to the laboratory is anticipated, but this should be kept to a minimum.
 - c. Freeze the original specimen in transport medium at –70°C or in liquid nitrogen if specimen will be shipped to a reference laboratory for processing or if storage will exceed 24 h.
 - d. Ship frozen specimens in transport medium on dry ice to a reference laboratory for processing.
 - e. Do not store at –20°C for even short periods, since this will result in loss of viability.
2. Transport media
 - a. Broths used for mycoplasmal cultivation are most desirable for use as transport media. Refer to Appendix 3.15–1 for instructions for preparing these media.
 - (1) 10B or SP-4 (Remel, Inc.) for genital mycoplasmas
 - (2) SP-4 (Remel, Inc.) for *M. pneumoniae*
 - b. Other commercially available media for genital mycoplasmas
 - (1) Mycotrans (Irvine Scientific, Santa Ana, Calif., [800] 437-5706, <http://www.irvinesci.com>)
 - (2) A3B (Remel, Inc.)
 - (3) Arginine broth (Remel, Inc.)
 - c. For transport of culture specimens and for sample preparation for PCR assays
 - (1) 2-SP with 10% (vol/vol) heat-inactivated fetal calf serum with 0.2 M sucrose in 0.02 M phosphate buffer (pH 7.2)
 - (2) TSB with 0.5% (vol/vol) bovine serum albumin
3. Limits at receiving site
 - (1) Process all specimens immediately after receipt in the laboratory.
 - (2) If this is not possible, add transport medium to the specimen, if not already present, and store as described above.

D. Request submission

In addition to the usual essential information, including identifying information for the patient and body site cultured, clearly specify which organisms are to be sought (e.g., *M. pneumoniae* or genital mycoplasmas), since cultivation procedures differ.

E. Rejection criteria

1. Perform diagnostic cultures for mycoplasmas for patients who are suspected of having a condition known to be associated with or caused by these organisms, but not in circumstances in which there has been no such association. Screening the lower urogenital tract of asymptomatic adults for genital mycoplasmas is not recommended.
2. Reject specimens received in the laboratory >24 h after collection that have not been frozen at –70°C in transport medium, because the likelihood of finding viable mycoplasmas is significantly reduced.
3. If time of specimen collection and/or storage conditions cannot be documented after consultation with the ordering physician or clinic from which the specimen was obtained, do not process the specimen.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

4. If an improperly collected, transported, or handled specimen cannot be replaced, and it is deemed critical for patient management, perform the culture and document in the final report that specimen quality may have been compromised in the event that no organisms are detected.
5. Do not process blood, tissues, or swab specimens that are not received in transport medium.

III. MATERIALS

A. Media (from Remel, Inc., or see instructions for medium preparation and formulations in Appendix 3.15-1)

1. SP-4 broth and agar—a glucose-based medium appropriate for cultivation of *M. pneumoniae* and *M. hominis*

☑ **NOTE:** This medium can also be used for cultivation of the more fastidious species, e.g., *M. genitalium* and *M. fermentans*, but as stated earlier, non-culture-based techniques such as the PCR assay are recommended for detection of these organisms.

- a. Add agar to SP-4 broth for preparation of solid medium.
 - b. Add arginine as a metabolic substrate if *M. hominis* is being sought.
2. 10B broth—an enriched urea- and arginine-containing medium for cultivation of ureaplasmas and *M. hominis*
 - a. Add clindamycin or lincomycin (10 µg/ml) to make selective for ureaplasmas.
 - b. Add erythromycin (10 µg/ml) to select for *M. hominis*.
 3. A8 agar—a differential agar medium useful for isolating *M. hominis* and ureaplasmas

☑ **NOTE:** Urea and CaCl₂ are provided to allow differentiation of ureaplasmas from non-urea-hydrolyzing mycoplasmas.

B. Diagnostic kits (Irvine Scientific)

1. Mycoscreen GU for genital mycoplasmas
 2. Mycotrim GU triphasic flask system for genital mycoplasmas
 3. Mycotrim RS for *M. pneumoniae*
- ☑ **NOTE:** Consult the *Manual of Commercial Methods in Clinical Microbiology* (5) and *Cumitech 34* (4) for a more comprehensive discussion of these products.

C. Stain reagents

1. Direct specimens
- ☑ **NOTE:** Mycoplasmas lack a cell wall and are not visualized by Gram stain.

a. Giemsa stain for examination of body fluids. Results can be difficult to interpret because debris and artifacts can be confused with mycoplasmas because of their very small size.

b. DNA fluorochrome stains, such as Hoechst 33258 (ICN Biochemicals, Inc., Costa Mesa, Calif., [800] 854-0530), for clinical specimens or culture do not distinguish mycoplasmas from other bacteria. Refer to procedure 3.2.2 for acridine orange stain.

2. Stains to distinguish mycoplasmal colonies on agar from artifacts (Sigma Diagnostics, St. Louis, Mo.)

a. Diene's methylene blue stain—10% in distilled water or ethanol

b. Neutral red stain

3. Urease stain for ureaplasmas

a. Add 0.2 ml of CaCl₂ solution to isolated colonies.

b. Observe whether colonies change from colorless to dark brown within 15 min.

☑ **NOTE:** Incorporation of CaCl₂ directly into A8 agar eliminates the need for a separate test to detect urease production to identify colonies as *Ureaplasma* spp.

D. Strains

Purdue University Mollicutes Collection contains a large variety of ATCC type strains, clinical isolates, and diagnostic reagents for use in mycoplasmal culture.

Room VPRB B 13

West Lafayette, IN 47907-2027

Phone: (765) 496-6753

Fax: (765) 496-2627

E-mail: mkdAVIDS@purdue.edu

III. MATERIALS (continued)**E. Immunological reagents**

Plain and fluorescein isothiocyanate-conjugated antisera for the identification of mollicutes can be obtained from the University of Florida Mollicutes Collection.

F. Other supplies

1. Pipetting device and sterile pipette tips
2. Sterile 2-ml screw-cap vials suitable for freezing organisms isolated in culture

3. Racks for broth tubes

4. Parafilm, American National Can
5. Candle jar or anaerobe jar with GasPak (BD Diagnostic Systems, Sparks, Md.) if CO₂ incubator is unavailable
6. Fluorescent microscope for fluorescent stains

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL****A. Shelf life**

1. Store broths and agars containing inhibitory antimicrobials at 4°C, where they should usually provide satisfactory growth parameters over a 4-week period.
2. Store broths in tubes that are tightly capped.
3. Store agar plates in sealed plastic bags.

■ **NOTE:** Some commercial broth media are available in small lyophilized vials designed to be used for individual cultures that can be rehydrated as needed. This can substantially prolong shelf life.

B. Perform sterility checks on all new batches or lots of broth and agar by overnight incubation of an aliquot of broth and an agar plate at 37°C. Note and record the appearance of agar plates and verify clarity, surface, and color of media.**C. If any of the commercial media or kits are used for diagnostic purposes**

1. Confirm with the manufacturer the extent of QC performed prior to shipment.
2. Perform rigorous QC on site, since many products have not been subjected to extensive comparative studies to document their abilities to detect mycoplasmas in clinical specimens.

D. QC testing of a new batch of broth

1. Include type strains of each species to be cultivated in the broth, a low-passage clinical isolate of each species, and a minimum of two strains of *Ureaplasma* species. Recommended choices are serotypes 3 and either 5, 7, or 8 since some ureaplasmas are more fastidious than others. Some choices include the following.
 - a. *Ureaplasma* serotype 3 ATCC 27815
 - b. *Ureaplasma* serotype 5 ATCC 27817
 - c. *Ureaplasma* serotype 7 ATCC 27819
 - d. *Ureaplasma* serotype 8 ATCC 27618
 - e. *M. hominis* ATCC 23114
 - f. *M. pneumoniae* ATCC 15531
2. Thaw frozen stock cultures of the desired organisms, mix on a vortex mixer, and serially dilute each strain 1:10 (0.1 ml of culture into 0.9 ml of broth) in the reference and the new batch out to 10⁻⁹.
3. Incubate broths at 37°C under atmospheric conditions for up to 72 h for *M. hominis* and *Ureaplasma* spp. and 7 days for *M. pneumoniae*.
4. Compare the number of tube dilutions with color change (color changing units) between the reference broth and the new batch.
5. Consider new lots or batches of broth satisfactory if the numbers of all strains tested grow within 10-fold (1 dilution) of the number in the reference batch.

IV. QUALITY CONTROL (continued)

6. If growth in the new broth is >1 dilution less than the reference batch, repeat the test. If results are still outside the acceptable range, do not use the broth for specimens.
 7. Maintain records of all media QC tests (refer to section 14 for general QC principles).
- E. QC testing of a new batch of agar
1. Include the same assortment of mycoplasmas and ureaplasmas and record keeping as described above for testing broths.
 2. Use one new and one reference plate for each group of three strains to be tested.
 3. Prewarm agar plates bottom side up for 5 to 10 min in a 37°C incubator prior to testing.
 4. Thaw organisms as described above and serially dilute (0.1 ml of culture into 0.9 ml of broth) in the appropriate broth (e.g., 10B when checking A8 agar and SP-4 when checking SP-4 agar) so that there will be approximately 30 to 300 colonies on each plate after incubation. The number of dilutions necessary to yield plates with this colony density will depend on the number of organisms in the original culture. Plating the 10⁻², 10⁻³, and 10⁻⁴ dilutions will usually yield this number of colonies.
 5. Plate 0.02 ml of the 10⁻² to 10⁻⁴ dilutions of each strain onto the test agar and the reference agar, allow to dry, and incubate at 37°C under 5% CO₂ in air. Colonies of *M. hominis* and *Ureaplasma* spp. may be visible in 48 to 72 h, whereas *M. pneumoniae* will take 7 days or more.
 6. Count colonies and determine the number of CFU per milliliter.
 7. Calculate the percentage of growth on new medium compared to old medium by dividing the CFU per milliliter of the new test plate by that of the old test plate. Agar plates should differ by not more than 1/2 log in the number of colonies from the reference batch.
 8. If >1/2-log difference occurs for any of the test strains, repeat the QC test. If a second test is still out of the acceptable range, do not use the agar for diagnostic purposes.

V. PROCEDURES

■ **NOTE:** Refer to Fig. 3.15–1 for flowchart descriptions of culture techniques for *M. pneumoniae* and Fig. 3.15–2 for *M. hominis* and *Ureaplasma* spp.

A. Direct nucleic acid amplification by the PCR assay is important for detection of *M. pneumoniae* in clinical specimens, since culture may fail to detect the organism in some instances even when done properly.

■ **NOTE:** There are no commercial PCR kits available for mycoplasmas, but procedures have been described using widely available primers and are included in procedure 12.2.3, part 10. Nonamplified direct antigen detection kits for mycoplasmas or ureaplasmas are no longer available commercially in the United States.

B. Culture methods

1. Inoculation

- a. Mix fluid specimens by gently rotating the container and then centrifuge at 600 × g for 15 min. Use the pellet for medium inoculation.
- b. Mince tissues with a sterile scalpel blade prior to inoculation. Mincing is preferable to grinding since it minimizes release of tissue inhibitors that may affect growth.
- c. Perform serial 10-fold dilutions (0.1 ml of specimen into 0.9 ml of appropriate broth) out to at least 10⁻³ in order to overcome inhibitors that may be present in original specimen.

It is imperative that these cultures be handled in a biosafety hood.

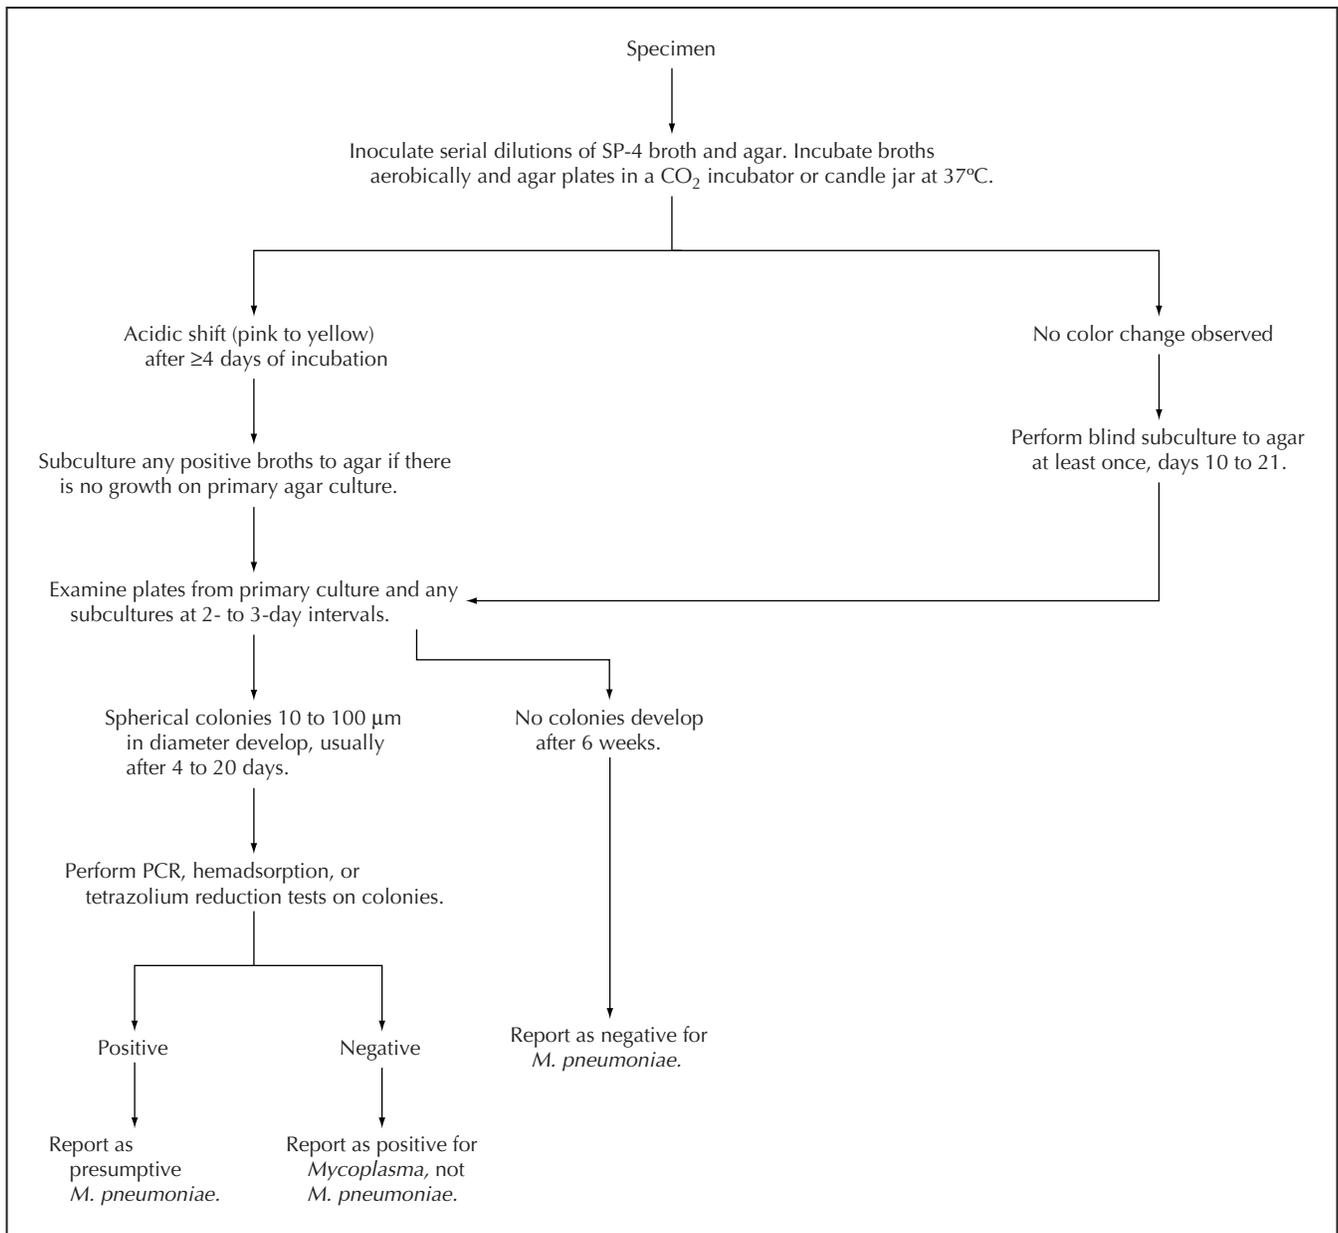

Figure 3.15–1 Algorithm for isolation of *M. pneumoniae* from clinical specimens.

V. PROCEDURES (continued)

- d. Label each plate with patient’s name and laboratory accession number.
- e. Mark the bottom of the appropriate agar plate with a felt tip pen into at least four sections: one for the original specimen and three for the three 10-fold dilutions.
- f. Inoculate agar plate with 0.02 ml of the original specimen and each dilution.
- g. Seal agar plates with Parafilm to prevent desiccation.
- 2. Incubation
 - a. Incubate broths at 37°C under atmospheric conditions in a humidified incubator. Agitate broths on a mechanical rotator to shorten time by about 1 day for detection of *M. pneumoniae*.

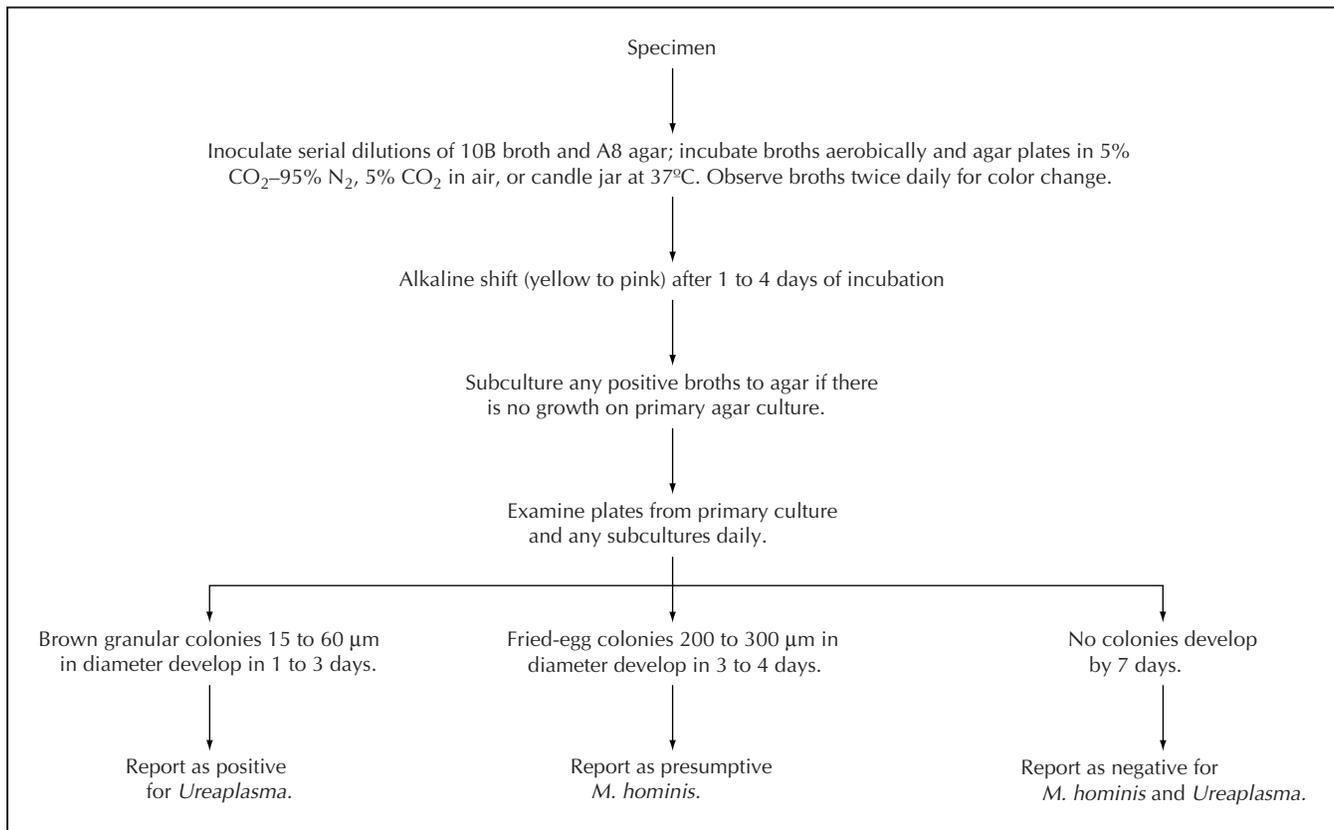

Figure 3.15–2 Algorithm for isolation of *M. hominis* and *Ureaplasma* spp. from clinical specimens.

V. PROCEDURES (continued)

- b. Incubate specimens for genital mycoplasmas at 37°C in an atmosphere of 95% N₂–5% CO₂ or room air plus 5% CO₂. Incubate specimens for *M. pneumoniae* in room air plus 5% CO₂. Use candle jars or anaerobe jars with a CO₂-generating system, if a CO₂ incubator is not available.
 3. Examination of culture media
 - a. *M. pneumoniae* cultures
 - (1) Visually inspect SP-4 broth cultures daily for acidic shift (pink to yellow).
 - (2) Subculture 0.02 ml of positive SP-4 broths to SP-4 agar if there has been no growth on primary agar culture, and incubate as described above.
 - (3) Perform blind subculture of broth to agar at least once after 10 to 21 days of incubation if no color change has occurred.
 - (4) Using a stereomicroscope, examine agar plates from primary culture and any subcultures at 2- to 3-day intervals for the presence of spherical colonies of *M. pneumoniae* that are 10 to 100 µm in diameter (Fig. 3.15–3).
 - (5) Incubate specimens for 6 weeks before discarding.
 - b. *M. hominis* and *Ureaplasma* cultures
 - (1) Visually inspect 10B broths twice daily for basic shift (yellow to pink).

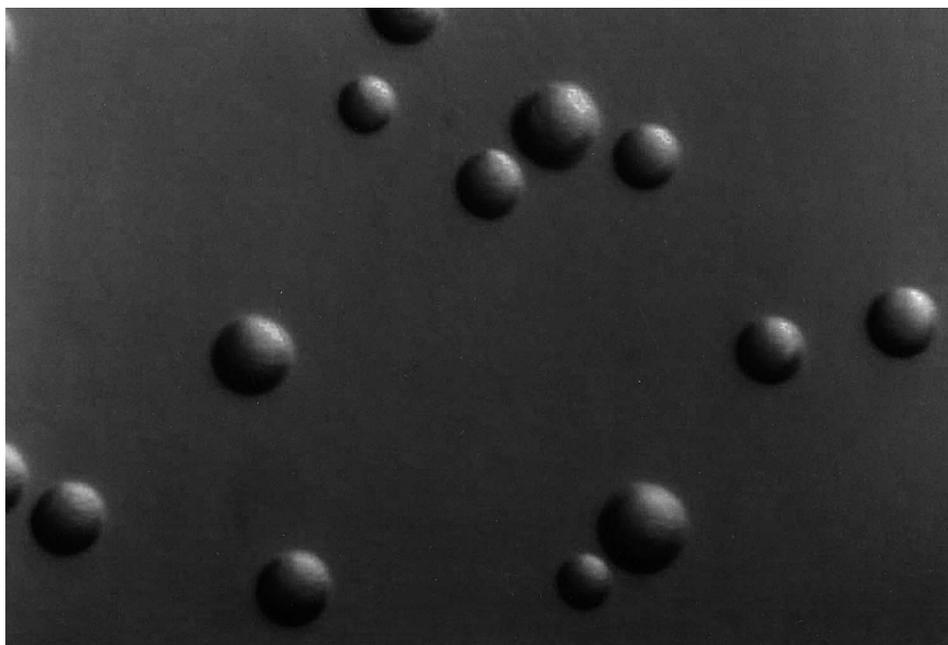

Figure 3.15-3 Spherical colonies of *M. pneumoniae* up to 100 μm in diameter growing on SP-4 agar. Magnification, $\times 126$.

V. PROCEDURES (continued)

- (2) Subculture 0.02 ml of positive broths to A8 agar if there is no growth on primary agar culture.
- (3) Using a stereomicroscope, examine agar plates from primary culture and any subcultures daily.
 - (a) Brown granular colonies 15 to 60 μm in diameter characteristic of *Ureaplasma* spp. develop in 1 to 3 days (Fig. 3.15-4).
 - (b) Fried-egg colonies 200 to 300 μm in diameter typical of *M. hominis* develop in 2 to 4 days (Fig. 3.15-4).
- (4) Incubate plates for 7 days before discarding.
4. Further workup of positive cultures
 - a. Enumerate each type of mycoplasma or ureaplasma present by colony counts, and record results.
 - b. Perform procedures as described below if definitive species identification is desired for large-colony mycoplasmas.
5. Freeze an aliquot of the original specimen at -70°C in case additional procedures are necessary.
6. Freeze any positive mycoplasma broths detected by culture at -70°C in case further workup is required or antimicrobial susceptibility tests are to be performed.

■ **NOTE:** It is important to freeze genital mycoplasmas soon after color change occurs in broth due to a rapid death phase in liquid medium.

 - a. To remove mycoplasmal colonies from agar for subculture or freezing, use a sterile scalpel or Pasteur pipette to cut out a block of agar that contains the colonies.
 - b. Immerse block in a small vial containing approximately 1 to 1.5 ml of broth, and mix on a vortex mixer.
 - c. Incubate or freeze the broth, depending on the need.
7. If broth is turbid, indicating bacterial contamination, filter original liquid specimens through a 0.45- μm -pore-size filter to remove bacteria and allow the smaller mycoplasmas to pass through. Inoculate media and repeat culture.

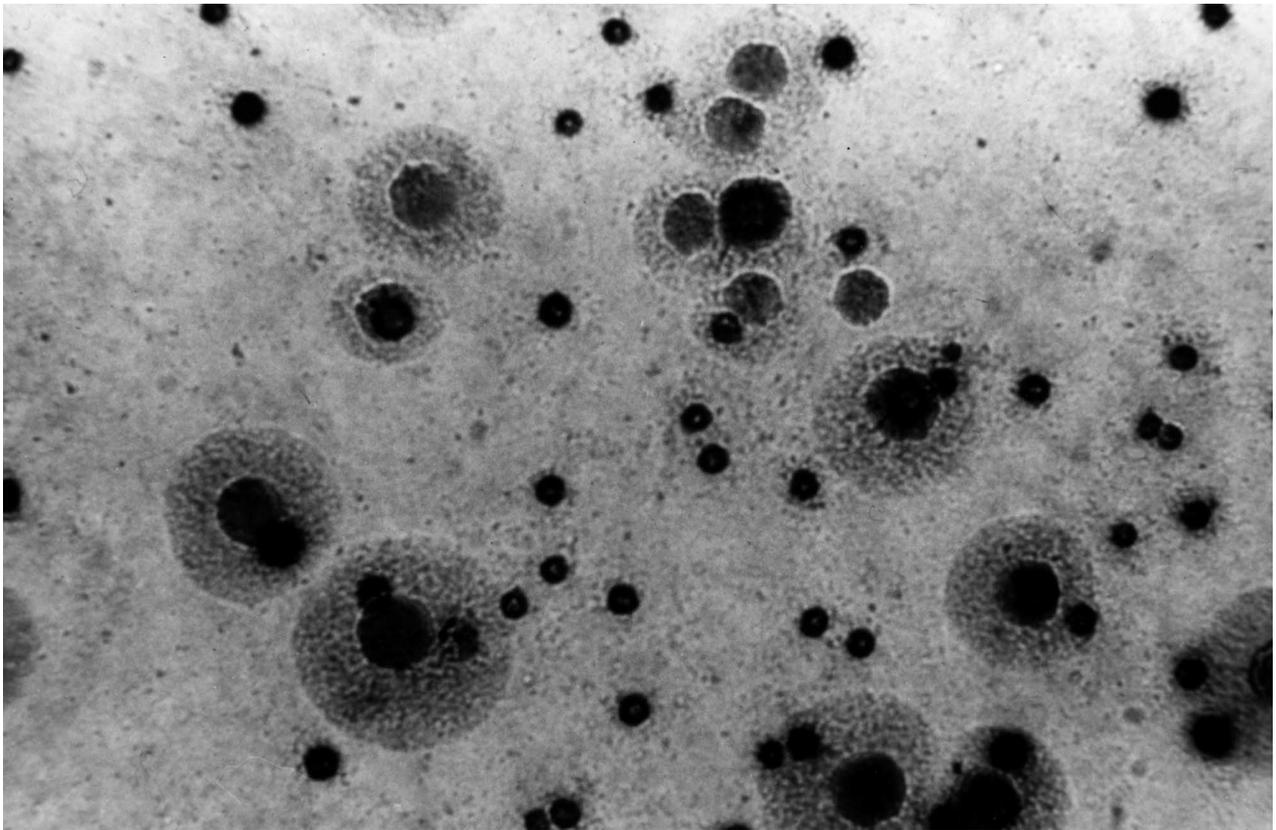

Figure 3.15–4 Small colonies typical of *Ureaplasma* spp. and larger fried-egg colonies of *M. hominis*. Diene's stain; magnification, $\times 100$. Reprinted from **M. G. Gabridge**. 1981. *Pathogenic Mycoplasma*, part 2, no. 6702 (teaching set). American Society for Microbiology, Washington, D.C.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. Report presumptive *M. pneumoniae* based on spherical colonies that will be evident on SP-4 agar after 4 to 20 days or more of incubation and on glucose utilization. Definitive species identification requires supplemental tests.
 1. Perform additional procedures, such as tetrazolium reduction, hemadsorption, or PCR assay, for definitive identification of *M. pneumoniae* to distinguish it from commensal mycoplasmas that commonly inhabit the respiratory tract.
 2. Refer isolate to a reference laboratory or see procedures for PCR assay (procedure 12.2.3, part 10) and hemadsorption activity (Appendix 3.15–2).
- B. Report at the genus level for *Ureaplasma* spp. Definitive identification sufficient for clinical purposes is based on characteristic granular brown colonies on A8 agar within 1 to 3 days of incubation, due to urease production in the presence of the CaCl_2 indicator in A8 agar.
- C. Report presumptive *M. hominis* based on fried-egg colonies on A8 agar within 2 to 4 days of incubation and on arginine utilization. Definitive identification requires additional procedures such as PCR, agar growth inhibition in the presence of homologous antisera, or colony epiimmunofluorescence. Refer to procedure 12.2.3, part 10, or submit to reference laboratory for confirmation.

VI. REPORTING RESULTS*(continued)*

- D. Identification to the species level of large-colony mycoplasmas is generally not clinically indicated, unless the infection occurs in a normally sterile site such as CSF and/or the patient is immunocompromised. Submit organisms to a reference laboratory, such as the UAB Diagnostic Mycoplasma Laboratory (University of Alabama at Birmingham, Birmingham, Ala., [205] 934-9142) unless a laboratory has molecular diagnostic capabilities for performance of the PCR assay.
- E. Document all testing in hard copy and computerized work card, according to the laboratory information system in use.

VII. INTERPRETATION

- A. Isolation of *M. pneumoniae* from respiratory tract specimens is clinically significant in most instances, but it should be correlated with the presence of clinical respiratory disease since a small portion of asymptomatic carriers may exist. Detection of *M. pneumoniae* in normally sterile body fluids is always clinically significant.
- B. Isolation of ureaplasmas in any quantity in normally sterile body fluids or tissue is significantly associated with disease. The presence of fewer than 10⁴ organisms in the male urethra is less likely to be significant.
- C. Isolation of *M. hominis* in any quantity in normally sterile body fluids or tissue is significantly associated with disease, but reporting the quantities of organisms present in nonsterile body sites may be of value in interpreting the significance of its presence.
- D. Treatment considerations (see Appendix 3.15–3 for methods)
 - 1. *M. pneumoniae*: macrolides, including erythromycin, azithromycin, and clarithromycin; tetracyclines; fluoroquinolones, including levofloxacin, moxifloxacin, and gatifloxacin
 - 2. *M. hominis*: clindamycin; fluoroquinolones, including levofloxacin, moxifloxacin, and gatifloxacin; tetracyclines (some strains may be resistant)
 - 3. *Ureaplasma* spp.: macrolides, including erythromycin, azithromycin, and clarithromycin; tetracyclines (some strains may be resistant); fluoroquinolones, including levofloxacin, moxifloxacin, and gatifloxacin

VIII. LIMITATIONS

- A. Culture is the method of choice for detection of organisms such as *M. hominis* and *Ureaplasma* spp. that can be isolated rapidly and easily from clinical specimens, and it has the advantage of being able to provide quantitative results and an isolate for antimicrobial susceptibility testing.
- B. Culture alone is not optimum for fastidious and/or slow-growing species such as *M. genitalium*, *M. fermentans*, and, to some degree, *M. pneumoniae*. Serology has been used for many years for detection of *M. pneumoniae* infection, and more recently PCR assays have been developed for human mycoplasma species of clinical importance.
- C. In some circumstances, particularly in systemic infections of sterile sites such as CSF or synovial fluid, for immunocompromised hosts or neonates it may be appropriate to collect a follow-up specimen after treatment has been initiated or completed to determine whether the mycoplasma is still present. This may be particularly relevant in the event that the patient has not responded to antimicrobial therapy in a satisfactory manner and because mycoplasmas tend to produce chronic infections that can be difficult to eradicate.
- D. Due to the fastidious nature of mycoplasmas, it is not uncommon for batches of culture medium to fail to support the growth of some strains. If this occurs, it is necessary to systematically evaluate each individual component of the medium, if self-prepared, and to choose a different lot if medium is commercially obtained.

APPENDIX 3.15–1

Medium Formulations for Cultivation of Mycoplasmas from Humans

A. A8 agar

1. Purpose. A8 is a differential agar medium useful for isolating genital mycoplasmas. Urea is included in this medium to enhance differentiation of *Ureaplasma* spp. from non-urea-hydrolyzing mycoplasmas.

2. Ingredients

a. Base

- (1) 825 ml of ultrapurified water (Milli-Q; Millipore, Inc.)
- (2) 0.15 g of CaCl₂ dihydrate (dissolve before adding other ingredients)
- (3) 24 g of TSB (BD Diagnostic Systems)
- (4) 2 g of yeast extract (Difco, BD Diagnostic Systems)
- (5) 1.7 g of putrescine dihydrochloride
- (6) 0.2 g of DNA
- (7) 10.5 g of Select Agar (BD Diagnostic Systems)

b. Supplements

Filter sterilize (0.2-  m-pore-size filter) each supplement separately, if not received sterile from manufacturer.

- (1) 200 ml of horse serum (HyClone, Logan, Utah)
- (2) 5 ml of IsoVitalX (BD Diagnostic Systems)
- (3) 10 ml of 10% urea
- (4) 1 ml of GHL tripeptide solution (Calbiochem-Novabiochem International, Inc., La Jolla, Calif.)
- (5) 5 ml of 2% L-cysteine (prepare fresh on day of use)
- (6) 1,000 IU of penicillin per ml to prevent bacterial overgrowth

3. Preparation

- a. Mix the base ingredients in a flask in the order specified above to prepare 1 liter.
- b. Adjust pH to 5.5 with 2 N HCl.
- c. Autoclave for 15 min at 121  C. Cool in a 56  C water bath before adding supplements.
- d. After preparing and filter sterilizing each supplement separately, mix together and add supplements to autoclaved and cooled base agar.
- e. Adjust pH to 6.0.
- f. Pour plates, and after 2 h, invert and keep at room temperature overnight. (Small petri plates [60 mm] that can be used for agar require 10 ml, whereas standard 100-mm plates require 20 ml).
- g. Place plates in sealed plastic bags and refrigerate at 4  C.

4. Limitation

Plates will usually perform in a satisfactory manner for at least 4 weeks. Loss of inhibitory effect of antimicrobial agents when plates older than 4 weeks are used may result in bacterial overgrowth and inability to detect mycoplasmas when culturing specimens from nonsterile sites.

B. 10B broth

1. Purpose

10B is an enriched broth medium useful for cultivation of *Ureaplasma* spp. and *Mycoplasma hominis*.

APPENDIX 3.15–1 (continued)

2. Ingredients
 - a. Base
 - (1) 825 ml of ultrapurified water (Milli-Q; Millipore Inc.)
 - (2) 14 g of mycoplasma broth base without crystal violet (BD Diagnostic Systems)
 - (3) 2 g of arginine
 - (4) 0.2 g of DNA
 - (5) 1 ml of 1% phenol red (prepare fresh monthly)
 - b. Supplements

Filter sterilize (0.2- μ m-pore-size filter) each supplement separately, if not received sterile from manufacturer.

 - (1) 200 ml of horse serum (HyClone) (heat-inactivated fetal bovine serum can also be used instead of horse serum)
 - (2) 100 ml of 25% yeast extract (Difco, BD Diagnostic Systems)
 - (3) 5 ml of IsoVitalX (BD Diagnostic Systems)
 - (4) 4 ml of 10% urea
 - (5) 2.5 ml of 4% L-cysteine (prepare fresh on day of use)
 - (6) 1,000 IU of penicillin per ml to prevent bacterial overgrowth
 3. Preparation
 - a. Mix the base ingredients in a flask in the order specified above to prepare 1 liter.
 - b. Adjust the pH to 5.5 with 2 N HCl.
 - c. Autoclave for 15 min at 121°C. Cool in a 56°C water bath before adding supplements.
 - d. After preparing and filter sterilizing each supplement separately, mix together and add supplements to autoclaved and cooled base agar.
 - e. Adjust the pH to 5.9 to 6.1.
 - f. Dispense broth aseptically into sterile tubes each containing 0.9 to 1.0 ml.
 4. Limitation

10B broth will usually perform in a satisfactory manner for at least 4 weeks when stored at 4°C. Loss of inhibitory effect of antimicrobial agents when broths older than 4 weeks are used may result in bacterial overgrowth and inability to detect mycoplasmas.
- C. SP-4 broth and agar
1. Purpose

SP-4 broth is an enriched growth medium used for cultivation of many *Mycoplasma* species, including *Mycoplasma pneumoniae*. Agar may be added to SP-4 broth for preparation of solid medium and glucose and/or arginine and urea may be added as metabolic substrates, depending on which mycoplasmas are being sought.
 2. Ingredients
 - a. Base
 - (1) 643 ml of ultrapurified water (Milli-Q; Millipore, Inc.)
 - (2) 3.5 g of mycoplasma broth base without crystal violet (BD Diagnostic Systems)
 - (3) 10 g of tryptone (Difco; BD Diagnostic Systems)
 - (4) 5.3 g of peptone (Difco; BD Diagnostic Systems)
 - (5) 2 g of arginine (only if medium is to be used to isolate *M. hominis*) (Sigma)
 - (6) 2 ml of 1% phenol red (prepare fresh monthly)
 - (7) 0.2 g of DNA
 - (8) 15 g of Noble agar (only if preparing SP-4 agar) (Difco, BD Diagnostic Systems)
 - b. Supplements
 - (1) 50 ml of 10 \times CMRL 1066 (formula no. 01-0127DJ, in 10-liter volumes; Invitrogen Life Technologies, Carlsbad, Calif.)
 - (2) 35 ml of 25% yeast extract (Difco, BD Diagnostic Systems)
 - (3) 100 ml of 2% yeastolate (Difco, BD Diagnostic Systems)
 - (4) 170 ml of fetal bovine serum (HyClone) (heat inactivate at 56°C for 30 min)
 - (5) 10 ml of 50% glucose
 - (6) 1,000 IU of penicillin per ml to prevent bacterial overgrowth
 3. Preparation
 - a. Mix the base ingredients in a flask in the order specified above to prepare 1 liter.
 - b. Autoclave for 15 min at 121°C and cool before adding supplements.
 - c. For agar, cool in a 56°C water bath. For broth, cool to room temperature.
 - d. After preparing and filter sterilizing each supplement separately, mix together and add supplements to autoclaved and cooled base.
 - e. Adjust the pH to 7.4 to 7.6.

APPENDIX 3.15–1 (continued)

- f. If agar is added, pour plates, and after 2 h, invert and keep at room temperature overnight. (Small petri plates [60 mm] that can be used for agar require 7.5 ml, whereas standard 100-mm plates require 10 ml.) Place plates in plastic bags and refrigerate at 4°C.
 - g. Dispense broth in sterile tubes. (The volume of broth required for individual cultures is dictated by the length of incubation required, e.g., 1.8 to 4.5 ml for *M. pneumoniae* and 0.9 to 1 ml for the genital mycoplasmas.)
4. Limitation
Plates will usually perform in a satisfactory manner for at least 4 weeks. Loss of inhibitory effect of antimicrobial agents when broths or agar plates older than 4 weeks are used may result in bacterial overgrowth and inability to detect mycoplasmas when culturing specimens from nonsterile anatomic sites.
- D. Contact information for manufacturers not listed in procedure 3.1

APPENDIX 3.15–2

Hemadsorption Test for Identification of *Mycoplasma pneumoniae*

I. PRINCIPLE

This procedure involves flooding colonies on agar with a dilute suspension of washed guinea pig erythrocytes, incubating and washing them, and examining them microscopically for adherent erythrocytes. Hemadsorption is unique to *Mycoplasma pneumoniae* and *Mycoplasma genitalium* among mycoplasmas isolated from humans. Since *M. genitalium* is much more fastidious and very slow-growing and has not been reliably isolated from humans using culture methods described for *M. pneumoniae*, a positive hemadsorption test provides a strong basis for an organism's identification as *M. pneumoniae*.

II. MICROORGANISMS TESTED

Unidentified *Mycoplasma* colonies <10 days old on SP-4 agar

III. SUPPLIES

- A. Guinea pig erythrocytes (Biowhittaker, Walkersville, Md.)
- B. Sterile phosphate-buffered saline (PBS) (pH 7.2)
- C. 15-ml conical centrifuge tubes
- D. Pipetting device and sterile disposable pipette tips

IV. QUALITY CONTROL

- A. Use *M. pneumoniae* ATCC 15531 (positive control) and *Mycoplasma hominis* ATCC 23114 (negative control) grown for <10 days on SP-4 agar.
- B. The *M. pneumoniae* positive control should show hemadsorption. The *M. hominis* negative control should not show any hemadsorption.

V. PROCEDURE

- A. Prepare a 10% working suspension of washed guinea pig erythrocytes by transferring 5 to 8 ml of the blood and an equal volume of sterile PBS (pH 7.2) aseptically into a 15-ml conical centrifuge tube.
- B. Centrifuge at $900 \times g$ for 5 min at room temperature. Discard supernatant, and resuspend cell pellet in 10 ml of PBS by gently pipetting cells up and down several times.
- C. Centrifuge at $900 \times g$ for 5 min at room temperature, and repeat washing procedure.
- D. Discard supernatant and measure packed-cell volume. Add a volume of PBS equal to nine times the packed-cell volume to yield a 10% suspension.
- E. Store the suspension at 4°C and use within 7 days. Do not use if there is evidence of hemolysis or bacterial contamination.
- F. Use this stock solution to prepare a 0.5% working solution by combining 1 part 10% suspension to 19 parts sterile PBS.
- G. Flood agar plates containing the unknown mycoplasma and positive and negative controls with 0.5% guinea pig erythrocytes.
- H. Cover plates and incubate at room temperature for 30 min.
 - I. Tilt plates and aspirate the cell suspension from the agar surface.
 - J. Flood plate with PBS to wash the agar surface, rocking the plate back and forth.
 - K. Aspirate and discard the PBS.

APPENDIX 3.15–2 (continued)

- L. Observe the plate macroscopically and microscopically under a stereomicroscope for absorption of erythrocytes to the surface of the colonies.
- M. *M. pneumoniae* will hemadsorb; *M. hominis* and other large-colony mycoplasmas that are cultivable on SP-4 agar in 4 to 20 days will not do so.

APPENDIX 3.15–3

Performance of Antimicrobial Susceptibility Testing for Mycoplasmas

I. PRINCIPLE

Susceptibility testing is useful mainly for systemic infections, particularly in immunosuppressed hosts, caused by *Mycoplasma hominis* or *Ureaplasma* spp. Testing is limited to antimicrobial agents that are commonly used to treat such infections, such as the tetracyclines, to which the organism may be resistant. Broth microdilution, agar dilution, and agar gradient diffusion (Etest technique) have been described for testing of antimicrobial agents against mycoplasmas and ureaplasmas in vitro (3). Broth microdilution is the most widely used method and the one most amenable to use in diagnostic laboratories for testing multiple antimicrobials. At present, there are no NCCLS standardized methods or approved MIC breakpoints for testing mycoplasmas. However, the broth microdilution method described below has been endorsed by the Chemotherapy Working Group of the International Research Program for Comparative Mycoplasmaology (2).

II. SUPPLIES

- A. Reference powders of antimicrobial agents of known purity
- B. Conical centrifuge tubes (10 and 50 ml)
- C. 96-well microtiter plates with covers
- D. Acetate sealers for microtiter plates
- E. Multichannel pipetting device and sterile pipette tips
- F. Plastic bags
- G. Paper towels
- H. SP-4 broth for testing *Mycoplasma* spp. or 10B broth for testing *Ureaplasma* spp. without antimicrobials added (Remel, Inc., or Appendix 3.15–1)
- I. SP-4 or A8 agar plates (Remel, Inc., or Appendix 3.15–1)

III. QUALITY CONTROL

- A. Results are valid only if the inoculum is 10^4 to 10^5 CFU/ml based on the assay performed at the time the microtiter plate is inoculated.
- B. Results are invalid if the positive control does not show color change, the drug or broth controls show color change, or there is turbidity indicating bacterial contamination.
- C. Read MICs when the positive control first shows evidence of color change, because the value tends to shift over time because of nonspecific color change after prolonged incubation.
- D. There are no type strains with expected MIC ranges for specific drugs that have been recommended for universal QC by the NCCLS. Always include an isolate for which the MICs of the drugs being used are reproducible to ensure validity of results for the test organisms, until reliable type strains have been designated for this purpose.
- E. When testing a new antimicrobial agent, test a type strain of a reference bacterium such as *Staphylococcus aureus* against the drug simultaneously in cation-adjusted Mueller-Hinton broth according to NCCLS standards (1) and in 10B or SP-4 broth to determine whether there is any interaction between the enriched mycoplasmal media and the antimicrobial being tested. The MICs should agree within ± 1 two-fold dilution. Commonly tested drugs that are used for testing against mycoplasmas and ureaplasmas do not show such an interaction.

IV. PROCEDURE

- A. Test the following drugs.
 - 1. A fluoroquinolone such as levofloxacin, gatifloxacin, or moxifloxacin
 - 2. Tetracycline or doxycycline
 - 3. A macrolide such as erythromycin, azithromycin, or clarithromycin (for *Mycoplasma pneumoniae* and *Ureaplasma* spp.)
 - 4. Clindamycin (for *M. hominis*)
 - 5. Optional: test chloramphenicol on isolates from CSF.

APPENDIX 3.15–3 (continued)

- B. Preparation of stocks
 1. Weigh out an appropriate amount of powdered drug to prepare 10 ml of a stock solution containing 2,048 $\mu\text{g/ml}$.
 2. Dissolve antimicrobial agents according to manufacturer's instructions and in accordance with NCCLS guidelines (1).
 3. Depending on drug stability, store most stock solutions at -70°C . Some agents work best if prepared on the day of assay.
- C. Prepare a stock strain of known titer by incubating a stock culture of each strain to be tested, including controls, in the appropriate broth medium (10B for ureaplasmas, SP-4 for mycoplasmas) until color change occurs, and then freeze immediately at -70°C in $\leq 1\text{-ml}$ volumes.
 1. The approximate number of organisms in the frozen vials is determined by serially diluting a thawed vial.
 - a. Place 0.1 ml of culture into 0.9 ml of appropriate broth.
 - b. Make dilutions to at least 10^{-8} to achieve an endpoint titer.
 - c. Incubate tubes and count the dilutions that exhibit color change, indicative of mycoplasmal growth.
 2. Thaw vials of the organisms to be tested on the day the assay is to be performed and dilute in appropriate media to yield concentrations of 10^4 to 10^5 CFU/ml, based on the original predetermined inoculum.
 3. Prepare a total of 40 ml of each isolate for testing up to six drugs.
 4. Incubate the inoculated broth at 37°C for 2 h prior to use to allow organisms to become metabolically active prior to inoculating microtiter plates.
- D. Prepare two microtiter plates for every three drugs tested to allow testing a full range of drug concentrations from 0.008 to 256 $\mu\text{g/ml}$.
 1. If fewer concentrations are required, all testing for an individual drug can be performed in a single microtiter plate and the concentrations adjusted accordingly.
 2. Test each drug in duplicate, skipping a row between drugs. (Drug one, rows A and B; drug two, rows D and E; drug three, rows G and H.)
 3. Add 0.025 ml of appropriate medium in rows 2 to 12 of the first microtiter plate and rows 1 to 4, 6, and 10 of the second microtiter plate.
 4. Add 0.175 ml of appropriate medium to well 10 (total of 0.2 ml) for the broth control and row 8 (total of 0.175 ml) for the drug control.
 5. Add 0.025 ml of drug 1 to wells 1 and 2 in rows A and B in the first microtiter plate and well 8 in rows A and B of the second microtiter plate for drug control. (The other drugs to be tested will be added the same way in their respective rows.)
 6. Dilute the antimicrobial agent through all wells in the first microtiter plate using a 0.025-ml multichannel pipette, beginning at the second well and continuing through wells 1 to 4 in the second microtiter plate. Discard the final 0.025 ml.
 7. Add 0.175 ml of inoculated medium that has been prewarmed for 2 h to each well in rows 1 to 12 in the first microtiter plate and rows 1 to 4 and to the positive organism control (well 6) in the second microtiter plate as soon as the dilutions are completed for each drug to be tested. Start with row 6, move to row 4, and work backwards to row 1 in first microtiter plate to prevent drug carryover.
 8. Repeat the above procedure for each drug and organism to be tested.
- E. Perform a final determination of color changing units (CCU) by serial dilution of the cultures, as described above, at this time to check that a proper dilution was made and that the inoculum contains 10^4 to 10^5 CCU/ml.
- F. Place plastic covers over plates being tested against *M. pneumoniae*, and seal them in plastic bags with a piece of paper towel moistened with water to prevent desiccation of the broth. Cover plates being tested for *Ureaplasma* spp. and *M. hominis* with adhesive-back acetate sealers before placing lid to prevent urea by-products escaping to other wells and causing color change. Incubate aerobically at 37°C .
- G. Read the microtiter plates daily for color change in the organism control wells.
 1. Ureaplasmas will normally grow after 12 to 18 h of incubation. A positive reaction for *Ureaplasma* in 10B broth will be evidenced by a color change from yellow to pink.
 2. *M. hominis* may take 1 to 3 days. A positive reaction for *M. hominis* in SP-4 broth will be evidenced by a color change from pink to deeper red.

APPENDIX 3.15–3 (continued)

3. *M. pneumoniae* may take 5 to 10 days for completion of the assay. A positive reaction for *M. pneumoniae* in SP-4 broth will be evidenced by a color change from pink to yellow.
 - H. Record the MIC as the concentration of antimicrobial agent inhibiting color change in broth medium at the time when the organism control well first shows color change.
 - I. Determine minimal bactericidal concentrations (MBC), if desired, by subculturing 0.3 ml of fluid from wells of the microbroth dilution system that do not show color change into a volume of fresh broth sufficient to dilute the antimicrobial beyond the MIC. Usually a 1:100 dilution is sufficient.
 1. Incubate broths and examine for color change.
 2. Subculture to agar if color change occurs.
 3. Subculture fluid from the growth control to make certain organisms have remained viable in the absence of antimicrobials.
 4. Determine the MBC as the lowest concentration of antimicrobial at which there is no evidence of color change and no colonies formed on subculture to agar.
- V. REPORTING ANTIMICROBIAL SUSCEPTIBILITY RESULTS
- A. Report actual MICs since there are no breakpoints specified for mycoplasmas or ureaplasmas.
 - B. In addition, interpretive breakpoints developed for conventional bacteria may be reported for mycoplasmas, but *add a comment* to the report indicating that breakpoints used for interpretation of results have not been developed specifically for mycoplasmas and may not be valid.
 - C. Ureaplasmas must be tested at an acidic pH (6.0 to 6.5) in order for organisms to grow adequately. MICs for some macrolides such as erythromycin will be 2 to 3 dilutions higher at this pH than at neutral pH, making these organisms appear less susceptible in vitro than they may be in vivo. Include an explanatory comment with all MIC reports for macrolides when testing ureaplasmas.
 - D. Correlation of MICs for tetracycline with the presence or absence of the *tetM* transposon, which mediates resistance to this drug, has indicated that the MICs for *tetM*-containing strains of *M. hominis* or *Ureaplasma* spp. will be ≥ 8 $\mu\text{g/ml}$, whereas the MICs for strains that do not contain this resistance determinant will be ≤ 2 $\mu\text{g/ml}$, with no overlap between these two distinct populations.

Guidelines for Identification of Aerobic Bacteria

On the following pages are 48 biochemical procedures in alphabetical order, including both simple, rapid test procedures and standard conventional methods, for the identification of gram-positive and gram-negative bacteria. The biochemical tests have been selected that are most useful to laboratories, with emphasis on rapid testing. The list of tests includes the generally accepted tests that all laboratories should be able to perform to identify the clinically important microorganisms encountered in the laboratory, as well as some for use by reference or referral laboratories. Smaller laboratories may choose to perform fewer tests and refer cultures when less common microorganisms are found in culture. When identification to the species level is not clinically important, tests to separate these species are not included. When there is a choice of different tests that can be performed, both are presented and the user can choose which is preferable for use in the laboratory.

Rapid and overnight commercial identification systems, containing many tests, provide very accurate identifications (Tables 3.16–1 to 3.16–4) (1, 2) with little hands-on time. The tests listed here are intended to supplement those systems, not replace them. For more detailed instructions on the performance of those test systems, refer to the instruction manual received with the product. If individual tests are available on a kit system, then the separate purchase of that biochemical test

may not be needed. However, commercial systems can be expensive, and rapid spot tests can often be a substitute or can be used to screen in order to suggest which commercial system might yield an identification. Serologic tests are not listed and should be a part of the identification methods used in most laboratories for various bacteria. See section 11.

As a policy, manufacturers are not listed if the product is available from most vendors. When a test has unique names depending on the manufacturer, attempts are made to list each of the product names. Product suppliers, addresses, and websites are listed in the introduction to this section, procedure 3.1. Often useful, detailed procedural information can be found on the vendor's website.

Generally, the formulas are presented, if it is likely that a laboratory might make the media or reagents in-house or the ingredients are of interest for the purchase or use of the test. Otherwise, only the key ingredients are listed for informational purposes, since good-quality commercial products are readily available and preparation of media in most laboratories is not cost-effective.

Below are a few reminders for performing the biochemical tests described in the following procedures. (i) Use only fresh cultures (18 to 24 h) as inoculum. (ii) Most reactions are aerobic. Keep caps loose, and incubate at 35°C without CO₂

unless otherwise indicated. (iii) Perform the oxidase, indole, and sometimes catalase tests on gram-negative bacteria before selecting additional tests. Perform a catalase and Gram stain on gram-positive bacteria prior to inoculation of other tests. (iv) Properly identify all material, prepared or purchased, with a legible label. Include the expiration date on the label and also log in a work record or on a receipt record. (v) Perform QC testing to ensure proper functioning of each reagent and of the test procedure with a negatively and a positively reacting microorganism prior to use of each new lot and possibly more often, depending on local regulations and on the frequency of usage. (vi) Although specific ATCC strains are listed for each procedure, any strain that will give the same result is acceptable. (vii) Record on each package, tube, or vial or in the QC records the date the reagent or test medium was initially put into use. (viii) Inoculum can be important in the use of medium and kit identifications. When appropriate, this is indicated with the appropriate McFarland standard. Refer to Appendix 3.16–1 for details on McFarland standards. (ix) Perform spot tests only from BAP or CHOC; *do not use selective media with dyes or biochemical tube agars for spot testing.*

Information presented in the following procedures was taken in part from HUGO, the product information manual from Hardy Diagnostics, with permission.

Table 3.16–1 Summary of bacterial identification systems^a

System	Manufacturer	Database	Storage temp (°C)	No. of tests	Length of incubation (h)	Automated
<i>Enterobacteriaceae</i>						
API 20E	bioMérieux	See Table 3.16–2	2–8	21	24–48 ^b	No

APPENDIX 3.16-1

Preparation of McFarland Turbidity Standards

I. PRINCIPLE

A chemically induced precipitation reaction between barium chloride and sulfuric acid to form barium sulfate (BaSO_4) can be used to approximate the turbidity of a bacterial suspension (2). Alternatively, a latex particle suspension can be purchased as an optical equivalent to the chemical standard (Remel, Inc.; Hardy Diagnostics), or a nephelometer can be used directly on the bacterial suspension. Varying BaSO_4 turbidities are referred to as McFarland turbidity standards and range between 0.5 and 10 (2).

II. REAGENTS AND SUPPLIES

A. The following reagents are prepared in sterile distilled water (3).

1. Solution A: 0.048 mol of BaCl_2 per liter (1.175% [wt/vol] $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$)
2. Solution B: 0.18 mol of H_2SO_4 , chemically pure grade, per liter (1% [vol/vol])

B. Supplies

1. Nine thoroughly cleaned test tubes that hold 10 ml of reagent
2. Test tubes with screw caps that have the same diameter as broth or saline tubes that are used to prepare bacterial suspensions

APPENDIX 3.16–1 (continued)

Include QC information on reagent container and in QC records.

3. Parafilm, liquid paraffin, or airtight tape, such as duct tape.
4. White card with contrasting black lines (available from Remel, Inc., and Hardy Diagnostics).

III. QUALITY CONTROL

As a control of the ability to prepare appropriate turbidity standards, a colony count of the bacterial suspension can be determined. Generally the suspension will have to be diluted 1:100 or 1:10 several times in broth and vortexed until the expected concentration of the suspension is 10^5 /ml (see chart below for corresponding cell density). Such a suspension will yield 100 to 300 colonies on a plate when inoculated with a 0.001-ml loop. Inoculate a second plate with a 0.01-ml loop in case there is no growth on the first plate. Spread with a bent rod for greatest accuracy.

IV. PROCEDURE

A. Procedure for preparation of standards (1)

1. Label each test tube from 0.5 to 8.
2. Dispense the appropriate aliquot of solution A into the appropriate aliquot of solution B with constant agitation to maintain a suspension, using the chart below.

Barium sulfate turbidity standard	Vol (ml) of:		Turbidity equivalent to cell density of <i>Escherichia coli</i> broth culture (10^8 /ml)
	Solution A, 0.048 mol of BaCl_2 /liter	Solution B, 0.18 mol of H_2SO_4 /liter	
0.5	0.05	9.95	1.5
1	0.1	9.9	3
2	0.2	9.8	6
3	0.3	9.7	9
4	0.4	9.6	12
5	0.5	9.5	15
6	0.6	9.4	18
7	0.7	9.3	21
8	0.8	9.2	24

3. Verify the correct density of the 0.5 turbidity standard by using a spectrophotometer with a 1-cm light path and matched cuvette to determine the absorbance. The absorbance at 625 nm should be 0.08 to 0.10 for the 0.5 McFarland standard (3).
4. Transfer the barium sulfate suspensions in aliquots into screw-cap tubes of the same size as those used in growing or diluting the bacterial inoculum. Label each tube with the appropriate turbidity equivalent.
5. Tighten tubes and seal with airtight tape, melted paraffin, or Parafilm, and store in the dark at room temperature.
6. Vigorously agitate the barium sulfate turbidity standard on a mechanical vortex mixer before each use, and inspect for a uniformly turbid appearance. If large particles appear, the standard should be replaced. Latex particle suspensions should be mixed by inverting gently, not on a vortex mixer.
7. Verify the density of the 0.5 standard monthly and replace the standards if the density falls outside of the acceptable limits (3).

B. Procedure for use of standards

1. Vigorously agitate the chosen standard on a mechanical vortex mixer before use.
2. Obtain a screw-cap tube with the same diameter as the standard containing either broth, saline, or sterile water, as appropriate for the use of the bacterial suspension.
3. While working in a biological safety cabinet prepare a suspension of the bacteria matching the turbidity of the standard as closely as possible. Recap tube. Vortex suspension.
4. Using adequate light, hold the standard next to the culture tube and display them both against a white card with contrasting black lines.
5. Add culture (if suspension is too light) or additional broth (if suspension is too heavy) to achieve a turbidity optically comparable to the standard.

It is imperative that these cultures be handled in a biosafety hood.

3.17.1

Acetamide Utilization Test

I. PRINCIPLE

Acetamide agar is used to test an organism's ability to utilize acetamide by deamidation. The medium contains acetamide as the sole carbon source and inorganic ammonium salts as the sole source of nitrogen. Growth is indicative of a positive test for acetamide utilization. When the

bacterium metabolizes acetamide by the enzymatic action of an acylamidase, the ammonium salts are broken down to ammonia, which increases alkalinity. The shift in pH turns the bromthymol blue indicator in the medium from green to blue, indicative of a positive test. Assimilation

of acetamide will result in a yellow color and should not be mistaken for a positive result (2). In general, deamidation is limited to only a few organisms. This medium is recommended for differentiating *Pseudomonas aeruginosa* from other non-glucose-fermenting, gram-negative rods.

II. MICROORGANISMS TESTED

- A. Isolated colonies of non-glucose-fermenting, gram-negative rods that are suggestive of *P. aeruginosa* and produce a fluorescent pigment
- B. Unusual non-glucose-fermenting, gram-negative rods, as part of the identification

III. MEDIA, REAGENTS, AND SUPPLIES**A. Medium**

1. Agar slant containing the following per liter

sodium chloride	5.0 g
magnesium sulfate	0.2 g
ammonium phosphate, monobasic	1.0 g
potassium phosphate, dibasic	1.0 g
acetamide	10.0 g
agar	15.0 g
bromthymol blue	0.08 g

2. The final pH is 6.8.

3. Store at 2 to 8°C.

☑ **NOTE:** Tablets (Key Scientific) are also available. Tablet is dissolved in 1 ml of distilled water and boiled to destroy any vegetative bacteria present. It is then heavily inoculated and incubated at 35°C for up to 6 days. A color change from yellow to purple is a positive reaction.

B. Supplies

1. Sterile inoculating loops or sticks
2. Incubator at 35°C

IV. QUALITY CONTROL

- A. Perform QC on each new lot or shipment of media prior to putting it into use.
- B. Inspect agar for evidence of prior freezing, contamination, cracks, dehydration, and bubbles prior to storage and before use. Discard any tubes that are blue.
- C. Organisms
 1. *P. aeruginosa* ATCC 27853—acetamide positive (growth; blue color)
 2. *Escherichia coli* ATCC 25922—acetamide negative (no growth; green color)

V. PROCEDURE

- A. Streak the slant back and forth with inoculum picked from the center of a well-isolated colony.
- B. Place cap loosely on tube.
- C. Incubate aerobically at 35 to 37°C for up to 4 days.
- D. Observe a color change from green to blue along the slant.

VI. INTERPRETATION

- A. A positive test is growth and change from green to intense blue color along the slant.
- B. A negative test is no growth, no color change, and slant remains green.

VII. REPORTING RESULTS

- A. Acetamide deamination is most actively accomplished by *Delftia (Comamonas) acidovorans*, *P. aeruginosa*, and *Alcaligenes faecalis* (3).
- B. Of the fluorescent pseudomonads, *P. aeruginosa* is positive for acetamide. Unless the isolate is from a normally sterile site, the combination of fluorescent pigment, acetamide deamination, and oxidase positivity is sufficient to identify *P. aeruginosa* (1, 3).

VIII. LIMITATIONS

- A. Growth on the slant without an accompanying color change may indicate a positive test. However, if the agar does not turn blue with further incubation, the test should be repeated with less inoculum.
- B. A negative test does not rule out an identification of *P. aeruginosa*, and 6% of *Pseudomonas fluorescens* organisms have been reported to give a positive reaction (1, 3). Other fluorescent *Pseudomonas* spp. do not give positive reactions.
- C. Other tests should be performed, such as growth at 42°C, to separate *P. aeruginosa* from the other fluorescent pseudomonads if the isolate is from a blood culture, since the patient could have received blood products contaminated with *P. fluorescens*, which can grow at refrigeration temperatures (1).
- D. Tests with equivocal results should be repeated.
- E. Do not stab the slant, since the test requires an aerobic environment.
- F. Do not inoculate from broth cultures, due to carryover of media.
- G. To avoid false-positive reactions, use a light inoculum to prevent carryover of substances from previous media.

3.17.2

Acetate Utilization Test

I. PRINCIPLE

Acetate agar is used to test an organism's ability to utilize acetate. The medium contains sodium acetate as the sole carbon source and inorganic ammonium salts as the sole source of nitrogen. Growth is indicative of a positive test for acetate utilization.

When the bacteria metabolize acetate, the ammonium salts are broken down to ammonia, which increases alkalinity. The shift in pH turns the bromthymol blue indicator in the medium from green to blue (2). This medium is recom-

mended in differentiating *Shigella* spp. from *Escherichia coli* (1). Approximately 84% of *E. coli* strains utilize acetate, whereas the majority of *Shigella* species are incapable of acetate utilization.

II. MICROORGANISMS TESTED

- A. Non-lactose-fermenting, gram-negative rods that are oxidase negative, non-motile, and anaerogenic, which are likely to be either *E. coli* or *Shigella*
- B. Nonfermentative, gram-negative rods

III. MEDIA, REAGENTS, AND SUPPLIES

A. Media

1. Sodium acetate agar slants contain the following ingredients per liter of solution.

sodium chloride	5.0 g
magnesium sulfate	0.1 g
ammonium phosphate, monobasic	1.0 g
potassium phosphate, dibasic	1.0 g
sodium acetate	2.0 g
agar	20.0 g
bromthymol blue	0.08 g

2. The final pH is 6.7.

3. Vendors include Hardy Diagnostics; Remel, Inc.; and BD Diagnostic Systems.

B. Supplies

1. Sterile inoculating loops or sticks
2. Sterile pipette
3. Incubator at 35°C
4. Sterile saline

IV. QUALITY CONTROL

- A. Perform QC on new lots of media prior to putting them into use.
- B. Inspect agar for evidence of prior freezing, contamination, cracks, dehydration, and bubbles prior to storage and before use. Discard any tubes that are blue.
- C. Organisms
 1. *E. coli* ATCC 25922—acetate positive (growth; blue color)
 2. *Shigella flexneri* ATCC 12022—acetate negative (no growth or trace of growth)

V. PROCEDURE

- A. Using an 18- to 24-h culture from a noninhibitory culture plate, prepare a turbid saline suspension. Inoculate the slant with 1 drop of the suspension.
- B. Alternatively, streak the slant back and forth with a light inoculum picked from the center of a well-isolated colony.
- C. *Place cap loosely on tube.*
- D. Incubate aerobically at 35 to 37°C for up to 5 days for *Enterobacteriaceae*; incubate at 30°C for nonfermenting, gram-negative rods for up to 7 days.
- E. Observe a color change from green to blue along the slant.

VI. INTERPRETATION

- A. A positive test is growth and change from green to intense blue color along the slant.
- B. A negative test is no growth, no color change, and slant remains green.

VII. REPORTING RESULTS

- A. Most *E. coli* organisms are positive for acetate utilization; most *Shigella* organisms are negative.
- B. Some *S. flexneri* organisms are acetate positive. Lysine decarboxylase, citrate, and serologic tests (e.g., Alkalescens-Dispar [AD] antisera for *E. coli*) are also helpful to rule out *Shigella*, if any of these results are positive.

VIII. LIMITATIONS

- A. Growth on the slant without an accompanying color change may indicate a positive test. However, if the agar does not turn blue on further incubation, the test should be repeated with less inoculum.
- B. Tests with equivocal results should be repeated.
- C. Do not stab the slant, since the test requires an aerobic environment.
- D. Do not inoculate from broth cultures, due to carryover of media.
- E. To avoid false-positive reactions, use a light inoculum to prevent carryover of substances from previous media.

3.17.3

ALA (δ -Aminolevulinic Acid) Test for Porphyrin Synthesis

I. PRINCIPLE

The δ -aminolevulinic acid (ALA) test is a rapid test used to determine the growth requirement for heme (X factor) in the identification of *Haemophilus* spp. (1). Organisms which do not require heme can produce porphobilinogen from ALA by the enzyme porphobilinogen synthase. The porphobilinogen is then converted to protoporphyrin IV, the immediate precursor of the heme moiety, in a series of steps. The presence of porphyrins is detected by

the emission of red-orange fluorescence under UV light (360 nm). This method is more rapid than the X factor strip and is superior because it avoids erroneous results due to carryover (2). In the tube test, if no fluorescence is observed, indole reagent can be added to detect porphobilinogen, the precursor to porphyrin (3), which is considered a positive test for porphobilinogen synthase.

ALA has also been described for detecting cytochromes in catalase-negative, gram-positive cocci (4). A positive test for porphobilinogen in a gram-positive coccus indicates that the organism is a member of the family *Micrococcaceae*, even if it is catalase negative. This test is useful for identification of organisms that have the colony morphology of staphylococci but are catalase negative.

II. MICROORGANISMS TESTED

- A. Tiny gram-negative rods or coccobacilli growing only on CHOC with the typical *Haemophilus* colonial morphology (e.g., large size colony in 24 h) and which do not grow on BAP. They do grow on BAP by satelliting around *Staphylococcus* spp.
- B. Gram-positive cocci that have the colonial appearance of staphylococci but are catalase negative

III. REAGENTS AND SUPPLIES

Include QC information on reagent container and in QC records.

- A. **ALA reagent (3)**
 1. Purchase disks (BD Diagnostic Systems; Hardy Diagnostics; Remel, Inc.). Store at 4°C or
 2. Prepare by combining the following.
 - a. 33.5 mg of ALA (Sigma) (stored at -20°C)
 - b. 19.72 mg of $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$
 - c. 100 ml of 0.1 M Sorensen's phosphate buffer, pH 6.9
 - (1) 3.15 g of $\text{NaH}_2\text{PO}_4 \cdot \text{H}_2\text{O}$ and 7.4 g of $\text{Na}_2\text{HPO}_4 \cdot 7\text{H}_2\text{O}$ in 500 ml of deionized water
 - (2) Check pH; adjust with either 0.1 M HCl or 0.1 M NaOH.
 - (3) Store at 2 to 8°C. Reagent is stable for 6 months.
 - d. Dispense in 0.5-ml aliquots into 13- by 100-mm tubes. Cover tightly and store at -20°C.
 - e. Label rack of tubes with preparation date, expiration date (9 months from preparation), storage requirements, and preparer's initials.
- B. **Kovács' indole reagent**
 1. Prepare in isoamyl alcohol for porphobilinogen test.
 2. See Appendix 3.17.23-1.
- C. **Other supplies**
 1. Filter paper or test tubes
 2. Petri dish
 3. Sterile wooden sticks, plastic or wire inoculating loops
 4. Long-wave UV light (360 nm or Wood's lamp)
 5. Incubator at 35°C

IV. QUALITY CONTROL

- A. Perform QC on each new lot or shipment of disks or reagent prior to putting it into use.
- B. Test positive control with use to verify length of incubation and color reaction (optional).
- C. Organisms
 1. *Haemophilus influenzae* ATCC 10211—ALA negative; no red fluorescence
 2. *Haemophilus parainfluenzae* ATCC 7901—ALA positive; red fluorescence

V. PROCEDURE**A. Inoculation**

1. Filter paper method
 - a. Place piece of filter paper to fit flat in a petri dish.
 - b. With a pencil, make circles approximately 10 mm in diameter for each test, plus a circle for the positive control.
 - c. Inoculate center of each circle heavily with colony of test organism using a wooden stick or loop.
 - d. Slowly pour thawed ALA reagent over filter paper, covering all test circles.
2. Disk method
 - a. Place ALA-containing disks in bottom of petri dish, marking the petri dish near each disk with culture identifying number.
 - b. Add 0.04 ml (one small drop) of saline to each disk.
 - c. Inoculate center of each disk heavily with test organism using wooden sticks; repeat for each control organism. Colony should be visible on disk. Alternatively, touch disk to colony and then place in petri dish.
 - d. Place a filter paper saturated with water on lid of dish. Cover.
3. Tube method: add a heavy inoculum of organism to 0.5 ml of ALA reagent.

B. Incubation and observation

1. Incubate test in non-CO₂ incubator at 35°C for 2 h.
2. Observe reactions for red fluorescence under Wood's lamp in darkened room.
3. Reincubate for 2 to 4 h more if control is negative and reread.
4. If the *tube* test is negative, incubate for 18 to 24 h, add 0.5 ml of Kovács' reagent to the tube, and shake vigorously. Observe for immediate color change.

VI. INTERPRETATION

- A. The presence of red fluorescence is a positive test, indicating that the organism does not require X factor or hemin and that the ALA has been utilized.
- B. The lack of red fluorescence is a negative test, indicating that the organism requires X factor and that the ALA has not been utilized.
- C. When the indole reagent is added, a red color in the *lower* aqueous phase indicates a positive test for porphobilinogen, which is also indicative that the organism does not require hemin for growth.

VII. REPORTING RESULTS

- A. A negative test or no fluorescence for a gram-negative rod that grows as large colonies in 24 h on CHOC but not on BAP indicates *H. influenzae*.
- B. A negative test or no fluorescence for a catalase-negative, oxidase-positive, gram-negative rod that takes several days to grow on CHOC, does not grow on BAP, even with a streak of staphylococci, and is sodium polyanethol sulfonate sensitive indicates *Haemophilus ducreyi*.
- C. A positive test for fluorescence or the red color in the lower aqueous phase after adding indole reagent is consistent with *H. parainfluenzae*, *Haemophilus parahaemolyticus*, or *Haemophilus paraphrophilus*. The last organism is lactose

VII. REPORTING RESULTS*(continued)*

positive. Further biochemical tests are needed to separate (2). See Table 3.18.2–2.

- D.** A positive test for porphobilinogen in a gram-positive coccus indicates that the organism is a member of the family *Micrococcaceae*, even if it is catalase negative (4). *Aerococcus* and *Streptococcus* are porphobilinogen negative, and *Staphylococcus* and *Rothia mucilaginosa* (*Stomatococcus mucilaginosus*) are positive.

VIII. LIMITATIONS

- A.** Many organisms will give a positive reaction. If test is performed only on gram-negative rod colonies that grow well on CHOC in 24 h and not on BAP, results are for *Haemophilus* species.
- B.** The ALA test will not separate *H. influenzae* from *Haemophilus haemolyticus*; the latter is rare and not pathogenic. It will sometimes grow on BAP without the need for staphylococcal streak, if it is able to hemolyze the blood to supply it with V factor.
- C.** Read test only in a darkened room.
- D.** Make a heavy inoculum to avoid false-negative results.
- E.** Test only cultures less than 24 h old.
- F.** If test paper is not kept moist during the incubation, the reaction can be falsely negative.
- G.** *Francisella tularensis* is ALA negative but does not grow in 24 h on CHOC and is oxidase negative. It does not satellite around staphylococci on BAP.

3.17.4

Antimicrobial Disk Tests for Identification (Especially of Staphylococci)

I. PRINCIPLE

Identification of coagulase-negative staphylococci to the species level is often not clinically useful (14). The use of the pyrrolidonyl- β -naphthylamide (PYR) test in combination with the coagulase test, ornithine decarboxylase, and a number of disk susceptibility tests allows identification of clinically important species: *Staphylococcus saprophyticus* in urinary tract and genital infections, *S. lugdunensis* in blood and joint cultures, and *S. haemolyticus*, which is important only because it can be intermediately susceptible to vancomycin. For repeatedly isolated coagulase-negative staphylococci from blood and clinically significant or post-operative specimens, antimicrobial susceptibility profiles are required. Nosocomial strains may need to be typed by pulse-field gel electrophoresis to determine the spread of clonal strains in outbreak situations.

For urinary tract specimens, for which a report of either *S. saprophyticus* or coagulase-negative staphylococci is suffi-

cient, only the novobiocin disk need be tested, along with testing for any antimicrobials that are requested by caregivers (10, 12). *S. saprophyticus* is resistant to novobiocin (1, 6, 9); a few other staphylococcal species are also resistant to novobiocin, but they are rarely found in clinical specimens, especially in the urinary tract. Evaluations of the novobiocin disk method on both Mueller-Hinton (MH) agar (1, 6) and BAP (9, 11) have been published. Generally, zone sizes are larger for novobiocin on MH agar, and a 16-mm breakpoint has been recommended. Hébert et al. (9) tested 1,000 clinical isolates of coagulase-negative staphylococci on BAP and found that a lower zone size (<12 mm) for resistance increased the specificity of the test.

The bacitracin 0.04-U disk, previously considered useful for identification of *Streptococcus pyogenes*, is a very sensitive assay to separate staphylococci from *Rothia mucilaginosa* (formerly *Stomatococcus mucilaginosus* [2]) and *Micrococ-*

cus (3, 9, 11). This separation is generally performed restrictively, usually on strains with pigment or sticky colony morphology from significant anatomic sites. Bacitracin differentiation may also be useful for penicillin-susceptible strains, since the great majority of *Micrococcus* and *Rothia* organisms are susceptible to penicillin and most coagulase-negative staphylococci are not (13). Alternatively, the furazolidone disk test (3), from BD Diagnostic Systems, or the modified oxidase test using a 6% solution of tetramethylphenylenediamine in dimethyl sulfoxide (4) sold as the Microdase test by Remel, Inc., can be used to separate these genera (*see* procedure 3.17.39). These tests are not covered in this procedure, since the bacitracin disk is easily obtained and does not require additional QC organism stocks.

The polymyxin B disks (or colistin disks) are useful to separate species of staphylococci and are also very useful in the identification of *Neisseria* and gram-negative rods (procedure 3.18.2).

II. MICROORGANISMS TESTED

A. Novobiocin

For gram-positive cocci in clusters which are catalase positive and coagulase negative isolated from urine specimens, usually from sexually active young women

B. Bacitracin

For penicillin-susceptible or "sticky" colonies of gram-positive cocci in clusters which are catalase positive and coagulase negative from invasive-site specimens to separate staphylococci from micrococci. Do not test lemon-yellow colonies, because they are presumed to be *Micrococcus*.

C. Polymyxin B

For differentiation of *R. mucilaginosa* from *Micrococcus* spp. and for separation of *S. aureus* and *S. intermedius* or characterization of other species of staphylococci, especially *S. epidermidis*, in unusual circumstances. This disk is also

II. MICROORGANISMS TESTED (continued)

used as part of the identification of *Neisseria*, *Vibrio*, and non-glucose-fermenting, gram-negative rods, especially from cystic fibrosis patients.

D. Penicillin and vancomycin

For screening gram-positive cocci in clusters from positive blood cultures for confirmation of Gram stain, for induction for the beta-lactamase test, for detection of unusual resistance, and for *Pediococcus* and *Leuconostoc* identification

III. MEDIA, REAGENTS, AND SUPPLIES

A. Disks

Store a small supply at 4°C; store stock at –20°C.

1. Novobiocin, 5 µg
2. Bacitracin, 0.04 U
3. Penicillin, 10 U
4. Vancomycin, 30 µg
5. Polymyxin B, 300 U (colistin [10-µg] disk can be substituted)

B. Media

1. BAP *or*
2. MH agar

C. Supplies

1. Swabs
2. Broth for inoculum

IV. QUALITY CONTROL

- A. Perform QC of disks weekly or with each use for tests that are performed less often than weekly. Test on the medium that is used for test performance. For disks used for identification only (bacitracin, novobiocin), testing need not be performed weekly, but test each new lot or shipment of disks with both a susceptible and resistant strain prior to using for identification tests. Testing should be repeated monthly with a susceptible control organism for disks that are stored at 4°C rather than –20°C.

B. Strains, media, and zone size requirements

Antimicrobial agent	Test organism	Zone size (mm) with 6-mm disk
Novobiocin, 5 µg, on BAP or MH agar	<i>Staphylococcus aureus</i> ATCC 25923	≥22
	<i>Staphylococcus saprophyticus</i> ATCC 15305	≤15
Bacitracin, 0.04 U, on BAP	<i>Streptococcus pyogenes</i> ATCC 19615	≥12
	<i>Staphylococcus aureus</i> ATCC 25923	6
Polymyxin B, 300 U, on MH agar	<i>Pseudomonas aeruginosa</i> ATCC 27853	17–21 (5)
	<i>Escherichia coli</i> ATCC 25922	17–20 (5), 12–16 (BD package insert)
Colistin, 10 µg, on MH agar	<i>Pseudomonas aeruginosa</i> ATCC 27853	15–19 (5)
	<i>Escherichia coli</i> ATCC 25922	16–20 (5), 11–15 (BD package insert)
Penicillin, 10 U, on MH agar	<i>Staphylococcus aureus</i> ATCC 25923	26–37
Vancomycin, 30 µg, on MH agar	<i>Staphylococcus aureus</i> ATCC 25923	17–21

V. PROCEDURE**A. Hébert method (8, 9, 11) using BAP**

1. Prepare no. 1 McFarland suspension of organism from overnight growth.
2. Inoculate a section of a BAP in one direction; area of inoculation should allow a separation of 10 mm between each disk to be placed on the inoculum.
3. After allowing 10 min for drying, place the disks on agar.
4. Tap disk with sterile stick to ensure adherence.
5. Incubate for 24 h at 35°C in non-CO₂ incubator.

B. MH agar method (1, 6)

1. If other disk susceptibility testing is being performed to report susceptibility to antimicrobial agents on a urinary isolate, use MH agar for the novobiocin test (1, 6).
2. Prepare a no. 0.5 McFarland suspension of the organism and inoculate MH agar in three directions as for a disk susceptibility test (12).
3. Place novobiocin and other susceptibility test disks on agar.
4. Incubate for 18 h at 35°C in a non-CO₂ incubator.

C. For positive blood cultures

1. Place a drop from the positive culture onto BAP and spread with a loop over one-fourth of the plate.
2. Place penicillin and vancomycin disks on this area of the plate.
3. Use interpretations for MH agar only for identification purposes, not for susceptibility reporting.

VI. INTERPRETATION**A. Novobiocin**

1. Hébert method using BAP (9)
 - a. Zone of <12 mm is resistant.
 - b. Zone of ≥12 mm is susceptible.
2. NCCLS method using MH agar (1, 6, 12)
 - a. Zone of ≤16 mm is resistant.
 - b. Zone of >16 mm is susceptible.
3. Resistance corresponds to an MIC of ≥1.6 µg/ml.

B. Bacitracin, 0.04 U (3, 9, 11), on either BAP or MH agar

1. Zone of 6 mm is resistant.
2. Zone of ≥10 mm is susceptible.
3. Repeat tests with values between 7 and 10 mm; these are probably susceptible.

C. Polymyxin B (9) on either BAP or MH agar

1. Zone of <10 mm is resistant.
2. Zone of ≥10 mm is susceptible.
☑ **NOTE:** If colistin is substituted for polymyxin B, the zone sizes may be smaller for susceptible strains; for gram-negative rods, any zone is considered susceptible (M. York, personal observation).

D. Penicillin (12)

1. Zone of ≤28 mm is resistant.
2. Zone of ≥29 mm is susceptible.

E. Vancomycin (12)

1. Zone of <15 mm is resistant.
2. Zone of ≥15 mm is susceptible.

VII. REPORTING RESULTS

- A. For gram-positive cocci in clusters which are catalase positive and coagulase negative
 - 1. Novobiocin-resistant strains
 - a. In a urine culture, report as *S. saprophyticus* (10).
 - b. From other body sites, *do not use this result* alone for species identification. Generally refer to the organism as “coagulase-negative staphylococci.”
 - 2. If an isolate is penicillin susceptible and from a significant body site, use the bacitracin 0.04-U disk to separate coagulase-negative staphylococci (resistant) from *Micrococcus* (susceptible) and *Rothia* (susceptible) (3, 9, 11). The latter also adheres to the agar.
 - 3. Most staphylococcal species are susceptible to polymyxin B, but *S. aureus*, *S. lugdunensis*, and *S. epidermidis* (97.2% are resistant) are notable exceptions (9). Use this resistance as part of the identification of *S. epidermidis* and to separate *S. aureus* from *S. intermedius*. *Rothia* is also polymyxin B resistant. See Table 3.18.1–1.
- B. Any gram-positive coccus that is resistant to vancomycin is either *Enterococcus*, *Pediococcus*, *Leuconostoc*, or possibly a vancomycin-resistant staphylococcus, which must be further tested to confirm the result (*see* section 5 and procedure 3.18.1).
- C. Refer to procedure 3.18.2 for use of the polymyxin B disk in the identification of gram-negative rods.

VIII. LIMITATIONS

- A. Strains of staphylococci, other than *S. saprophyticus*, that are resistant to novobiocin include *S. xylosus*, *S. kloosi*, and *S. cohnii*. Any strain may become resistant to novobiocin, including *S. aureus*; reporting *S. saprophyticus* should be limited to urinary tract isolates unless further tests for identification to the species level are performed.
- B. While Goldstein et al. (6) recommend using <16 mm as the breakpoint for resistance to novobiocin for BAP and MH agar, their data and those of others demonstrate greater specificity without loss of sensitivity by using the <12-mm breakpoint for BAP (6, 9).
- C. While *Micrococcus* and *R. mucilaginosus* can be resistant to penicillin, this is a very rare event (11, 13).
- D. Staphylococci should show no zone of inhibition around the bacitracin 0.04-U disk on BAP (9). Zone sizes of >7 mm but less than the 10-mm breakpoint may be obtained for *Micrococcus* if incubation is not a full 24 h or MH agar is used (9).
- E. Direct tests from blood cultures are not standardized but can work well to provide preliminary reports and guide subsequent identifications and more standardized antimicrobial susceptibility testing.
- F. Harrington and Gaydos (7) reported a rapid novobiocin test that is completed in 5 h.

3.17.5

Bile-Esculin and Esculin Tests

I. PRINCIPLE

The basis of the esculin test is the hydrolysis of esculin (a glucoside) into glucose and esculetin by a microorganism that has a constitutive (noninducible) β -glucosidase or esculinase enzyme. When esculetin is produced by the hydrolysis of esculin, it reacts with an iron salt in the

medium to form a phenolic iron complex which produces a dark brown or black color (3). Alternatively, esculin is a fluorescent compound and its hydrolysis can be observed by a loss of fluorescence. If bile is added to the medium, the microorganism must be able to grow in its pres-

ence in order to hydrolyze esculin. The 40% bile (equivalent to 4% oxgall) in bile-esculin medium inhibits most strains of streptococci, other than *Streptococcus bovis*, but does not inhibit enterococci or *Listeria* (1, 2).

II. MICROORGANISMS TESTED

- A. Gram-positive cocci in chains, which are catalase negative and morphologically identified as presumptive *S. bovis*
- B. Isolates of alpha- or gamma-hemolytic, gram-positive cocci as part of differentiation of enterococci from other pyrrolidonyl- β -naphthylamide (PYR)-positive organisms
- C. Non-spore-forming, hemolytic, gram-positive rods that are catalase positive and morphologically identified as presumptive *Listeria*
- D. Positive blood cultures with gram-positive cocci in chains or gram-positive rods, to rapidly (4 h) identify enterococci and *Listeria*
- E. Esculin without bile for the identification of oxidase-positive aerobic gram-negative rods, including *Aeromonas* spp. and yellow-pigmented non-glucose-fermenting rods (4)

III. MEDIA, REAGENTS, AND SUPPLIES

A. Media

Store at 2 to 8°C.

1. Bile-esculin agar slants with iron(III) citrate. Agar plate media, such as Enterococcosel agar (BD Diagnostic Systems), have a similar formulation.
2. Bile-esculin-azide agar or broth with iron(III) citrate and azide. Azide will inhibit most gram-negative bacteria.
3. Peptose-yeast-esculin broth (usually in anaerobic atmosphere)
 - **NOTE:** This medium can be decanted into small volumes for use on aerobic and microaerobic organisms.
4. Esculin agar (0.1% esculin in heart infusion basal medium) without

bile or azide but with iron(III) citrate (Hardy Diagnostics)

■ **NOTE:** Color Spot (Remel, Inc.) and Wee-Tab (Key Scientific) incorporate PYR and esculin tests on filter paper cards in a rapid test. BactiCard Strep (Remel, Inc.) and StrepQuick (Hardy Diagnostics) contain PYR, leucine aminopeptidase (LAP), and a rapid esculin test. Enterococcus/Group A Screen (Remel, Inc.) is a rapid tube test for esculin and PYR.

B. Reagents and supplies

1. Long-wave (360 nm) UV light
2. 1% ferric [iron(III)] ammonium citrate if iron(III) is not incorporated into the medium

IV. QUALITY CONTROL

- A. Perform QC on new lots or shipments of media and ferric ammonium citrate reagent prior to putting them into use.
- B. Inspect agar for freezing, contamination, cracks, dehydration, and bubbles prior to storage and before use.
- C. Examine uninoculated broth for fluorescence.
- D. Organisms
 - 1. *Enterococcus faecalis* ATCC 29212—bile-esculin and esculin positive
 - 2. *Escherichia coli* ATCC 25923—bile-esculin and esculin negative
 - 3. *Streptococcus pyogenes* ATCC 19615—bile-esculin and esculin negative

V. PROCEDURE

- A. **Tube test**
 - 1. Inoculate slant or broth with a single colony. For enterococcus and *S. bovis* identification, use only 40% bile and inoculate with a 10- μ l calibrated loopful of a 0.5 McFarland standard suspension prepared in sterile water (1).
 - 2. Place cap loosely on tube.
 - 3. Incubate for 24 h at 35°C (or up to 7 days for slow-growing gram-negative rods and anaerobes) and observe color change. For enterococci and *S. bovis*, read only at 18 to 24 h.
 - 4. For esculin broth without iron(III) citrate, observe daily for loss of fluorescence. Add 2 or 3 drops of 1.0% ferric ammonium citrate to the esculin tube if no fluorescence is observed. Observe for a color change. Aliquot broth for daily testing with indicator, if desired.
 - 5. When evaluating loss of fluorescence, use an uninoculated control tube for comparison.
- B. **Disk test**
 - 1. Moisten disk with a single drop of distilled or deionized water. Do not saturate.
 - 2. Using a sterile loop, pick two or three well-isolated colonies from an overnight (18- to 24-h) culture.
 - 3. Allow to react at room temperature for 10 min.
 - 4. Observe the disk for the development of a dark brown or black color.

VI. INTERPRETATION

- A. A positive tube test in medium containing ferric ammonium citrate is demonstrated by blackening of the medium.
- B. A negative tube test is indicated by lack of color change. The medium will fluoresce under UV light (366 nm).
- C. For esculin broth without iron(III) citrate, a positive test is demonstrated either by blackening of the broth after addition of the ferric [iron(III)] reagent or by the loss of fluorescence of the medium.
- D. A negative test result also occurs in bile-esculin medium if the organism cannot grow in the presence of bile, regardless of the ability to hydrolyze esculin.
- E. A positive disk test is the development of a dark brown or black color.
- F. A negative disk test remains colorless.

VII. REPORTING RESULTS

- A. *Listeria monocytogenes* is a bile-esculin-positive, beta-hemolytic, CAMP-positive, catalase-positive, motile, nonpigmented, small gram-positive rod.
- B. Esculin- or bile-esculin-positive, catalase-negative, gram-positive cocci in chains may be *Enterococcus*. Confirmation includes large-diameter (1-mm) colonies that are PYR and LAP positive. *Lactococcus* organisms are not easily separated from enterococci.

VII. REPORTING RESULTS*(continued)*

- C. Esculin- or bile-esculin-negative, gamma- or alpha-hemolytic, gram-positive cocci in *chains* that are bile insoluble (procedure 3.17.6) and catalase negative and grow well on BAP are presumptively identified as viridans group streptococci.
- D. If the inoculum is controlled and the medium contains 40% bile, PYR-negative streptococci (catalase-negative, gram-positive cocci in chains) can be presumptively identified as *S. bovis* with a 97% sensitivity by a positive bile-esculin test (1).
- E. Positive esculin reactions can separate the species of yellow, non-glucose-fermenting, gram-negative rods (Tables 3.18.2–6 and 3.18.2–7) and *Aeromonas* species.

VIII. LIMITATIONS

- A. If the inoculum is too great or the concentration of bile is less than 40%, viridans group streptococci other than *S. bovis* can give a positive reaction on bile-esculin agar (1, 2). Esculin tests without bile do not separate *S. bovis* (previously referred to as group D streptococci, not enterococci) from other viridans group streptococci.
- B. H₂S, which is produced by several organisms during metabolism, also reacts with iron to produce a black complex, which interferes with the interpretation of the esculin hydrolysis test. Therefore, for gram-negative rods, check tubes showing darkening after the addition of the reagent under UV light; intact esculin fluoresces white-blue, whereas hydrolyzed esculin has lost its fluorescence.
- C. Some microorganisms, such as *E. coli*, have an inducible β-glucosidase and will react in this test only after prolonged incubation. Prolonged incubation should not be used if the test is being used to detect only constitutive β-glucosidase.

3.17.6

Bile Solubility Test

I. PRINCIPLE

The bile solubility test is used to differentiate *Streptococcus pneumoniae* from alpha-hemolytic *Streptococcus* spp. It may be performed using a cell suspension on a slide or in a tube or by applying the reagent directly to the colony.

The bile solubility test is based on the observation that pneumococcal cells lyse

when sodium desoxycholate (bile salts) is applied to the colony under specific conditions of time and temperature, but other streptococci do not lyse (6). The pneumococcus has an intracellular autolytic enzyme, an amidase, that causes the organism to undergo rapid autolysis when cultivated on artificial medium. The bile

salts alter the surface tension of the medium and cause cell membrane rearrangement. The working mechanism of the test is not clearly understood; however, one theory is that the bile salts facilitate lysis of pneumococcal cells by activating the autolytic enzyme (2).

II. MICROORGANISMS TESTED

- A. Any alpha-hemolytic, catalase-negative, gram-positive cocci in chains, having the characteristic central depression (flattened center) or mucoid colony morphology suggestive of *S. pneumoniae*
- B. Any gram-positive cocci in lancet-shaped pairs from a positive blood culture

III. REAGENTS AND SUPPLIES

Include QC information on reagent container and in QC records.

A. Reagents

- 1. Bile salts
 - a. Purchase or prepare 10% bile salt solution
 - sodium desoxycholate (Sigma) 10 g
 - deionized water 100 ml
 - b. Dispense in small amounts to minimize contamination. Shelf life is 270 days.

- c. Store at 15 to 30°C. Storage of the reagent at cool temperatures can cause it to thicken.

- 2. 0.85% NaCl (sterilized)
- 3. Broth culture medium (e.g., BHI)

B. Supplies

- 1. Loops
- 2. Test tubes or slide
- 3. Pasteur pipettes

IV. QUALITY CONTROL

- A. Test each new lot of reagent with known positive and negative controls before putting it into use.
- B. Do not use if bile reagent is not a clear and very light amber.
- C. Organisms
 - 1. *S. pneumoniae* ATCC 49619—positive (bile soluble)
 - 2. *Enterococcus faecalis* ATCC 29212—negative (bile insoluble)

V. PROCEDURE**A. Test tube method**

1. Dispense 0.5 ml of sterile saline or suitable broth into a small test tube.
2. Prepare a heavy suspension of the organism in the saline (equivalent to no. 1 McFarland standard). Shake or vortex to form a uniform suspension.
3. Divide the suspension into two tubes, one labeled "TEST" and the other labeled "CONTROL."
4. Dispense 5 drops of bile reagent into the tube marked "TEST." Add 5 drops of saline to the tube marked "CONTROL." Gently mix each tube.
5. Incubate the tubes for 3 h at 35°C, checking hourly for clearing, or examine each tube by Gram stain or methylene blue wet mount for lysis of cells at 15 min.

B. Direct plate method

1. Place a drop of bile spot reagent near a suspected 18- to 24-h colony; gently roll the drop over several representative colonies by tilting the plate. Take care not to dislodge the colonies.
NOTE: Do not touch the agar surface with the tip of the dropper of bile reagent.
2. Keep the plate right side up and incubate at 35°C for 15 to 30 min or until the drop has evaporated. Placing the plate on a heat block is a substitute for use of an incubator.
3. Observe for flattening of the colony. Be sure the colony did not simply float away.

C. Direct slide blood culture test (4)

1. Add 1 drop of blood culture broth to 1 drop of bile reagent on a glass slide and allow to dry.
2. As a control, add 1 drop of broth blood culture to 1 drop of *water* and allow to dry.
3. Gram stain and examine for cocci.

VI. INTERPRETATION**A. Test tube method**

Bile solubility is demonstrated as a clearing or loss of turbidity, relative to the "CONTROL" tube, within 3 h or lysis of cells observed microscopically.

B. Direct slide blood culture method

If all the cocci in the smear are completely lysed and the control smear shows intact bacteria, the organism is bile soluble.

C. Direct plate method

1. Bile solubility is demonstrated as a disintegration or flattening of the colony within 30 min, leaving an area of alpha-hemolysis where the colonies were located.
2. Insolubility is demonstrated when there is no change in the integrity of the colony within 30 min.

VII. REPORTING RESULTS

- A. If either the spot or tube test demonstrates bile solubility of an alpha-hemolytic colony from a catalase-negative, lancet-shaped, gram-positive coccus, definitively report as *Streptococcus pneumoniae* (5).
- B. If the test does not demonstrate bile solubility, the organism is likely a viridans group streptococcus, but a percentage of bile-resistant organisms may still be *S. pneumoniae*; further testing is indicated from typical pneumococcal colonies (3).

VIII. LIMITATIONS

- A. Some *S. pneumoniae* organisms will not lyse in the presence of bile, possibly due to the loss of virulence factor or capsule. If lysis is not present, the isolate may still be *S. pneumoniae*. Therefore, colonies resembling *S. pneumoniae* which are not bile soluble should be further identified using another method, such as optochin susceptibility and/or DNA probe (3).
- B. Use bile solubility only to differentiate *S. pneumoniae* from other alpha-hemolytic streptococci.
- C. In one study comparison with the DNA probe and Quellung test, using 529 presumed viridans group streptococci, the tube test had a 96% specificity (23 false positives) and the colony test had a 99.4% specificity (3). For greatest specificity, tube test-positive, spot test-negative strains should be confirmed with an optochin disk test or DNA probe.
- D. The colony test has a sensitivity of 99% and the tube test has a sensitivity of 99 to 100% for encapsulated strains of *S. pneumoniae* (1, 3). However, Mundy et al. (3) showed that the colony test was not very sensitive (three positive results) in the detection of 33 unencapsulated strains that were detected by DNA probe. The tube test detected 19 of the 33 unencapsulated strains positive by probe. All 33 had some zone of inhibition of optochin, although most were in the intermediate category. Whether DNA probe-positive, bile-negative strains are important pathogens or represent false-positive DNA probe tests is not known.
- E. Normal autolysis of *S. pneumoniae* may be inhibited by a high concentration of bile salts. Evaporation may cause the reagent to become more concentrated, thus affecting the test.
- F. The bile solubility test is not reliable with old cultures that have autolysed.
- G. When performing the bile solubility tube test using saline or unbuffered broth, it is essential to adjust the pH to neutral before adding the reagent, in order to avoid false-negative reactions.
- H. When testing using the plate method, care must be taken not to dislodge the colony being tested, thus leading to false-positive results. If the direct plate is difficult to interpret, the test should be repeated using the tube or slide method.
- I. Storage of the reagent at cool temperatures can cause it to thicken. Warm the reagent bottle in a 37°C incubator to liquefy the reagent before use.

3.17.7

Butyrate Esterase Test

I. PRINCIPLE

The butyrate test is a rapid test for the detection of the enzyme butyrate esterase. When used in conjunction with characteristic morphology on BAP, typical Gram stain, and a positive oxidase test, the butyrate test is useful for the definitive identification of *Moraxella catarrhalis*.

The value of tributyrin hydrolysis for differentiating *M. catarrhalis* from *Neis-*

seria spp. was first reported by Berger in 1962 (1). Subsequently, several authors have reported the usefulness of butyrate esterase in differentiating *M. catarrhalis*, using various substrates. Both bromochloro-indolyl butyrate (IB) (2, 3) and 4-methylumbelliferyl butyrate (MUB) (4, 5, 6, 7) can serve as substrates. Hydrolysis of

the IB substrate by the butyrate esterase releases indoxyl, which in the presence of oxygen spontaneously forms indigo, a chromogenic compound which appears blue to blue-violet. Hydrolysis of the MUB substrate produces a fluorescent compound visible under UV light.

II. MICROORGANISMS TESTED

Gram-negative, oxidase-positive diplococci growing on BAP as white colonies that remain together when lifted with a loop or wire

III. REAGENTS AND SUPPLIES

Include QC information on reagent container and in QC records.

A. Disks

1. Disks impregnated with IB or MUB
2. Store at 2 to 8°C. Protect from light.
3. Vendors include Hardy Diagnostics; Remel, Inc.; and Key Scientific.

■ **NOTE:** The BactiCard *Neisseria* (Remel, Inc.) includes the IB substrate as one test in the kit.

B. MUB tube test

1. MUB stock solution
 - MUB (Sigma) 100 mg
 - dimethyl sulfoxide
 - (Sigma) 10 ml
 - Triton X-100 100 ml
2. 0.1 M citrate buffer, 90 ml; final pH, 5.0
 - a. 0.1 M citric acid
 - b. 0.05 M Na₂HPO₄ · 12H₂O
3. Dissolve the MUB powder in dimethyl sulfoxide–Triton X-100 solution.

4. Prepare a 1:10 dilution of the stock solution in the citrate buffer.
5. Dispense 250-μl aliquots into sterile snap-cap tubes.
6. The substrate is stable for at least 1 month.
7. Clearly label the substrate, indicating preparation and expiration dates.
8. Record the expiration date in a work record.
9. Store frozen at –20°C or below. Protect from light.

C. Supplies

1. Sterile wooden applicator sticks or bacteriologic loops
2. Distilled water
3. Petri dish, slide, or tube.
4. Long-wave (360 nm) UV light (Wood's lamp) (MUB reagent only)

IV. QUALITY CONTROL

- A. Discard disks if they do not appear white with no visible color.
- B. Perform QC on each new lot and shipment of disks or MUB reagent prior to putting them into use.
- C. Organisms
 - 1. *M. catarrhalis* ATCC 25240—butyrate positive
 - 2. *Neisseria gonorrhoeae* ATCC 43069 or *Neisseria lactamica* ATCC 23970—
butyrate negative

V. PROCEDURE

- A. **Disk method**
 - 1. Remove disk from vial and place on a clean glass slide or petri dish.
 - 2. Add 1 drop of distilled or deionized water to moisten the disk.
 - 3. Obtain a heavy, visible inoculum with a sterile wooden applicator stick or loop from a 24- to 72-h culture and rub it onto the disk.
 - 4. Incubate at room temperature (15 to 30°C) for up to 5 min.
 - 5. *Incubation for slightly longer periods may yield false-positive results. Do not read after 5 min.*
- B. **Tube method**
 - 1. Thaw tubes at room temperature.
 - 2. Inoculate substrate using several colonies to obtain a turbid suspension.
 - 3. Incubate at room temperature (15 to 30°C) for up to 5 min. *Incubation for slightly longer periods may yield false-positive results.*
 - 4. Observe fluorescence using long-wave UV light in a darkroom.

VI. INTERPRETATION

- A. A positive test results in a blue to blue-violet color (IB substrate) or fluorescence (MUB substrate) within 5 min, indicating the hydrolysis of IB or MUB, respectively, by butyrate esterase.
- B. A negative test is indicated by no color change.

VII. REPORTING RESULTS

- A. Report as *Moraxella catarrhalis* if an oxidase-positive, gram-negative diplococcus meets the following criteria.
 - 1. Grows on BAP as colonies that remain together when sampled *and*
 - 2. Is butyrate positive
- B. Test butyrate-negative colonies that are suggestive of *M. catarrhalis* by the above-listed criteria for DNase production. Report DNase-positive colonies as *Moraxella catarrhalis*.

VIII. LIMITATIONS

- A. Do not incubate test beyond 5 min, to avoid false-positive reactions.
- B. Many strains of other *Moraxella* species, as well as *Eikenella* and *Acinetobacter*, may give a positive or weakly positive reaction (2, 6). The organism must be an oxidase-positive, gram-negative *diplococcus* with typical morphology to be accurately identified as *M. catarrhalis*.
- C. Unrelated organisms such as staphylococci and pseudomonads may also give positive results.
- D. False-negative tests may result from using too small an inoculum. If the organism is suspected but the test is negative, repeat with a large inoculum or test for DNase production.

3.17.8

CAMP Factor Tests (Standard and Rapid)

I. PRINCIPLE

Streptococcus agalactiae produce a thermostable, extracellular, diffusible protein that acts synergistically with the beta-lysin produced by *Staphylococcus aureus* to produce a zone of enhanced lysis of sheep or bovine erythrocytes (1, 3). The protein was named CAMP factor for the initials of the authors of the manuscript that first described the phenomenon (2). The standard CAMP test relies on the elaboration of two toxins during growth to form a typical ar-

rowhead or flame-shaped clearing at the juncture of the two organisms when they are placed perpendicular to each other (Fig. 3.17.8-1). The rapid test utilizes an extract of staphylococcal beta-lysin that acts directly with the CAMP factor previously diffused in the medium around the *S. agalactiae* colony. A positive CAMP reaction is indicated by an enhanced hemolysis within 30 min of adding the

CAMP factor reagent (4, 9). The test is useful in the identification of both *S. agalactiae* and many gram-positive rods, including *Listeria monocytogenes*.

In addition, hemolysis by some organisms is inhibited by the beta-lysin of staphylococci. An arrow of no hemolysis is formed at the junction of the organism with the staphylococci. This is referred to as a reverse CAMP test (Fig. 3.17.8-1).

II. MICROORGANISMS TESTED

- A. Gram-positive cocci in pairs and chains that are catalase negative with medium-sized, smooth, whitish colonies with a small halo of beta-hemolysis. Nonhemolytic isolates also may be tested, since the CAMP factor can still be present.
- B. Gram-positive rods, as part of their identification
- C. Gram-positive cocci in clusters, as part of the identification of staphylococci to the species level, if *Staphylococcus intermedius* AB148 is used as the strain that supplies the hemolysin (5)

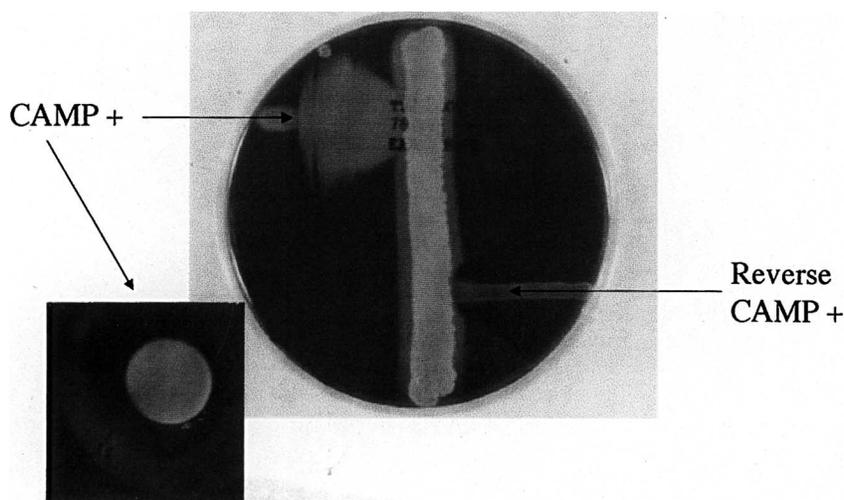

Figure 3.17.8-1 Demonstration of positive CAMP and reverse CAMP test, using *S. aureus* streak and CAMP disk.

III. MEDIA, REAGENTS, AND SUPPLIES

Include QC information on reagent container and in QC records.

A. BAP

B. Beta-lysin reagent

1. Culture of *S. aureus* ATCC 25923
2. Commercial reagents
 - a. Disks containing beta-lysin of *S. aureus* (catalog no. SS697; Remel, Inc.); store at 4°C (Fig. 3.17.8–1).
 - b. Spot CAMP liquid reagent (catalog no. Z206; Hardy Diagnostics)
3. Preparation of spot CAMP reagent (7)
 - a. Inoculate two 5-ml tubes of BHI with a swab of growth from a fresh subculture of *S. aureus* ATCC 25923.
 - b. Incubate overnight (shaking is optional) at 35°C in air.

- c. Working with gloves in a laminar-flow safety cabinet, combine the two broth suspensions and filter sterilize them using a 0.45- μ m-pore-size cellulose-acetate filter.
- d. Aliquot the filter-sterilized broth into small tubes of about 1 ml.
- e. Label with the name of reagent (CAMP), date of preparation, and expiration date of 6 months from preparation.
- f. Freeze at –20°C or lower.
- g. Store defrosted reagent at 4°C and use within 2 weeks. Do not refreeze.

IV. QUALITY CONTROL

- A. Test each lot of rapid beta-lysin reagent with a positively and negatively reacting organism in the same manner as patient isolates are tested prior to putting the reagent into use.
- B. Test each lot or shipment of commercial beta-lysin reagent or disks with a positively and negatively reacting organism in the same manner as patient isolates are tested prior to putting the reagent into use.
- C. Test each lot or shipment of BAP with a positively reacting organism. This can be performed on the same plate as the test organism when the test is performed, by streaking the positive control in a line parallel to the test organism. Alternatively, if BAP is purchased from a commercial medium vendor, omit testing if vendor supplies documentation that BAP has tested acceptably for the CAMP reaction (8).
- D. Organisms
 1. *S. agalactiae* ATCC 12386—positive
 2. *Streptococcus pyogenes* ATCC 19615—negative
 3. Periodically use an in-house laboratory strain of *Arcanobacterium haemolyticum* to demonstrate the reverse CAMP test for training purposes.

V. PROCEDURE

A. Standard method

1. Streak *S. aureus* ATCC 25923 in a straight line across the center of the plate.
2. Streak the unknown microorganism in the same manner perpendicular to the staphylococcus, but avoid touching the previously streaked area.
3. Streak the positive control organism parallel to and approximately 1 in. from the unknown organism.
4. Label the location of each streak on the back of the plate.
5. Incubate the plate overnight at 35°C in a CO₂ incubator.

B. Disk method

1. Place disk on warmed BAP.
2. Streak microorganism 2 to 3 mm from the edge of the disk.
3. Incubate the plate overnight at 35°C in a CO₂ incubator.

C. Spot rapid method

1. Place 1 drop or a 10- μ l loopful of reagent next to a presumptive *S. agalactiae* colony growing on BAP. Do not worry if the liquid touches or even engulfs the colony.

V. PROCEDURE (*continued*)

2. Incubate the plate right side up, to prevent the spot CAMP reagent from running over the plate's surface, for 20 min at 35°C.
3. Examine with transmitted light for a zone of enhanced hemolysis next to the colony.
4. Reincubate for up to 30 min if reaction is initially negative. Use a hand lens if necessary for examining the plate.
5. Refrigeration may enhance reaction after incubation.

VI. INTERPRETATION

- A. A positive result in the standard assay is the formation of a distinct arrowhead of hemolysis at the intersection of the staphylococcus and test organism streaks (Fig. 3.17.8-1).
- B. A positive reverse CAMP is indicated by a distinct arrow of no hemolysis at the intersection of the two hemolytic organisms (Fig. 3.17.8-1).
- C. In the disk test, a positive result is indicated by a distinct crescent- or arc-shaped zone of complete hemolysis at the intersection of the disk of beta-lysin and the isolate (Fig. 3.17.8-1).
- D. In the rapid spot test, the presence of clear enhanced hemolysis only where the diffused hemolysis overlaps is a positive result.
- E. Lack of enhanced hemolysis near the colony being tested is a negative test.

VII. REPORTING RESULTS

- A. A streptococcus which gives a positive CAMP test and is morphologically and biochemically consistent (catalase-negative, gram-positive cocci in pairs and chains) is reported as *Streptococcus agalactiae*.
- B. The following gram-positive rods are CAMP test positive: *Rhodococcus equi*, *L. monocytogenes*, *Propionibacterium avidum/granulosum*, *Actinomyces neuii*, *Turicella otitidis*, *Corynebacterium glucuronolyticum*, *Corynebacterium colyaeae*, *Corynebacterium imitans*, and some strains of *Corynebacterium striatum* and *Corynebacterium afermentans* group.
- C. *Corynebacterium pseudotuberculosis*, *Corynebacterium ulcerans*, and *A. haemolyticum* are reverse-CAMP positive.

VIII. LIMITATIONS

- A. Increased nonspecific hemolysis at the intersections (a "matchstick" effect) may be seen with other streptococci, but only group B streptococci will produce a definite arrowhead. Verify typical group B streptococcus, colony morphology and hemolysis.
- B. The test has a 98% sensitivity in detecting *S. agalactiae* (6). Isolates with a negative CAMP test could still be *S. agalactiae* and require further testing.
- C. *S. pyogenes* can give a reaction that may be interpreted as positive. When there is a question, *S. pyogenes* is pyrrolidonyl- β -naphthylamide (PYR) positive but *S. agalactiae* is PYR negative.
- D. The CAMP test separates *L. monocytogenes*, the human pathogen, from most other *Listeria* species.
- E. If the agar is too thin or hemolyzed, the reaction may be very weak.

I. PRINCIPLE

The ability of a microorganism to utilize carbohydrates can be key to its identification. There are a wide array of media available, using different pH indicators and nutrients. Usually the medium contains a protein source, pH indicator, and a 1% concentration of carbohydrate. The 1% concentration is optimal for most reactions and decreases the possibility of reversal reactions. Reversion occurs when the carbohydrate is depleted, thereby resulting in the masking of acid by-products by alkaline by-products of protein product utilization. It is very important that the correct base and indicator are used in testing so that the results will match the biochemical reactions expected from identification tables.

To detect fermentation with acid production of various sugars by gram-positive microorganisms, the medium used generally contains bromcresol purple (4), which turns from purple to yellow at pH 5.2. For gram-negative rods that ferment glucose, the preferred medium contains Andrade's indicator, acid fuchsin. The medium is straw colored and turns fuchsia-red when acid is produced. Andrade's indicator is very difficult to make correctly and must be aged for 6 months to produce the correct color (11). Commercial identification systems often use neutral red or phenol red, which turns from red to yellow with a drop in pH. Results using these indicators compare favorably with results with Andrade's indicator or the bromcresol purple base, and published table reactions generally apply whether media with Andrade's indicator, bromcresol purple, or phenol red or commercial systems are used for enterococcus, gram-positive rods, and gram-negative rods (reference 9, p. 426, 480, and 648, respectively). Since

staphylococcus tables were created using the bromcresol purple indicator, results with commercial systems may be slightly different from the reactions in the tables (reference 9, p. 394).

Bacteria can be divided by their ability to degrade carbohydrates anaerobically (ferment) or aerobically (oxidize). Fermentation is a metabolic process in which an organic substrate serves as the final hydrogen acceptor rather than oxygen. Agar-based media are recommended for this determination, since the oxidative reaction can be observed at the top of the tube and fermentation can be observed in the bottom of the tube. The best medium to use for the determination of whether a gram-negative rod is an oxidizer or fermenter is either triple sugar iron agar (TSI) or Kligler's iron agar (KIA) (11). Fermenters will turn the butt yellow, while oxidizers and nonutilizers produce no change or alkalization of the butt in the tube. Once the organism is determined to be a fermenting rod, either Andrade's or neutral or phenol red base broths are used to determine which other sugars are fermented. Once an organism is determined to be non-glucose-fermenting, oxidative-fermentative (OF) medium is used to establish whether an organism can oxidize glucose or other sugars or does not produce acid from sugar fermentation. This medium contains bromthymol blue, which turns yellow when acid is produced from glucose (5). King (8) developed another medium with phenol red as the indicator, but it is not commercially available. OF basal medium is used to detect utilization of other sugars by non-glucose-fermenting rods. The recommended medium to determine whether a gram-positive rod is an oxidizer or fermenting rod is reported to be semisolid

cystine Trypticase agar (CTA) with glucose, rather than KIA, TSI, or OF medium (reference 9, p. 479).

To complicate testing, some gram-negative organisms (generally those that do not grow on MAC) will not react in the KIA or TSI media, OF medium, or even Andrade's broth, because these bacteria are too fastidious for growth. In such cases rapid or conventional CTA media with phenol red indicator is the choice (6, 10) to detect the ability to utilize carbohydrates. The indicator turns from red to yellow at pH 6.8. The rapid medium does not require the growth of the organism to detect acid production but relies on preformed enzymes for the reactions. These microorganisms include *Neisseria*; *Haemophilus*, *Kingella*, *Capnocytophaga*, *Actinobacillus*; and lipid-requiring gram-positive rods (reference 9, p. 593, 609, and 479, respectively). Another alternative that is often used for demonstration of fermentation of fastidious gram-negative rods and gram-positive rods is to add a few drops of sterile rabbit serum to the Andrade's broth to allow the organism to grow. However, maltose cannot be tested since serum can split maltose (reference 9, p. 609). Carbohydrate reactions for *Neisseria* are problematic due to growth inhibition and poor oxidative metabolism; enzymatic tests are preferred (see Table 3.18.2-1 and reference 9, p. 593).

The production of gas from the fermentation of sugars can be determined by one of several methods. In agar-based tubes inoculated with gram-negative rods, disruption of the agar is evidence of gas production. If a Durham tube is inverted into broth, gas is apparent if the broth in the tube is displaced with air. When examining gram-positive bacteria, gas pro-

duction may be discerned with the use of melted paraffin overlay. The “hot loop” method is useful for fastidious gram-negative rods, such as *Haemophilus aphrophilus*, where the production is key to the identification (7). In this method, a red-hot

inoculating needle is plunged near the side of the glass tube of a 48- to 72-h culture of the organism in THIO in a biological safety cabinet (11). Gas bubbles appear along the line of insertion to indicate posi-

tive gas from glucose. Occasionally organisms ferment lactose better than glucose and will demonstrate gas from lactose in the Durham tube when no gas is seen in the glucose tube.

II. MICROORGANISMS TESTED

A. Gram-positive rods and fermentative gram-negative rods

1. Andrade’s “Enteric fermentation medium” is preferred. Add rabbit serum for fastidious gram-negative rods.
2. Heart infusion purple broth base medium can be used if the organism is not fastidious.
3. Rapid sugar fermentation media and CTA are used for fastidious rods.

B. Gram-positive cocci (staphylococci, streptococci, enterococci)

1. Generally these tests are present in commercial kits, and laboratories rarely stock sugar tests for identification.
2. Use heart infusion purple broth base media for conventional testing (4).

☑ **NOTE:** *Leuconostoc* produces copious amounts of gas from glucose in MRS broth (procedure 3.17.32) as evidenced by displacement of a melted Vaspar, liquid paraffin or petroleum jelly plug (reference 9, p. 440). However, leucine aminopeptidase (LAP) (procedure 3.17.26) and arginine dehydrolase (procedure 3.17.15) testing can substitute for this test to separate *Leuconostoc* from *Weissella confusa* and *Pediococcus* (see Fig. 3.18.1–3).

C. Glucose-oxidizing gram-negative rods, which are generally oxidase positive and grow on MAC, as part of the identification process

1. OF basal medium is used for testing.
2. See TSI and KIA procedure (procedure 3.17.25) to determine if the organism is a glucose-fermenting organism rather than a glucose oxidizer before using the OF basal medium.

D. Identification of *Neisseria* species

1. Phenol red-based media, such as rapid sugars and CTA
2. The addition of ascitic fluid to CTA is recommended but not necessary.

III. MEDIA, REAGENTS, AND SUPPLIES

A. Media

1. Heart infusion purple broth
 - a. BHI, peptone, yeast extract, NaCl
 - b. Bromcresol purple, pH 7.4
 - c. 1% Carbohydrates, filter sterilized and added after sterilizing the broth

☑ **NOTE:** This medium was developed for streptococci. A plate medium with gelatin rather than agar and another protein source was developed for staphylococci and enteric bacteria.
2. Enteric fermentation broth medium (1, 3)
 - a. Peptone, meat extract, and NaCl
 - b. Andrade’s indicator, pH 7.2
 - c. 1% Carbohydrates, filter sterilized and added after sterilizing the broth

3. CTA with or without ascitic fluid (11)

- a. Cystine, Trypticase peptone, inorganic salts, and agar (low concentration for semisolid agar) available in dehydrated powder (BBL, BD Diagnostic Systems)
- b. Phenol red, pH 7.3
- c. The addition of ascitic fluid (or serum or yeast extract) is recommended for testing *Neisseria* species.
- d. 1% Carbohydrates, filter sterilized and added after sterilizing and cooling the agar to 50°C
- e. This medium is modified by adding 2% carbohydrates to CTA in a small-volume tube (Remel, Inc.) for rapid fermentation.

III. MEDIA, REAGENTS, AND SUPPLIES (continued)

Include QC information on reagent container and in QC records.

4. Rapid sugar broth medium
 - a. Formula for buffer-salt solution (6, 11)

K ₂ HPO ₄ (anhydrous) ..	0.04 g
KH ₂ PO ₄	0.01 g
KCl	0.8 g
1% phenol red,	
aqueous	0.4 ml
distilled water	100 ml

 Adjust pH to 7.0. Filter sterilize and store at 4°C.
 - b. Prepare 20% carbohydrate solution in either distilled water or peptone broth (per liter: peptone, 10 g; meat extract, 3 g; NaCl, 5 g) and filter sterilize.
 - c. Add 1 drop (0.05 ml) of carbohydrate to 2 drops (0.1 ml) of buffer. Final concentration of sugars after adding 1 drop (0.05 ml) of culture will be 5%.
5. OF basal medium
 - a. Tryptone, inorganic salts, agar
 - ☑ **NOTE:** Hugh and Leifson's formula (5) employs a low peptone/carbohydrate ratio and a minimal amount of agar (semisolid).
 - b. Bromthymol blue, pH 7.1 (color of medium is green)
 - c. 1% Carbohydrates, filter sterilized and added after sterilizing and cooling the agar to 50°C.

B. Other products

1. Carbohydrate oxidation tablets for glucose oxidizers (Key Scientific Products)
2. Carbohydrate fermentation, Wee-Tab (Key Scientific Products) for staphylococci, streptococci, and enteric rods, but not for *Neisseria* spp.
3. Commercial kits (2, 9; procedure 3.16)
4. Ten-millimeter disks with carbohydrate are available and can be added to the phenol red broth or semisolid basal medium or OF medium without carbohydrate after inoculation (BD Diagnostic Systems).
5. Aerobic low-peptone (ALP) medium (Hardy Diagnostics) for the identification of nonfermenting, gram-negative bacilli. ALP medium can be used to detect acidification of carbohydrates or alkalinization of organic salts and amides.

C. Supplies

1. Rabbit serum (catalog no. 16120-099; Invitrogen Life Technologies, Carlsbad, Calif.). Heat for 1 h at 60°C prior to use.
2. Sterile tubes
3. Wire or disposable inoculating needles or loops
4. 35°C heat block or incubator without increased CO₂

IV. QUALITY CONTROL

- A. Perform QC using a positively and negatively reacting organism on each new lot and shipment of media prior to putting them into use.
- B. Inspect agar for evidence of prior freezing, contamination, cracks, dehydration, and bubbles prior to storage and before use. Discard any tubes with bubbles in the agar. Discard tubes that are not the appropriate color.
- C. Check rabbit serum for sterility by inoculation onto CHOC.
- D. Since carbohydrates are filter sterilized, check media and carbohydrate solutions for contamination when received or prepared.
- E. Organisms

Because the number and type of organism used for QC are extensive, refer to the QC section of the manual (section 14, Table 14.2–2).

V. PROCEDURE

- A. Warm medium to room temperature.
- B. Inoculation
 1. Purple broth and enteric fermentation broth medium
 - a. Before inoculating broth with Durham tube, check for trapped air bubbles. If necessary, invert tube until air bubbles are gone.
 - b. Inoculate (carbohydrate of choice) with isolated colonies from an 18- to 24-h pure culture of the organism.
 - c. Inoculate colony directly with a loop or wire or prepare a broth or saline suspension and inoculate with 1 drop per tube if a battery of carbohydrates is being tested.

V. PROCEDURE (continued)

- d. Add 1 drop of rabbit serum for fastidious gram-negative rods or corynebacteria.
 - e. Incubate for up to 7 days at 35°C in a non-CO₂ incubator with caps loose.
2. CTA
 - a. Inoculation
 - (1) Standard media: with a loop, inoculate media heavily, mixing throughout the entire top 5 to 10 mm.
 - (2) Rapid test media: fill a 3-mm loop with organisms and vigorously inoculate below the surface of the agar.
 - (3) Inoculate a control tube without carbohydrate for comparison.
 - b. *Tighten caps.*
 - c. Incubate for 2 to 4 h or up to 24 h for rapid media and up to 7 days for standard media at 35°C in a non-CO₂ incubator or heat block (preferred).
 3. Rapid sugar broth medium
 - a. Prepare a very heavy suspension of organism in buffer-salt solution (equivalent to no. 2 McFarland turbidity standard).
 - b. Inoculate 1 drop (0.05 ml) to each tube containing 2 drops (0.1 ml) of buffer-salt and 1 drop (0.05 ml) of 20% carbohydrate. Alternatively, inoculate the combined carbohydrate buffer-salt solution with a loopful of the suspected organism.
 - c. Inoculate 1 drop of distilled water and 1 drop of organism suspension to 2 drops of buffered salt as a control tube.
 - d. *Tighten caps.*
 - e. Incubate for 2 h or up to 4 h at 35°C in a heat block.
 4. OF basal medium
 - a. With a needle, pick up a large amount of organism from an agar plate or slant and stab into the medium four or five times to a depth of 2.5 cm.
 - b. Inoculate a control tube without carbohydrate for comparison.
 - c. *Cap the tubes loosely* and incubate for 24 h and up to 7 days at 30°C in a non-CO₂ incubator or heat block (preferred).
☑ **NOTE:** Inoculation of a tube overlaid with oil, petroleum jelly, or Vaspar (advocated for gas production of *Leuconostoc*) is not recommended to differentiate fermentation from oxidation among gram-negative rods. Rather, use KIA, TSI, or glucose broth medium with serum in conjunction with OF medium to determine if the organism is a glucose-fermenting rod (11).
 5. Carbohydrate oxidation tablets (COT) for glucose oxidizers
 - a. Add each tablet to 1 ml of distilled water in a small test tube.
 - b. Heat in a boiling water bath for 10 min. Cool before using.
 - c. For multiple carbohydrate tests, inoculate with a heavy bacterial suspension made in 1 to 2 ml of sterile distilled water. Transfer 1 or 2 drops of this suspension to each tube with a sterile pipette. For a single test, inoculate the tube with a loopful of the organism being tested without making a suspension.
 - d. *Cap the tubes loosely* and incubate at 37°C for 24 h and up to 4 days.
 6. Wee-Tabs
 - a. Add one tablet to a small tube and add 0.25 ml of distilled water.
 - b. Inoculate with a loopful of the organism being tested. If doing multiple tests, make a heavy suspension of the organism into 1 ml of water and add a drop of this suspension to each tube.
 - c. Add oil overlay if desired.
 - d. Incubate at 35°C for 6 to 24 h.
☑ **NOTE:** Do not use Wee-Tabs for *Neisseria* or any organism that will not grow in high salt.
- C. Examine for color change compared to control tubes without carbohydrate.

VI. INTERPRETATION**A. Purple broth**

1. Acid (positive) reaction: yellow (pH 5.2)
2. Alkaline (negative) reaction: purple
3. Gas production: bubbles in Durham tube

B. Andrade's enteric fermentation broth

1. Acid (positive) reaction: pink to red (pH 5.0)
2. Alkaline (negative) reaction: straw to tan (no change)
3. Gas production: bubbles in Durham tube

C. CTA, rapid fermentation broth or agar, COT, carbohydrate fermentation Wee-Tabs

1. Acid (positive) reaction: yellow (pH 6.8)
2. Alkaline (negative) reaction: red or no change compared to control

D. OF medium

1. Acid (positive) reaction: yellow (pH 6.0). Fermenters generally turn the entire tube yellow in 18 h, whereas oxidizers turn the top half of the tube yellow.
2. Weak acid reaction: yellow-green to green compared to the control, which is more alkaline or blue-green
3. Negative or nonoxidizer: inoculated control and carbohydrate tube are the same color.

VII. REPORTING RESULTS

- A. Record each carbohydrate result separately. Indicate whether gas is produced or not. When using OF medium, also note whether the organism is an oxidizer, fermenter, or nonoxidizer.
- B. *Acinetobacter* may be a nonoxidizer or an oxidizer.
- C. *Neisseria*, *Pseudomonas*, *Stenotrophomonas*, and *Burkholderia* are glucose oxidizers.
- D. *Enterobacteriaceae* are glucose fermenters.
- E. Arabinose fermentation is important in the separation of *Enterococcus faecium* (positive) from *Enterococcus faecalis* (negative).
- F. *Neisseria* species are separated by the utilization of glucose, maltose, lactose, and sucrose.
- G. *Alcaligenes xylosoxidans* subsp. *xylosoxidans* oxidizes xylose but may not demonstrate oxidation of glucose.

VIII. LIMITATIONS

- A. CTA basal medium without sugars is excellent for the maintenance of stock cultures at room temperature for several months (10).
- B. Glucose oxidizers do not ferment other sugars.
- C. If an organism appears to be a nonoxidizer in OF medium, it may be a fermenter that is not able to grow in OF medium. Repeat the test using fermentation media and rabbit serum to determine if the organism is a fermenter.
- D. Inoculation of the basal medium without carbohydrate is important in the determination of true utilization of the sugar.
- E. The Durham tube is usually placed in the glucose tube only, but it can be helpful in the lactose tube.
- F. Even a small bubble indicates gas production.
- G. Andrade's medium is not appropriate for testing *Neisseria* or streptococci.

3.17.10

Catalase Test

I. PRINCIPLE

Bacteria that synthesize the enzyme catalase hydrolyze hydrogen peroxide into water and gaseous oxygen, which results in the liberation of gas bubbles. The test is useful in the initial characterization of most bacteria (1, 2).

II. MICROORGANISMS TESTED

- A. Young (18 h old, if possible) colonies of bacteria growing on agar media, preferably BAP or CHOC
- B. For anaerobes, expose colonies to air for 30 min prior to testing.
- C. See section 7 for catalase testing of mycobacteria.

III. REAGENTS AND SUPPLIES

- A. **Hydrogen peroxide reagent**
 - 1. 30% For *Neisseria* (4)
Caution: 30% H_2O_2 is extremely caustic to skin. If contact occurs, wash immediately with 70% ethyl alcohol, not water.
 - 2. 15% For anaerobes
 - 3. 3% For other bacteria (purchase or dilute 30% 1:10 in deionized water prior to use)
 - **NOTE:** 30% Reagent can be used for all tests, but it is more hazardous.
 - 4. Store at 2 to 8°C.
- B. **Supplies**
 - 1. Glass slide
 - 2. Sterile wooden sticks or plastic or platinum loops or wires

IV. QUALITY CONTROL

- A. Perform QC on each new lot or shipment of reagent prior to putting it into use.
- B. Organisms
 - 1. *Staphylococcus aureus* ATCC 25923—catalase positive
 - 2. *Streptococcus pyogenes* ATCC 19615—catalase negative

V. PROCEDURE

- A. Touch the center of an 18- to 24-h, well-isolated colony to a clean glass slide.
 1. Be sure colony is visible to the naked eye on slide.
 2. If colony is from BAP, use care not to pick up blood.
- B. Place 1 drop of peroxide reagent on slide and observe *immediately* for effervescence.
 1. Use a magnifying lens if necessary.
 2. Hold over dark background to enhance bubbles.
- C. Discard slide into sharps container.

VI. INTERPRETATION

- A. A positive test shows immediate appearance of bubbles.
- B. A weak reaction has one or two bubbles.
- C. A negative test shows no bubbles or a few bubbles after 20 s.

VII. REPORTING RESULTS

- A. The catalase test separates staphylococci (positive) from streptococci and enterococci (negative).
- B. *Bacillus* spp. are catalase positive, and *Clostridium* spp. are catalase negative.
- C. The test is useful to separate among the fastidious gram-negative rods.
- D. *Neisseria gonorrhoeae* produces an enhanced elaboration of bubbles not seen with other members of the genus due to superoxol (4).

VIII. LIMITATIONS

- A. RBCs contain catalase. To avoid false-positive results, do not pick up blood agar with colony. If colony does not easily pick up or grow well, repeat the test from CHOC, which does not interfere with the assay.
- B. Do not test from Mueller-Hinton agar (2).
- C. Selecting colonies with some metal bacteriological loop materials will yield false-positive results; platinum loops do not yield false-positive results.
- D. Because the enzyme is present in viable cultures only, do not test colonies that are older than 24 h. Older cultures may give false-negative results.
- E. Do not reverse the order of adding the reagent to the colony; false-negative results can occur.
- F. Do not mix the reagent and the colony.
- G. Some strains of *S. aureus* may appear catalase negative by this method. See the aminolevulinic acid (ALA) test (procedure 3.17.3) for further testing to identify these problematic organisms.
- H. To confirm the lack of catalase for *Gardnerella vaginalis*, Reimer and Reller (3) recommend streaking a CHOC plate as for disk susceptibility testing and adding a dot of viridans group streptococci (*Streptococcus sanguis* ATCC 35557). A clear zone of inhibition around a dot of viridans group streptococci confirms the lack of catalase.

3.17.11

Cetrimide Test

I. PRINCIPLE

Cetrimide is a quaternary ammonium, cationic detergent that is toxic to most bacteria, except *Pseudomonas aeruginosa* and a few other bacteria (1, 2). When cetrimide is in contact with bacteria, nitrogen and phosphorus are released from the

bacterial cell. Organisms, other than *P. aeruginosa* and a few other pseudomonads, are unable to withstand this germicidal activity. Growth is observed on the inoculated slant of agar medium contain-

ing cetrimide for a positive result. Magnesium chloride and potassium sulfate in the medium enhance the production of pyocyanin and pyoverdin (fluorescein) by *P. aeruginosa*.

II. MICROORGANISMS TESTED

Isolated colonies of non-glucose-fermentative, gram-negative rods that are suggestive of *P. aeruginosa*

III. MEDIA, REAGENTS, AND SUPPLIES

A. Medium

1. Agar slants containing the following ingredients per liter of deionized water

pancreatic digest of	
gelatin	20.0 g
K ₂ SO ₄	10.0 g
MgCl ₂	1.4 g
cetyltrimethylammonium	
bromide	0.3 g
agar	13.6 g
glycerin	10.0 ml

2. Four milliliters of a 22.5% solution of cetrimide (0.9 g of hexadecyltrimethylammonium) can substitute for the cetyltrimethylammonium bromide.

3. Final pH, 7.2
4. Store at 2 to 8°C.

B. Supplies

1. Sterile inoculating loops or sticks
2. Wood's or UV light (360 nm) or short-wavelength (254-nm) UV light (preferred)

IV. QUALITY CONTROL

- A. Perform QC on each new lot or shipment of media prior to putting it into use.
- B. Inspect agar for evidence of freezing, contamination, cracks, dehydration, and bubbles prior to storage and before use.
- C. Organisms
 1. *P. aeruginosa* ATCC 27853—growth; yellow-green to blue pigment
 2. *Escherichia coli* ATCC 25922—inhibited

V. PROCEDURE

- A. Streak the slant back and forth with inoculum picked from the center of a well-isolated colony.
- B. Place cap loosely on tube.
- C. Incubate aerobically at 35 to 37°C for up to 7 days.
- D. Observe for growth and pigment.

V. PROCEDURE (*continued*)

- E. If no pigment is visible, examine growth under UV light for the presence of fluorescein.
- F. If negative for pigment at 24 h, incubate additional days at 25°C in the dark to enhance pigment production.

VI. INTERPRETATION

- A. Positive: growth. Optionally a yellow-green (fluorescein) to dark blue-green (pyocyanin) color may be observed.
- B. Negative: no growth

VII. REPORTING RESULTS

- A. *P. aeruginosa* is definitively identified if an oxidase-positive, gram-negative rod grows on cetrimide agar and produces a blue-green (pyocyanin) pigment.
- B. *Pseudomonas fluorescens* and *Pseudomonas putida* may also grow and may produce a fluorescent pigment on this medium (2) but are separated from *P. aeruginosa* because they do not grow at 42°C.

VIII. LIMITATIONS

- A. Growth on this medium alone is not sufficient for identification of *P. aeruginosa* to the species level, since other non-glucose-fermenting species (e.g., *Achromobacter xylosoxidans* subsp. *xylosoxidans* and *Alcaligenes faecalis*) may grow. Pigment must also be present.
- B. Lack of growth on cetrimide agar does not rule out an identification of *P. aeruginosa*.

REFERENCES

1. Lowburg, E. J. L. 1955. The use of cetrimide product in a selective medium for *Pseudomonas pyocyanea*. *J. Clin. Pathol.* **8**:47–48.
2. Weyant, R. S., C. W. Moss, R. E. Weaver, D. G. Hollis, J. G. Jordan, E. C. Cook, and M. I. Daneshvar. 1995. *Identification of Unusual Pathogenic Gram-Negative Aerobic and Facultatively Anaerobic Bacteria*, 2nd ed., p. 6. Williams & Wilkins, Baltimore, Md.

3.17.12

Citrate Utilization Test (Simmons)

I. PRINCIPLE

Citrate agar is used to test an organism's ability to utilize citrate as a source of energy. The medium contains citrate as the sole carbon source and inorganic ammonium salts as the sole source of nitrogen (3). Growth is indicative of utilization of citrate, an intermediate metabolite in the Krebs cycle. When the bacteria metabolize

citrate, the ammonium salts are broken down to ammonia, which increases alkalinity. The shift in pH turns the bromthymol blue indicator in the medium from green to blue above pH 7.6 (1). This medium is recommended as part of differentiating among the species of *Enterobac-*

teriaceae. With the exception of a few species, *Salmonella*, *Edwardsiella*, *Citrobacter*, *Klebsiella*, *Enterobacter*, *Serratia*, and *Providencia* usually give a positive reaction and *Escherichia*, *Shigella*, *Morganella*, and *Yersinia* give a negative reaction. *Proteus* is citrate variable.

II. MICROORGANISMS TESTED

Enterobacteriaceae, as part of the identification to the species level

III. MEDIA, REAGENTS, AND SUPPLIES

A. Medium

1. Agar slants containing citrate, ammonium salts, buffer, and bromthymol blue
2. Store at 2 to 8°C.
3. Final pH, 6.8

B. Supplies

1. Sterile inoculating loops or sticks
2. Incubator at 35°C

IV. QUALITY CONTROL

- A. Perform QC on each new lot or shipment of media prior to putting it into use.
 NOTE: NCCLS has proposed elimination of user QC for citrate agar purchased from commercial sources. Consult with current regulatory agencies prior to discontinuation of user QC (2).
- B. Inspect agar for evidence of freezing, contamination, cracks, dehydration, and bubbles prior to storage and before use. Discard any tubes that are blue.
- C. Organism
 1. *Klebsiella pneumoniae* ATCC 13883—citrate positive (growth; blue color)
 2. *Escherichia coli* ATCC 25922—citrate negative (no growth or trace of growth)

V. PROCEDURE

- A. Streak the slant back and forth with a light inoculum picked from the center of a well-isolated colony.
- B. Place cap loosely on tube.
- C. Incubate aerobically at 35 to 37°C for up to 4 days.
- D. Observe a color change from green to blue along the slant.

VI. INTERPRETATION

- A. A positive test is growth with color change from green to intense blue along the slant.
- B. A negative test is no growth and no color change; slant remains green.

VII. REPORTING RESULTS

- A. *E. coli* is citrate negative.
- B. Many other *Enterobacteriaceae* are citrate positive.

VIII. LIMITATIONS

- A. Luxuriant growth on the slant without an accompanying color change may indicate a positive test. However, if the agar does not turn blue on further incubation, the test should be repeated with less inoculum.
- B. Tests with equivocal results should be repeated.
- C. Do not stab the slant, since the test requires an aerobic environment.
- D. Do not inoculate from broth cultures, due to carryover of media.
- E. To avoid false-positive reactions, use a light inoculum to prevent carryover of substances from previous media.
- F. The reactions of this medium alone are not sufficient for identification to the species level.

3.17.13

Coagulase Test—Protein A/ Clumping Factor Agglutination Method

I. PRINCIPLE

Staphylococcus aureus is separated from other species of staphylococci by the presence of coagulase, which is demonstrated in the 4- to 24-h tube test to detect free coagulase. Clumping factor, termed bound coagulase, can be detected rapidly in the slide test, but this test requires several colonies and lacks sensitivity. *S. aureus* produces another substance in its cell wall, protein A, which binds to the FC moiety of human immunoglobulin G (IgG) (7). If latex or erythrocyte particles are coated with IgG and with human fibrinogen, a staphylococcus will agglutinate if either clumping factor or protein A is present in the bacterial cell wall (1, 2, 3, 4, 5, 11). Other species, such as *Staphylococcus lugdunensis* and *Staphylococcus schleiferi*

subsp. *schleiferi*, produce clumping factor and can be positive in the assay. These species are important in serious infections and require that positive agglutination results be confirmed with other tests or observations. Still other staphylococci possess protein A, including *Staphylococcus saprophyticus*, so the test should be performed restrictively on urinary isolates.

More recently, it was discovered that some *S. aureus* organisms, especially methicillin-resistant *S. aureus* (MRSA), can mask the cell wall with capsular polysaccharides (6, 10) and prevent the reaction between the IgG or fibrinogen. Newer kits have added antibodies to the latex or erythrocytes, which bind to the specific

bacterial surface antigens that have been reported to interfere with the test. These new reagents are more sensitive but have reduced the specificity further (9, 12, 13). In the United States these clones of MRSA, having the specific surface antigens, are less common. Thus, most laboratories choose to use tests with higher specificity and use the tube coagulase test when it is important to detect MRSA (13).

Despite all the problems with agglutination tests, they are very useful in rapid identification of staphylococci and in increasing the sensitivity of the identification of *S. aureus*, since there are also problems of sensitivity with the tube and slide coagulase tests (procedure 3.17.14).

II. MICROORGANISMS TESTED

- A. Colonies of gram-positive cocci in clusters which are catalase positive, as part of the identification of *S. aureus*
- B. From urine cultures, use test with caution on nonhemolytic colonies that are presumptive for staphylococci, since *S. saprophyticus* may give a false-positive result.
- C. Only test colonies that are less than 24 h old and are not from mannitol salt agar.

III. REAGENTS AND SUPPLIES

A. Reagents

1. Products

- a. Murex Staphaurex and Staphaurex Plus (Wellcome Diagnostics; Remel, Inc.)
- b. Prolex Staph kit (Pro-Lab Diagnostics, Austin, Tex.)
- c. StaphTex (Hardy Diagnostics)
- d. Bacti Staph (Remel, Inc.)
- e. Staphyloslide (BD Microbiology Systems)

This is a hemagglutination test rather than a latex test.

- f. Slidex Staph kit and Slidex Staph Plus (bioMérieux Vitek, Hazelwood, Mo.)

■ **NOTE:** “Plus” indicates that the additional antibodies to surface antigens have been used to coat the particles.

2. Test suspension

- a. Store at 2 to 8°C in an upright position.
- b. Do not freeze. Protect reagents from bright light.

III. REAGENTS AND SUPPLIES (continued)

- c. Do not *vortex* latex reagents.
- d. Store at workbench on cold pack during working hours and return to 4°C for overnight storage.
3. Some kits have a negative control latex of unsensitized particles to detect autoagglutination.

B. Supplies

1. Loops or sterile sticks
2. Black coated cards (supplied by vendors for serologic agglutination tests); white cards for erythrocyte suspensions

IV. QUALITY CONTROL

- A. Inspect suspension for granularity each time the test is performed, as it is dropped onto the test card. If there is evidence of autoagglutination, do not use the suspension.
- B. At a minimum, perform QC on each new lot or shipment of reagent prior to putting it into use.
- C. Organisms
 1. *Staphylococcus aureus* ATCC 25923—agglutination positive
 2. *Staphylococcus epidermidis* ATCC 12228 or ATCC 14990—agglutination negative

V. PROCEDURE

☑ **NOTE:** Verify any differences between this general procedure and the package insert prior to using test.

- A. Warm the reagents to room temperature.
- B. Invert the reagent bottle several times to obtain an even suspension.
- C. Dispense a drop of the test suspension into a circle on the reaction card for each culture to be tested.
- D. From a plate that is <24 h old, touch two to four colonies with the flat end of a stick.
- E. Emulsify the sample of culture in the suspension and spread over a 10-mm area of the circle.
- F. If an autoagglutination control is included in the kit, repeat the above steps with the control reagent.
- G. Rotate the card gently for up to, *but no longer than*, 20 s and examine for agglutination. Do not use a magnifying lens.
- H. Dispose of the card in infectious-waste container.

VI. INTERPRETATION

- A. A positive result is indicated by the development of an agglutination pattern showing rapid strong clumping of the particles with *clearing* of the background. Most positive results are instantaneous.
- B. A negative result is indicated when the particles do not agglutinate and the appearance remains substantially unchanged throughout the test.
- C. If the control test shows clumping or the test shows clumping but the background remains unchanged, autoagglutination has likely occurred. Perform a tube coagulase test.

VII. REPORTING RESULTS

- A. Only test gram-positive cocci in clusters which are catalase positive. Report as *Staphylococcus aureus* if the test is positive and the isolate is clearly beta-hemolytic.
- B. If the test is positive and the colony is nonhemolytic and from a urine specimen or a normally sterile site, confirm with tube coagulase. In a urine specimen, this may be *S. saprophyticus*. In a blood culture, it may be *S. lugdunensis* or another coagulase-negative staphylococcus.
- C. Report negative tests from catalase-positive, gram-positive cocci in clusters as "coagulase-negative staphylococci," but confirm with a tube test if the isolate is from a normally sterile body site, especially if it is methicillin resistant.

VIII. LIMITATIONS

- A. The advantage of agglutination assays is that they are very sensitive and rapid in separating *S. aureus* from coagulase-negative staphylococci. False-positive reactions do occur with strains of *Staphylococcus capitis*, *S. saprophyticus*, and *Staphylococcus warneri*, since these species possess protein A (2). *S. lugdunensis* and *S. schleiferi* can also give a positive result, since they possess clumping factor. Positive tests must be confirmed with the tube test for nonhemolytic strains from urine specimens or for all isolates from sites where identification to the species level is critical for clinical reasons (e.g., blood cultures).
- B. Although *S. lugdunensis* and *S. schleiferi* produce clumping factor, the reaction is less efficient in the latex test and cannot be relied upon to detect these species. Use other methods, such as pyrrolidonyl- β -naphthylamide (PYR), to detect these strains in invasive sites.
- C. A false-negative test, especially for MRSA with capsular antigens, can result. For isolates from significant sites where MRSA is important, e.g., blood and joint isolates, performing both the agglutination and the tube coagulase test will detect all strains of *S. aureus*.
- D. *Staphylococcus intermedius* and *Staphylococcus hyicus* may agglutinate the latex reagent, but it is clinically not important to separate these animal pathogens from *S. aureus*, because they are rarely found in humans (less than 0.1% in one study [8]) and they are considered as pathogenic as *S. aureus*.
- E. Do not perform testing from growth on mannitol salt agar.

3.17.14

Coagulase Test—Rabbit Plasma Method

I. PRINCIPLE

Staphylococcus aureus, the most pathogenic of the staphylococci, is separated from other species by the presence of coagulase. Coagulase is a thermostable thrombin-like substance that activates fibrinogen to form fibrin, resulting in a fibrin clot (2, 4). This is demonstrated in the test tube by the formation of a clot when plasma is inoculated with the staphylococcus. The substance is known as free coagulase, since it is liberated by the cell. In most, but not all, *S. aureus* organisms, fibrinogen binding cell surface receptor is also present in cell wall, called “bound coagulase” or “clumping factor.” Clumping factor is demonstrated by the ability of the

organism to act directly on the fibrinogen in the plasma to clump it in a slide assay. The test for clumping factor is rapid but requires several colonies, and as stated above, the factor is not present in all *S. aureus* organisms. In addition, clumping factor can be masked by cell surface capsular polysaccharides and can be present in other species, namely, *Staphylococcus lugdunensis* and *Staphylococcus schleiferi* (7). Negative slide tests must be followed with a confirmatory tube test.

Coagulase is also present in highly pathogenic species of staphylococci from animals: *Staphylococcus intermedius* from dogs, *Staphylococcus delphini* from dol-

phins, *Staphylococcus lutrae* from otters, and *Staphylococcus hyicus* from pigs. It is generally not cost-effective to separate these species in most human specimens, because infections with them either are very rare or present with morbidity similar to that of *S. aureus* (5).

In addition, the coagulase clot can be destroyed by *S. aureus* fibrinolysin or staphylokinase, a plasmid-carried enzyme which is more active at 35°C than at 25°C (2, 6, 8). Despite these caveats, algorithms can easily be implemented in the laboratory to rapidly identify *S. aureus* with a high degree of accuracy.

II. MICROORGANISMS TESTED

- A. Colonies of gram-positive cocci in clusters which are catalase positive, as part of the identification of *S. aureus*
- B. Positive blood cultures containing gram-positive cocci in clusters for rapid detection of *S. aureus*

III. REAGENTS AND SUPPLIES

Include QC information on reagent container and in QC records.

A. Plasma

■ **NOTE:** Do not use human plasma for the test, as it is less sensitive and potentially infectious with human pathogenic viruses (6, 8).

1. Dehydrated and reconstituted rabbit plasma in EDTA
 - a. Rehydrate according to manufacturer’s instructions.
 - b. Dispense 0.5 ml into sterile 12-by 75-mm tubes.
 - c. Reagent expires after 1 month if stored at –20°C or 5 days if stored at 2 to 8°C.

2. Frozen rabbit plasma with EDTA (Coagulase Cryovial, Hardy Diagnostics)

3. 5% CaCl₂ (optional)

B. Supplies

1. Loops or sterile sticks
2. Glass or plastic tubes
3. Glass slides or black coated cards (supplied by vendors for serologic agglutination tests)

IV. QUALITY CONTROL

- A. Do not use plasma that has not been stored refrigerated or frozen or that appears turbid.
- B. Perform QC of coagulase plasma on new lots prior to putting them into use.
- C. Organisms
 - 1. *S. aureus* ATCC 25923—coagulase positive
 - 2. *Staphylococcus epidermidis* ATCC 12228 or ATCC 14990—coagulase negative

V. PROCEDURE**A. Slide test**

☑ **NOTE:** To avoid misidentifications, only perform this test on classic-looking white to yellow, creamy, opaque, *hemolytic* colonies of gram-positive cocci in clusters that are catalase positive. Hemolysis should only be observed on fresh BAP at ≤ 18 h.

1. Add 10 μ l of deionized water to slide or black card.
2. Emulsify several colonies into the water to obtain a smooth milk-colored suspension.

☑ **NOTE:** If clumps occur and the organism does not suspend in the water, the slide test cannot be performed. The organism is inherently sticky and is said to autoagglutinate. Perform the tube test for free coagulase instead.

3. Add 1 to 3 μ l of rabbit plasma and observe for clumping immediately, not to exceed 10 s.
4. Dispose of the card in an infectious-waste container or the slide in a sharps container.

B. Tube test

1. Bring tube of plasma to 25°C.
2. Inoculate with one colony of staphylococcus growing on *noninhibitory medium* or 2 drops of blood from a positive blood culture.
3. Incubate at 35°C without CO₂ for *up to* 4 h and observe for clot formation hourly. Do not agitate the tube during observations; rather, gently tilt to observe the clot.
4. Incubate for an additional 20 h at 25°C for late clot formation (2).

☑ **NOTE:** Do not leave the test at 35°C for more than 4 h, since *S. aureus* fibrinolysin can lyse the clot. If 4 h of incubation at 35°C is inconvenient for staffing, the test is most sensitive when incubated at 25°C for the entire time, but the clot may take longer to form (1). Alternatively, if the tube is left at 35°C, add a drop or two of 5% CaCl₂ at 24 h. If a clot forms, the isolate is coagulase negative; if a clot does not form, fibrinolysin has lysed a previously formed clot and this result confirms the isolate as coagulase positive (H. D. Isenberg, unpublished data).

VI. INTERPRETATION**A. Slide test**

1. A positive test is the demonstration of agglutination of the bacterial cells after the plasma is added.
2. A negative test is demonstrated by the lack of agglutination.

B. Tube test

1. A positive test meets one of the following criteria.
 - a. Complete clot formation or any degree of clot formation before 24 h
 - b. No clot formation after addition of 1 or 2 drops of 5% CaCl₂ to a tube without a clot at 24 h

VI. INTERPRETATION*(continued)*

2. A negative test meets one of the following criteria.
 - a. A lack of clot formation at 24 h at 25°C
 - b. No clot after 24 h at 35°C, but after addition of 1 or 2 drops of 5% CaCl₂ to the tube, a clot forms.
 - ☑ A flocculent or fibrous precipitate is not a true clot and is recorded as a negative test.

VII. REPORTING RESULTS

- A. Report as *Staphylococcus aureus* if the tube test is positive and the organism is catalase positive and a gram-positive coccus in clusters.
- B. For gram-positive cocci in clusters from a positive blood culture that are coagulase positive, report as “Probable *Staphylococcus aureus*; confirmation to follow” until the colony can be observed and the catalase test is performed.
- C. For a negative tube test from catalase-positive, gram-positive cocci in clusters that have creamy white colonies, report as “coagulase-negative staphylococci.”
- D. A positive slide test is reported as *S. aureus*; however, the test should be confirmed with a tube test from nonhemolytic or only slightly hemolytic colonies from sterile sites, such as blood, to separate *S. aureus* from *S. lugdunensis* and *S. schleiferi*.
- E. A negative slide test is not valid and should be followed with a tube test for confirmation.

VIII. LIMITATIONS

- A. Methicillin-resistant *S. aureus* can be deficient in bound coagulase, which results in a negative slide test (3).
- B. *S. intermedius* and *S. hyicus* may be positive in the tube test; these species are generally found only in dogs and pigs, respectively, but are as infectious as *S. aureus* when they infect humans. Both form nonhemolytic colonies on fresh (≤ 18 -h) plates and are Voges-Proskauer negative, which separates them from *S. aureus*. *S. intermedius* is also pyrrolidonyl- β -naphthylamide (PYR) positive (Table 3.18.1–1).
- C. *S. lugdunensis* and *S. schleiferi* produce slide coagulase, but the reaction is more efficient if human plasma is used rather than rabbit plasma. They can be separated from *S. aureus* by their strongly positive PYR reaction and from *S. intermedius* by a negative tube coagulase test (*see* Table 3.18.1–1).
- D. Do not use citrated blood, as false-positive results can occur.
- E. Coagulase testing cannot be performed from growth on mannitol salt agar.

3.17.15

Decarboxylase-Dihydrolase Tests

I. PRINCIPLE

Arginine, lysine, and ornithine decarboxylase media are used to detect an organism's ability to decarboxylate or hydrolyze an amino acid, forming an amine that produces an alkaline pH. The basal medium is usually Møller's formula (7) and contains meat peptones and beef extract, which supply nitrogenous nutrients to support bacterial growth. Glucose is the fermentable carbohydrate. The pH indicators are bromcresol purple and cresol red. Pyridoxal is an enzyme cofactor which enhances decarboxylase activity. Arginine, lysine, and ornithine are amino acids that

are singly added to basal medium to detect the production of enzymes which decarboxylate or hydrolyze these substrates. When an organism in the medium ferments glucose, acids are produced which lower the pH, resulting in a color change from purple to yellow. If decarboxylation or hydrolysis of the amino acid occurs in response to the acid pH, alkaline end products (amines) are formed which result in the medium reverting to its original color (purple). When the organism does not ferment glucose, the medium does not turn yellow; the test can still be performed, but

it is important to include a control without amino acids for comparison.

Decarboxylation of lysine yields cadaverine, decarboxylation of ornithine yields putrescine, and decarboxylation of arginine yields agmatine, which is hydrolyzed by a dihydrolase to form putrescine. In another reaction arginine dehydrolase converts arginine to citrulline, which is converted to ornithine and then to putrescine. Since decarboxylation is an anaerobic reaction, the contents of each tube must be sealed with oil or paraffin.

II. MICROORGANISMS TESTED

- A. Enteric gram-negative rods and *Vibrio*, *Plesiomonas*, and *Aeromonas* for identification to the species level
- B. Probable *Stenotrophomonas* and *Burkholderia* (lysine and arginine)
- C. Fluorescent *Pseudomonas* (arginine)
- D. Coagulase-negative staphylococci (ornithine)
- E. Viridans group streptococci (arginine)
- F. Miscellaneous non-glucose-fermenting, gram-negative rods (arginine)
- G. Spreading indole-negative *Proteus* (ornithine)

III. MEDIA, REAGENTS, AND SUPPLIES

- A. **Media**
 1. Peptone, beef extract, glucose, pyridoxal with bromcresol purple and cresol red indicators, and amino acids as listed below
 - a. Møller's decarboxylase base (no amino acids)
 - b. Møller's arginine decarboxylase (1% arginine)
 - c. Møller's lysine decarboxylase (1% lysine)
 - d. Møller's ornithine decarboxylase (1% ornithine)
 2. Motility-indole-ornithine medium (MIO) (*see* motility tests [procedure 3.17.31] for inoculation method)
 3. Tablets (Key Scientific Products) Refer to <http://www.keyscientific.com> for procedure.

III. MEDIA, REAGENTS, AND SUPPLIES (continued)

4. Lysine iron agar
Used as a screen for stool pathogens to detect lysine decarboxylase-positive (purple color in butt) *Salmonella*; however, the medium is also helpful to distinguish *Salmonella* from *Proteus* and *Providencia*, which deaminate lysine and produce a red slant.

B. Reagents

1. Mineral oil
2. Vaspar, liquid paraffin, or petroleum jelly, maintained at 56°C in liquid form

C. Other supplies

1. Sterile sticks or inoculating loops
2. Incubator at 35°C

IV. QUALITY CONTROL

- A. Examine media for lack of turbidity and purple color. Discard if not purple.
- B. Test new lot or shipment of medium with a positive and negative control prior to putting it into use. Use the staphylococcus controls for validating use with staphylococci.
- C. Organisms

Test organism	Control tube	Result ^a		
		Arginine	Lysine	Ornithine
<i>Klebsiella pneumoniae</i> ATCC 13883	Yellow	–	+	–
<i>Enterobacter cloacae</i> ATCC 23355	Yellow	+	–	+
<i>Staphylococcus aureus</i> ATCC 25923	Yellow	NA	NA	–
<i>Staphylococcus lugdunensis</i> ATCC 700328	Yellow	NA	NA	+

^a –, yellow; +, purple; NA, not applicable.

V. PROCEDURE

- A. Inoculate each broth being tested with one or two colonies from an 18- to 24-h culture.
 1. For non-glucose-fermenting, gram-negative rods
 - a. Include the control tube
 - b. Inoculate the tubes *heavily* (\geq no. 8 McFarland turbidity standard [7]; see Appendix 3.16–1).
 2. For *Enterobacteriaceae*, the control tube is not needed, since all strains ferment glucose.
 3. For gram-positive cocci, the control tube is usually not needed.
- B. Overlay the inoculated tubes with approximately 1 ml of mineral oil or a 4-mm plug of melted petroleum jelly, Vaspar, or paraffin, being careful to cover broth layer entirely without introducing air.
- C. Tighten the caps on the tubes.
- D. Incubate aerobically at 35°C for at least 18 h and up to 7 days, and observe daily for purple color.

☑ **NOTE:** MIO is stabbed with a wire; oil overlay is not necessary if reactions are read only at 18 h. Incubation and color interpretations are the same as for broth media. Refer to <http://www.keyscientific.com> for procedure for tablets.

VI. INTERPRETATION

- A. A positive test is turbid purple to faded-out yellow-purple color (alkaline).
- B. A negative test is bright clear yellow color (acid) or no change (nonfermenting rods).
- C. Control tube must remain its original color or turn yellow. Turbidity must be seen. An alkaline or purple color in the control invalidates the test. Compare questionable results to the control tube.

VII. REPORTING RESULTS

- A. *Staphylococcus lugdunensis* is the only staphylococcus that is pyrrolidonyl- β -naphthylamide (PYR) and ornithine positive (5).
- B. *Leuconostoc* is arginine negative, and *Weissella confusa* is arginine positive. Both are PYR-negative, vancomycin-resistant, gram-positive cocci with rod-like forms.
- C. Arginine is useful in the identification of *Enterococcus* to the species level; *Enterococcus avium* is arginine negative, but *Enterococcus faecalis* and *Enterococcus faecium* are arginine positive (2).
- D. *Stenotrophomonas maltophilia* and *Burkholderia cepacia* are among the few non-glucose-fermenting, gram-negative rods that are lysine positive.
- E. Among the polymyxin B-resistant nonfermenters, *Burkholderia mallei* and *Burkholderia pseudomallei* are arginine positive.
- F. *Streptococcus anginosus* and *Streptococcus sanguis* are the viridans group streptococci that are arginine positive (1).
- G. Reactions for *Enterobacteriaceae* are found in references 3 and 4.
- H. *Plesiomonas* is positive for lysine, arginine, and ornithine, which separates it from *Vibrio* and *Aeromonas*, whose results are variable with each species but are not positive for all three decarboxylases (see Table 3.18.2–8).
- I. Other reactions for the non-glucose-fermenting, gram-negative rods are found in the tables in Weyant et al. (8) and in the tables in procedure 3.18.2.

VIII. LIMITATIONS

- A. Mineral oil or a similar barrier to gas release must be applied to the surface of each inoculated broth medium. Oil overlay decreases the possibility of an alkaline shift occurring in the medium due to oxidation.
- B. Test interpretation should *not* be made prior to 18 to 24 h of incubation. Earlier interpretation may lead to erroneous results. Glucose fermentation occurs within the first 10 to 12 h of incubation. Fermentation produces an acidic environment which results in a yellow color development. The production of decarboxylase enzymes will not be induced until the acidic state has been established.
- C. Non-glucose-fermenting microorganisms may display weak decarboxylase activity, thereby resulting in an insufficient production of amines necessary to convert the pH indicator system. Some nonfermenters, however, will produce sufficient amines to result in a deeper purple color than in an uninoculated tube of basal medium.
- D. A gray color may indicate reduction of the indicator, rather than production of alkaline end products. To aid in reading the reaction, add additional bromcresol purple.
- E. If two layers of different colors appear, shake the tube gently before interpreting the reaction (6).
- F. Nonfermenting bacteria that are arginine positive must be lysine and ornithine negative (6).

3.17.16

DNase Test-Rapid Thermo-nuclease Test

I. PRINCIPLE

DNases are enzymes that hydrolyze DNA and release free nucleotides and phosphate. The DNases produced by bacteria are extracellular endonucleases that cleave DNA, yielding a high concentration of oligonucleotides. There are several media used to detect these enzymes, using no indicators (2) or various indicators (toluidine blue [5, 7] or methyl green [MG] [6]) to detect the hydrolysis of DNA. The first medium was developed by Jeffries et al.

(2), with no indicator. The hydrolysis of DNA was observed by a clearing of the agar after addition of HCl (the oligonucleotides dissolve in acid but DNA salts are insoluble). When MG indicator is added, DNA combines with the MG to produce a green color. When the DNA is hydrolyzed, the complex is released and the free MG is colorless at pH 7.5 (4). When toluidine blue O (TBO) is added, a complex is formed with the DNA, which changes

structure when DNA is hydrolyzed, resulting in a bright pink color (4). The media with dyes can inhibit some microbial growth. Using a heavy inoculum prevents this problem and makes the test more rapid, as it detects preformed enzymes. *Staphylococcus aureus* possesses a heat-stable enzyme, a thermo-nuclease. To detect this enzyme, first the organisms are destroyed by heat and then the free DNase reacts with the medium.

II. MICROORGANISMS TESTED

- A. Gram-negative rods that are presumptive for *Stenotrophomonas maltophilia* (positive) and are colistin or polymyxin B resistant to separate from *Burkholderia cepacia* (negative). MG agar is preferred.
- B. Gram-negative diplococci that are presumptive *Moraxella catarrhalis* (positive). TBO agar is preferred.
- C. Gram-positive cocci that are presumptive for *S. aureus* (positive) and are difficult to separate from other closely related species and have a questionable coagulase reaction. Use only TBO for staphylococcus heat-stable testing, since it is more sensitive in detection of preformed enzyme. Some staphylococci do not grow on media containing dyes.
- D. *Enterobacteriaceae* to identify *Serratia* spp. (positive) and separate them from *Klebsiella* and *Enterobacter* (1, 5). *Serratia fonticola* is the only *Serratia* sp. that is negative for DNase.
- E. Oxidase-positive, indole-positive, gram-negative rods to separate *Aeromonas* spp. and *Vibrio cholerae* (positive) from *Plesiomonas shigelloides* (negative) (3)

III. MEDIA, REAGENTS, AND SUPPLIES

A. Media

1. TBO agar
Medium is royal blue and provides better delineation of DNase activity (4).
2. MG agar
Medium is green and supports the growth of both gram-positive and gram-negative bacteria.
3. BHI for staphylococci

B. Supplies

1. Sterile sticks, needles or inoculating loops
2. Pasteur pipettes or drinking straws
3. Boiling heat block
4. Incubators at 35 and 30°C

IV. QUALITY CONTROL

- A. Inspect agar for freezing, contamination, cracks, and dehydration prior to storage and before use. Discard plates that are not blue (TBO) or green (MG).
- B. Perform QC on each new lot or shipment of media prior to putting it into use. If plates are reused after incubation, add a positive and negative control to the plate each time the test is performed.
- C. Organisms
 1. Thermonuclease test
 - a. Positive control: *S. aureus* ATCC 25923—change to pink color (TBO)
 - b. Negative control: *Staphylococcus epidermidis* ATCC 12228—no color change
 2. DNase test (choose one or more positive controls)
 - a. Positive controls
 - (1) *M. catarrhalis* ATCC 25240—change to pink color (TBO) or colorless (MG)
 - (2) *Serratia marcescens* ATCC 13880—change to pink color (TBO) or colorless (MG)
 - (3) *S. aureus* ATCC 25923—change to pink color (TBO) or colorless (MG)
 - b. Negative control: *Escherichia coli* ATCC 25922—no color change

V. PROCEDURES

- A. **DNase test method**
 1. After touching several colonies from an 18-h culture, inoculate a segment of the agar surface with a very *visible, heaping* amount of organism equivalent to an entire colony. Several colonies can be placed on a single plate. Use either circular (1/4-in diameter) or line (1/2-in length) method for inoculation. Do not streak the entire plate, as it will be difficult to see the reaction.
 2. Incubate without added CO₂ for 24 h and up to 72 h at the following temperatures.
 - a. 35°C for staphylococci or *M. catarrhalis* (TBO agar is more sensitive and rapid, since organism does not grow well on media with dyes)
 - b. 25°C for enteric gram-negative rods and *Vibrionaceae*
 - c. 25 or 30°C for non-glucose-fermenting, gram-negative rods (MG agar is preferred)
 - ☑ **NOTE:** DNases are generally most active at lower temperatures, and all testing may be performed at room temperature (e.g., 22 to 25°C) if the organism will grow at a lower temperature (4).
 3. Examine for color change. Incubate a full 72 h before calling result negative.
- B. **Thermonuclease method**
 1. After touching several well-isolated staphylococcal colonies with a sterile needle, inoculate BHI.
 2. Incubate at 35°C for 18 h. Growth from a positive blood culture can also be used.
 3. Place broth in boiling heat block for 15 min.
 4. Cool to room temperature.
 5. Punch a hole in the TBO agar with the large end of a Pasteur glass pipette or drinking straw and remove the agar plug.
 6. Fill the well with 2 drops of cooled broth culture.
 7. Incubate at 35°C for 3 h, and observe for color change.

VI. INTERPRETATION**A. MG agar**

1. Hold plates against a white background in indirect light.
2. Positive test: the development of a clear halo around the colony or the well in the agar
3. Negative test: no clear zone in the medium or around the well in the agar. Agar remains green.

B. TBO agar

1. Use transmitted light to observe changes in color.
2. Positive test: the development of a pink or red halo around the colony or the well in the agar
3. Negative test: no change in the royal blue color of the medium

VII. REPORTING RESULTS

- A. Gram-negative rods that are non-glucose-fermenting and that are lysine and DNase positive but negative or weakly positive for oxidase are *S. maltophilia*.
- B. Gram-negative diplococci that are oxidase positive and DNase positive are *M. catarrhalis*.
- C. Gram-positive cocci in clusters that have a thermostable DNase are usually *S. aureus*, but some other staphylococci can give a positive test. *S. schleiferi* is DNase and pyrrolidonyl- β -naphthylamide (PYR) positive. See Table 3.18.1–1 for other tests to separate.
- D. *Serratia* spp. produce a DNase, which separates nonpigmented strains from most other *Enterobacteriaceae* (1, 5).
- E. Oxidase-positive, indole-positive, gram-negative rods that grow on MAC and are DNase negative are likely to be *P. shigelloides*, rather than the closely related *Aeromonas* and *Vibrio* spp., which are generally DNase positive.

VIII. LIMITATIONS

- A. An inoculum that is too broad may result in complete decolorization of the media, due to the reduction of the dye. If this occurs, the test must be repeated.
- B. MG medium is better for organisms, such as gram-negative rods, that first grow on the medium and then demonstrate a positive test.
- C. For *Moraxella* and gram-positive cocci with TBO testing, a low inoculum can result in a false-negative test, since these organisms may not grow well on the medium.

3.17.17

Fluorescent-Pigment Agars for *Pseudomonas* Identification

I. PRINCIPLE

The kind of peptone in the basal medium markedly affects the production of pigment by bacteria (1). Two pigment-enhancing media were developed by King et al. (1). The pyocyanin or pyorubrin pigment of *Pseudomonas aeruginosa* is enhanced on P agar or "Tech" agar. The fluorescein or pyoverdine pigment of the

fluorescent pseudomonads is enhanced on F agar or "Flo" agar. When the P agar is incubated at 42°C, the ability of *P. aeruginosa*, but not *Pseudomonas fluorescens* or *Pseudomonas putida*, to grow at that temperature is also determined. The peptone choices in F agar were found to enhance the production of fluorescein and in-

hibit the production of pyocyanin. *Pseudomonas* P agar contains a peptone containing less than 0.1% phosphorus to minimize the inhibitory effect on pyocyanin production. The incorporation of magnesium chloride and potassium sulfate stimulates the production of pyocyanin and pyorubrin.

II. MICROORGANISMS TESTED

Isolated colonies of oxidase-positive, indole-negative, non-glucose-fermentative, gram-negative rods growing on MAC and suggestive of *Pseudomonas* spp.

III. MEDIA, REAGENTS, AND SUPPLIES

A. Media (3)

1. P agar slants (P agar [Remel, Inc.]

a. P agar

Bacto Peptone 20.0 g
magnesium chloride 1.4 g
potassium sulfate 10.0 g
agar 15 g
glycerol 10.0 ml
water, distilled 990 ml
pH 6.8 to 7.0

b. Cetrimide agar (procedure 3.17.11) contains all the essential ingredients to enhance both pyocyanin and fluorescein production, with 3% cetrimide to inhibit organisms other than *P. aeruginosa* (Pseudoseal [BD Diagnostic Systems, Hardy Diagnostics])

2. F agar slants (F agar [Remel, Inc.]

a. F agar

Proteose Peptone
no. 3 20.0 g
magnesium sulfate
(hydrated) 1.5 g
dipotassium phosphate .. 1.5 g
agar 15 g
glycerol 10.0 ml
water, distilled 990 ml
pH 6.8 to 7.0

b. Fluorescence-denitrification (FN), fluorescence indole denitrification (FIN), and fluorescence lactose denitrification (FLN) media are similar to F agar but have added nitrate, tryptophan, and lactose, respectively, with a pH indicator to allow for additional testing (FIN and FLN; Hardy Diagnostics).

B. Supplies

1. Sterile inoculating loops or sticks
2. Wood's or long-wave (360 nm) UV light or short-wavelength (254 nm) UV light (preferred)
3. 35°C incubator or heat block
4. 42°C incubator or heat block

IV. QUALITY CONTROL

- A. Perform QC on each new lot or shipment of media prior to putting it into use.
- B. Inspect agar for freezing, contamination, cracks, dehydration, and bubbles prior to storage and before use.
- C. Organisms
 - 1. P agar
 - a. *P. aeruginosa* ATCC 27853—positive (blue-green pigment)
 - b. *P. fluorescens* ATCC 13525—negative (no blue-green pigment)
 - 2. F agar
 - a. *P. fluorescens* ATCC 13525—positive (fluorescent pigment)
 - b. *Escherichia coli* ATCC 25922—negative (no fluorescent pigment)

V. PROCEDURE

- A. Streak each slant back and forth with inoculum picked from the center of a well-isolated colony. Also stab the deep of FN, FIN, and FLN media.
- B. Place cap loosely on tube.
- C. Incubate aerobically at 35°C for up to 7 days; alternatively, when using two agar media, incubate P agar at 42°C for up to 7 days.
- D. Observe for growth and color visually and, if negative, under UV light for fluorescent pigment.
- E. If negative at 24 h, incubate additional days in the dark at 25°C.

VI. INTERPRETATION

- A. *Pseudomonas* F agar, cetrimide, and FN, FIN, and FLN agars
 - 1. Positive: bright yellow-green color diffusing into the agar; fluorescent zone surrounding growth
 - 2. Negative: no yellow-green pigment (or no growth on cetrimide agar)
- B. *Pseudomonas* P agar and cetrimide
 - 1. Positive: a blue-green color indicating pyocyanin production
 - 2. Negative: no pigment production (or no growth on cetrimide agar)
- C. Pyorubin production is indicated by a pink, red, or red-brown color on any medium.
- D. FN, FLN, and FIN agar for nitrate reduction (*see* nitrate test, procedure 3.17.35, for QC)
 - 1. Positive: slits in medium indicative of gas bubbles
 - 2. Negative: no slits in medium
- E. FLN for lactose acidification (*see* procedure 14.2 for QC of medium for acid from lactose)
 - 1. Positive: yellow color change of the slant as a result of lactose acidification
 - 2. Negative: slant remains red.

VII. REPORTING RESULTS

- A. *P. aeruginosa* is definitively identified if it is oxidase positive and does one of the following.
 - 1. Produces a blue-green pigment
 - 2. Produces a red-brown pigment
 - 3. Produces a yellow-green pigment or fluorescent pigment and grows at 42°C
- ☐ **NOTE:** *P. aeruginosa* is nitrate positive and lactose negative.
- B. *P. fluorescens* or *P. putida* is identified if there is a yellow-green pigment or fluorescent pigment and no growth at 42°C (3). See lecithinase or gelatin procedure (procedure 3.17.27 or 3.17.18, respectively) to separate.
- C. *P. putida* is nitrate negative, and *P. fluorescens* is infrequently positive.

VIII. LIMITATIONS

- A. If *P. aeruginosa* has a characteristic odor and is oxidase positive and indole negative, no further testing is indicated, except from cystic fibrosis (CF) patients (2).
- B. Not all *P. aeruginosa* isolates produce pigments, especially those from CF patients. If the isolate is from a CF patient and lacks pigments, it is identified as *P. aeruginosa* if it meets all of the following criteria.
 - 1. Is oxidase positive and indole negative
 - 2. Has characteristic mucoid colony form and has the characteristic odor
 - 3. Is polymyxin B susceptible
- C. Mueller-Hinton agar when being used for disk susceptibility testing may substitute for F agar.
- D. Not all fluorescent pseudomonads grow on cetrimide or produce pigments.

REFERENCES

- 1. King, E. O., M. K. Ward, and D. E. Raney. 1954. Two simple media for the demonstration of pyocyanin and fluorescein. *J. Lab. Clin. Med.* **44**:301–307.
- 2. NCCLS. 2001. *Abbreviated Identification of Bacteria and Yeast*. Proposed guideline M35-P. NCCLS, Wayne, Pa.

IV. QUALITY CONTROL

- A. Inspect tubes for contamination, dehydration, and lack of liquefaction at refrigeration temperatures before storage and before use.
- B. Inspect X-ray film for loss of gelatin coating.
- C. Perform QC on each new lot or shipment of media prior to putting it into use. Use an uninoculated control with each use.
- D. Organisms
 - 1. *Pseudomonas aeruginosa* ATCC 10145—liquefaction (positive)
 - 2. *Escherichia coli* ATCC 25922—no liquefaction (negative)

V. PROCEDURE

- A. **Incubation temperatures**
 - 1. 22°C for *Enterobacteriaceae* and fluorescent *Pseudomonas*
 - 2. 30°C for nonfermenting, gram-negative rods
 - 3. 35°C for other organisms and for X-ray and Kohn methods
- B. **Tube method**
 - 1. The medium should be solidified at room temperature. After touching several well-isolated colonies with a sterile needle, stab directly down the center of the tube to approximately 10 mm from the bottom. Repeat to inoculate heavily.
 - 2. Incubate the test and an uninoculated control tube for 48 h.
 - 3. Gently remove the inoculated and uninoculated tubes from the incubator and refrigerate for at least 30 min or until the control tube solidifies. (Gelatin is a liquid at 28°C or higher.)
 - a. Do not shake or invert the tubes prior to refrigeration.
 - b. Gently invert to detect liquefaction by the test organism after 30 min of refrigeration.
 - 4. Reincubate a negative test for up to 2 weeks if indicated by the nature of the organism, and examine at regular intervals.
- C. **X-ray method**
 - 1. After touching several colonies from an 18-h culture, inoculate 1 ml of sterile distilled water equivalent to a no. 2 McFarland standard.
 - 2. Place a gelatin strip or X-ray strip in the water and cap tube. Do not press the strip to the side of the tube such that it is not in contact with the water.
 - 3. Prepare a tube without inoculum as a control.
 - 4. Incubate for up to 48 h at 35°C.
 - 5. Examine at regular intervals for clearing of the strip.
- D. **Kohn method**
 - 1. Inoculate gelatin-charcoal tube heavily, equivalent to a no. 2 McFarland standard, with growth of microorganism from an 18-h culture.
 - 2. Set up an uninoculated control tube.
 - 3. Incubate for 24 h or longer at 35°C.
 - 4. Shake and observe for particles dispersed throughout medium.

VI. INTERPRETATION

- A. **Tube method**
 - 1. Positive test: at the end of the refrigeration period, the control tube will be resolidified and the test tube will remain liquid at least to the depth of the stab. (Some organisms only partially liquefy gelatin or liquefy just at the surface of the tube.)
 - 2. Negative test: at the end of the refrigeration period, the control tube and the test tube will be resolidified, even at the top of the tube.

VI. INTERPRETATION*(continued)***B. X-ray film method**

1. Positive test: green gelatin layer is removed on immersed portion of film, exposing transparent, bluish film.
2. Negative test: green gelatin layer remains undisturbed.

C. Kohn gelatin disks

1. Positive test: a visible black cloud observed after tube is shaken.
2. Negative test: no free charcoal particles in medium and tube remains as the uninoculated tube after shaking.

VII. REPORTING RESULTS

- A. *Proteus* spp. are gelatinase positive.
- B. *P. fluorescens* is gelatinase positive, but *P. putida* is gelatinase negative.
- C. *Serratia* spp. are usually gelatinase positive.

VIII. LIMITATIONS

- A. Gelatinase usually acts at the surface of the tube medium. Shaking the tube while it is warm may result in a false-negative interpretation.
- B. Gelatin may vary in its gelling ability; therefore, incubate an uninoculated control with the test. The control must be refrigerated along with the test, prior to reading.
- C. For the X-ray film method, the strips must be immersed in the liquid and not cling to the sides of the tube without immersion. Only part of the film must be immersed, so that a difference in reaction can be visualized.
- D. Do not use photographic film.
- E. False-positive results may occur with the X-ray film method in some media or saline on prolonged incubation, i.e., greater than 4 h. This can be detected in the uninoculated control tube.

3.17.19

Glucan and Polysaccharide Production

I. PRINCIPLE

Streptococci can produce glucans (extracellular polysaccharides) on agar containing sucrose. The two types of glucans, dextrans and levans, yield different consistencies. Characteristic colonies and type

of glucans produced (e.g., slime, adherence) can be used to identify streptococci to the species level.

Some saprophytic *Neisseria* spp. can produce an amylosucrase enzyme that

synthesizes an iodine-reacting polysaccharide from sucrose. The polysaccharide is detected by the production of a brown to black color when iodine is added to the agar medium.

II. MICROORGANISMS TESTED

- A. Gram-positive cocci that are catalase negative
 - 1. To separate *Streptococcus bovis*, which produces copious amounts of watery slime, from other viridans group streptococci that are Voges-Proskauer positive and esculin positive
 - 2. To separate *Streptococcus mutans*, which is glucan positive, from other streptococci
- B. To detect the production of iodine-reacting polysaccharide from sucrose to separate *Neisseria meningitidis*, *Neisseria gonorrhoeae*, and *Neisseria lactamica* from saprophytic strains of *Neisseria* (4)

III. MEDIUM, REAGENT, AND SUPPLIES

- A. **Medium**
Heart infusion agar with 5% sucrose (2) (Remel, Inc.)
- B. **Reagent**
0.2% Iodine with 0.4% potassium iodide freshly diluted 1:5 with distilled water

- C. **Supplies**
 - 1. Sterile sticks or inoculating loops
 - 2. Incubators at 35°C

IV. QUALITY CONTROL

- A. Inspect agar for freezing, contamination, cracks, and dehydration prior to storage and before use.
- B. Perform QC on new lots of media prior to putting them into use.
- C. Organisms
 - 1. *S. bovis* ATCC 33317—copious amounts of glucans (positive)
 - 2. *Enterococcus faecalis* ATCC 25922—no glucans produced (negative)
 - 3. *Neisseria polysaccharea* ATCC 43768—polysaccharides produced (positive)
 - 4. *N. gonorrhoeae* ATCC 43069—no polysaccharide production (negative)

V. PROCEDURE

- A. After touching several colonies from an 18-h culture, inoculate plate, streaking in quadrants for isolation.
- B. Incubate without added CO₂ for 24 to 48 h. The plate may be incubated with the lid up for streptococci, since glucans can fall onto the lid in the inverted position.
- C. Observe colonies for glucan production.
- D. For *Neisseria*, apply 2 drops of iodine solution and observe for dark reddish brown to black color that fades quickly. The color returns with the addition of more iodine.

VI. INTERPRETATION

- A. Positive glucan test: formation of large mucoid, runny material external to the colonies (levans). In some cases, large opaque gumdrop-like refractile colonies that are adherent are present (2). Colonies may be white-dry-adherent and form a depression in the agar.
- B. Negative glucan test: no mucoid or runny colonies and no adherent colonies
- C. Positive amylosucrase test: brown to black color with addition of iodine
- D. Negative amylosucrase test: no brown color with addition of iodine

VII. REPORTING RESULTS

- A. *S. bovis* produces great amounts of watery glucans (levans), promoting very large colonies, which run together and can drip into the cover if the plate is inverted (1).
- B. *Streptococcus salivarius* produces colonies that are opaque, gummy, and non-adherent (levans). They can be similar to those of *S. bovis* but are more gummy (1).
- C. *Streptococcus sanguis* and *Streptococcus mitis* may produce glucans, which are hard and adherent, with the texture and consistency of polyethylene. The agar can be depressed. Less than half of the strains of these species produce glucans (1).
- D. *S. mutans* produces puddles of glucans that even produce a droplet on the top of the colony (1).
- E. A positive test for amylosucrase indicates that an oxidase-positive, gram-negative diplococcus is not *N. gonorrhoeae* or *N. meningitidis*.

VIII. LIMITATIONS

- A. The identification of *S. bovis* is difficult, and the organism can be confused with *S. mutans* and *S. salivarius* (3). Glucan agar is helpful in the identification.
- B. The API Rapid Strep and RapID 32 (bioMérieux, Inc.) do an excellent job of separating *S. bovis* from other streptococci.

3.17.20

Gram Reaction Enzymatic Test

I. PRINCIPLE

In the Gram stain, some gram-positive rods appear gram variable or gram negative, especially members of the genera *Bacillus*, *Erysipelothrix*, *Lactobacillus*, and *Listeria*, which may result in misclassification. Alternatively, some organisms that are gram negative may, at times, appear to be gram positive, since they have been known to resist the alcohol-acetone decolorization step in the Gram stain. Among these problem organisms are members of the *Neisseriaceae* family, which include

Moraxella catarrhalis, *Neisseria*, *Kingella*, and *Acinetobacter* spp. Erroneous Gram stain reactions represent one of the most frequent causes of misidentification, which can result in a delay of appropriate therapy.

In 1976, Cerny reported using L-alanine-4-nitroanilide to detect the presence of cell wall aminopeptidase, which correlated with gram negativity (2). In their comparison study with the 3% KOH method, Carlone et al. yielded more cor-

rect Gram stain determinations with L-alanine-4-nitroanilide than with the 3% KOH method (1). Manafi and Kneifel in 1990 (3) evaluated various chromogenic and fluorogenic substrates for their ability to distinguish gram-positive from gram-negative bacteria. They preferred the fluorogenic compound L-alanine-7-amido-4-methylcoumarin for a rapid test due to the pronounced blue fluorescence of a positive reaction and increased test sensitivity.

II. MICROORGANISMS TESTED

Use a fresh colony, less than 48 h old, of an aerobic or facultative microorganism growing on any laboratory medium.

III. REAGENTS AND SUPPLIES

A. Disks

1. Impregnated with L-alanine-7-amido-4-methylcoumarin (Gram-Sure; Remel, Inc.), L-alanine-4-nitroanilide (LanaGram; Hardy Diagnostics), and L-alanine-*p*-nitroanilide (APNA; Key Scientific)
2. Store in original container at 2 to 8°C until used.
3. Minimize exposure to light.

4. Protect disks from moisture by removing only those disks necessary for testing from the vial. Promptly replace the cap and return the vial to 2 to 8°C.

B. Supplies

1. Inoculating loop, swab, or stick
2. Long-wave UV light

IV. QUALITY CONTROL

- A. Do not use product if any of the following is true.
 1. The color of the disk has changed (refer to manufacturer's package insert).
 2. The color of the desiccant has changed to pink.
 3. There are other signs of deterioration.
- B. Perform QC on each new lot or shipment of reagent prior to putting it into use, with the following QC organisms.
 1. *Escherichia coli* ATCC 25922—positive
 2. *Staphylococcus aureus* ATCC 25923—negative

V. PROCEDURE

- A. Add 0.25 ml of purified water to a 10- by 75-mm test tube.
- B. Inoculate heavily with an isolated bacterial colony to produce a milky suspension.
- C. Add one disk to the inoculated tube.
- D. Incubate at room temperature (25°C) for 5 to 20 min.
- E. Observe under long-wave UV light for the appearance of blue fluorescence (methylcoumarin substrate), or observe visually for the development of a pale yellow to bright yellow color (nitroanilide substrate).

VI. INTERPRETATION

- A. A positive test (gram negative) shows blue fluorescence (methylcoumarin substrate) or pale to bright yellow color (nitroanilide substrate).
- B. A negative test (gram positive) shows no fluorescence (methylcoumarin substrate) or no change in color (nitroanilide substrate).

VII. REPORTING RESULTS

- A. Aerobic, gram-negative rods and coccobacilli demonstrate a bright blue fluorescence (methylcoumarin substrate) or a pale to bright yellow color change (nitroanilide substrate).
- B. Gram-positive rods and coccobacilli demonstrate no fluorescence (methylcoumarin substrate) or no change in color (nitroanilide substrate).

VIII. LIMITATIONS

- A. This test is designed to serve as an adjunct to (not a replacement for) the traditional Gram stain method.
- B. Obligate anaerobic and gram-positive cocci may fail to give the expected results and should not be tested with this product. Such genera as *Campylobacter*, *Bacteroides*, and *Streptococcus* are likely to produce false results.
- C. Do not use the nitroanilide substrate to test yellow colonies or colonies from media with dye.
- D. Nitroanilide substrate requires up to 20 min. Negative test reactions (no color change) should be held for the full 20 min.

2. Cerny, G. 1976. Method for the distinction of gram-negative from gram-positive bacteria. *Eur. J. Appl. Microbiol.* **33**:223–225.
3. Manafi, M., and W. Kneifel. 1990. Rapid methods for differentiating gram-positive from gram-negative aerobic and facultative anaerobic bacteria. *J. Appl. Bacteriol.* **69**:822–827.

3.17.21

Hippurate Hydrolysis Rapid Test

I. PRINCIPLE

The hippurate test is used in the identification of *Campylobacter jejuni*, *Listeria monocytogenes*, *Gardnerella vaginalis*, and *Streptococcus agalactiae*, by detecting the ability of the organism to hydrolyze sodium hippurate to benzoic acid and glycine by the action of the enzyme hippuricase.

The ability of bacterial species to hydrolyze hippurate was classically tested using ferric chloride indicator to detect benzoic acid. However, a 2-h rapid method, as opposed to the 48-h classical method, for detecting hippurate hydrolysis has since been developed (3). The rapid test employs ninhydrin as the indicator,

which reacts with any protein or amino acid and, in this case, detects glycine. The rapid hippurate hydrolysis test has been shown to be as specific and as sensitive as the classical method, which detects the benzoic acid by-product.

II. MICROORGANISMS TESTED

- A. Presumptive *L. monocytogenes*: tiny gram-positive rods that are catalase positive, motile at 25°C, and beta-hemolytic
- B. Presumptive *S. agalactiae*: gram-positive cocci that are catalase negative, displaying a translucent colony with a characteristic narrow zone of beta-hemolysis
- C. Presumptive *C. jejuni*: curved gram-negative rods that are oxidase and catalase positive and do not grow aerobically at 35°C (2, 4)
- D. Presumptive *G. vaginalis*: catalase-negative, tiny gram-variable rods

III. MEDIA, REAGENTS, AND SUPPLIES

A. Rapid hippurate tubes

1. Commercial hippurate reagents
 - a. Tube containing 20 g of sodium hippurate per liter when rehydrated (Hardy Diagnostics)
 - b. Disks or tablets to be reconstituted in a tube (BD Diagnostic Systems; Key Scientific; Oxoid, Inc.; Remel, Inc.)
2. Prepare 1.0% hippurate.
 - a. Add 1 g of sodium hippurate (Sigma Chemical Co.) to 100 ml of distilled water.
 - b. Dissolve completely by mixing well.
 - c. Dispense in capped tubes in 0.2- to 0.4-ml amounts (e.g., Durham tubes work well).

- d. Freeze at -20°C. Shelf life is very long. Discard when QC fails.

■ **NOTE:** Piot et al. (6) found that a pH of 6.4 was optimal to detect positive reactions for *G. vaginalis*.

B. Ninhydrin

1. If reagent is lyophilized, reconstitute by adding distilled water in the amount recommended by the manufacturer.
2. Ninhydrin preparation
 - a. Mix 50 ml of acetone and 50 ml of 1-butanol thoroughly in a dark glass bottle.
 - b. Add 3.5 g of ninhydrin; mix.

Include QC information on reagent container and in QC records.

III. MEDIA, REAGENTS, AND SUPPLIES *(continued)*

c. Store at room temperature for up to 6 months.

■ **NOTE:** Care must be taken when handling this solution not to spill reagent onto skin or clothing, as a blue color will develop that does not wash off but will wear off the skin in 24 to 48 h.

C. Supplies

1. Sterile wooden sticks or inoculating loops
2. Incubator at 35°C
3. Test tubes
4. Distilled water

IV. QUALITY CONTROL

- A. Test each new lot and shipment of reagent with known positive and negative controls, and retest at least monthly thereafter. Discard all reagents and prepare new ones if the reagents do not pass QC.
- B. Organisms
 1. *S. agalactiae* ATCC 12386—hippurate positive
 2. *Streptococcus pyogenes* ATCC 19615—hippurate negative

V. PROCEDURE

- A. Prepare hippurate tube.
 1. Add 0.2 ml (3 or 4 drops) of distilled water at a pH of 6.8 to 7.2 to reconstitute lyophilized tube test reagent.
 2. Add 2 drops of distilled water to empty tube for disk or tablet tests.
 3. Defrost one 0.4-ml tube per test for prepared reagent.
- B. In the tube, make a heavy suspension (equivalent to no. 3 McFarland standard) from an 18- to 24-h culture. Use care not to pick up agar, which contains protein.
- C. For disk or tablet tests, add reagent after inoculation of the tube with the culture.
- D. Incubate the tube for 2 h at 35 to 37°C.
- E. After the 2-h incubation period, add 2 drops of the ninhydrin solution to the hippurate reagent-organism mixture. Add an additional 2 drops if test has 0.4 ml of hippurate.
- F. Reincubate at 35 to 37°C for 30 min. Observe the tubes at 10-min intervals for the appearance of a deep blue color, which is a positive test. The color change will usually appear within 10 to 15 min after the ninhydrin indicator solution has been added.

VI. INTERPRETATION

- A. A positive reaction is indicated by the appearance of a deep blue color (about the color of crystal violet) within 30 min.
- B. A negative reaction is indicated by a faint purple color or no color change.

VII. REPORTING RESULTS

- A. *L. monocytogenes* organisms are tiny gram-positive rods that are catalase positive, motile at 25°C, beta-hemolytic, CAMP positive, and hippurate positive.
- B. *S. agalactiae* organisms are catalase-negative, gram-positive cocci that are identified by having a characteristic narrow zone of beta-hemolysis and are hippurate positive.
- C. *C. jejuni* organisms are curved, gram-negative rods that are identified by having a positive oxidase and catalase reaction, having no growth aerobically at 35°C, and being hippurate positive.
- D. *G. vaginalis* organisms are catalase-negative, gram-variable rods that are hemolytic on human blood agar and are hippurate positive.

VII. REPORTING RESULTS*(continued)*

- E. *Arcanobacterium haemolyticum* is hippurate negative and reverse-CAMP positive, while *Arcanobacterium pyogenes* is hippurate positive and reverse-CAMP negative. Both are hemolytic.

VIII. LIMITATIONS

- A. Not all *S. agalactiae* organisms are beta-hemolytic. Viridans group streptococci can be hippurate positive; another test must be done on nonhemolytic colonies to confirm the identification.
- B. A small number of enterococci are beta-hemolytic and may hydrolyze hippurate, but they are pyrrolidonyl- β -naphthylamide (PYR) positive.
- C. A small percentage of *C. jejuni* organisms are hippurate negative and must be identified by other methods (5).
- D. A negative test does not rule out the identification of *G. vaginalis*, since the biotypes that cause bacterial vaginosis can be hippurate negative (1).
- E. False-positive results can occur if incubation with ninhydrin exceeds 30 min.

3.17.22

Hydrogen Sulfide Production

I. PRINCIPLE

Certain organisms are capable of enzymatically liberating sulfur from inorganic sulfur as hydrogen sulfide (H_2S) compounds or from sulfur-containing amino acids through proteolysis of proteins. Detection of H_2S from inorganic sulfur compounds is a two-step process where the bacterium reacts with sodium thiosulfate in the medium to yield a sulfite and H_2S . The colorless H_2S gas released reacts with ferric ions or lead acetate to yield ferrous sulfide or lead sulfide, which are insoluble black precipitates. The most common sul-

fide indicators are ferrous sulfate, ferric citrate, ferric ammonium sulfate or citrate, peptonized iron, and lead acetate. The sensitivity of each indicator varies, and H_2S detected by one indicator may not be detected by another (2).

Lead acetate is the most sensitive reagent and should be used for organisms that produce trace amounts of H_2S . Since all members of the family *Enterobacteriaceae* are capable of producing various amounts of H_2S , the least sensitive approach (Kligler's iron agar [KIA] or triple

sugar iron agar [TSI]) is best for routine identification of these organisms. Several plate media, such as xylose-lysine-desoxycholate (XLD), Hektoen enteric agar, and salmonella-shigella agar (SS), are also capable of detecting H_2S production. While these media are used primarily as screening tests for fecal pathogens, the tube tests are also useful biochemical tests for H_2S production by *Erysipelothrix* and fastidious gram-negative rods, such as *Campylobacter*.

II. MICROORGANISMS TESTED

A. Organisms

1. Gram-negative rods, to determine their ability to produce hydrogen sulfide
2. Catalase-negative gram-positive rods, to detect H_2S production to separate lactobacilli from *Erysipelothrix*
3. *Campylobacter*, to detect H_2S production (For use in testing campylobacters, media should be less than 1 week old or boiled and reslanted prior to use.)

- B. Use as part of the battery to distinguish enteric pathogens (procedure 3.8.1).

III. MEDIA, REAGENTS, AND SUPPLIES

A. Media

1. KIA (refer to procedure 3.17.25 for details on preparation)
2. TSI (refer to procedure 3.17.25 for details on preparation)
3. Sulfide-indole-motility agar (SIM)
4. XLD, Hektoen, or other primary culture media to select for fecal pathogens

B. Supplies

1. Wire or disposable inoculating needles for tubed media and inoculating loops for plate media
2. 35°C heat block for tubes or incubator without increased CO_2
3. Optional: lead acetate paper

IV. QUALITY CONTROL

- A. Perform QC on each new lot or shipment of tubed media prior to putting it into use.

1. Refer to motility procedure (procedure 3.17.31) for QC of SIM and the KIA and TSI procedure (procedure 3.17.25) for QC of KIA and TSI.
2. It is not necessary for users to QC Hektoen, XLD, and SS agar if it has been done by the manufacturer. Refer to NCCLS document M22-A2 for more information (3).

IV. QUALITY CONTROL (continued)

- B.** Inspect agar for freezing, contamination, cracks, dehydration, and bubbles prior to storage and before use. Discard any tubes with bubbles in the agar. Discard TSI or KIA tubes that are not red or that lack a deep butt. The slant and butt should be equal in length.

V. PROCEDURE

A. Tube media

1. Warm medium to room temperature and examine for cracks. Do not use if cracks appear.
2. Using a sterile inoculating needle, touch the center of a well-isolated colony.
3. Stab to within 3 to 5 mm from the bottom of the tube.
4. Withdraw the needle.
5. For KIA or TSI, streak the entire surface of the agar slant.
6. Optional for fastidious organisms: add a strip of lead acetate paper to top of tube and hold in place with the cap of the tube so that it extends 1 in. into the tube.
7. *Place cap loosely on tube.* Do not tighten the cap to allow for release of gas in the tube.
8. Incubate aerobically at 35 to 37°C for 18 to 24 h.
9. Observe for black precipitate indicating hydrogen sulfide production.
10. If desired, extend incubation only to detect H₂S production. Campylobacters may take 3 days for production of H₂S.

B. Plate media

1. Streak plate so as to obtain isolated colonies.
2. Incubate aerobically at 35 to 37°C for 18 to 24 h.
3. Observe for blackened colonies.

VI. INTERPRETATION

A. Positive reactions

1. H₂S production in tube media: black color throughout the medium, a black ring at the junction of the butt and slant, or any black precipitate in the butt. Blackening usually begins at the line of inoculation.
2. H₂S production in plate media: black colonies surrounded by a brownish black zone or metallic sheen
3. Lead acetate paper: brownish black coloration of the paper strip

B. Negative reactions

1. H₂S production in tube media: no blackening in tube
2. H₂S production in plate media: no blackening and no metallic-sheen colonies
3. Lead acetate paper: no change in color of strip

VII. REPORTING RESULTS

- A. If a catalase-negative, vancomycin-resistant, gram-positive rod is H₂S positive, report as "*Erysipelothrix rhusiopathiae*."
- B. If a campylobacter-like organism is H₂S positive, report as "Probable *Campylobacter hyointestinalis*." See Table 3.8.2–4 for other tests to confirm the identification.
- C. For evaluation of enteric pathogens, see procedure 3.8.1.
- D. *Shewanella putrefaciens/algae* is a foul-smelling, oxidase-positive, gram-negative rod that is H₂S positive and does not produce acid on TSI or KIA (4).

VIII. LIMITATIONS

- A. H₂S production may be inhibited on TSI for organisms that utilize sucrose and suppress the enzyme mechanism that results in production of H₂S (1).
- B. SIM is more sensitive in the detection of H₂S than either TSI or KIA, because of its semisolid nature, its lack of interfering carbohydrates, and the use of peptonized iron as an indicator (2).
- C. Lead acetate paper is 10 times more sensitive than other media (5).
- D. Lead acetate is toxic to bacteria and may inhibit the growth of some bacteria. Do not allow the media to touch the strip.

3.17.23

Indole Test

I. PRINCIPLE

The ability of an organism to split indole from the amino acid tryptophan is due to the presence of tryptophanase. Indole, if present, combines with the aldehyde in the reagent to produce a pink to red-violet qui-

noidal compound (benzaldehyde reagent) or a blue to green color (cinnamaldehyde reagent). In the rapid spot test, indole is detected directly from a colony growing on a medium rich in tryptophan.

II. MICROORGANISMS TESTED

- A. Fresh growth of a gram-negative rod on medium that does not contain dyes and contains tryptophan, e.g., BAP or CHOC
- B. Anaerobic gram-positive rods
- C. Anaerobic gram-negative rods

III. MEDIA, REAGENTS, AND SUPPLIES

A. Reagents

Obtain indole reagents commercially, or prepare in-house.

1. Rapid spot indole: see Appendix 3.17.23-1.
 - a. Prepare either 5% *p*-dimethylaminobenzaldehyde or 1% paradimethylaminocinnamaldehyde in 10% (vol/vol) concentrated HCl (1, 6)
 - b. Do not use the spot benzaldehyde reagent for anaerobes.
2. Tube indole
 - a. Kovács' method for aerobically growing organisms (3)
 - (1) Reagent: see Appendix 3.17.23-1.
 - (2) Medium: broth that contains tryptophan (containing peptone, tryptone, or casein). Semisolid agar, such as motility-indole-ornithine agar or sulfide-indole-motility agar, can be used.

b. Ehrlich's method for anaerobes and weak indole producers (2)

- (1) Reagent: see Appendix 3.17.23-1.
 - (2) Medium: heart infusion or anaerobic medium with tryptophan
 - (3) Xylene
3. Clearly label indole reagents, indicating preparation and expiration dates.
 - a. Record the expiration date in a work record (in-house preparation) or on a receipt record (commercial record).
 - b. Store indole reagents in a dark bottle at 4°C.

B. Supplies

1. Sterile loop, swab, or stick for harvesting
2. Filter paper (optional)

IV. QUALITY CONTROL

- A. Do not use benzaldehyde reagents (including Ehrlich's and Kovács') if color is not pale yellow.
- B. Perform QC
 - 1. On each new lot or shipment of reagent prior to putting it into use
 - 2. Although not required, QC in-house-prepared reagents weekly, as they can deteriorate, especially if not stored at 4°C. Discard if reactions become weak (4).
- C. Organisms
 - 1. *Escherichia coli* ATCC 25922—indole positive
 - 2. *Pseudomonas aeruginosa* ATCC 27853—indole negative
 - 3. For Ehrlich's reagent for use with anaerobic microorganisms
 - a. *Porphyromonas asaccharolytica* ATCC 25260—indole positive
 - b. *Bacteroides fragilis* ATCC 25285—indole negative

V. PROCEDURE

- A. **Rapid spot indole**

Use one of the methods below.

 - 1. Moisten filter paper with reagent. Using a wooden stick, rub portion of colony onto paper.
 - 2. Sweep the colony onto a swab. Add drop of indole reagent to the colony swab.
 - 3. Add reagent directly to the colony growing on the agar surface.
- B. **Tube test**
 - 1. Inoculate liquid tube medium or stab agar medium with colony.
 - 2. Incubate for 18 to 24 h. If broth is used for indole production, decant a portion of the medium to a second tube before testing.
 - 3. For Ehrlich's method
 - a. Add 0.5 ml of xylene to tube and invert to mix. Let settle.
 - b. Add 6 drops of Ehrlich's indole reagent down the side of the tube and observe color below the xylene layer.
 - 4. For Kovács' method, add 3 drops of Kovács' reagent down the side of the tube and observe color change at meniscus.
 - 5. If test is negative, repeat test after an additional 24 h of incubation, if desired.

VI. INTERPRETATION

- A. The development of a brown-red to purple-red color (benzaldehyde reagents) or blue color (cinnamaldehyde reagent) within 20 s indicates the presence of indole.
- B. A negative test is colorless or slightly yellow.

VII. REPORTING RESULTS

- A. *E. coli* is indole positive, as are many other *Enterobacteriaceae*, *Vibrio*, *Aeromonas*, *Plesiomonas*, and *Pasteurella*.
- B. Several fastidious gram-negative rods are indole positive, such as *Cardiobacterium hominis* and *Pasteurella bettyae*. See Table 3.18.2–3 for others.
- C. *Propionibacterium acnes* is indole positive.
- D. *Delftia (Comamonas) acidovorans* produces a pumpkin orange reaction from the production of anthranilic acid, rather than indole, from tryptophan with Kovács' reagent (5).

VIII. LIMITATIONS

- A. Detectable indole will diffuse to colonies within 5 mm of a 2- to 3-mm colony, giving false-positive results.
- B. Do not use media that contain dyes (e.g., EMB, MAC).
- C. Growth medium must contain an adequate amount of tryptophan. Do not use Mueller-Hinton agar for test, because tryptophan is destroyed during the acid hydrolysis of casein.
- D. Only the cinnamaldehyde reagent can be used for spot testing of anaerobic microorganisms. It is the more sensitive reagent, but it is less stable.
- E. Do not use a plate with a nitrate disk to perform the indole test, as nitrate can interfere with the spot indole test by inducing false-negative results.
- F. If the rapid indole test is negative, the isolate could be positive in the more sensitive tube test. Extraction with xylene is the most sensitive test. Xylene substitutes are less sensitive.
- G. For fastidious gram-negative rods, such as *C. hominis*, a heavy inoculum and extraction are necessary.

APPENDIX 3.17.23–1

Include QC information on reagent container and in QC records.

Reagent Preparation

Caution: HCl is toxic and burns. Make indole reagents in a fume hood. Add acid to water; do not add water to acid.

A. Ehrlich's reagent

p-dimethylaminobenzaldehyde 1 g
ethyl alcohol, 95%95 ml
hydrochloric acid, concentrated20 ml

1. Dissolve the aldehyde in the alcohol (this may require gentle heating).
2. Working under a fume hood, slowly add the acid (never add alcohol to acid). Mix constantly.
3. The reagent should be pale yellow and stable for 1 year.

B. Kovács' reagent

p-dimethylaminobenzaldehyde10 g
isobutyl or isoamyl alcohol (absolute) 150 ml
hydrochloric acid, concentrated50 ml

1. Dissolve the aldehyde in the alcohol (this may require gentle heating).
2. Working under a fume hood, slowly add the acid (never add alcohol to acid). Mix constantly.
3. The reagent should be pale yellow and stable for 1 year.

APPENDIX 3.17.23-1 (continued)

C. 5% *p*-Dimethylaminobenzaldehyde

p-dimethylaminobenzaldehyde 5 g
10% (vol/vol) hydrochloric acid 100 ml

1. Add 10 ml of concentrated HCl to 90 ml of water.
2. Dissolve the aldehyde in the acid (use a fume hood).
3. Shelf life is 4 months.

D. 1% *p*-Dimethylaminocinnamaldehyde

p-dimethylaminocinnamaldehyde 1 g
10% (vol/vol) hydrochloric acid 100 ml

1. Add 10 ml of HCl to 90 ml of water.
2. Dissolve the aldehyde in the acid (use a fume hood).
3. Shelf life is 2 months (1).

3.17.24

Indoxyl Acetate Disk Test

I. PRINCIPLE

Indoxyl is a tryptophan product of putrefactive decomposition in the intestines of humans by a bacterial esterase (3). The presence of this enzyme can be confirmed in vitro by the bacterial hydrolysis of indoxyl acetate to release indoxyl. Indoxyl then combines with oxygen to spontane-

ously form indigo. In 1987, Mills and Gherna (2) found this test to be useful to distinguish *Campylobacter jejuni* and *Campylobacter coli* (positive) from *Campylobacter lari* and *Campylobacter fetus* (negative).

II. MICROORGANISMS TESTED

- A. Oxidase-positive, motile, curved, gram-negative rods suggestive of *Campylobacter* spp. and related organisms (*Helicobacter* and *Arcobacter*)
- B. Gram-negative, oxidase-positive diplococci growing on BAP as white colonies that remain together when lifted with a loop or wire (4)

III. REAGENT AND SUPPLIES

- A. Disks
 - 1. Purchase (Hardy Diagnostics, Remel, Inc.) *or*
 - 2. Prepare in-house.
 - a. 10% Indoxyl acetate (Sigma Chemical Co., St. Louis, Mo.) in acetone
 - b. Add 50 μ l (25 μ l at a time) to a 6-mm blank paper disk (BD Diagnostic Systems, Hardy Diagnostics).
 - c. Dry the disks at room temperature.
 - 3. Store at 4°C in a brown bottle to protect from light; add desiccant to keep dry.
- B. Supplies
 - 1. Sterile wooden sticks
 - 2. Petri dish
 - 3. Sterile distilled water or saline

IV. QUALITY CONTROL

- A. Do not use if disks are discolored and no longer white.
- B. Perform QC on each lot or shipment of disks using a positive and negative control prior to putting it into use.
- C. Organisms
 - 1. *C. jejuni* ATCC 33560 or *Moraxella catarrhalis* ATCC 25240—positive (blue color)
 - 2. *Campylobacter hyointestinalis* ATCC 35217 or *C. fetus* ATCC 27374—negative (no color change)

V. PROCEDURE

- A. Place indoxyl acetate disk in a plastic petri dish and transfer a large loopful of 24- to 48-h growth from plate onto the disk.
- B. Add a drop of sterile distilled water to the disk for *Campylobacter* (3). For *Moraxella*, premoisten the disk with saline prior to inoculation.
- C. Incubate at room temperature for up to 30 min for *Campylobacter* (3) and up to 3 min for *Moraxella* (4).

VI. INTERPRETATION

- A. A positive test shows dark blue color development on disk in 3 min for *Moraxella* and 5 to 10 min for *Campylobacter*.
- B. A negative test shows no color change.
- C. Weakly positive reactions are pale blue in 10 to 30 min.

VII. REPORTING RESULTS

- A. *C. jejuni*, *C. coli*, *Campylobacter upsaliensis*, *Arcobacter cryaerophilus*, and *Helicobacter fennelliae* are indoxyl acetate positive (1, 3).
- B. *C. lari*, *Helicobacter pylori*, *Helicobacter cinaedi*, and *Helicobacter pullorum* are negative for indoxyl acetate (1, 3).
- C. Report as *Moraxella catarrhalis* if oxidase-positive, gram-negative diplococci grow on BAP as colonies that remain together when sampled and are strongly indoxyl acetate positive in 3 min (4).

VIII. LIMITATIONS

- A. The test is reliable regardless of the media used for growth (2).
- B. The disk test is more rapid and reliable than the tube method (3).

3.17.25

Kligler's Iron Agar Test and Triple Sugar Iron Agar Test

I. PRINCIPLE

Kligler's iron agar (KIA) contains casein and meat peptones, phenol red as the pH indicator, 0.1% glucose, and 1% lactose for fermentation (3, 4). Ferric or ferrous ions and sodium thiosulfate are present to detect hydrogen sulfide production. Triple sugar iron agar (TSI) is similar in formulation; however, TSI also contains 1% sucrose, which is not included in KIA (2, 7).

Organisms that are non-lactose fermenting initially produce a yellow slant due to the production of acid from the glucose. The small amount of glucose is rapidly depleted. Oxidative metabolism continues in the slant after the low concentration of glucose has been depleted, producing an alkaline pH from the aerobic

breakdown of peptone; the slant turns red. There is no oxygen penetration into the butt and no oxidative metabolism; the butt remains acid and yellow. Thus, a non-lactose fermenting organism yields an alkaline (K) slant over an acid (A) butt (K/A; red slant; yellow butt). Lactose-fermenting (and/or sucrose-fermenting in the case of TSI) bacteria continue to produce a large amount of acid in the slant and in the butt so the reaction in both remains acid (A/A; yellow slant; yellow butt). If the slant and the butt remain neutral, the organism is not capable of fermenting glucose or other sugars (K/K; red slant; red butt). Gas production from sugar fermentation is indicated by bubbles, fracturing

of the medium, or displacement of the medium.

Hydrogen sulfide is produced by the action of the bacteria with sodium thiosulfate. This is detected by the reduction of ferric ions to produce a black precipitate. While these media are used primarily as screening tests for fecal pathogens, they are useful biochemical tests for H₂S production by *Erysipelothrix* and other organisms, such as *Campylobacter*. In addition, these media are very useful for the determination of the ability of fastidious organisms to ferment glucose, since many organisms will not react in OF medium and appear to be non-glucose fermenting (8).

II. MICROORGANISMS TESTED

A. Organisms

1. Gram-negative rods, especially fastidious organisms, to determine their ability to ferment glucose and lactose (or sucrose, for TSI) and to produce hydrogen sulfide
 2. Oxidase-negative, catalase-positive, nonmotile, gram-negative coccobacilli that grow on MAC, to identify *Acinetobacter* spp.
 3. Catalase-negative, gram-positive rods to detect H₂S production, to separate lactobacilli from *Erysipelothrix*
 4. *Campylobacter*, to detect H₂S production
- B. Use as part of the battery to screen for enteric pathogens (procedure 3.8.1).
- C. Use to determine whether a gram-negative rod is glucose fermenting, in deciding whether to use an oxidative or fermentative system for the identification of the organism.

III. MEDIA, REAGENTS, AND SUPPLIES

A. Media

1. Characteristics
 - a. Agar slants with deep butts
 - b. Purchase commercially or prepare from dehydrated powder (5).
- (1) Rehydrate commercial TSI or KIA according to manufacturer's instructions.
- (2) Dispense 5- to 7-ml aliquots into 16- by 125-mm screw-cap tubes.

III. MEDIA, REAGENTS, AND SUPPLIES *(continued)*

- (3) Autoclave at 121°C for 15 min. Do not overheat.
- (4) Cool as slants with deep butts.
- (5) Store at 2 to 4°C. Some prefer to store at 25°C so that cracks will not form when medium is warmed prior to inoculation.

2. Options

- a. KIA
- b. TSI

☑ **NOTE:** For best results with campylobacters, agar must be freshly pre-

pared and used in 1 week. One manufacturer recommends that KIA be prepared fresh or melted and resolidified just before use (5).

B. Supplies

1. Wire or disposable inoculating needles
2. 35°C heat block or incubator without increased CO₂
3. Optional: lead acetate paper

IV. QUALITY CONTROL

- A. Perform QC on each new lot and shipment of media prior to putting it into use.
 - ☑ **NOTE:** NCCLS has proposed elimination of user QC for TSI purchased from commercial sources. Consult with current regulatory agencies prior to discontinuation of user QC (6).
- B. Inspect agar for freezing, contamination, cracks, dehydration, and bubbles prior to storage and before use. Discard any tubes with bubbles in the agar. Discard tubes that are not red or that lack a deep butt. The slant and butt should be equal in length.
- C. Organisms

Organism	ATCC no.	TSI	KIA	H ₂ S
<i>Escherichia coli</i>	25922	A/A, gas	A/A, gas	–
<i>Salmonella enterica</i> serovar Typhimurium	14028	K/A, ± ^a gas	K/A, ± ^a gas	+
<i>Pseudomonas aeruginosa</i>	27853	K/K, no gas	K/K, no gas	–
Optional for special species: <i>Campylobacter hyointestinalis</i>	35217	K/K, no gas	K/K, no gas	+

^a ±, with or without.

V. PROCEDURE

- A. Warm medium to room temperature and examine for cracks. Do not use if cracks appear.
- B. Using a sterile inoculating needle, touch the center of a well-isolated colony.
- C. Stab to within 3 to 5 mm from the bottom of the tube.
- D. Withdraw the needle, and streak the entire surface of the agar slant.
- E. Optional for fastidious organisms: add a strip of lead acetate paper to top of tube and hold in place with the cap of the tube.
- F. *Place cap loosely on tube. Do not tighten the cap.*
- G. Incubate aerobically at 35 to 37°C for 18 to 24 h.
- H. Examine the reaction in the slant and the butt. Observe for gas and hydrogen sulfide production.
- I. Do not attempt to interpret sugar fermentation reactions after 24 h. Refrigerate tubes if readings will be delayed.
- J. If desired, extend incubation only to detect H₂S production. Campylobacters may take 3 days for production of H₂S.

VI. INTERPRETATION

A. Observations

1. Acid reaction: yellow
2. Alkaline reaction: red

VI. INTERPRETATION*(continued)*

3. H₂S production: black color throughout the medium, a black ring at the junction of the butt and slant, or a black precipitate in the butt. Low levels of H₂S production present as no blackening of the agar but blackening of the lead acetate paper.

4. Gas production: bubbles, cracks, or displacement of media

B. Interpretation of carbohydrate observations

1. A/A: glucose and lactose (and/or sucrose for TSI) fermented
2. K/A: only glucose fermented (non-lactose fermenter or glucose fermenter).
3. K/K: no carbohydrates fermented (non-glucose fermenter).

VII. REPORTING RESULTS

- A. If a catalase-negative, gram-positive rod is vancomycin resistant and H₂S positive, report as “probable *Erysipelothrix rhusiopathiae*.” See Table 3.18.1–5.
- B. If a campylobacter-like organism is H₂S positive, report as “probable *Campylobacter hyointestinalis*.” See Table 3.8.2–4 for other tests to confirm identification.
- C. For evaluation of the identification of *Salmonella*, see the screening flowchart in Fig. 3.8.1–2.
- D. For other organisms, refer to procedure 3.18.2.

VIII. LIMITATIONS

- A. Do not read the test before 18 h, since false readings of acid in the slant may result.
- B. Copious amounts of H₂S may mask the glucose reaction. If this exists, glucose has been fermented and should be recorded as such. Check for gas production.
- C. When using KIA for screening fecal cultures, it is not able to separate some uncommon non-lactose fermenters (e.g., *Providencia*) that ferment sucrose from fecal pathogens which are lactose and sucrose negative.
- D. If TSI is used to screen fecal cultures, the sugar reactions of acid/acid may be obtained with *Yersinia enterocolitica* and *Edwardsiella tarda*, since both can ferment sucrose but not lactose (5).
- E. Neither KIA nor TSI, without the use of pyrrolidonyl-β-naphthylamide (PYR), will separate lactose-positive *Salmonella* (lysogenized) from *Citrobacter*.
- F. Gas production is better in TSI than in KIA. However, H₂S production may be inhibited on TSI for organisms that utilize sucrose and suppress the enzyme mechanism that results in production of H₂S (1).
- G. Sulfide-indole-motility (SIM) agar is more sensitive in the detection of H₂S than either TSI or KIA.

3.17.26

LAP (Leucine Aminopeptidase) Test

I. PRINCIPLE

Detection of the enzyme leucine aminopeptidase (LAP) is one of the tests in the definitive identification of catalase-negative, gram-positive cocci. Specifically, it differentiates *Aerococcus* and *Leuconos-*

toc from *Streptococcus*, *Enterococcus*, *Lactococcus*, and *Pediococcus* (1, 2). The former are LAP negative, and the latter are positive. Hydrolysis of the leucine-*p*-naphthylamide substrate on a paper disk

inoculated with the bacteria releases leucine and free β -naphthylamide. The β -naphthylamide combines with cinnamaldehyde reagent to form a pink to cherry-red pigment.

II. MICROORGANISMS TESTED

Fresh growth less than 24 h old of catalase-negative, gram-positive cocci. If growth is poor, a culture that has been incubated for up to 72 h may be used.

III. MEDIA, REAGENTS, AND SUPPLIES

A. Reagents

1. Disks (Key Scientific Products Company; Hardy Diagnostics; Remel, Inc.; Oxoid, Inc.)

■ **NOTE:** BactiCard Strep (Remel, Inc.) incorporates both LAP and pyrrolidonyl- β -naphthylamide (PYR) on one card. StrepQuick (Hardy Diagnostics) incorporates LAP, PYR, and esculin on one card.

2. 0.01% *p*-Dimethylaminocinnamaldehyde (the same reagent as used in PYR test)

B. Supplies

1. Sterile loop or stick for harvesting
2. Distilled water (neutral pH)
3. Petri dish

IV. QUALITY CONTROL

- A. Perform QC on each new lot or shipment of disks and color reagent prior to putting it into use. Since the test is performed infrequently and most gram-positive cocci are LAP positive, verify potency by testing the positive control each time a negative test is obtained.

B. Organisms

1. *Enterococcus faecalis* ATCC 29212—LAP positive
2. *Aerococcus viridans* ATCC 11563—LAP negative

V. PROCEDURE

- A. Place disk onto slide or petri dish. Moisten (do not saturate the disk) with a loopful of distilled water.
- B. Using a sterile stick or loop, smear with the suspected isolate.
- C. Incubate at room temperature for 5 min.
- D. Add 1 drop of cinnamaldehyde developer reagent and wait 2 min to observe color.

VI. INTERPRETATION

- A. A positive test after adding reagent shows a deep red to reddish purple color.
- B. Weak reactions are pink.
- C. A negative test is colorless or yellow.

VII. REPORTING RESULTS

- A. *Aerococcus* and *Leuconostoc* are LAP negative, whereas other organisms in the group (*Streptococcus*, *Enterococcus*, *Lactococcus*, and *Pediococcus*) are almost always positive.
- B. See Table 3.18.1–4 for further testing (2).

VIII. LIMITATIONS

- A. This test is only one of a battery of useful tests for identifying catalase-negative, gram-positive cocci and is most helpful when kit tests yield uncommon identifications or Gram stain results do not show chaining cocci.
- B. False negatives may result from insufficient inoculum.

REFERENCES

- 1. **Facklam, R., and J. A. Elliott.** 1995. Identification, classification, and clinical relevance of catalase-negative, gram-positive cocci, excluding the streptococci and enterococci. *Clin. Microbiol. Rev.* **8**:479–495.
- 2. **LaClaire, L. L., and R. R. Facklam.** 2000. Comparison of three commercial rapid identification systems for the unusual gram-positive cocci *Dolosigranulum pigrum*, *Ignavigranum ruoffiae*, and *Facklamia* species. *J. Clin. Microbiol.* **38**:2037–2042.

3.17.27

Lecithinase and Lipase Detection

I. PRINCIPLE

Lecithinases or phospholipases are enzymes released by the bacteria that destroy animal tissues. Lecithin is a normal component of egg yolks. In egg yolk agar (EYA) the lipoprotein component, lecithovitellin, can be split by lecithinase into phosphorylcholine and an insoluble diglyceride, which forms a precipitate in the

medium (2). This precipitate appears as a white opaque halo surrounding the colony that produces the lecithinase. CCFA agar (procedure 3.8.3), used to identify *Clostridium difficile*, also contains egg yolks.

Bacterial lipases hydrolyze the breakdown of triglycerides into glycerol and

free fatty acids. Fatty acids are mostly insoluble and cause opacity on EYA, producing an iridescent sheen on the colonies and the surface of EYA. Unlike lecithinase, lipase is not diffusible, and the reaction occurs only on the surface of the agar in the immediate vicinity of the colony.

II. MICROORGANISMS TESTED

- A. Spore-forming gram-positive rods: lecithinase will separate *Bacillus cereus* group (positive) and *Bacillus anthracis* (positive) from other *Bacillus* species (negative) and *Clostridium perfringens* (positive) from some other *Clostridium* species.
- B. Catalase-negative, hemolytic, gram-positive rods: lecithinase separates *Arca-nobacterium haemolyticum* from *Actinomyces pyogenes*.
- C. Spore-forming, catalase-negative, gram-positive rods: *Clostridium sporogenes* is lipase positive. *C. difficile* is both lipase and lecithinase negative.
- D. Non-glucose-fermenting, gram-negative rods of the fluorescent group: lecithinase will separate *Pseudomonas putida* (negative) from *P. fluorescens* (positive).
- E. Catalase-negative, gram-variable rods identified as presumptive *Gardnerella vaginalis*, which is often lipase positive

III. MEDIA, REAGENTS, AND SUPPLIES

A. Media: EYA

1. Media available from most medium vendors, or see Appendix 3.17.27–1 for preparation.
2. Store in moist container at 2 to 8°C until expiration date (usually 2 to 4 weeks).

B. Supplies

1. Sterile sticks or inoculating loops
2. Incubators at 42, 35, and 30°C

IV. QUALITY CONTROL

- A. Inspect agar for freezing, contamination, cracks, and dehydration prior to storage and before use. Discard plates that are opaque.
- B. Perform QC on each new lot or shipment of media prior to putting it into use.
- C. Organisms
 1. *B. cereus* ATCC 14579—opaque halo around colony (lecithinase positive)
 2. *Staphylococcus aureus* ATCC 12600—iridescent sheen on and around colony (lipase positive)
 3. *Escherichia coli* ATCC 25922—no change in medium (negative)

V. PROCEDURE

- A. After touching several colonies from an 18- to 72-h culture, inoculate a segment of the agar surface with a very *visible circular* amount of organism about the size of a dime. Then, streak an area to obtain isolated colonies.
- B. For accurate results, incubate as follows without added CO₂ for 24 to 48 h or anaerobically for up to 72 h for anaerobes.
 1. 35°C for *Bacillus*, other gram-positive rods, and anaerobes
 2. 42°C for probable *C. perfringens*
 3. 25°C for fluorescent non-glucose-fermenting, gram-negative rods, except *Pseudomonas aeruginosa*
 4. 30°C for other non-glucose-fermenting, gram-negative rodsExamine for halo and iridescence.

VI. INTERPRETATION

- A. **Lecithin**

Use transmitted light to observe halo.

 1. Positive test: development of a milky white opaque halo around the colony
 2. Negative test: no halo in the medium or around the colony
- B. **Lipase**

Hold the plate on an angle with good lighting.

 1. Positive test: development of an iridescent sheen (mother-of-pearl) on the surface of the colony and the surrounding agar
 2. Negative test: no change in the medium

VII. REPORTING RESULTS

- A. Catalase-positive, spore-forming, gram-positive rods that are lecithinase positive, with large zones of opacity, belong to the *B. cereus* group. Lack of motility separates *B. anthracis* from the other members of the group.
- B. *G. vaginalis* organisms are catalase-negative, gram-variable coccobacilli that are hemolytic on human blood and are lipase positive. A negative test does not rule out the identification, since the biotypes that cause bacterial vaginosis are often lipase negative (1).
- C. A gram-positive rod that is catalase negative, hemolytic, and lecithinase positive is *A. haemolyticum*.
- D. Lecithinase and lipase are useful as part of identification of *Clostridium* to the species level.
 1. *C. perfringens* is lipase negative and lecithinase positive, which can be neutralized by adding anti- α toxin prior to inoculation of the agar (the Nagler reaction).
 2. *C. sporogenes* is lipase positive.
 3. *C. difficile* is both lipase and lecithinase negative.
 4. See section 4 for further tests for identification of *Clostridium* spp.
- E. Among the fluorescent group of non-glucose-fermenting, gram-negative rods, *P. putida* is lecithinase negative and most *P. fluorescens* isolates are lecithinase positive. This test can substitute for gelatin hydrolysis.
- F. *Burkholderia* organisms are often lecithinase positive.

VIII. LIMITATIONS

- A. Ignore a slight clearing around the inoculum.
- B. Zones of opacity are small with non-glucose-fermenting rods.
- C. A negative lecithinase test should be compared to an uninoculated control plate, as lecithinase can diffuse throughout the entire agar plate and make interpretation difficult.
- D. Some microorganisms may require up to 1 week to produce a positive lipase reaction.
- E. Not all *P. fluorescens* isolates are lecithinase positive.

REFERENCES

- 1. **Aroucheva, A. A., J. A. Simoes, K. Behbakht, and S. Faro.** 2001. *Gardnerella vaginalis* isolated from patients with bacterial vaginosis and from patients with healthy vaginal ecosystems. *Clin. Infect. Dis.* **33**:1022–1027.
- 2. **MacFaddin, J. F.** 2000. *Biochemical Tests for the Identification of Medical Bacteria*, 3rd ed., p. 273–281, 286–293. The Lippincott, Williams & Wilkins Co., Philadelphia, Pa.

APPENDIX 3.17.27–1

Preparation of Egg Yolk Agar Medium (1)

McClung and Toabe agar, modified for lecithinase and lipase tests

Proteose no. 2 peptone or	
Polypeptone (BBL)	40.0 g
disodium phosphate	5.0 g
monopotassium phosphate	1.0 g
sodium chloride	2.0 g
magnesium sulfate	0.1 g
glucose	2.0 g
hemin solution, 5 mg/ml	1.0 ml
agar	20.0 g
water	1.0 liter

- A. Suspend ingredients, and adjust the pH to 7.6.
- B. Mix, and boil to dissolve.
- C. Dispense 20 ml per tube, and autoclave at 118°C for 15 min.
- D. Cool to 50°C, and to each tube, add 2 ml of commercial egg yolk emulsion or 1 ml of egg yolk emulsion prepared as follows.
 - 1. Scrub, and then soak, an antimicrobial agent-free hen egg in 95% ethanol for 1 h.
 - 2. Aseptically aspirate or separate the egg yolk.
 - 3. Add equal volumes of egg yolk to sterile saline and stir to make smooth suspension.
- E. Mix, and pour into plates.

Reference

- 1. **Phillips, E., and P. Nash.** 1985. Culture media, p. 1064–1065. In E. H. Lennette, A. Balows, W. J. Hausler, Jr., and H. J. Shadomy (ed.), *Manual of Clinical Microbiology*, 4th ed. American Society for Microbiology, Washington, D.C.

3.17.28

Lipophilism Test for *Corynebacterium*

I. PRINCIPLE

Some strains of *Corynebacterium* grow better in the presence of added lipid. Such strains are called lipophilic or rabbit serum stimulated. They may also require lipid for growth (3). By adding a drop of serum to a plain Mueller-Hinton agar (MH) plate on which the isolate has been inoculated, the

requirement or enhancement of growth with added lipid can be determined. In the tube test, growth is evaluated compared to growth in a broth culture that has not been enriched with rabbit serum. 1.0% Tween 80 can be used as a substitute for serum.

II. MICROORGANISMS TESTED

Catalase-positive, gram-positive rods as part of the identification of *Corynebacterium* to the species level

III. MEDIA, REAGENTS, AND SUPPLIES

A. Media and reagents

1. MH
2. Andrade's glucose broth or BHI
3. Filter-sterilized rabbit serum (no. 16120-099; Invitrogen Life Technologies, Carlsbad, Calif.)
 - a. Store at -20°C in small aliquots.
 - b. Heat for 1 h at 60°C prior to use.
4. Sterile 0.85% NaCl

B. Other supplies

1. Sterile sticks and swabs
2. Incubator at 35°C with 5% CO_2
3. 0.5 McFarland standard

IV. QUALITY CONTROL

- A. Test each lot of rabbit serum for sterility by inoculating 1 drop into BHI or onto MH. No increase in turbidity should be seen, and Gram stain of broth should show no organisms. No colonies should be present on MH.
- B. Test each lot of rabbit plasma to verify that it will enhance the growth of *Corynebacterium*.
- C. Organism
Corynebacterium jeikeium ATCC 43734—growth in broth or on MH with rabbit serum but not without it

V. PROCEDURE

A. Plate method

1. Emulsify the test organism in sterile saline to match a no. 0.5 McFarland standard.
2. Dip swab into saline and inoculate MH for confluent growth as for disk susceptibility testing (procedure 5.1). Allow to dry.
3. Place 1 drop of rabbit serum on plate. Allow to dry.
4. Incubate for 24 h at 35°C in 5% CO_2 .
5. Observe for growth.

V. PROCEDURE (*continued*)**B. Broth method**

1. Warm two tubes of either Andrade's broth with glucose or BHI broth to room temperature.
2. Add 1 drop of rabbit serum to one tube; label as "rabbit serum added."
3. Inoculate both tubes from several colonies of a 24- to 48-h culture.
4. Incubate for 24 h at 35°C in 5% CO₂.
5. Observe for growth.

VI. INTERPRETATION**A. Positive test**

1. Plate test: enhanced growth on top of and immediately around the drop size area where the serum was inoculated compared to the areas where no serum was present
2. Tube test: enhanced growth (and red color in Andrade's tube if glucose positive) in tube with serum but no growth or poor growth and no color change in tube without serum

B. Negative test

1. Plate test: no enhancement of growth around the serum drop. Growth will be uniform on MH.
2. Tube test: growth (and red color in Andrade's tube if glucose positive) in both tubes.

VII. REPORTING RESULTS

The following species of *Corynebacterium* are lipophilic (3): *C. afermentans* subsp. *lipophilum*, *C. accolens*, *C. bovis*, *C. diphtheriae/intermedius*, *C. jeikeium*, CDC group G, *C. lipophiloflavum*, *C. macginleyi*, CDC group F-1, and *C. urealyticum*.

VIII. LIMITATIONS

- A. This test is an excellent adjunct to kit identification of *Corynebacterium*; results with the kit should be consistent with the results of this test (1, 2, 4).
- B. This test cannot be performed using CHOC, since most species of *Corynebacterium* will grow on this medium.
- C. Tween 80 (polysorbate 80) can be used as an alternative to rabbit serum.

3.17.29

Malonate Test

I. PRINCIPLE

The medium for the malonate test contains sodium malonate (1). Malonate is an enzyme inhibitor and inhibits utilization of succinic acid by bacteria, shutting down the Krebs and glyoxylic cycles. Growth is indicative of malonate utilization as a carbon source; a small amount of glucose is also present to stimulate growth of some

organisms. The medium also contains inorganic ammonium salts as the sole source of nitrogen. When the bacterium ferments sodium malonate, sodium hydroxide and sodium bicarbonate are formed, which increases alkalinity of the medium. The shift in pH turns the bromthymol blue indicator

in the medium from green to blue (2). Malonate-negative organisms that ferment glucose cause the indicator to turn yellow or acid. This medium is recommended as part of differentiating among the *Enterobacteriaceae*, especially species of *Klebsiella* and *Salmonella*.

II. MICROORGANISMS TESTED

Enterobacteriaceae as part of the identification to the species level

III. MEDIA, REAGENTS, AND SUPPLIES

A. Media

- Ingredients per liter of deionized water
 - yeast extract1.0 g
 - ammonium sulfate2.0 g
 - dipotassium phosphate0.6 g
 - monopotassium phosphate ...0.4 g
 - sodium chloride2.0 g
 - sodium malonate3.0 g
 - glucose 0.25 g
 - bromthymol blue 0.025 g

- Malonate tablets are also available (Key Scientific). Refer to <http://www.keyscientific.com> for procedure.

B. Supplies

- Sterile inoculating loops or sticks
- Incubator at 35 to 37°C

- Final pH, 6.7
- Store at 2 to 8°C.

IV. QUALITY CONTROL

- Perform QC on each new lot or shipment of media prior to putting it into use.
- Inspect broth for contamination prior to storage and before use. Discard any tubes that are blue.
- Organisms
 - Klebsiella pneumoniae* ATCC 13883—malonate positive (blue color)
 - Escherichia coli* ATCC 25922—malonate negative (green color)

V. PROCEDURE

- Using a loop or stick, inoculate tube with a light inoculum picked from the center of a well-isolated colony (turbidity should be less than a no. 0.5 McFarland standard, i.e., no visible turbidity).
- Incubate aerobically at 35 to 37°C for up to 48 h.
- Observe a color change from green to blue along the slant.

VI. INTERPRETATION

- A. A positive test is growth and change to light blue or deep Prussian blue color throughout the medium.
- B. A negative test is no color change or change from green to yellow due to fermentation of glucose.

VII. REPORTING RESULTS

- A. *Klebsiella ozaenae* is malonate negative; *K. pneumoniae* is malonate positive.
- B. *Citrobacter amalonaticus* is malonate negative; *Citrobacter koseri* is malonate positive.
- C. Use as part of the identification of other *Enterobacteriaceae*.

VIII. LIMITATIONS

- A. Some reactions are slight. Compare to an uninoculated tube when reading.
- B. Do not read reactions before 48 h.
- C. *Yeast extract and glucose are needed to stimulate growth of some Salmonella, organisms but are not generally necessary for other species.*

REFERENCES

- 1. **Leifson, E.** 1933. Fermentation of sodium malonate as a means of differentiating *Aerobacter* and *Escherichia*. *J. Bacteriol.* **26**:329–330.

3.17.30

MGP (Methyl Glucopyranoside) Test

I. PRINCIPLE

MGP broth is used to differentiate enterococci based on the ability to acidify the carbohydrate methyl- α -D-glucopyranoside (MGP). Vancomycin-resistant *Enterococcus faecium* (VREF) is a serious nosocomial problem. *Enterococcus gallinarum* and *Enterococcus casseliflavus*, while not important for purposes of control of nosocomial infections, show intrinsic resistance to vancomycin due to the *vanC* gene (5). *E. gallinarum* and *E. casseliflavus* are difficult to differentiate from

VREF by conventional biochemical tests (4), since they are phenotypically closely related.

Typically, *E. gallinarum* and *E. casseliflavus* can be differentiated from *E. faecium* based on motility: *E. gallinarum* and *E. casseliflavus* are motile, while *E. faecium* is not. However, nonmotile strains of *E. gallinarum* have been detected using standard motility agar (2, 8), although this has not been reported when

the rapid (2-h) motility test is performed (9). Correct identification of these strains is critical due to their difference in pathogenicity. *E. gallinarum* and *E. casseliflavus* acidify MGP, but *Enterococcus faecalis* and *E. faecium* do not (1, 2, 3, 6, 8). This makes the MGP test useful in preventing the misidentification of vancomycin-resistant *E. gallinarum* as VREF for laboratories that cannot perform the rapid tube motility test.

II. MICROORGANISMS TESTED

- A. As an alternative to the motility test
 1. Test any gram-positive coccus that is catalase negative and pyrrolidonyl- β -naphthylamide (PYR) positive and grows on plates with 6 μ g of vancomycin per ml or demonstrates resistance to vancomycin by antimicrobial susceptibility testing but shows susceptibility to ampicillin.
 2. Test any isolate that is identified as *E. faecium* by a commercial kit system but is ampicillin susceptible.
- B. Test any *nonmotile* enterococcus that demonstrates resistance to vancomycin with an MIC less than 32 μ g/ml but is ampicillin susceptible.
- C. Test can be performed from any BAP or any plate medium with enterococcal growth, including media with bile-esculin or azide.

III. MEDIA AND SUPPLIES

- A. **Media (Hardy Diagnostics)**
 1. Standard medium per liter of deionized water
 - pancreatic digest of
 - casein 10.0 g
 - sodium chloride 5.0 g
 - MGP 10.0 g
 - phenol red 18.0 mg
 2. Rapid medium per liter of deionized water
 - basal medium 15.0 g
 - indicator 50.0 mg
 - MGP 50.0 g
 3. Store at 2 to 8°C, away from direct light, for up to 6 months.
- B. **Supplies**
 1. Incubator
 2. Sterile sticks, loops, or inoculating needle

IV. QUALITY CONTROL

- A. Examine media for red-orange color (standard tube) or blue color (rapid tube) and lack of turbidity.
- B. Test each lot of medium with a positive and negative control prior to putting it into use.
- C. Organisms
 1. *E. gallinarum* ATCC 49573—medium turns yellow (positive).
 2. *E. faecalis* ATCC 29212—medium remains red or orange (negative).

V. PROCEDURE

- A. **Standard medium**
 1. Inoculate the MGP broth by lightly touching a single, isolated colony. Do not use a heavy inoculum.
 2. Incubate aerobically at 35°C for 24 h.
 3. Observe for yellow color change in the media.
- B. **Rapid medium**
 1. Using a “sweep” of colonies from an 18 to 24-h pure culture of the organism to be tested, stab the rapid MGP medium with an inoculating needle. There should be a cell paste visible on the needle as the medium is being inoculated.
 2. Incubate aerobically at 35°C for 5 h.
 3. Observe for the development of a yellow color along the stab line; this is indicative of a positive test.
 4. Replace weak or inconclusive reactions in the incubator for a total of 24 h for development of a yellow color.
 5. Optional: run controls with each test run to easily distinguish between a negative and positive reaction.

VI. INTERPRETATION

- A. A yellow color change is a positive test for acidification of MGP.
- B. Red or orange color is a negative test in standard media. Blue color is a negative test in the rapid medium.

VII. REPORTING RESULTS

- A. Report as either *Enterococcus gallinarum* or *Enterococcus casseliflavus* if the reaction is positive and the organism is vancomycin resistant or intermediately resistant. The yellow pigment of *E. casseliflavus* separates these two species. Report vancomycin MIC result for treatment purposes; however, do *not* label either of these species, which have the *vanC* genotype, as vancomycin-resistant enterococcus (VRE) for infection control purposes.
 - **NOTE:** The intrinsic, intermediate-level vancomycin resistance (*vanC*) is distinct from acquired resistance (*vanA* or *vanB*) for infection control purposes and does not require measures to prevent nosocomial spread (7).
- B. Report as *Enterococcus faecium* if result is negative and the organism keys out as *E. faecium* by a kit identification method. Also alter infection control to VRE if isolate is vancomycin resistant.
- C. Other enterococci are positive for MGP but are not resistant or intermediate in susceptibility to vancomycin. See Table 3.18.1–3.

VIII. LIMITATIONS

- A. A heavy inoculum may give false-positive results in the standard test.
- B. Extended incubation times may result in false-positive reactions.
- C. Do not test organisms identified as *E. faecalis*, since false-positive results have been reported (1).
- D. Rapid MGP has a sensitivity of 100% and a specificity of 96.5%. The standard test has reported sensitivities of 100% (2) and 98% (6) and a specificity of 95% (2), but two of the three misidentified *E. faecium* isolates were not VREF.
- E. *Vagococcus* gives a positive result (1).
- F. Use of an inoculating needle is recommended for the rapid test, as inocula from a loop can overwhelm the media.
- G. Negative rapid MGP tests may change from their original color, becoming fainter shades of blue. This color change is easily distinguished if positive and negative control tubes are used in parallel with each test being performed.

3.17.31

Motility Tests

I. PRINCIPLE

The motility test is used to detect the presence of flagella by bacteria, allowing them to travel in and out of the microscopic field or beyond their initial inoculation in agar (3). For the wet preparation, a drop of organism in broth is suspended on a clean glass slide, a coverslip is added, and the culture is observed microscopically for

motility. Occasionally the organism is incubated in the broth prior to examination.

In the tube test, semisolid motility medium is inoculated in a straight line down through the center of a tube (4). Motile organisms will migrate out from the line of inoculation, causing visible turbidity

throughout the tube. Nonmotile organisms will grow only along the line of inoculation. Other substrates which allow simultaneous testing of other biochemical reactions that aid in the identification of microorganisms may be added to the medium.

II. MICROORGANISMS TESTED

Campylobacter; *Legionella*; enterococci; *Enterobacteriaceae*; *Listeria*; *Bacillus*; other gram-positive rods; non-glucose-fermenting, gram-negative rods; and any other organism where motility is useful for identification

III. MEDIA, REAGENTS, AND SUPPLIES

A. Media and reagents

1. Broth medium for wet preparation
 - a. TSB, nitrate, or BHI broth
 - b. Voges-Proskauer (VP) cupule of the API strip
 - c. Any agar slants with TSB or BHI broth added (*see* item VIII)
 - d. Saline or distilled water
 - **NOTE:** Cleary (1) reported that some motile organisms can become immobile in distilled water.
2. Motility tube media
 - a. Combination of sulfide for H₂S detection, indole, and motility test medium (SIM)
 - b. Motility test medium with or without TTC (triphenyltetrazolium chloride, a colorless vital dye incorporated into the medium, which turns red as it is reduced when incorporated into bacteria; the dye allows visualization of the bacteria)

c. Motility nitrate medium

- d. Combination of motility test medium, indole, and lysine decarboxylase
- e. Combination of motility test medium, indole, and ornithine decarboxylase (MIO)
 - **NOTE:** Motility medium contains 5 g of agar per liter and can be prepared in-house in agar plates that are incubated agar side down. Motile organisms move from the point of inoculum to the edges of the plate.

B. Supplies

1. 22- by 22-mm coverslips and microscope slides
2. Phase-contrast or bright-field microscope
3. Sterile inoculating needle or sticks

IV. QUALITY CONTROL

A. Test each new lot or shipment of tube media prior to use with a positively and negatively reacting organism and for sterility.

B. Organisms

Organism	ATCC no.	Media	Motility	Indole	H ₂ S	Lysine	Ornithine
<i>Escherichia coli</i>	25922	All	+	+	-	-	+

C. Competence of technologists in the hanging-drop test is validated by testing known motile enterococci or *Listeria* in the broth assay.

V. PROCEDURE
A. Wet mount preparation

1. Inoculum: use *fresh* growth from an agar plate and suspend isolated colonies in broth. Use a light inoculum (not visibly turbid).

a. It is acceptable to suspend the organism in a small amount of medium for an initial wet mount, but follow with incubation of a larger amount of broth media if the result is negative.

b. Choosing the medium

(1) Use any broth which does not contain carbohydrate and will support the growth of the organisms (BHI, nitrate broth).

(2) Always use a broth for *Bacillus* spp. (1).

(3) Use 0.5 ml of BHI or TSB for enterococci.

(4) Saline can be used for gram-negative rods.

(5) Use warm sterile tap water for *Legionella*.

(6) A drop from the VP microtube of the incubated API 20E strip may be used before the reagents are added. However, a negative test must be repeated in a non-carbohydrate-containing broth.

(7) For problem organisms, streak an agar slant and then carefully add a few drops of BHI or nutrient broth to the base of the slant, covering just a bit of the streaked slant. After overnight incubation, use a drop of the BHI broth for the wet mount (this works very well for non-fermenting gram-negative rods).

2. Examination

a. While wearing gloves, place a small drop of fresh liquid on the center of a microscope slide; add coverslip. Allow organisms to “settle” for a minute.

b. Observe under high power (40×).

(1) For a light microscope, decrease the light by closing the diaphragm.

(2) Preferably, use a phase-contrast microscope.

3. For all organisms negative for motility by initial wet mount, repeat the wet mount after incubation in broth, or test by tube method below.

a. Incubate at 30°C for nonfermenting, gram-negative rods (24 h).

b. Incubate enterococci and *Listeria* at 30°C for 2 h (5, 8).

c. Other organisms may be incubated at temperatures optimal for their growth, usually 35°C.

B. Tube media for *Enterobacteriaceae*; nonfermenting, gram-negative rods; and *Listeria*

1. With a sterile inoculating wire, pick an isolated colony and stab the medium straight down through the center to a depth of 1/2 in. for small tubes and 1 in. for larger tubes.

V. PROCEDURE (*continued*)

2. Incubate as follows.
 - a. At 35°C for *Enterobacteriaceae* for 24 h.
 - b. At 30°C for nonfermenting, gram-negative rods and enterococci for 24 h.
 - c. If there is a question regarding a negative result, incubate at 25°C.
 - d. For *Listeria* and *Yersinia*, incubate two tubes, one at 35°C and one at 25°C.

VI. INTERPRETATION**A. Wet mount preparation**

1. Directional purposeful motility is a positive test. Motile organisms change position with respect to one another. Brownian movement (random jiggling or shaking due to molecular bombardment), where the organisms remain in the same relative position with respect to each other, should not be mistaken for true motility (9).
2. *Campylobacter* organisms display a very active motility which appears as tiny dots darting in and out of the field.

B. Tube media

1. Diffuse growth outward away from stab line or turbidity of the media is a positive test.
2. A clear tube (the same as the uninoculated media) with growth only along the line of inoculation indicates that the organism is nonmotile.
3. In media with TTC, the red color forms in the area of bacterial growth. Motile organisms produce a pink color that diffuses from the stab line. Organisms that are nonmotile produce a pinkish red pigment that is confined to the stab line.

VII. REPORTING RESULTS

- A. *Bacillus* spp. should be motile. Lack of motility could indicate *Bacillus anthracis*.
- B. *Enterococcus casseliflavus* and *Enterococcus gallinarum* are motile.
- C. *Listeria* organisms are motile at 25°C but not at 35°C, with a characteristic umbrella-shaped growth at the top of the tube. On wet mount they exhibit tumbling motility.
- D. *Yersinia enterocolitica* is motile at 25°C but not at 35°C.
- E. *Acinetobacter* organisms are nonmotile.
- F. Nonfermenting, gram-negative rods and *Enterobacteriaceae* vary in their motility.

VIII. LIMITATIONS

- A. Studies by Edmondson and Sanford (2) showed that nonmotile, mucoid *Klebsiella* strains may give a false-positive motile reaction in tube media; this is due to mucoid strains spilling between medium and the tube, giving a cloudy appearance which is often confused with motility. False-positive results can be avoided by use of media with adequate tube depth and careful reading with attention to the density of growth in the central stab.
- B. *Bacillus* species are best tested directly from a fresh plate. If a fresh plate is not available, inoculate a plate and incubate for 4 h. Then perform wet mount.
- C. A large number of *E. casseliflavus* and *E. gallinarum* organisms have been reported as nonmotile using some tube motility agar (6, 7). If a vancomycin MIC is between 4 to 16 µg/ml and the isolate is ampicillin susceptible, but the enterococcus is nonmotile, confirm results with the 2-h broth method or perform the MGP test (procedure 3.17.30).

VIII. LIMITATIONS (continued)

- D. Motility results for enterococci with MIO have been reported to have poor sensitivity (7).
- E. Excessive heat on a microscope slide can affect the results.
- F. False-negative reactions may occur if bacterial flagella are damaged due to heating, shaking, or other trauma. Such environmental shock will render the organism nonmotile.
- G. Some microorganisms do not produce flagellar proteins at 35 to 37°C but do so at 22°C.
- H. TTC may be inhibitory to certain fastidious bacteria.

3.17.32

MRS Broth

I. PRINCIPLE

Gas production by gram-positive rods is tested in glucose-containing medium called lactobacillus MRS broth, named for the authors of the publication (1). MRS broth is helpful to differentiate *Leuconostoc* spp. and *Weissella confusa* (previously called *Lactobacillus confusus*) from

Pediococcus, which is gas negative (2, 4, 5). The gas is detected by a rise in a petroleum jelly plug or displacement of broth with air in the Durham tube. Sufficient gas is not produced in ordinary sugar fermentation tubes to detect these organisms.

II. MICROORGANISMS TESTED

Vancomycin-resistant, catalase-negative, gram-positive coccobacilli that are pyridonol- β -naphthylamide (PYR) negative and grow aerobically

III. MEDIUM, REAGENTS, AND SUPPLIES

A. MRS broth

Store at 4 to 8°C.

1. Purchase from most vendors.
2. Prepare from dehydrated powder (Difco, BBL, BD Diagnostic Systems, Hardy Diagnostics), dispense into tubes with Durham tube (optional), and autoclave.

B. Gas detection options

1. Vaspar, liquid paraffin, or petroleum jelly, maintained at 56°C in liquid form
2. Durham tube

C. Other supplies

1. Sterile sticks
2. Incubator at 35°C

IV. QUALITY CONTROL

- A. Examine media for lack of turbidity. Invert if there is a Durham tube and it contains a bubble.
- B. Test each new lot or shipment of medium with a positive and negative control prior to putting it into use.
- C. Organisms
 1. *Leuconostoc mesenteroides* ATCC 10830—Gas produced (positive)
 2. *Enterococcus faecalis* ATCC 29212—no gas (negative)

V. PROCEDURE

- A. Inoculate MRS broth lightly with one or two colonies from an 18- to 24-h BAP.
- B. If a Durham tube is not used, overlay the inoculated MRS broth with a plug of melted Vaspar or petroleum jelly, being careful to cover broth layer entirely without introducing air.
- C. Incubate aerobically at 35°C for up to 7 days, and observe daily for gas trapped in the Durham tube or solid plug.

VI. INTERPRETATION

- A. A positive test shows a visible lifting of the Vaspar plug resulting in complete separation from the broth surface or trapped gas in the Durham tube. Positive reactions usually raise wax plugs within 48 h.
- B. A negative test shows no lifting of the wax plug or no gas bubble in the Durham tube.

VII. REPORTING RESULTS

- A. Streptococci, lactobacilli, and *Pediococcus* do not produce gas from glucose.
- B. *Leuconostoc* and *W. confusa* are positive for gas.
 1. Prepare a Gram stain from the MRS broth.
 2. *Leuconostoc* is the only genus that produces coccoid forms as well as coccobacilli and rods. It is arginine deaminase negative and does not grow at 42°C (3).
 3. *W. confusa* is a gas producer but does not have coccoid forms, is generally arginine positive, and grows at 42°C (3).

VIII. LIMITATIONS

- A. The Durham tube is a safer alternative to petroleum jelly, since strains of *Leuconostoc* can produce copious amounts of gas. However, the Durham tube method does not work as well.
- B. The difficulty in separating *Weissella* and *Leuconostoc* may result in a misidentification, if the Gram stain is equivocal and other biochemical tests are not performed.

3.17.33

MR-VP (Methyl Red–Voges-Proskauer) Tests

I. PRINCIPLE

The methyl red (MR) test is used to determine if an organism is able to produce stable acid end products from glucose fermentation (2). Methyl red indicator (red color below pH 4.4; yellow color at pH 5.8) is used to determine the pH after an enteric gram-negative rod has fermented glucose to completion. All members of the *Enterobacteriaceae* give a positive methyl red reaction when tested up to 24 h due to conversion of glucose to pyruvic acid by the Embden-Meyerhof pathway. After further incubation (2 to 5 days) those organisms that are MR positive continue to me-

tabolize pyruvic acid to lactic, acetic, and formic acids by the mixed acid pathway and are able to maintain the acid pH (<4.4). Organisms utilizing the butylene glycol pathway produce acetylmethylcarbinol (acetoin) and butanediol, neutral end products that raise the pH towards neutrality (pH > 6) and result in a high final pH. Most *Enterobacteriaceae* demonstrate one or the other metabolic pathway but rarely both.

The Voges-Proskauer (VP) test (9) is used to determine if an organism produces

acetylmethylcarbinol from glucose fermentation. If present, acetylmethylcarbinol is converted to diacetyl in the presence of α -naphthol, strong alkali (40% KOH), and atmospheric oxygen. The α -naphthol was not part of the original procedure but was found to act as a color intensifier by Barritt (1) and must be added first. The diacetyl and guanidine-containing compounds found in the peptones of the broth then condense to form a pinkish red polymer (8).

II. MICROORGANISMS TESTED

- A. MR test for enteric gram-negative rods, as part of identification to species level
- B. VP test for identification to the species level of the following groups of organisms
 - 1. Enteric gram-negative rods, *Aeromonas*, and *Vibrio*
 - 2. Viridans group streptococci (4)
 - 3. Staphylococci

III. MEDIA, REAGENTS, AND SUPPLIES

- A. **Media**
 - Store broths at 4 to 8°C.
 - 1. Andrade's 1% glucose broth (*to be used for VP testing only, not for MR testing*)
 - 2. MRVP broth (pH 6.9)
 - Ingredients per liter of deionized water:
 - buffered peptone7.0 g
 - glucose5.0 g
 - dipotassium phosphate5.0 g
 - 3. Volumes
 - a. Generally dispense approximately 5 ml per tube.
 - b. Use enough broth to cover an inverted Durham tube, if it is used.
 - c. Dispense 2 ml of MRVP broth for rapid VP testing and 0.5 ml for rapid MR testing.
 - 4. MRVP tablets with creatine (Key Scientific) for rapid test. Refer to <http://www.keyscientific.com> for procedures.
- B. **Reagents**
 - 1. 40% Potassium hydroxide
 - Caution:** KOH is hygroscopic and becomes caustic when moist. Weigh quickly in tared beaker. Store away from acids. Avoid exposure to skin.
 - a. Dissolve 40 g of potassium hydroxide pellets in 100 ml of distilled water in a polyethylene bottle. Keep bottle in cool water bath during preparation.

III. MEDIA, REAGENTS, AND SUPPLIES (continued)

Include QC information on reagent container and in QC records.

- b. Optional: add 0.3 g of creatine (*N*-methyl-*N*-guanylglycine) for more rapid and sensitive reaction (3). Creatine should *not* be added if reagent is used for the API 20E or the tablets from Key Scientific, since it is in the media.
 - c. Store at 4 to 8°C.
 - d. Shelf life: 2 to 3 weeks (8)
2. 5% α -Naphthol (5 g/100 ml) in 95% ethyl alcohol (3)
 - a. Store at 4 to 8°C in the dark.
 - b. Shelf life: 2 to 3 weeks
 - c. Reagent should be almost colorless.
3. Methyl red solution, 0.02%
 - a. Dissolve 0.1 g of methyl red in 300 ml of ethyl alcohol, 95%.
 - b. Add sufficient distilled water to make 500 ml.
 - c. Store at 4 to 8°C in a brown bottle.
 - d. Solution is stable for 1 year.
4. Reagents with extended shelf life are commercially available from most vendors.

C. Supplies

1. Sterile wooden sticks or inoculating loops
2. Test tubes

IV. QUALITY CONTROL

- A. Examine broth for signs of contamination, dehydration, and deterioration.
- B. Perform QC on each new lot or shipment of media and reagent prior to use with one organism known to demonstrate a positive reaction and one organism known to give a negative reaction.
- C. Organisms
 1. *Klebsiella pneumoniae* ATCC 13883—MR negative (yellow), VP positive (red)
 2. *Escherichia coli* ATCC 25922—MR positive (red), VP negative (no change)

V. PROCEDURE

A. VP test

1. Inoculate a tube of 1% glucose broth (Andrade's base) or MRVP broth with colony of the organism to be tested and incubate at 35°C for 18 to 24 h. *Do not tighten caps.*
 - **NOTE:** Some organisms may produce acetylmethylcarbinol at room temperature and not 35°C (e.g., *Hafnia alvei*, *Yersinia*, *Listeria*). In this case, inoculate another broth and incubate at room temperature.
2. If a 5-ml broth culture is used, aliquot 2.0 ml of broth into a nonsterile 13-by 100-mm test tube. Hold the remainder for possible reincubation.
 - **NOTE:** If the glucose broth contains a Durham tube, be careful not to introduce air bubbles into it when the 2.0 ml of broth is poured into the nonsterile tube for testing.
3. Add 6 drops of 5% α -naphthol, and mix well to aerate.
4. Add 2 drops of 40% potassium hydroxide, and mix well to aerate.
5. Observe for a pink-red color at the surface within 30 min. Shake the tube vigorously during the 30-min period.
 - **NOTE:** If the result is negative, the glucose or MRVP broth can be incubated for up 48 h and the test repeated.

B. MR test

1. Inoculate tube as for VP test and incubate at 35°C for at least 48 h.
 - **NOTE:** If the center of one colony is inoculated to a 0.5-ml volume of MRVP broth, the test can be read at 18 to 24 h (8).
2. Remove approximately 1 ml of the 48-h broth to a nonsterile 13-by 100-mm tube. (The remainder should be reserved for testing at 3 to 5 days if necessary.)
3. Add 3 to 6 drops (or 1 drop to 0.5 ml) of methyl red indicator to aliquot.
4. Observe for red color immediately.

VI. INTERPRETATION**A. VP test**

1. A pink-red color at the surface is a positive reaction.
2. A lack of a pink-red color is a negative reaction.
3. A copper color should be considered negative. A rust color is a weak positive reaction.

B. MR test

1. A positive reaction is a distinct red color.
2. A negative reaction is a yellow color.
3. A weak positive is red-orange.
4. If an orange color is seen, incubate the remainder of the broth for up to 4 days and repeat the test after further incubation. In this case it may also be helpful to set up a duplicate broth at 25°C.

VII. REPORTING RESULTS

- A. Organisms in the *E. coli* group are MR positive, and those in the *Enterobacter-Klebsiella* group are MR negative (5, 7).
- B. Most members of the family *Enterobacteriaceae* give opposite MR and VP reactions; however, certain organisms, like *H. alvei* and *Proteus mirabilis*, may give both a positive MR reaction and a positive VP reaction (often delayed) (5, 7).
- C. *Streptococcus mitis* group organisms are VP negative, whereas the other viridans group streptococci are VP positive, except *Streptococcus vestibularis*, which is VP variable (4).
- D. Refer to procedure 3.8.1 for VP reactions of *Vibrio*, *Plesiomonas*, and *Aeromonas*.
- E. *Listeria* organisms are beta-hemolytic, gram-positive rods that are VP positive at 25°C, but this test is not a key test in the identification.

VIII. LIMITATIONS

- A. Increased exposure of the organism to atmospheric oxygen in the microtechnique decreases the incubation period.
- B. Avoid overinoculation. Bacterial growth is inhibited when the inoculum exceeds approximately 10⁹ viable cells per ml (8).
- C. If not enough incubation time is allowed before the methyl red indicator is added, a false-positive result may be obtained.
- D. With prolonged incubation (>3 days), some VP-positive organisms can produce an acid condition in the medium, yielding weak positive reactions or false-negative VP reactions.
- E. Shaking the tubes enhances the VP reaction.
- F. Do not add more than 2 drops of KOH per 2 ml of medium. Excess amounts of KOH can give a weak positive reaction, which may be masked by the formation of a copperlike color because of the reaction of KOH with α -naphthol alone.
- G. Do not read the test more than 1 h after adding the VP reagents. A copperlike color may develop, resulting in a potential false-positive interpretation.
- H. Reagents must be added in the specified order. A reversal of order may result in a weak positive or false-negative VP result.
- I. When performing the VP test for the API 20E, add 1 drop of KOH followed by 1 drop of α -naphthol. This is opposite to the order for adding reagents in the standard test. Creatine is present in the cupule and is not needed in the KOH reagent used for the test (API 20E package insert).

VIII. LIMITATIONS (continued)

J. The original study by Barritt (1) using α -naphthol indicated that it should be prepared in absolute (100%) ethanol, but the Coblenz method (3) using 95% ethanol and creatine in the KOH is more rapid and sensitive (6, 8, 10). For the Coblenz method, use a very heavy inoculum in 2 ml of MRVP broth and creatine in the KOH, and read the test as soon as 6 h (6, 10).

3.17.34

MUG (4-Methylumbelliferyl- β -D-Glucuronide) Test

I. PRINCIPLE

Escherichia coli and rare other *Enterobacteriaceae* (*Salmonella*, *Yersinia*, and *Shigella*) produce the enzyme β -glucuronidase. This enzyme hydrolyzes the substrate 4-methylumbelliferyl- β -D-glucuronide (MUG), releasing 4-methylumbelliferone, which fluoresces blue under

long-wave UV light (4). Since 97% of *Escherichia coli* strains possess the β -glucuronidase enzyme, the MUG test can be used for rapid identification of *E. coli*, the most common gram-negative rod seen in clinical specimens (1, 2, 4, 5, 6, 8, 10). Since verotoxin-producing *E. coli* strains

are among the few *E. coli* strains that do not produce MUG, this test can also be used to detect the absence of the enzyme in a fecal isolate of *E. coli* to alert the microbiologist to the possible presence of a verotoxin-producing strain (7, 9).

II. MICROORGANISMS TESTED

A. Fresh colonies on BAP of possible *E. coli* organisms that are indole-positive, oxidase-negative, gram-negative rods, whether they are lactose positive or negative.

▣ **NOTE:** For the tube test, colonies from EMB, but not MAC, can be used.

B. Do not use this test as part of an algorithm to rapidly identify *E. coli* in abdominal sources, since occasional isolates of both *Salmonella* and *Shigella* can be MUG positive. However, the test can be used to separate potential verotoxin-producing *E. coli* (MUG negative) from other *E. coli* strains (usually MUG positive) in gastrointestinal specimens, once the isolate has been identified as *E. coli*.

III. MEDIA, REAGENTS, AND SUPPLIES

Include QC information on reagent container and in QC records.

A. Reagents

1. Purchase MUG as disks from commercial vendors.

a. MUG disks: Hardy, Inc.; Key Scientific; Oxoid, Inc.; Remel, Inc.

b. BactiCard *E. coli*: MUG and indole on a filter card (Remel, Inc.)

2. Prepare MUG from powder (Sigma Chemical Co.).

a. M/15 Sorensen's phosphate buffer, pH 7.5

(1) M/15 Na_2PO_4 (solution A)

(a) 4.730 g of Na_2HPO_4

(b) q.s. to 500 ml with sterile distilled water.

(2) M/15 KH_2PO_4 (solution B)

(a) 4.535 g of KH_2PO_4

(b) q.s. to 500 ml with sterile distilled water.

(3) Combine 85 ml of solution A and 15 ml of solution B.

▣ **NOTE:** Check final pH; adjust to pH 7.5 with either solution if necessary (solution A to make more alkaline; solution B to acidify).

(4) Store at room temperature.

III. MEDIA, REAGENTS, AND SUPPLIES (continued)

- b. MUG liquid reagent or stock for disks
- (1) Dissolve 50 mg of MUG in 100 ml of Sorensen's buffer.
 - (2) This is a 500- μ g/ml stock solution.
 - (3) Label, aliquot, and store at -20°C in convenient amounts.
 - (4) Shelf life: 1 year at -20°C or 1 week at 4°C in the dark (cover tubes in refrigerator with foil to keep from light).
- c. Disk preparation
- (1) Add 0.2 ml of stock MUG solution to 3.2 ml of M/15 Sorensen's phosphate buffer to prepare a 1:16 dilution.
 - (2) Add 1.25 ml to a vial of 50 sterile 6-mm-diameter paper disks (BD Diagnostic Systems; Hardy, Inc.). Allow to thoroughly saturate disks so that no fluid hangs on the sides of vial (0.78 μ g/disk).
 - (3) Spread the saturated disks onto a metal screen and place in a dry environment until the disks are completely dry. Protect from light.
 - (4) Store disks at -20°C , away from the light, for up to 1 year or at 4°C for up to 1 month.
- B. Supplies**
1. Long-wave UV light (366 nm; e.g., Wood's lamp)
 2. Wooden sticks or inoculating loops
 3. 35 to 37°C incubator
 4. Empty petri dish or Durham tubes

IV. QUALITY CONTROL

- A. Perform QC on each new lot or shipment of disks or liquid reagent prior to putting it into use.
- B. Organisms
1. *E. coli* ATCC 25922—blue fluorescence (positive)
 2. *Klebsiella pneumoniae* ATCC 13883 or ATCC 27736—no fluorescence (negative)

V. PROCEDURE

- A. MUG tube test
1. Place 2 drops of MUG reagent in Durham tube.
 2. Remove one colony from BAP or EMB with sterile stick and inoculate tube.
 - **NOTE:** For commercial products, place 0.25 ml of deionized water in a glass (not soda lime glass) tube and add the MUG disk to the tube after inoculation with the colony.
 3. Incubate for at least 2 h at 35°C without added CO_2
 - **NOTE:** MUG reactions occasionally take 4 h to turn positive.
 4. Observe fluorescence using long-wave UV light in a darkroom.
- B. MUG disk method
1. Place disk in sterile empty petri dish and wet with 1 drop of water.
 - **NOTE:** If excess water is used, test may be falsely negative.
 2. Using a wooden stick or bacteriological loop, roll colony from a BAP onto the disk.
 - **NOTE:** Alternatively, place the disk directly over the colony and incubate for 30 min. Observe for fluorescence and reincubate disk for up to 2 h.
 3. Incubate at 35°C for a minimum of 2 h (test can be read up to 24 h, but 2 h is usually sufficient).
 4. Observe the disk using long-wave UV light in a darkened room.

VI. INTERPRETATION

- A. A positive test is bright blue-white fluorescence.
- B. A negative test is lack of blue fluorescence.
- ☑ **NOTE:** It may be helpful, when interpreting the tube test, to observe an uninoculated tube when evaluating the fluorescence. When interpreting weak reactions with the disk test, after incubation, place the disk in 2 ml of sterile saline. Observe as for tube test after 10 min.

VII. REPORTING RESULTS

- A. *E. coli* is definitively identified if a gram-negative rod is indole positive, oxidase negative, and MUG positive (11).
- B. *E. coli* O157:H7 is indole positive and MUG negative.

VIII. LIMITATIONS

- A. Not all *E. coli* organisms are MUG positive. A negative test does not mean that the organism is not *E. coli*.
- B. Do not use media that contain dyes (e.g., EMB, MAC) for the disk test, although the dyes do not interfere with the tube test.
- C. Of *Shigella* species that are indole positive, approximately 8% are also MUG positive. Rare isolates of *Salmonella* and *Yersinia* are also MUG positive. However, they are rarely indole positive. Thus, to avoid a misidentification, lactose-negative organisms from abdominal sources or from blood should not be tested using this method.
- D. Some fluorescing organisms, such as *Pseudomonas aeruginosa*, may resemble a positive MUG result. Therefore, the test should not be performed on oxidase-positive organisms.
- E. Some organisms fluoresce orange, which is not considered a positive reaction.
- F. Rare MUG-positive *E. coli* O157 strains have been reported (3).

3.17.35

Nitrate/Nitrite Reduction Test

I. PRINCIPLE

Nitrate broth and nitrite broth are used to determine if an organism can reduce nitrate (NO_3^-) to nitrites (NO_2^-) and reduce nitrites further. The reduction of nitrate is associated with anaerobic respiration in which the organism derives its oxygen from nitrate. The end products of nitrate reduction include nitrite, ammonia, molecular nitrogen (N_2), hydroxylamine, and other related compounds.

The presence of nitrites resulting from the reduction of nitrate is detected by the formation of a red diazonium compound when sulfanilic acid, α -naphthylamine, and nitrite react. The nitrite combines with

acetic acid to form nitrous acid which will diazotize sulfanilic acid to a diazonium salt. The dimethyl-naphthylamine couples with the diazo compound to form a red dye. Nitrogen gas is detected as gas trapped in a Durham vial inverted in the nitrate or nitrite broth (3).

The reduced nitrogen compounds are not detected directly but are inferred if there is no gas or nitrite but nitrate has been reduced. This is tested by adding zinc dust to the reaction tube to detect unreduced nitrate after the sulfanilic acid and α -naphthylamine have been added but did not produce the red color. The zinc dust

will reduce the remaining nitrate to nitrite and the red color develops. If nitrite is not present, because it has been previously reduced to nitrogen compounds, no red color develops after addition of zinc and the test is positive for both nitrate and nitrite reduction.

The test is useful in the evaluation of non-glucose-fermenting and fastidious gram-negative rods and in differentiating *Moraxella catarrhalis* from *Neisseria* (2). The test also confirms membership in the family *Enterobacteriaceae*. The disk test is used for anaerobic nitrate testing (see section 4).

II. MICROORGANISMS TESTED

- A. Gram-negative rods and gram-negative cocci (*Neisseria* spp.) as part of their identification (2, 4)
- B. Gram-positive, non-spore-forming bacilli that grow aerobically
- C. Anaerobic organisms

III. MEDIA, REAGENTS, AND SUPPLIES

Include QC information on reagent container and in QC records.

A. Media

1. Nitrate broth: store at 2 to 8°C.
 - peptone 20 g *or*
 - heart infusion broth for
 - fastidious organisms 25 g
 - potassium nitrate 2 g
 - distilled water 1,000 ml

Dispense 4-ml aliquots in 16- by 125-mm screw-cap tubes with Durham tube. Autoclave at 121°C for 15 min.

2. Nitrite broth: store at 2 to 8°C.
 - heart infusion broth 25 g
 - potassium nitrite 0.1 to 1 g
 - distilled water 1,000 ml

Dispense 4-ml aliquots in 16- by 125-mm screw-cap tubes with Dur-

ham tube. Autoclave at 121°C for 15 min.

3. Glucose cupule of the API 20E strip
4. Nitrate disk (available commercially) for anaerobic organisms
5. Nitrate tablets (Key Scientific) for both media and reagents

B. Reagents

1. 0.8% Sulfanilic acid (reagent A)
 - sulfanilic acid 0.8 g
 - distilled water 70 ml
 - glacial acetic acid 30 ml
 - a. Mix sulfanilic acid with water; heat to dissolve.
 - b. Cool, and then add acetic acid.

III. MEDIA, REAGENTS, AND SUPPLIES (continued)

- c. Store at 2 to 8°C.
d. Shelf life is 3 months.
2. 0.5% *N,N*-Dimethyl- α -naphthylamine (reagent B)
- glacial acetic acid 30 ml
distilled water 70 ml
N,N-dimethyl- α -naphthylamine0.5 g
- a. Combine acetic acid and water. Add α -naphthylamine.
- b. Store at 2 to 8°C.
c. Shelf life is 3 months.
 NOTE: The purchase of this reagent is preferred to preparation in-house, since special precautions must be taken in handling concentrated *N,N*-dimethyl- α -naphthylamine, a potential carcinogen.
3. Zinc metal dust

IV. QUALITY CONTROL

- A. Examine tubes for contamination. Invert to remove bubbles in the Durham tube prior to storage of product.
- B. Test each new lot or shipment of media and reagents with a positively and negatively reacting organism prior to putting it into use.
 NOTE: New lots of reagent can be checked without inoculation either with nitrate broth by adding zinc after the reagents are added or with nitrite broth directly. If the reagents give a red color, they are acceptable and have detected nitrite.
- C. Organisms
1. *Escherichia coli* ATCC 25922—nitrate positive, gas negative
 2. *Pseudomonas aeruginosa* ATCC 27853—nitrate positive, gas positive
 3. *Acinetobacter baumannii* ATCC 19606—nitrate negative
 4. Alternative positive control: *Campylobacter jejuni* ATCC 33560—nitrate positive

V. PROCEDURE

- A. **Tube method**
1. Before inoculating the broth, check the Durham tube for trapped air bubbles. If necessary, invert the tube until the air bubbles are gone.
 2. Inoculate the tube of nitrate broth from an isolated colony; a pure subculture or, preferably, 1 to 2 drops of an overnight broth culture of the organism. Subsequently, if nitrate has *not* been reduced, determine reduction of nitrite by inoculation of nitrite broth in the same manner.
 3. Incubation
 - a. Nonfermenting, gram-negative rods, 25 to 30°C
 - b. Other organisms, 35°C
 - c. Two to five days of incubation may be necessary for some organisms.
 - d. Incubate *Campylobacter* at 35°C in a microaerobic atmosphere for 72 h.
 4. Look for and record any gas in the Durham vial and growth in the tube. *Do not add reagents if there is no visible growth in the tube.*
 5. *If gas is present* and the organism does not ferment glucose in Kligler's iron agar or triple sugar iron agar, do not add reagents because the test is considered positive for nitrate reduction, nitrite reduction, and gas.
 6. If no gas is present *or* the organism is a glucose-fermenting, gram-negative rod (i.e., *Enterobacteriaceae*), remove approximately 0.5 ml of broth into a nonsterile 13- by 100-mm tube.
 - a. Add 2 or 3 drops of reagent A. Mix well by tapping or shaking tube.
 - b. Then, add 2 or 3 drops of reagent B. Mix again.
 - c. Look for a red color within 1 to 2 min.

V. PROCEDURE (*continued*)

7. If no red color is observed, add a small amount of zinc dust to the nitrate tube. *Do not add zinc dust to nitrite.*
 - a. The amount of zinc dust should not exceed that which adheres to the end of an applicator stick.
 - b. Examine for red color within 10 min.
8. If nitrate or nitrite has not been reduced or there is no gas production, reincubate the remaining broth and retest at 48 h. Test nitrite broth additionally at 5 days.

B. Disk method (used only for anaerobes)

1. Make a fresh subculture of the organism to be tested onto a supportive agar and place a nitrate disk in the heavy inoculum area. Incubate anaerobically for 24 to 48 h.
2. Remove the disk from the surface of the plate and place it in a clean petri dish or on a slide.
3. Add 1 drop each of reagents A and B. If no color develops in a few minutes, drop a small amount of zinc dust onto the surface of the disk and observe for up to 5 min.

C. Rapid method

1. Prepare 0.5 ml of broth or use tablet (Key Scientific). Refer to <http://www.keyscientific.com> for instructions on tablet preparation and testing.
2. Inoculate *heavily* with organism.
3. Incubate for 2 h at 35°C.
4. Add reagents A and B and observe for red color.
5. Interpret as for standard test.

VI. INTERPRETATION

- **NOTE:** If nitrate has been reduced, inoculation of nitrite broth is unnecessary.
- A. Gas bubbles (even a single gas bubble) in the Durham vial, except for glucose-fermenting, gram-negative rods (no reagent added)
 1. In nitrate tube: nitrate reduction positive, nitrite reduction positive, gas positive
 2. In nitrite tube: nitrite reduction positive, gas positive
 - B. No gas bubbles: gas negative; add reagents for evaluation of reduction.
 - C. Organisms that ferment glucose and non-glucose-fermenting, gram-negative rods that are gas negative
 1. In nitrate tube
 - a. Red color after the addition of reagents: nitrate reduction positive, nitrite reduction negative
 - b. No red color after the addition of reagents *plus* no red color after the addition of zinc to nitrate broth: nitrate reduction positive, nitrite reduction positive
 2. In nitrite tube—no color development after addition of reagents: nitrite reduction positive
 - D. Negative results (final reading at ≥ 48 h)
 1. In nitrate broth—no color development after adding reagents and red color development after adding zinc (zinc catalyzes the change from nitrate to nitrite): nitrate reduction negative
 2. In nitrite broth—a red color after addition of reagents: nitrite reduction negative

VII. REPORTING RESULTS

- A. Report as nitrate reduction positive or negative and nitrite reduction positive or negative.
- B. Report the production of gas for non-glucose-fermenting rods.
- C. Use the results in the determination of the species, using charts in procedures 3.18.1 and 3.18.2.
- D. EF-4 is among the few unique microorganisms that reduce nitrate and nitrite, but no gas is produced (4).
- E. Among the gram-negative diplococci that infect humans, only *Neisseria mucosa* and *M. catarrhalis* are able to reduce nitrate (2).

VIII. LIMITATIONS

- A. Gas production in *Enterobacteriaceae* is not due to nitrate reduction but is hydrogen gas.
- B. Failure to recognize that the organism did not grow in the medium will result in possible false-negative test(s).
- C. Interpretation of color reactions should be made immediately, as color reactions with a positive test may fade rapidly.
- D. Failure to remove air bubbles prior to inoculation may result in reading the result as a false-positive reaction for gas reduction.
- E. A faint pink color may be produced following addition of the nitrate reagents. This is not a positive result.
- F. A negative zinc reduction (no color change) test, in combination with a negative nitrite reaction, is presumptive indication that the nitrate was reduced beyond the nitrite stage. Although a very common end product of nitrite reduction is nitrogen gas, other end products may be formed.
- G. Excess zinc dust has been reported to cause false-positive nitrite reduction reactions due to complete reduction of previously unreduced nitrate to ammonia.
- H. Most positive reactions are detected in 12 to 24 h; however, rare isolates may take up to 5 days (1).

3.17.36

O/129 Disk Susceptibility Testing for *Vibrio* and *Aeromonas* spp.

I. PRINCIPLE

Disks containing 10 and 150 µg of O/129, the vibriostatic agent 2,4-diamino-6,7-diisopropylpteridine phosphate, are used in a method resembling disk susceptibility testing to differentiate *Vibrio* spp. from *Aeromonas* spp. (3, 4, 5). *Aeromonas* species are resistant, with no zone of inhibi-

tion at 24 h, with both disks. *Vibrio* and *Plesiomonas* species will show susceptibility, with a distinct zone of inhibition with the 150-µg disk; results for the 10-µg disk will vary among the *Vibrio* and *Plesiomonas* species.

Some *Vibrio* spp. require salt for growth. Therefore, the test is run in duplicate on Mueller-Hinton media (MH) with low salt (approximately 0.5%) and with added NaCl (4%) to ensure growth on at least one of the plates.

II. MICROORGANISMS TESTED

- A. Gram-negative rods which are oxidase positive, indole positive, and nonpigmented and grow on MAC
- B. Microorganisms identified by kits as either *Vibrio* or *Aeromonas* species
- C. *Corynebacterium*, to separate *Corynebacterium amycolatum* from *Corynebacterium xerosis*

III. MEDIA, REAGENTS, AND SUPPLIES

Include QC information on reagent container and in QC records.

A. O/129 disks

1. Purchase (Oxoid, Inc.; Hardy Diagnostics) or
2. Prepare in-house.
 - a. Using sterile technique, dissolve 30 mg of O/129 (2,4-diamino-6,7-diisopropylpteridine phosphate, Sigma Chemical Company, St. Louis, Mo.) in a small amount of sterile deionized water.
 - b. Add sufficient water to make a total of 4.0 ml at 7.5 mg/ml. This is solution A.
 - c. Dilute this 1:15 (add 0.5 ml of stock solution to 7.0 ml of H₂O) to make solution B of 0.5 mg/ml.
 - d. Lay out blank 1/4-in. paper disks (6 mm) (BD Diagnostic Systems, Hardy Diagnostics) in an empty petri dish.
 - e. Pipette 20 µl of solution A onto each disk to produce 150-µg disks.
 - f. Pipette 20 µl of solution B onto each disk to produce 10-µg disks.

- g. Place petri dishes with lids slightly ajar at 35°C until disks are dry, 10 to 30 min.
- h. Return disks to blank vials and close tops tightly.
- i. Label each vial with type of content (10-µg O/129 disks or 150-µg O/129 disks).
- j. Expiration date is set at 1 year from date of preparation but can be extended if the zone sizes of controls remain within a 5-mm range over time.
- k. Place each vial in a separate container half-filled with desiccant.
- l. Label this container similarly.
- m. Store at -20°C.

B. Media

1. MH
2. MH with 4% NaCl (sold by most vendors for oxacillin screening)

C. Supplies

1. Swabs
2. Broth for inoculum

IV. QUALITY CONTROL

- A. Perform QC on each new lot of disks and with each use with both an organism that is susceptible and one that is resistant to O/129.
- B. Organisms

Test organism	MH		MH with 4% salt	
	10 µg	150 µg	10 µg	150 µg
<i>Aeromonas hydrophila</i> ATCC 7966	6 mm	6 mm	NA	NA
<i>Vibrio fluvialis</i> ATCC 33809	NA ^a	NA	7–15 mm	≥20 mm

^a NA, not applicable because the organism will not grow on the medium.

V. PROCEDURE

- A. Remove disks from freezer and equilibrate to room temperature.
- B. Allow test media (MH and MH with 4% NaCl) to equilibrate to room temperature. If the plates have excess moisture, dry them for 10 to 30 min at 35°C with lids slightly ajar.
- C. Suspend an overnight growth of the organism and each of the controls in TSB to a turbidity of a no. 0.5 McFarland standard.
- D. Divide each plate in half with a marker.
- E. Using a swab dipped into the broth, inoculate the surface of one-half of each plate with organism suspension in three planes as for antimicrobial susceptibility disk testing.
- F. In the same manner, inoculate the other half of the MH plate with 4% salt with the *Vibrio* control and the MH plate without salt with the *Aeromonas* control.
- G. Allow plates to dry for 3 to 5 min but no longer than 15 min.
- H. Place a 10-µg O/129 disk and a 150-µg O/129 disk on each half of the two plates in well-separated locations. Add antimicrobial susceptibility disks, if desired.
- I. Using sterile forceps, press each disk gently onto the agar surface to ensure good contact.
- J. Incubate for 18 to 24 h at 35°C in a non-CO₂ incubator.
- K. Read zone of inhibition on plate with best growth and most clear-cut zone(s).

VI. INTERPRETATION

- A. The organism is O/129 resistant if there is no zone of inhibition around the respective disk.
- B. The organism is O/129 susceptible if there is any zone around the respective disk.
- C. The organism is generally salt requiring if it does not grow on MH.
- D. The organism is salt tolerant or enhanced if it grows on MH with 4% salt.
- E. The organism is inhibited by salt if it does not grow on MH with 4% salt.

VII. REPORTING RESULTS

- A. Gram-negative rods that are oxidase positive, grow on MAC, and ferment glucose (most are indole positive) are reported as follows.
1. *Aeromonas*, if resistant to 150 µg of O/129, grows without salt, and is arginine positive. Strains are also usually DNase positive.
 - a. *Aeromonas veronii* bv. *Veronii* is arginine negative.
 - b. *Vibrio cholerae* is arginine negative, and some strains are resistant to O/129 and may not grow on media with 4% salt (1). Perform further testing on strains with these characteristics, or submit to reference laboratory to separate *V. cholerae* from *A. veronii* bv. *Veronii*.
 - c. *Vibrio fluvialis* is arginine positive and may be resistant to 150 µg of O/129, but it usually grows only with 4% salt.

VII. REPORTING RESULTS

(continued)

2. *Plesiomonas shigelloides*, if susceptible to 150 µg of O/129 and positive for indole, arginine dihydrolase, and ornithine and lysine decarboxylases. *P. shigelloides* is also inhibited on 4% salt agar and is DNase negative.
 3. *Vibrio* spp., if susceptible to 150 µg of O/129 even if they do *not* grow on MH with 4% salt but are either negative for arginine dihydrolase or negative for ornithine and lysine decarboxylases.
 - ☑ **NOTE:** Some vibrios may be resistant to 150 µg of O/129, but they will be arginine negative.
- B. Identify *Vibrio* to the species level with commercial kit using saline diluent.
 1. If isolate is resistant to 10 µg of O/129, it is likely to be *V. fluvialis*, *Vibrio alginolyticus*, or *Vibrio parahaemolyticus*, the most common isolates.
 2. If isolate is susceptible to 10 µg of O/129, it is likely to be *Vibrio vulnificus*.
 - C. Unless the organism identification from the kit agrees with the results of the O/129 and salt tolerance tests, submit to a reference laboratory for further identification. See Fig. 3.8.1–1 in procedure 3.8.1 for flowchart.
 - D. Submit *V. cholerae* and possibly *V. vulnificus* to the local health department, in accordance with local health department policies, or to a reference laboratory for confirmation of toxicity and identification.
 - E. *C. amycolatum* is usually resistant to 150 µg of O/129, with no zone of inhibition, while *C. xerosis*, *Corynebacterium minutissimum*, and *Corynebacterium striatum* are susceptible.

VIII. LIMITATIONS

- A. Kits can misidentify *V. vulnificus* as *V. parahaemolyticus*, *Aeromonas* as *V. fluvialis*, and *Vibrio damsela* as *Vibrio cholerae* (2). Use both O/129 disks and growth with salt testing to prevent initial misidentifications and potential public health consequences.
- B. *V. cholerae* strains that are resistant to O/129 have been reported, which is probably related to antimicrobial therapy (1).
- C. The 10-µg disk is not as important in the identification as the 150-µg disk and may be omitted.
- D. Some vibrios do not grow on MH with 4% salt, and some grow without added salt. All *Aeromonas* organisms grow without salt but may grow on medium with salt.

3.17.37

ONPG (*o*-Nitrophenyl- β -D-Galactopyranoside) Test

I. PRINCIPLE

o-Nitrophenyl- β -D-galactopyranoside (ONPG) is used in differentiating members of the *Enterobacteriaceae* and *Neisseria* based on β -D-galactosidase activity. The ability of a bacterium to ferment lactose depends on two enzymes, permease and β -galactosidase. Permease allows lactose to enter the bacterial cell wall, where it is then broken down into glucose and galactose by β -galactosidase. The glucose and galactose can then be metabolized by the bacteria. The enzymes are inducible

and are only present when lactose, rather than glucose, is available to the organism for metabolism. Some organisms lack permease and appear as late lactose fermenters or non-lactose fermenters. The ONPG test will detect true non-lactose fermenters that have the β -galactosidase enzyme, even if they lack the permease enzyme. A lactose fermentation test will not detect organisms lacking the permease.

ONPG is a colorless substrate, similar in structure to lactose, used in this test as

the substrate for β -galactosidase. If the organism possesses β -galactosidase, the enzyme will split the β -galactoside bond, releasing galactose and *o*-nitrophenol, which is a yellow compound. The activity of the galactosidase enzyme is increased in the presence of sodium ions (1). Other substrates can be used to detect β -galactosidase and are found in the commercial identification kits, especially those used to identify *Neisseria* species.

II. MICROORGANISMS TESTED

- A. Gram-negative rods growing aerobically
- B. Gram-negative diplococci growing aerobically

III. MATERIALS, REAGENTS, AND SUPPLIES

A. Reagents

- 1. Because of the instability of ONPG, the reagent should not be prepared but purchased.
- 2. Purchase ONPG as broth, disks, or tablets.
 - a. Store as directed by the manufacturer. Usually store broth at less than -10°C and disks and tablets at 4°C .
 - b. Store away from direct light; ONPG is *light sensitive*.

B. Supplies

- 1. Plastic or glass tubes for disk test
- 2. Wooden sticks or inoculating loops
- 3. Sterile saline
- 4. Incubator at 35 to 37°C

IV. QUALITY CONTROL

- A. Do not use if broth media or disk, after reconstitution, is not light amber and clear, with no precipitates.
- B. Perform QC on each new lot or shipment prior to putting it into use.
- C. Organisms
 - 1. *Escherichia coli* ATCC 25922—ONPG positive
 - 2. *Proteus mirabilis* ATCC 12453—ONPG negative
 - or
 - 3. *Neisseria lactamica* ATCC 23971—ONPG positive
 - 4. *Neisseria gonorrhoeae* ATCC 43069—ONPG negative

V. PROCEDURE**A. Tube medium**

1. Bring test medium to room temperature.
2. Using a heavy inoculum (no. 2 McFarland) from a pure 18- to 24-h culture, inoculate the test medium.
3. Incubate aerobically at 35°C.
4. Examine for yellow color development at 1 h.
5. If the tube has not changed color after 1 h of incubation or if the colony was not taken from lactose-containing medium, continue incubation up to 24 h.

B. Disk test

1. Inoculate colonies into 0.5 ml of saline to produce a heavy suspension (no. 2 McFarland).
2. Add disk to tube.
3. Incubate aerobically at 35°C for up to 6 h.
4. Observe for yellow color change.

VI. INTERPRETATION

- A. A yellow color change is a positive test for ONPG.
- B. A lack of color change is a negative test.

VII. REPORTING RESULTS

- A. An organism that produces a yellow color is considered ONPG positive and generally a lactose fermenter.
- B. An organism that does not produce a yellow color is considered ONPG negative and non-lactose fermenting.
- C. Among the *Neisseria* spp., *N. lactamica* is identified by its ONPG-positive reaction (2).

VIII. LIMITATIONS

- A. For the rapid test, colonies should be from a lactose-containing medium (e.g., triple sugar iron agar or MAC).
- B. Cultures that naturally produce a yellow pigment cannot be tested with this medium.
- C. If medium is not properly buffered, results may be inaccurate.
- D. Do not use if medium is yellow.
- E. Since glucose inhibits lactose fermentation by bacteria, organisms growing on glucose-containing medium show less activity than they would in the presence of lactose.

REFERENCES

1. Negut, M., and G. Hermann. 1975. A comparison of two methods for detecting β -D-galactosidase. *Public Health Lab.* **33**:190–193.
2. Weyant, R. S., C. W. Moss, R. E. Weaver, D. G. Hollis, J. G. Jordan, E. C. Cook, and M. I. Daneshvar. 1995. *Identification of Unusual Pathogenic Gram-Negative Aerobic and Facultatively Anaerobic Bacteria*, 2nd ed., p. 16. Williams & Wilkins, Baltimore, Md.

I. PRINCIPLE

Streptococcus pneumoniae is found commonly in the human respiratory tract, as are other streptococci, and has a hemolytic pattern indistinguishable from that of other alpha-hemolytic streptococci and lactobacilli. Optochin susceptibility is used to differentiate *S. pneumoniae* from other alpha-hemolytic streptococci, either as isolated colonies or as a test to recog-

nize *S. pneumoniae* colonies directly on cultures of respiratory specimens.

Sensitivity to optochin (ethylhydrocupreine hydrochloride) has been well-established for *S. pneumoniae* since the early 20th century (5). In 1955 Bowen and Jeffries impregnated disks with the reagent to demonstrate the susceptibility of the pneumococcus for identification purposes (2).

A positive identification in an organism with Gram stain and colony morphology consistent with *S. pneumoniae* is made when a well-defined zone of inhibition forms around the impregnated disk. Other alpha-hemolytic streptococci do not display this clear zone of inhibition in the presence of optochin.

II. MICROORGANISMS TESTED

- A. Test any fresh culture of alpha-hemolytic, catalase-negative, gram-positive cocci in pairs, growing on BAP or Columbia colistin-nalidixic acid agar (CNA) and having the characteristic central depression (flattened center) or mucoid colony morphology suggestive of *S. pneumoniae*.
- B. As a rapid detection and identification method, place the disks on plates inoculated with either respiratory specimens or subcultures from blood cultures. However, results for disks placed on plates directly inoculated with respiratory specimens can be very misleading unless a Gram-stained smear indicates an almost singular presence of lanceolate gram-positive diplococci.
- C. As a test of purity of culture, add the disk for any known *S. pneumoniae* isolate that is being tested for antimicrobial resistance.

III. REAGENTS AND SUPPLIES**A. Reagents**

1. Optochin disks—purchase from most vendors.
 - a. Each disk is impregnated with 5 µg of optochin.
 - b. Store stock at 2 to 8°C. Protect from light, excessive heat, and moisture.
 - c. The expiration date is at least 9 months (2) but may be considerably longer.

2. BAP—use only 5% sheep blood agar for identification test.

B. Supplies

1. Standard microbiological loops
2. CO₂ incubator at 35 to 37°C
3. Sterile forceps

IV. QUALITY CONTROL

- A. Perform QC with known positive and negative controls prior to use of new lots or shipments and, optionally, at weekly intervals.
 - B. Organisms and zone sizes
 - 1. *S. pneumoniae* ATCC 49619, ≥ 14 mm
 - 2. *Enterococcus faecalis* ATCC 29212, no zone
- ☑ **NOTE:** For a 10-mm disk, use ≥ 16 mm as the breakpoint for susceptibility. Compare weekly zone size results and if the size is decreasing, open a new vial, as the current supply in use may be deteriorating even before the expiration date.

V. PROCEDURE

- A. Using an inoculating loop, select a well-isolated colony of the alpha-hemolytic organism to be tested. Alternatively, a broth culture with a turbidity corresponding to a 0.5 McFarland standard can be used (3).
- B. Using a loop from a colony, or swab from a broth culture, streak the isolate onto BAP in at least two directions so as to obtain confluent growth. Several isolates may be placed on one plate by dividing the plate into quadrants and streaking one isolate per quadrant.
 - ☑ **NOTE:** Use of media other than 5% sheep blood agar is not recommended, as smaller zone sizes can result in lack of definitive identification (3). However, when performing a susceptibility test for purposes of detection of contamination of a culture of known *S. pneumoniae*, the Mueller-Hinton blood agar used for the susceptibility testing can be used without strict measurement of the zone size.
- C. Using sterile forceps, place an optochin disk onto the inoculated surface of the agar.
- D. Press disk gently with the sterile forceps or loop so that the disk adheres firmly to the agar surface.
- E. Incubate the plate at 35 to 37°C for 18 to 24 h in 5 to 10% CO₂.
- F. If zone of inhibition is present, measure the diameter with a millimeter ruler or caliper.

VI. INTERPRETATION

- A. A zone of inhibition of ≥ 14 mm (15 to 30 mm) around the disk is considered a susceptible result.
- B. Organisms with zone sizes of < 14 mm around the disk should be considered intermediate in susceptibility to optochin.
- C. If there is no zone around the disk, the organism is considered resistant to optochin.
- D. Colonies *within* the zone may or may not be *S. pneumoniae*, since this phenomenon can occur with *S. pneumoniae* (7).

VII. REPORTING RESULTS

- A. Report an identification of *S. pneumoniae*, if the alpha-hemolytic colony from gram-positive cocci in pairs is catalase negative and susceptible to optochin.
- B. For any alpha-hemolytic colonies from gram-positive cocci in pairs that are catalase negative but produce zone sizes with *intermediate* results, perform spot bile solubility test for confirmation of identification. Report as *Streptococcus pneumoniae* if positive.
- C. If the organism is optochin resistant and is a catalase-negative, alpha-hemolytic colony from gram-positive cocci in pairs, report as a viridans group streptococcus.
- D. For purposes of determination of contamination of a susceptibility test, any zone of inhibition of ≥ 10 mm indicates lack of contamination.

VIII. LIMITATIONS

- A. *S. pneumoniae* isolates should be incubated in a CO₂-enriched environment, as some isolates will grow poorly or not at all without increased CO₂ (3, 8).
- B. If the organism is optochin resistant, it is likely to be a nonpneumococcal alpha-hemolytic streptococcus; however, rare exceptions have been reported (1, 7).
- C. Optochin susceptibility is an excellent test to identify *S. pneumoniae*, with a 99% sensitivity for *encapsulated* strains and 98 to 99% specificity (4, 6). However, Mundy et al. (6) reported that only 10 of 33 nonencapsulated strains positive by DNA probe were detected as susceptible by optochin; the remainder had intermediate zone diameters with optochin.
- D. If the tube bile test is performed to confirm strains with zone of inhibition between 7 and 14 mm, the sensitivity in detection of nonencapsulated strains is increased; however, bile-resistant strains with intermediate zone sizes may still be *S. pneumoniae*. Further testing with a DNA probe (GenProbe, Inc.) is needed for definitive identification (6). Since most (85%) will *not* be *S. pneumoniae* and most nonencapsulated strains are from noninvasive sites, this approach may not be cost-effective (3).
- E. If there are colonies present within the zone of inhibition, these colonies may or may not be pneumococci. Pikiš et al. (7) reported that resistant strains may exhibit this phenomenon; however, it is rare. True optochin-resistant strains have only been reported for three cases (7). The resistance was shown to be a point mutation in strains from patients that had been treated with antimicrobial agents (7). Subculture such colonies and confirm with Gram stain, catalase test, and bile solubility to determine if they are contaminants or pneumococci prior to reporting susceptibility results.

3.17.39

Oxidase Test

I. PRINCIPLE

In the presence of atmospheric oxygen, a bacterium's intracellular cytochrome oxidase enzymes oxidize the phenylenediamine reagent (an electron acceptor) to form a deep purple compound, indol phenol (3). The test is useful in the initial characterization of gram-negative bacteria (2).

II. MICROORGANISMS TESTED

- A. Aerobic, facultatively anaerobic, or microaerobic gram-negative rods and cocci from BAP, Mueller-Hinton agar, brucella agar, BHI, or CHOC
- B. Restrictions
 - 1. Do not use media with dyes, such as EMB or MAC.
 - 2. Do not test strictly anaerobic organisms.
 - 3. Do not test organisms growing on media that contain glucose.

III. REAGENTS AND SUPPLIES

- A. Reagents
 - 1. Kovács' reagent
 - ☑ **NOTE:** Other formulas exist, but Kovács' is the most sensitive reagent.
 - a. For 0.5 to 1% solution, dissolve 0.1 g (size of a pea) *N,N,N,N*-tetramethyl-*p*-phenylenediamine dihydrochloride in 10 ml of sterile distilled water.
 - b. Mix well and allow to sit for 15 min.
 - c. Make fresh daily (preferred method), or store aliquots of the reagent in foil-wrapped test tubes at -20°C . Remove from the freezer and thaw before use.
 - d. Discard unused portion daily.
 - 2. Dried filter paper disks or strips impregnated with reagent
 - 3. Disposable glass ampoules (available from most vendors)
- B. Supplies
 - 1. Filter paper or swab
 - 2. Disposable petri dish
 - 3. Sterile wooden sticks or plastic or platinum loops or wires
 - 4. Deionized water

IV. QUALITY CONTROL

- A. Do not use once the pale purple color of the reagent or the filter paper begins to darken.
- B. Perform QC on each new lot of powdered reagent prior to putting it into use.
- C. Organisms
 - 1. *Pseudomonas aeruginosa* ATCC 27853—oxidase positive
 - 2. *Escherichia coli* ATCC 25922—oxidase negative

V. PROCEDURE

- A. **Filter paper method**
 - 1. Optional preparations
 - a. Place a small square of Whatman no. 1 filter paper in a petri dish and moisten with 1 or 2 drops of prepared Kovács' oxidase reagent *or*
 - b. Place impregnated dry disk or strip in petri dish and moisten with deionized water.
 - ☑ **NOTE:** Some manufacturers may not require that strip be moistened.
 - 2. Optional methods of colony testing
 - a. Pick an isolated colony with a stick and smear onto Kovács' reagent-dampened filter paper. Observe paper for purple color.
 - b. For fastidious bacteria, swipe colony onto white cotton swab and rub onto the dampened filter paper. Observe *swab* for purple color.
 - c. Touch moistened filter paper to colony and observe paper for purple color.
- B. **Plate method**
 - 1. Drop a few drops of reagent directly on top of a few suspected colonies. Do not flood entire plate because bacteria covered by the reagent generally are not viable for subculture.
 - 2. Expose the colonies to air by tilting the culture after flooding with oxidase reagent to allow oxygen to reach the colonies.
 - 3. Observe colony for purple color. Ignore any discoloration of surrounding medium.
 - ☑ **NOTE:** Colonies tested by this method are quickly nonviable. Subculture immediately.

VI. INTERPRETATION

- A. Positive test
 - 1. Development of a deep blue to purple color in 10 to 30 s is a positive reaction.
 - 2. Development of the color in 30 to 60 s is a weak positive reaction, characteristic of many *Pasteurella* spp.
 - 3. Do not read after 60 s.
- B. Negative test is no color change in 60 s.

VII. REPORTING RESULTS

- A. To avoid misidentifications, perform oxidase test on *all* gram-negative rods, except those that swarm.
 - ☑ **NOTE:** This test is especially important in separating *Aeromonas* from *Enterobacteriaceae*. Most commercial kits do not include an oxidase test as part of their biochemical reactions but require the user to record the result as part of their identification scheme. If the test is omitted, errors in identification can be made. In addition, oxidase testing can aid in rapid identifications, avoiding the need for costlier kit identifications (4).
- B. Gram-negative diplococci should give a positive reaction, since all members of the genus *Neisseria* are oxidase positive. *Moraxella* spp. which are either gram-negative diplococci or coccobacilli are also oxidase positive.

VII. REPORTING RESULTS*(continued)*

- C. Gram-negative rods that are oxidase positive do not belong to the *Enterobacteriaceae*, with the exception of *Plesiomonas shigelloides*, which is both oxidase and indole positive (see Table 3.18.2–8).
- D. *Campylobacter* spp. are oxidase positive.
- E. Use this test as a major characteristic for identification of gram-negative rods that are not in the *Enterobacteriaceae* family.

VIII. LIMITATIONS

- A. To avoid false-positive results
 - 1. Do not use a Nichrome wire to pick colony.
 - 2. Do not test organisms growing on media that contain glucose or dyes (e.g., MAC or EMB).
 - 3. Do not use if reagent or filter paper is purple.
- B. Mixed cultures of *Neisseria* and pseudomonads can give false-negative results, since the pseudomonads can elaborate an inhibitory substance that interferes with the production of oxidase by *Neisseria*.
- C. Timing is critical to accurate testing.
- D. Dry filter paper may be rewet with reagent for further use until it is purple in color.
- E. Some organisms may require several subcultures or colony growth for several days to produce a positive reaction.
- F. The modified oxidase test (Microdase disks; Remel, Inc.) to detect cytochrome *c* is one of several tests that can be used to separate *Micrococcus* (positive) from staphylococci (negative). The test is performed in the same manner as the oxidase test, except that the reagent is 6% tetramethylphenylenediamine hydrochloride in dimethyl sulfoxide (1).

3.17.40

Phenylalanine Deaminase Test

I. PRINCIPLE

The phenylalanine deaminase (PDA) test is used to differentiate among the urea-positive gram-negative bacilli based on the ability of the microorganisms to produce phenylpyruvic acid by oxidative deamination. Phenylalanine is an amino acid that, upon deamination by oxidase enzymes, results in the formation of phenylpyruvic acid. The deamination of phenylalanine to phenylpyruvic acid is detected by the addition of a ferric chloride solution that acts as a chelating agent with the α -keto acid by-product to pro-

duce a light to deep green cyclic compound.

Hendriksen, in 1950, demonstrated that *Proteus* spp. were able to convert phenylalanine to phenylpyruvic acid (3). This observation was incorporated into a medium by Ewing et al. (2) and into a disk along with urea by Ederer et al. (1). Of the *Enterobacteriaceae* that are urea positive, only members of the *Proteus*, *Providencia*, and *Morganella* group are capable of deaminating phenylalanine (2). The test

can also be used to identify other *Enterobacteriaceae*, *Buttiauxella*, *Rahnella*, and *Tatumella*, which are PDA positive but are urea negative.

Tryptophan can be substituted for phenylalanine; tryptophan deamination releases indole-pyruvic acid, which results in a purple to black color with the addition of ferric chloride. Either tryptophan or phenylalanine can be used to differentiate among the *Proteus* group of gram-negative rods.

II. MICROORGANISMS TESTED

- A. Gram-negative rods that grow well on MAC, are oxidase negative, and are usually urea positive
- B. This test can be used as part of screening for fecal pathogens to rule out *Proteus*, *Providencia*, and *Morganella*.
- C. Oxidase-positive, gram-negative coccobacilli and rods that are urea positive, to separate *Oligella* spp. and *Psychrobacter phenylpyruvicus* and others from PDA-negative strains

III. MEDIA, REAGENT, AND SUPPLIES

Include QC information on reagent container and in QC records.

- A. **Media**
 1. Phenylalanine agar slants (available from most medium vendors)
 - a. Contain L-phenylalanine and yeast extract in a buffered agar
 - b. Store at 15 to 30°C. Shelf life, 1 year
 2. Rapid tests
 - a. Urea-PDA disks (Hardy Diagnostics; Remel, Inc.; or prepare in-house [see reference 1])
 - b. Phenylalanine tablets (Key Scientific)
 - c. Indole-IPA tablets containing tryptophan (Key Scientific)
 - d. ONGP-PDA broth (Hardy Diagnostics)—store frozen at less than -10°C .
 NOTE: Commercial multitest systems often include a substrate to detect either PDA or tryptophan deaminase (TDA).
- B. **Reagent**

10% Ferric chloride, acidified

 1. Dissolve 12 g of ferric chloride in 97.5 ml of water.
 2. Slowly add 2.5 ml of concentrated HCl in a fume hood.
 3. Store in brown bottle at 4°C.

III. MEDIA, REAGENT, AND SUPPLIES (*continued*)

4. For in-house-prepared reagent, test monthly and discard when reaction is weak.

☑ **NOTE:** Acidified ferric chloride is recommended, but 10% aqueous ferric chloride (10 g in 100 ml of deionized water) can be used (4).

C. Supplies

1. Sterile wooden sticks or inoculating loops
2. Saline or water in small plastic tube for disk test
3. Incubator at 35 to 37°C

IV. QUALITY CONTROL

A. Examine phenylalanine agar to be sure that it is slightly opalescent and light amber. Check for signs of prior freezing, contamination, cracks, dehydration, and deterioration.

B. Perform QC on each new lot or shipment of medium, disks, and ferric chloride prior to use with one organism known to demonstrate a positive reaction and one organism known to give a negative reaction.

C. Organisms

1. *Proteus mirabilis* ATCC 12453—turns green after the addition of 4 or 5 drops of ferric chloride with agitation; may take 1 to 5 min (positive)
2. *Escherichia coli* ATCC 25922—remains yellow after addition of ferric chloride (negative)

V. PROCEDURE**A. Agar test**

1. Prior to inoculation, allow the medium to equilibrate to room temperature.
2. Using a heavy inoculum from an 18- to 24-h pure culture, streak the slant surface using a fishtail motion.
3. Incubate the inoculated slant aerobically at 35°C for 18 to 24 h. If a heavy inoculum is used, incubate for 4 to 6 h.
4. Following incubation, apply 4 or 5 drops of ferric chloride directly to the slant.
5. Gently roll the reagent over the slant to dislodge surface colonies, and observe for the development of a green color within 1 to 5 min.

B. Rapid tests

Check the package insert for differences from procedure below.

1. Prepare a small test tube with 0.25 ml (5 drops) of saline or water.
☑ **NOTE:** Preferably use plastic tubes for disk tests.
2. Make a heavy suspension of the actively growing organism.
3. Add disk (tablets are already in tube).
4. Incubate aerobically at 37°C for 1 h or up to 2 h for the urea-PDA test.
5. If urea is present in disk, observe for pink color indicative of a positive urea reaction. Add 2 drops of 1 N HCl to acidify the alkaline urea reaction (optional).
6. Add 2 drops of 10% ferric chloride, shake, and observe for green color.

VI. INTERPRETATION

A. A positive phenylalanine deamination reaction is indicated by the development of a light to dark green color (PDA) or purple to black color (TDA) within 1 to 5 min after applying ferric chloride reagent.

B. A negative test is indicated by the absence of a green color reaction. Negative results will take on a yellow color due to the color of the ferric chloride.

VII. REPORTING RESULTS

- A. A positive or negative PDA test is only one test in the identification of urea-positive *Proteus*, *Providencia*, and *Morganella*.
- B. If the PDA test is used as a screening test, PDA-positive *Enterobacteriaceae* can be eliminated as fecal pathogens.
- C. A positive PDA test can eliminate the identification of *Brucella* from oxidase-positive, urea-positive, gram-negative coccobacilli.

VIII. LIMITATIONS

- A. The green color reaction of a positive test fades rapidly. Test results must be interpreted within 5 min following the application of ferric chloride or false-negative results may occur.
- B. Slight agitation of the tube containing ferric chloride will produce a faster, more pronounced color reaction.
- C. TDA can be detected instead of PDA with the same interpretation of results.

3.17.41

PYR (L-Pyrrolidonyl- β -Naphthylamide) Test

I. PRINCIPLE

L-Pyrrolidonyl- β -naphthylamide (PYR) serves as a substrate for the detection of pyrrolidonyl peptidase. Following hydrolysis of the substrate by the peptidase, the resulting β -naphthylamide produces a red color upon the addition of 0.01% cinnamaldehyde reagent. When a visible inoculum of microorganism is rubbed onto a small area of a disk impregnated with the

substrate, the hydrolysis occurs within 2 min, at which time the cinnamaldehyde reagent is added to detect the reaction by a color change to purple.

Godsey et al. (5) first reported that the hydrolysis of this substrate serves as a useful tool in the identification of *Streptococcus pyogenes* (beta-hemolytic group A) and enterococci. Others soon tested the

method and demonstrated its accuracy (1, 3, 4). York et al. (7) and Chagla et al. (2) also found a high degree of accuracy using PYR for identification of *Escherichia coli*, separating it from other indole-positive, lactose-positive, gram-negative rods. Hébert et al. (6) demonstrated the utility of using PYR to differentiate among the coagulase-negative staphylococci.

II. MICROORGANISMS TESTED

- A. Catalase-negative, beta-hemolytic, gram-positive cocci with typical group A streptococcal morphology
- B. Catalase-negative, gamma- or alpha-hemolytic, gram-positive cocci with typical enterococcal morphology
- C. Oxidase-negative, indole-positive, gram-negative rods that are lactose positive on MAC, to identify *E. coli*
- D. Coagulase-negative staphylococci, to screen for *Staphylococcus lugdunensis* and identify other staphylococci to the species level (6)

III. MATERIALS, REAGENTS, AND SUPPLIES

- A. Reagents
 - 1. Disks impregnated with PYR
 - a. Store at 2 to 8°C in the dark.
 - b. Vendors: BD Diagnostic Systems; EY Laboratories; Hardy Diagnostics; Key Scientific; Oxoid, Inc.; PML; Remel, Inc.
Caution: PYR powder or liquid is a potential carcinogen; making the reagent in the clinical laboratory is discouraged.
 - c. A number of vendors combine several spot tests for identification of streptococci into a card with PYR. PYR in some kits is a liquid reagent, which is more suitable for staphylococci (6).
- 2. 0.01% *p*-Dimethylaminocinnamaldehyde
- B. Other supplies
 - 1. Sterile water
 - 2. Sterile sticks
 - 3. Petri dish and forceps

IV. QUALITY CONTROL

- A. Perform QC on each new lot or shipment of disks and color reagent prior to putting it into use.
- B. Organisms
 - 1. *Enterococcus faecalis* ATCC 29212—PYR positive
 - 2. *E. coli* ATCC 25923—PYR negative

V. PROCEDURE

- A. Using forceps, place PYR disk in petri dish.
- B. Moisten, but do not saturate, disk with sterile water.
- C. Using a sterile stick, remove one or two loopfuls of culture from a blood agar plate that is 24 to 48 h old. Use several loopfuls for organisms that take 48 h or more to grow.
- D. Rub onto PYR disk.
- E. Allow to react for 2 min (extend time to 10 min for poorly growing organisms).
- F. After incubation period, add 1 drop of cinnamaldehyde reagent and observe for red color.

VI. INTERPRETATION

- A. A positive test is indicated by the appearance of a bright pink or cherry-red color usually within 1 min.
- B. A negative test is indicated by no color change or a blue color due to a positive indole reaction.
- C. A pale pink reaction (weak) is considered negative.

VII. REPORTING RESULTS

- A. An identification of *S. pyogenes* may be made for PYR-positive, catalase-negative, beta-hemolytic, gram-positive cocci with typical group A streptococcal morphology from throat cultures.
 - 1. Confirm negative PYR tests on beta-hemolytic streptococci with further testing or a fresh subculture if inoculum is low or results are questionable.
 - 2. Confirm positive tests from nonrespiratory sites with either negative bile-esculin, negative esculin, or serologic typing for the group A antigen.
- B. An identification of *Enterococcus* may be made on PYR-positive, catalase-negative, nonhemolytic, gram-positive cocci with typical enterococcal morphology, short chains, and diplococci, *not* tetrads or clusters.
- C. Gram-negative rods are identified as *E. coli* if they are oxidase-negative, indole-positive, lactose-positive colonies that are PYR negative.
- D. Coagulase-negative staphylococci that are PYR positive could be *Staphylococcus lugdunensis*. Use a positive ornithine or other tests to confirm (*see* Table 3.18.1–1).
- E. *Citrobacter* is PYR positive and can be differentiated from H₂S-positive *Salmonella*, which is PYR negative.

VIII. LIMITATIONS

- A. Odd gram-positive cocci will be positive in this test but are not enterococci. Gram stain is most helpful with this issue. They are generally in tetrads or clusters in the smear, are tiny colonies, or are not significant pathogens.
- B. A false-negative test can result if the disk is too moist.
- C. Weak, pale results occur with the disk test for *Staphylococcus aureus*; positive results may need to be confirmed with other tests or with the tube PYR test, which is available in rapid identification kits, such as API Rapid Strep (6).
- D. False-negative tests result if selective media or tube biochemical agars are used to provide inocula.

3.17.42

Quellung Reaction for Pneumococci

I. PRINCIPLE

As a rapid method to definitively identify *Streptococcus pneumoniae* directly in sputum, pleural fluid, CSF, blood, or other body fluids, capsular swelling of the pneumococcus in the presence of specific capsular antibody is observed (3, 5). This procedure can also be used to identify difficult

isolates of presumptive pneumococci that are bile insoluble or optochin negative or to type these organisms after they have already been isolated and identified, using specific capsular typing sera, for evaluation of vaccine efficacy. Antigen-antibody

reaction between antiserum and the capsule causes the capsule to appear to swell, although the mechanism is probably due to a change in the refractive index of the capsule that enhances its visibility (Neufeld reaction [1]).

II. SPECIMEN OR MICROORGANISM TESTED

- A. Positive blood cultures containing lancet-shaped, gram-positive cocci in pairs suggestive of pneumococci
- B. Respiratory specimens or CSF with direct Gram stains positive for lancet-shaped, gram-positive cocci in pairs
- C. Colonies with characteristic pneumococcal morphology that are bile resistant

III. REAGENTS AND SUPPLIES

- A. **Reagents**
 - 1. Polyvalent *S. pneumoniae* antisera from Omniserum (Erna Lund, Pneumococcus Department, Statens Seruminstitut, Copenhagen, Denmark; distributed by DAKO, Carpinteria, Calif.).
 - a. Contents: antisera to 84 pneumococcal types in a small amount of methylene blue
 - b. Store at 4°C.
 - 2. Methylene blue solution (store at room temperature)
 - a. 0.3 g of methylene blue
 - b. 100 ml of H₂O
 - 3. Rabbit serum (stored at -20°C)
- B. **Supplies**
 - 1. Loops
 - 2. Slides and coverslips
 - 3. Pasteur pipettes

IV. QUALITY CONTROL

- A. Prior to use and every 6 months thereafter, test a fresh isolate of a bile-soluble colony (preferably from a blood culture) and a bile-insoluble colony to obtain the expected positive Quellung reaction (bile-soluble colony) and negative Quellung reaction (bile-insoluble colony).
- B. QC strains are not suitable for controls, as they easily lose their capsule.

V. PROCEDURE

- A.** Divide a slide into two sections with a wax pencil. Label one section as the test and the other as the control. (Two slides may be used instead.)
- B. Specimen**
1. Dilute growth from blood culture bottles containing pneumococci 1:10 in broth or saline before the slide is made, depending on the number of organisms seen in smear. Four organisms per field is ideal.
 2. Prepare a small saline or broth suspension of a colony; it should be barely visibly turbid.
 3. Dilute other direct specimens if needed in saline, especially if they are viscous.
- C.** Using a sterile 10- μ l loop (1:100 ml), place a drop of specimen suspension onto each of two sections of a slide; spread out and allow to air dry.
- D.** Using a sterile 10- μ l loop (1:100 ml), place a small drop of antiserum on the first section of the slide and spread out over the specimen.
- ☑ **NOTE:** Antiserum is very expensive, and a small amount will give the desired reaction.
- E.** Using a 10- μ l loop, place a similar-size drop of rabbit serum on the second section of the slide.
- F.** Put a small drop of methylene blue solution on each of two coverslips. Invert the coverslips onto each section of the slide.
- ☑ **NOTE:** Adding additional methylene blue solution to the pneumococcal antiserum will give a more readable preparation, as there is only a small amount of methylene blue in the reagent.
- G.** After 10 min, read the test and control slides.
1. Adjust the microscope to obtain oblique light by adjusting the iris diaphragm so that only one-third of the light passes through the condenser at low power (p. 163 in reference 2).
 2. Switch to oil immersion lens to view capsules.
- H.** If the test is negative
1. Repeat if inoculum is too heavy. Approximately four organisms per field is ideal.
 2. Hold for 30 min in a wet chamber before discarding as negative. (A petri dish with damp gauze upon which to rest slide(s) works well.)

VI. INTERPRETATION

- A.** A positive test shows marked swelling of the capsules in comparison to the control, giving a sharply demarcated halo. Capsules may be visible in the control but do not produce a clear demarcation and glassy appearance.
- B.** A negative test is marked by no difference between the test and control cells.

VII. REPORTING RESULTS

- A.** Report a positive test as “*Streptococcus pneumoniae* by Quellung test.”
- B.** Report a negative test as “Negative for *Streptococcus pneumoniae* by Quellung test.”

VIII. LIMITATIONS

- A.** A negative test does not indicate that the organism is not *S. pneumoniae*, since the organism could have lost the ability to express a capsule (6).
- B.** The test can be falsely negative if there are too many organisms on the slide (antigen excess); if this occurs, the test should be repeated with fewer organisms.

VIII. LIMITATIONS (*continued*)

- C. The Phadebact pneumococcus test (Boule Diagnostics, Huddinge, Sweden) is a coagglutination test using antibodies directed against the capsular antigens of *S. pneumoniae*. In the package insert, the manufacturer reports an 8% false-positive rate with other viridans group streptococci, but it had a 100% sensitivity and 98% specificity in one published study (4). The Directogen and Pneumoslide (BD Diagnostic Systems) had an 85 to 87% specificity with other species of streptococci in the same study (4).

3.17.43

6.5% Salt and Temperature Tolerance Test

I. PRINCIPLE

As part of the differentiation of catalase-negative, gram-positive cocci, growth in 6.5% salt and growth at low (10°C) and high (42 to 45°C) temperatures are used (1). Salt tolerance broth, containing heart infusion (HI), glucose, and bromcresol purple indicator with 6.5% salt, was initially designed by Qadri et al. (4) to aid in the differentiation of *Enterococcus* spp. from streptococci. Enterococci can grow in the presence of 6.5% NaCl, but streptococci do not. The salt concentration, acting as a selective agent, interferes with membrane permeability and osmotic equi-

librium for most bacteria. Salt-tolerant organisms produce heavy growth in the medium within 48 h. Organisms that are capable of growing in the high salt concentration will also ferment glucose. Glucose fermentation produces an acid reaction which results in the bromcresol purple indicator turning yellow. Appearance of a yellow color change in broth with indicator is indicative of a positive salt tolerance test, although turbidity of the media is also considered a positive reaction. The broth media, HI with dextrose and indicator

(without additional salt), can be used as a growth control medium for the organism, for comparison of its growth in the same formula with the added salt. The control medium can also be used to demonstrate growth of the microorganism at various temperatures.

The pyrrolidonyl- β -naphthylamide (PYR) test has replaced the salt agar test to differentiate enterococci, but salt agar continues to be useful in the separation of the more recently described genera of catalase-negative cocci (1, 2, 3).

II. MICROORGANISMS TESTED

- A. Catalase-negative, aerobic, gram-positive cocci, to aid in the identification of organisms that do not key out by multitest kits as streptococci and enterococci
- B. Catalase-negative, aerobic, gram-positive cocci in tetrads and clusters, as part of the identification, including *Aerococcus* and *Alloiococcus*
- C. For some gram-negative rods, growth at various temperatures is used in their identification (reference 5 and procedure 3.8.2).

III. MEDIA, REAGENTS, AND SUPPLIES

A. Media

Store at 4 to 8°C.

1. HI (Difco, BD Diagnostic Systems; Remel, Inc.)

Approximate formula per liter of purified water

beef HI	500.0 g
tryptose	10.0 g
sodium chloride	5.0 g

2. Add 0.1 to 1% glucose and bromcresol purple indicator (1 ml of 1.6-g/100 ml 95% ethanol to a liter of medium) for temperature studies.
3. Add 0.5 to 1% glucose and bromcresol purple indicator plus 6% NaCl (HI contains 0.5% NaCl).

■ **NOTE:** Agar may be added to solidify the medium. Slant tube while cooling. Color reactions are easier to observe when agar, rather than broth,

medium is used since reaction (yellow color change) on the slant is visible before entire broth tube changes pH to produce yellow color.

4. Commercial HI broth with 6.5% salt is available from Remel, Inc. BHI with 6.5% salt is available from BD Diagnostic Systems and Hardy Diagnostics. SF broth (BD Diagnostic Systems) is similar but contains 5% salt and sodium azide to inhibit organisms other than *Enterococcus* spp.

B. Other supplies

1. Sterile sticks or inoculation loop
2. Beakers of water
3. Incubator at 35°C
4. Refrigerator at 10°C
5. Incubator or heat block at 42 to 45°C

IV. QUALITY CONTROL

- A. Examine medium for lack of turbidity and purple color.
- B. Test each new lot or shipment of medium with a positive and negative control prior to putting it into use.
- C. Organism
 - 1. *Enterococcus faecalis* ATCC 29212—growth at all temperatures and in salt (positive)
 - 2. *Streptococcus bovis* ATCC 33317—no growth at 10°C or in salt broth (negative)

V. PROCEDURE

- A. Add 1 or 2 drops from an overnight broth culture or one or two colonies from a fresh plate to the broth.
- B. Tighten tube caps.
- C. Incubate aerobically for up to 7 days and observe for growth (turbidity) and color change.
 - 1. To hold the temperatures, place the tube in a beaker of water at 10°C and at 42 to 45°C if an incubator, rather than a heat block, is used.
 - 2. Incubation temperatures
 - a. HI at 35°C
 - b. HI with 6.5% salt at 35°C
 - c. HI at 10°C
 - d. HI at 42 to 45°C

VI. INTERPRETATION

- A. A positive test shows visible turbidity and/or change in color from purple to yellow under the above-listed conditions; this occurs usually within 24 h, but tests can be incubated for up to 14 days.
- B. A negative test shows no turbidity or yellow color.

VII. REPORTING RESULTS

- A. Viridans group streptococci (including *S. bovis*), *Granulicatella*, *Dolosicoccus*, and *Gemella* do not grow in 6.5% salt.
- B. *Streptococcus agalactiae* may grow in salt broth.
- C. *Enterococcus*, *Lactococcus*, *Globicatella*, and *Vagococcus* will grow at 10°C, but other catalase-negative, gram-positive cocci generally will not (3).
- D. *S. bovis* and *Enterococcus* will grow at 45°C (1).
- E. *Pediococcus* and *Leuconostoc* have variable reactions but are easily separated by their vancomycin resistance and PYR-negative reactions.
- F. *Weissella confusa* usually grows at 42°C (2).

VIII. LIMITATIONS

- A. Adding agar to 6.5% salt broth and slanting the tube will provide a medium that will easily allow visualization of weak reactions that start on the top of the slant.
- B. Use of BHI, instead of HI, has not been tested with the unusual gram-positive cocci that are confused with streptococci and enterococci.

I. PRINCIPLE

Haemophilus influenzae requires two factors, hemin and NAD, for growth. NAD is also referred to as V factor. BAP supplies hemin but not NAD. Although *H. influenzae* requires both hemin and NAD, other *Haemophilus* species require only NAD for growth. Species that require NAD will not grow on BAP unless they are hemolytic and can release the NAD from the RBCs. However, they will grow well on BAP near colonies of staphylococci,

which are capable of providing NAD. The NAD diffuses into the surrounding medium and stimulates growth of *Haemophilus* in the vicinity of the staphylococcus colony. This is known as satelliting. For *Haemophilus* spp., the satellite test substitutes for the V factor test and does not require the purchase or QC of any reagents or strips (3, 4).

Similarly, nutritionally variant streptococci (NVS; include *Abiotrophia defectiva*

and *Granulicatella adiacens*, *Granulicatella elegans*, and *Granulicatella balaenopterae*, previously in the genus *Abiotrophia*) require either L-cysteine or pyridoxal to grow in vitro (2). These organisms do not grow on BAP, since it lacks the nutritional requirements, but will grow in the medium surrounding staphylococci, which supplies the needed nutrients.

II. MICROORGANISM TESTED

- A. Any organism growing only on CHOC and not on BAP that meets the following criteria
 1. Is suggestive of *Haemophilus* by Gram stain (gram-negative coccobacilli or short rods)
 2. Is a possible NVS by Gram stain (e.g., cocci, filaments, and bulbous forms in smear)
- B. Perform test only in conjunction with Gram stain. If bizarre forms are seen on Gram stain, repeat the smear after subculture to fresh CHOC (1).
- C. Use for detection of *Haemophilus* from lower respiratory specimens by dotting directly on the primary BAP.

III. ORGANISMS, MEDIUM, AND SUPPLIES**A. Microorganisms**

1. *Staphylococcus aureus* ATCC 25923 or
2. *Staphylococcus epidermidis* strain that is nonhemolytic and penicillinase negative

■ **NOTE:** Most any staphylococcus will work for the test. However, if using on primary BAP, it might be useful to choose coagulase-negative, beta-lactamase-negative, nonhemolytic staphylococci to be able to easily detect contamination of primary media and see hemolysis of colonies that grow from the specimen.

B. BAP**C. Supplies**

1. Sterile sticks or inoculating loop
2. Incubator at 35°C with 5 to 10% CO₂ or a CO₂-generating system

IV. QUALITY CONTROL

- A. Demonstrate satelliting on *each lot* of BAP using the staphylococcus and *H. influenzae* ATCC 43065. Record lot numbers of BAP and results in QC log.
- B. Verify satellitism with an NVS (e.g., *A. defectiva* ATCC 49176) when choosing a staphylococcus for the test.
- C. Periodically verify that the strain has not become contaminated, especially if it is being used on the direct specimen plates for sputum cultures. Alternatively, get a new stock of staphylococci from the freezer monthly.
 - ☑ **NOTE:** It is convenient to do the QC test when new lots of CHOC are received and must be quality controlled. The fresh growth of *Haemophilus* on the CHOC provides a stock for use in QC of the satellite test.

V. PROCEDURE

- A. Gram stain suspected colony.
- B. Subculture colony to BAP and CHOC.
 - 1. Use a sterile stick to dot the staphylococcus on the inoculated BAP.
 - 2. Incubate plates for 24 h at 35 to 37°C in 5% CO₂.
 - 3. Examine for the presence of colonies that satellite around staphylococcus dots on BAP.
 - 4. Use colonies from CHOC to perform further tests for identification to the species level or for susceptibility testing.

VI. INTERPRETATION

- A. Growth of tiny colonies surrounding the staphylococcus dots is a positive test.
- B. Growth on BAP without the staphylococcus dots is a negative test. Colonies appear on media with no concentration around staphylococcus dots or there is no growth on BAP.

VII. REPORTING RESULTS

- A. A positive result for a tiny gram-negative rod or coccobacillus indicates that the organism is in the genus *Haemophilus*.
- B. A positive result for a gram-positive coccus indicates a *Granulicatella* or *Abiotrophia* sp. For practical purposes, report as “Nutritionally variant streptococci.”
- C. Some microorganisms grow only on CHOC and will not grow on BAP even with a staphylococcus dot. These include *Francisella tularensis*, *Haemophilus ducreyi*, and some *Methylobacterium* spp.

VIII. LIMITATIONS

- A. *Haemophilus ducreyi* does not require V factor (NAD) but due to its fastidious nature does not grow on BAP even with the staphylococcus dot.
- B. *Haemophilus haemolyticus* and *Haemophilus parahaemolyticus* may grow without the staphylococcus and thus may not demonstrate the satellite phenomenon even though they require V factor (NAD). Since they are hemolytic, they can release NAD into the medium.
- C. *Brucella* can be confused with *Haemophilus*; this test separates these genera, since *Brucella* spp. grow on BAP without staphylococci to supply NAD.
- D. A positive satellite test for NVS does not definitely demonstrate that the organism requires pyridoxal to grow. Disks for this purpose are available commercially (Hardy Diagnostics; Remel, Inc.).

3.17.45

SPS (Sodium Polyanetholesulfonate) Disk Test

I. PRINCIPLE

Gardnerella vaginalis is believed to be a contributing cause of bacterial vaginitis (BV). It has also occasionally been reported to cause bacteremia in postpartum women and in men after transurethral resection of the prostate. Differentiation of *G. vaginalis* from other catalase-negative, gram-variable coccobacilli is achieved by

demonstration of the susceptibility of *G. vaginalis* to sodium polyanetholesulfonate (SPS), a common anticoagulant. Using a standardized inoculum, susceptibility to SPS is easily determined by measuring a zone of inhibition around a disk containing SPS (3).

Other microorganisms are susceptible to SPS, including *Haemophilus ducreyi*, which can be demonstrated by this test. Unfortunately, the use of SPS as an anticoagulant in blood cultures may interfere with the ability to isolate SPS-susceptible organisms from bacteremic patients.

II. MICROORGANISMS TESTED

- A. Catalase-negative, gram-variable coccobacilli presumed to be *G. vaginalis*
- B. Catalase-negative, gram-negative rods, to separate *H. ducreyi* from other *Haemophilus* spp.
- C. See section 4 for use of this test to identify anaerobic cocci.

III. MEDIA AND SUPPLIES

- A. **Medium and reagent**
 1. Brucella or other agar on which the organism will grow
 2. SPS disks—1 mg
- B. **Other supplies**
 1. Sterile sticks, swabs, or inoculation loops
 2. Sterile saline
 3. Incubator at 35°C with 5 to 10% CO₂ or CO₂-generating system
 4. 0.5 McFarland standard

IV. QUALITY CONTROL

- A. Test each new lot and/or shipment of disks with a positive and negative control prior to putting it into use and monthly or with use if test is performed less often.
- B. **Organisms**
 1. *G. vaginalis* ATCC 14108, ≥ 12 mm
 2. *Streptococcus sanguis* ATCC 35557, < 12 mm

V. PROCEDURE

- A. Using a 24- to 48-h culture, prepare a suspension of the test organism in sterile saline to match a no. 0.5 McFarland standard.
- B. Dip a sterile swab into the saline suspension and inoculate brucella or other agar in three directions for confluent growth, as for disk susceptibility testing.
 NOTE: Reimer and Reller (3) recommend use of brucella agar for *G. vaginalis*. Other media may work well and may be preferred for other organisms.
- C. Place SPS disk on plate.
- D. Incubate for 24 to 48 h at 35°C in 5% CO₂.
- E. Observe zone of inhibition.

VI. INTERPRETATION

- A. Susceptible is a zone of inhibition of ≥ 12 mm.
- B. Resistant is a zone of inhibition of ≤ 11 mm.

VII. REPORTING RESULTS

- A. The definitive identification of *G. vaginalis* consists of the following (1).
 1. Colonies appear pinpoint and transparent, with no greening of the agar on BAP, Columbia colistin-nalidixic acid agar (CNA), or CHOC.
 2. Gram-variable to gram-negative small, pleomorphic coccobacilli that do not elongate into filaments or chains
 3. Catalase negative
 4. SPS sensitive
 5. Beta-hemolytic on human blood agar
- B. The identification of *G. vaginalis* may include positive hippurate and lipase reactions, but negative results for these tests do not rule out the identification.
- C. *H. ducreyi* is susceptible, with a zone of ≥ 12 mm; no other *Haemophilus* species are susceptible. The addition of 0.002% Tween 80 may aid in dispersion of the cells (4). *Capnocytophaga* is reported to be SPS susceptible, but it is aminolevulinic acid (ALA) positive (4).

VIII. LIMITATIONS

- A. A critical factor in performance of the test is the inoculum size, which must be 10⁸ CFU/ml (3).
- B. It is not necessary to confirm the identification of *G. vaginalis* with tests other than colony morphology, catalase, and typical smear, if the direct Gram stain of a vaginal specimen is consistent with diagnosis of BV (2).

3.17.46

SS (Salmonella-Shigella) Agar Test for Growth

I. PRINCIPLE

Salmonella-shigella (SS) agar is commonly used for the selective isolation and differentiation of *Salmonella* and *Shigella* in both clinical and nonclinical samples. However, SS agar is also useful as part of an overall identification scheme for other, more unusual gram-negative organisms

based on their ability to grow on the medium (3). SS agar is inhibitory to most gram-positive and many gram-negative organisms, because it contains bile salts and brilliant green and neutral red dyes. SS agar is similar to MAC and can differentiate among the lactose fermenting and

non-lactose-fermenting organisms, but it is more inhibitory. It is a modification of a formula originally described by Leifson (1). Sodium thiosulfate and ferric citrate enable the detection of hydrogen sulfide production as evidenced by colonies with black centers.

II. MICROORGANISMS TESTED

- A. Gram-negative rods that are able to grow on MAC, if needed, as part of the identification (3)
- B. Gram-negative rods identified as either *Ralstonia paucula* (CDC group IVc-2) or *Bordetella bronchiseptica*

III. MEDIUM AND SUPPLIES

- A. **SS agar**
 - 1. Store at 2 to 8°C.
 - 2. If purchased or prepared in tubes, the shelf life is extended beyond 6 months.
 - 3. Prepare from dehydrated medium (Difco, BBL; BD Diagnostic Systems; Hardy Diagnostics).
 - a. Weigh desired amount per manufacturer's instructions.
- b. Boil for 2 to 3 min to dissolve. Cool to 50 to 60°C.
- c. Dispense in tubes, slant, and tighten caps. Do not autoclave medium.
- B. **Other supplies**
 - 1. Sterile sticks or inoculating loop
 - 2. Incubator at 35°C

IV. QUALITY CONTROL

- A. Check plates for signs of contamination, cracks, dehydration, and deterioration.
- B. Test each lot or shipment of medium with a positive and negative control prior to putting it into use. End-user QC testing of commercially prepared SS agar is not required, if the manufacturer certifies that each lot has been verified to meet or exceed NCCLS guidelines (2).
- C. Organisms
 - 1. *Shigella flexneri* ATCC 12022—growth and colorless colonies (positive)
 - 2. *Escherichia coli* ATCC 25922—partial or complete inhibition of growth (negative); colonies are pink to rose.

V. PROCEDURE

- A. Inoculate 1 or 2 drops from an overnight broth culture or one or two colonies from a fresh plate to the agar slant or plate. Streak slant in a zigzag direction across the slant and streak plate in quadrants for isolation of colonies.
- B. Incubate aerobically for up to 7 days at 35°C, and observe for visible growth.

VI. INTERPRETATION

- A. A positive test shows visible growth, usually within 24 h, but tests can be incubated for up to 7 days (3).
- B. A negative test shows no growth on the agar slant.

VII. REPORTING RESULTS

- A. For oxidase-positive, urea-positive, gram-negative, non-glucose-oxidizing rods that are nonpigmented and grow on MAC, separation of species is accomplished with SS agar.
 - 1. *R. paucula* (CDC IVc-2) does not grow on SS agar (negative).
 - 2. *B. bronchiseptica* grows on SS agar (positive).
- B. Refer to Weyant et al. (3) for other gram-negative rods for which SS agar is useful in identification (e.g., *Alcaligenes faecalis*, *Achromobacter xylosoxidans*, *Bordetella avium/hinzii*, *Pseudomonas mendocina* [Vb-2], and *Ralstonia eutropha*).

VIII. LIMITATIONS

- A. *E. coli* may grow, but will grow poorly, on SS agar. *Enterococcus faecalis* will not grow.
- B. Organisms that do not grow on MAC will not grow on SS agar.
- C. Due to the dyes and bile salts, growth of some *Shigella* strains is inhibited.

3.17.47

Starch Hydrolysis Test

I. PRINCIPLE

Bacteria can excrete an amylase, endoamylase, which hydrolyzes amylose to maltose and glucose. If there is no enzyme present, and therefore no hydrolysis, the starch agar will turn blue in the presence of iodine, due to the action of iodine and the helical structure of amylose. When hy-

drolysis occurs and thus no amylose is present, there is no color development in the medium immediately surrounding the colony. To observe this hydrolysis, an organism is grown on medium containing amylose. Since amylose and iodine react together to form a blue color, the plates

can be flooded with iodine to visually detect the absence or presence of amylose, one of the components of starch. Mueller-Hinton agar (MH) contains amylose and can be used to test for starch hydrolysis, avoiding the purchase of additional media.

II. MICROORGANISMS TESTED

- A. To separate *Streptococcus bovis* (positive) from other viridans group streptococci that are bile-esculin positive, 6.5% NaCl negative, and pyrrolidonyl- β -naphthylamide (PYR) negative
- B. To separate *Chryseobacterium meningosepticum* (negative) from *Chryseobacterium indologenes* (positive)

III. MEDIA, REAGENT, AND SUPPLIES

A. Media

1. MH
2. Heart infusion agar with 2% starch

B. Reagent

Gram's iodine (Appendix 3.2.1-1)

C. Supplies

1. Sterile sticks or inoculating loops
2. Incubator at 35°C

IV. QUALITY CONTROL

- A. Inspect agar for freezing, contamination, cracks, and dehydration prior to storage and before use.
- B. Perform QC on each new lot or shipment of starch agar prior to putting it into use. MH agar can be tested with use for starch hydrolysis.
- C. Organisms
 1. *S. bovis* ATCC 33317—clear halo around colony with addition of iodine (starch positive)
 2. *Enterococcus faecalis* ATCC 25922—blue color with addition of iodine (starch negative)

V. PROCEDURE

- A. After touching several colonies from an 18-h culture, inoculate several segments of one-half of the agar surface with a very *visible circular* amount of organism about the size of a dime on each spot. *Be sure plate has no surface moisture.*
- B. Inoculate a positive and negative control on the other half of the plate in the same manner.

V. PROCEDURE (*continued*)

- C. Incubate without increased CO₂ for at least 48 h.
- D. To detect starch hydrolysis, transfer a piece of agar from one of the growth dots of the test or control organism to an empty sterile petri dish. Flood dropwise with Gram's iodine and observe for halos around colony.
- E. If negative for starch hydrolysis, reincubate and retest additional pieces of agar at 72 h or later.

VI. INTERPRETATION

- A. A positive test is development of a clear halo without color around the colony and a blue to blue-purple color in the surrounding medium after the addition of Gram's iodine.
- B. A negative test shows no clear halo around the colony. The medium around the colony turns blue to blue-purple after the addition of Gram's iodine.

VII. REPORTING RESULTS

- A. Catalase-negative, PYR-negative, gram-positive cocci that are bile-esculin positive, do not grow on 6.5% salt, and hydrolyze starch are *S. bovis*. If they are positive for group D antigen, they are definitively identified, without starch or salt testing.
- B. Catalase-negative, PYR-negative, gram-positive cocci that are bile-esculin positive, do not grow on 6.5% salt, and do not hydrolyze starch may be *S. bovis* variants, but other tests need to be done to confirm the identification.
- C. Among the yellow-pigmented indole-, catalase-, esculin-, and oxidase-positive gram-negative rods, *Chryseobacterium gleum/indologenes* is starch positive.

VIII. LIMITATIONS

- A. Avoid using glucose starch medium, since the metabolism of glucose may interfere with the assay (3).
- B. Read plates immediately after addition of iodine, as the blue color fades.
- C. Once the iodine is added, the organisms are nonviable.
- D. A red-violet color is due to partial hydrolysis, and the test should be repeated after further incubation.
- E. The identification of *S. bovis* is difficult, and the organism can be confused with *Streptococcus mutans* (starch negative) and *Streptococcus salivarius* (1, 4).
- F. *S. bovis* strains from humans are said to be biotype I if they hydrolyze starch. *S. bovis* biotype II strains do not hydrolyze starch (2).
- G. *Gardnerella vaginalis* organisms are starch positive but this test is not a reliable method to identify them, since they do not grow on MH and require special starch media to grow.

3.17.48

Urea Test

I. PRINCIPLE

Urea medium, whether a broth or agar, contains urea and the pH indicator phenol red. Many organisms, especially those that infect the urinary tract, have a urease enzyme, which is able to split urea in the presence of water to release two molecules of ammonia and carbon dioxide. The ammonia combines with the carbon dioxide and water to form ammonium carbonate, which turns the medium alkaline (5), turning the indicator from its original orange-yellow color to bright pink (2).

This test can be used as part of the identification of several genera and species of *Enterobacteriaceae*, including *Proteus*, *Klebsiella*, and some *Yersinia* and *Citrobacter* species, as well as some *Corynebacterium* species. It is also useful to identify *Cryptococcus* spp. (see section 8), *Brucella*, *Helicobacter pylori*, and many other bacteria that produce the urease enzyme.

Disks are available that combine urea and phenylalanine deaminase (PDA), allowing a one-disk test to identify *Proteus*, *Providencia*, and *Morganella* and separate them from *Klebsiella* and *Yersinia enterocolitica* (3). The disk reactions are rapid and sensitive and allow for the rapid detection of agents of serious infections, e.g., *Brucella* and *Cryptococcus*.

II. MICROORGANISMS TESTED

- A. The urea test is part of the battery of tests to identify the following.
 1. Gram-negative enteric pathogens, including *Yersinia* spp.
 2. Fastidious gram-negative rods—*Brucella*, *H. pylori*, and *Pasteurella*
 3. Gram-positive rods—*Corynebacterium* and *Rhodococcus* spp.
 4. Yeasts—*Cryptococcus* spp.
- B. Directly, this test is performed on gastric biopsy samples to detect the presence of *H. pylori* (see procedure 3.8.4 for details).

III. MEDIA, REAGENTS, AND SUPPLIES

A. Media and reagents

Use one of the following.

1. Christensen's urea agar slants containing urea, peptone, dextrose, and agar in buffered phenol red solution
 - ☑ **NOTE:** Urea cannot be autoclaved but must be filter sterilized and added to agar. Christensen's urea agar base 10× concentrate (BD Diagnostic Systems) can be added to autoclaved and cooled agar to prepare medium.
2. Christensen's urea broth
 - a. Dilute Christensen's urea agar base 10× concentrate 1:10 with sterile distilled water.
 - b. Dispense in 0.5-ml amounts into 13- by 100-mm tubes.
3. Rapid urea medium (Remel, Inc.; Hardy Diagnostics) containing agar

and urea in buffered phenol red solution. This medium can also be used for gastric biopsy specimens (1, 4).

4. Rapid urea broth (Remel, Inc.)
5. RSU broth containing sucrose and urea for rapid identification of *Corynebacterium* (Hardy Diagnostics)
6. Urea disks or tablets—stored at 2 to 8°C
 - a. Supplied by Remel, Inc.; Key Scientific; or Hardy Diagnostics
 - b. Supplied as urea-PDA disks (Remel, Inc.; Hardy Diagnostics)

B. Supplies

1. Sterile wooden sticks or loops
2. Saline or water in small plastic tube for disk test
3. Incubator at 35 and 30°C

IV. QUALITY CONTROL

- A. Inspect agar for evidence of prior freezing, contamination, cracks, and dehydration prior to storage and before use.
- B. Each time the test is performed for direct gastric specimens, test negative reactions for the ability of the medium to split urea and turn the medium red.
1. Insert a urease tablet (Kimberly Clark, Draper, Utah) into the negative patient test, as you would a biopsy sample.
 2. After 5 min, inspect for a positive red color change.
- C. Test each new lot or shipment of medium or reagent with a positive and negative control prior to putting it into use.
- **NOTE:** NCCLS has proposed elimination of user QC for urease agar purchased from commercial sources. Consult with current regulatory agencies prior to discontinuation of user QC (6).
- D. Organisms
1. *Proteus mirabilis* ATCC 12453—positive (red color)
 2. *Escherichia coli* ATCC 25922—negative (no color change)
- **NOTE:** Alternate controls should be used if test is being done for detection of *H. pylori*. The reaction time of *H. pylori* is much shorter than that of *P. mirabilis*.
- H. pylori* ATCC 43504—positive (red color)
Campylobacter jejuni ATCC 33560—negative (no color change)

V. PROCEDURE

- A. **Christensen's urea agar**
1. Using a sterile stick or loop, inoculate the agar slant surface from a well-isolated colony. Do not stab the butt.
 2. Incubate, with cap loosened, aerobically at 35 to 37°C.
 3. For nonfermenters, incubate at 30°C.
 4. Examine for the development of a pink color for as long as 7 days.
- **NOTE:** If the organism does not grow on the slant, inoculate heavily with growth from the plate to detect preformed urease.
- B. **Urea agar deeps or rapid urea broth**
1. Pick up colonies with either a stick or needle.
 2. Stab the agar or rotate in the broth with the inoculated stick or needle.
 3. For biopsy samples, refer to procedure 3.8.2.
- C. **Urea disks or tablets**
- Check the package insert for differences from procedure below.
1. Prepare a small test tube with 0.25 ml (5 drops) of saline or water.
- **NOTE:** Preferably use plastic tubes for disk tests.
2. Make a heavy suspension of the actively growing organism.
 3. Add urea disk. (Tablets are already in tube.)
 4. Incubate aerobically at 35°C for 1 to 24 h.
- D. **Gastric specimens**
- See procedure 3.8.4.

VI. INTERPRETATION

- A. A positive test is development of an intense magenta to bright pink color in 15 min to 24 h.
- B. A negative test shows no color change.

VII. REPORTING RESULTS

It is imperative that these cultures be handled in a biosafety hood.

- A. This test will help differentiate among gram-negative rods that grow well on MAC and are likely members of the *Enterobacteriaceae*.
- B. Urea-positive, oxidase-positive, gram-negative coccobacilli that do not grow on MAC in 24 h are presumptively identified as *Brucella*, unless they are isolated from urine. *Immediately transfer cultures to a biosafety cabinet.*
- C. Urea-positive, oxidase-positive, gram-negative coccobacilli that are isolated from the urinary tract may be *Oligella ureolytica*.
- D. Identify further any significant numbers of urea-positive corynebacteria from respiratory or urine specimens. See procedure 3.18.1.
- E. Urea-positive, oxidase-positive, curved rods from gastric specimens are identified as *H. pylori* (7).
- F. Use urea reaction as part of the identification of other microorganisms, following charts in procedure 3.18.2.

VIII. LIMITATIONS

- A. Some organisms rapidly split urea (*Brucella* and *H. pylori*), while others react slowly.
- B. When performing overnight tests from medium that contains peptone, the alkaline reaction may be due not to urease but to hydrolysis of peptone.
- C. Urea is light sensitive and can undergo autohydrolysis. Store at 2 to 8°C in the dark.
- D. The test is less sensitive if the medium is not buffered.

3.18.1

Identification of Gram-Positive Bacteria

I. PRINCIPLE

Unlike gram-negative rods, it can be very difficult to sort out the identification of gram-positive cocci and rods. Many kits for staphylococcal identification have proved to be less sensitive than desired, and new DNA studies indicate that we have misidentified many streptococci. Gram-positive rods have been difficult to identify because there are hundreds of named species and thousands of genotypes or biochemical variants found in the environment and the normal microbiota of the human body, including skin, mucosal membranes, oropharynx, and genitourinary and gastrointestinal tracts. Thus, it is not within the scope of this handbook to identify all isolates, but to detect and iden-

tify the known pathogenic microorganisms in the human biosphere and to limit other identifications to those bacteria that are involved in disease from invasively collected specimens. The figures and tables that follow are designed to rapidly determine the agents of infection and to provide guidance for when to perform a kit identification or pursue other microorganisms.

The charts may not include all the options at each step, since the observance of a colony morphology may lead to performing a test but the lack of that morphology may suggest doing a different test. The figures are designed to do the minimum to arrive at an excellent identi-

fication, without doing further tests unless the morphology warrants them. For species identification of viridans group streptococci, enterococci, and corynebacteria, commercial kits are easier to perform than standard tube biochemical tests (*see* Tables 3.16–1, 3.16–3, and 3.16–4) but are still limited in their accuracy. No system available can do as good a job as cell wall analysis and DNA studies, both of which are beyond the scope of most laboratories and beyond reasonable cost. For identification of other aerobic gram-positive rods in the actinomycete group, refer to section 6 of this handbook; for further information on *Actinomyces* spp., refer to section 4 and reference 5.

II. MICROORGANISMS TESTED

Gram-positive rods or cocci as determined by Gram stain.

☑ **NOTE:** Because of the lack of a unique colony morphology of many gram-positive microorganisms, the Gram stain *must* be performed on all isolates. Colonies of *Streptococcus* and *Aerococcus* may appear similar, but these organisms can be differentiated by the arrangement of the cells in the Gram stain. Group B streptococci and *Listeria* colonies may also have a similar appearance. Gram-variable microorganisms are considered to be gram positive. When in doubt, the Gram reaction enzymatic test (procedure 3.17.20) may be helpful.

III. MEDIA, REAGENTS, AND SUPPLIES

☑ **NOTE:** See individual tests in procedure 3.17 for methods for use of tests. To the extent that tests are available in kits, it is not necessary to stock the separate tests.

A. Media

1. Bile-esculin (procedure 3.17.5)
2. Glucans (optional) (procedure 3.17.19)
3. H₂S production medium (procedure 3.17.22)
4. Human blood agar for *Gardnerella*

5. Lipophilism test (procedure 3.17.28)
6. Ornithine and arginine decarboxylase (procedure 3.17.15)
7. 6.5% NaCl broth (procedure 3.17.43)
8. Broth for motility (procedure 3.17.31)
9. Lecithinase agar (procedure 3.17.27)

B. Reagents and supplies

1. Catalase (3% H₂O₂) (procedure 3.17.10)

III. MEDIA, REAGENTS, AND SUPPLIES (continued)

2. Polymyxin B (300 U), novobiocin (5 g), bacitracin (0.4 U), and vancomycin disks (procedure 3.17.4)
3. CAMP test (procedure 3.17.8)
4. Coagulase by rabbit plasma and (optionally) agglutination (procedures 3.17.13 and 3.17.14)
5. Spot bile reagent (procedure 3.17.6)
6. Hippurate (optional) (procedure 3.17.21)
7. Leucine aminopeptidase (LAP) (procedure 3.17.26)
8. Optochin disks (procedure 3.17.38)
9. Streptococcal grouping antisera (section 11)
10. Pyrrolidonyl- β -naphthylamide (PYR) (procedure 3.17.41)
11. Urea test (procedure 3.17.48)
12. Kits for identification of enterococci and viridans group streptococcus gram-positive and gram-positive rod identifications (corynebacterium and anaerobe kits) (Tables 3.16-1, 3.16-3, and 3.16-4)

IV. PROCEDURE

- A. Observe colony morphology on BAP and CHOC if growth is lacking on BAP.
- B. Perform catalase and Gram stain from BAP or CHOC.
 - **NOTE:** To avoid misidentifications, do not skip this step.
- C. Use Fig. 3.18.1-1 if the organism is a catalase-positive, gram-positive coccus.
- D. Use Fig. 3.18.1-2 if organism is a beta-hemolytic, catalase-negative, gram-positive coccus.
- E. Use Fig. 3.18.1-3 if organism is a catalase-negative, gram-positive coccus that is not hemolytic (except those with characteristic group B streptococcus morphology) and either is PYR negative or does not grow on BAP, except around staphylococci.
- F. Proceed to Fig. 3.18.1-4 if the catalase-negative, gram-positive coccus is PYR positive and not identified from the other figures.
- G. For gram-positive rods, proceed to Fig. 3.18.1-5.
 1. If isolate is catalase positive
 - a. Perform CAMP test (and test for lipophilism, if microorganism demonstrates small colonies or poor growth at 24 h).
 - b. Check for motility by wet mount from young growth of either broth or agar cultures.
 2. If isolate is catalase negative, follow Fig. 3.18.1-5 based on the anatomical site of isolation.

V. REPORTING AND INTERPRETATION OF RESULTS

- A. Follow tables and kit identifications to report genus and species as appropriate without delay.
- B. Use commercial kits for identification of *Enterococcus faecalis* and *Enterococcus faecium*, but perform motility testing on vancomycin-intermediate or -resistant *E. faecium*.

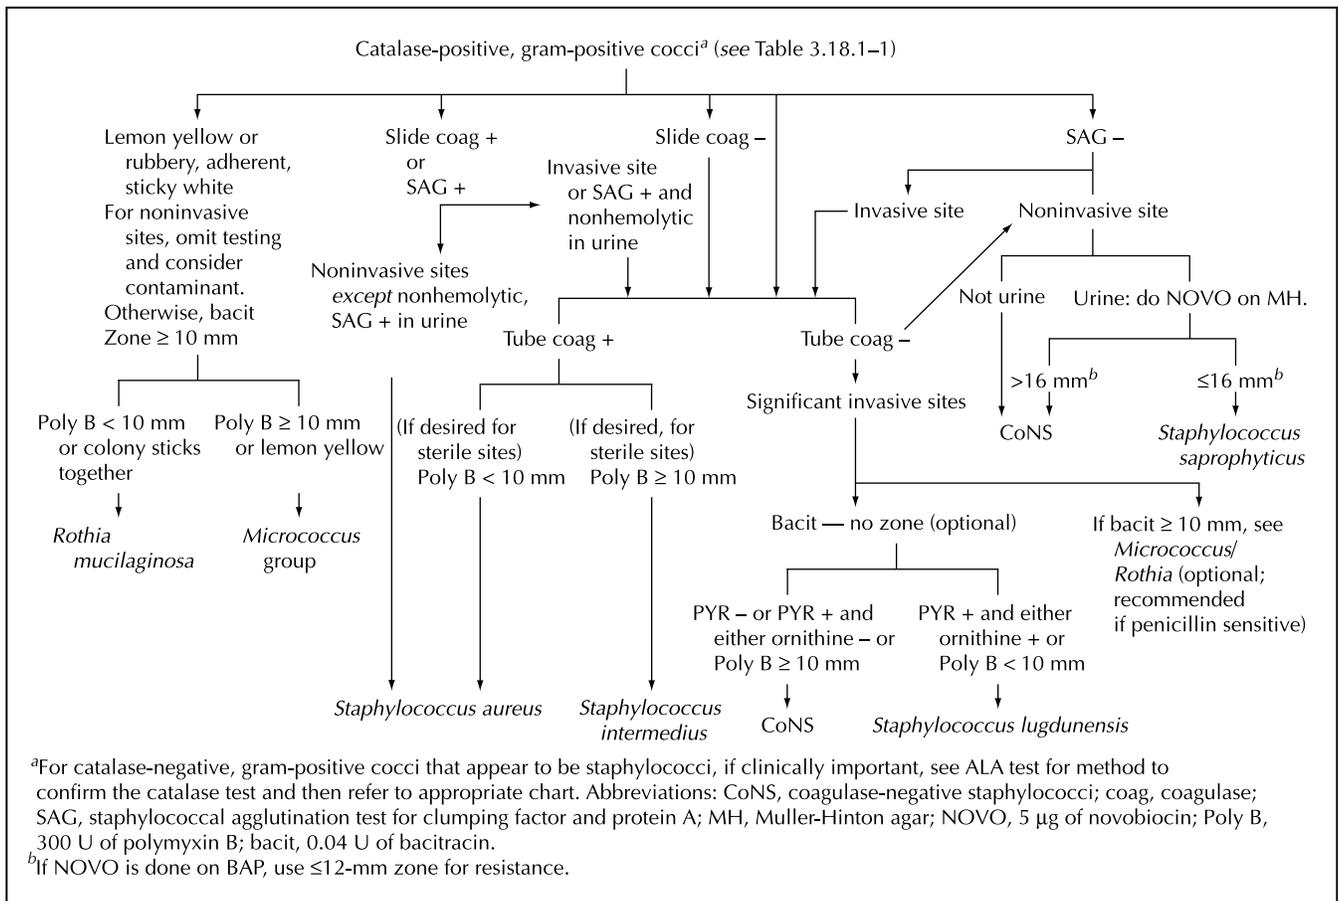

Figure 3.18.1-1 Flowchart for identification of catalase-positive, gram-positive cocci.

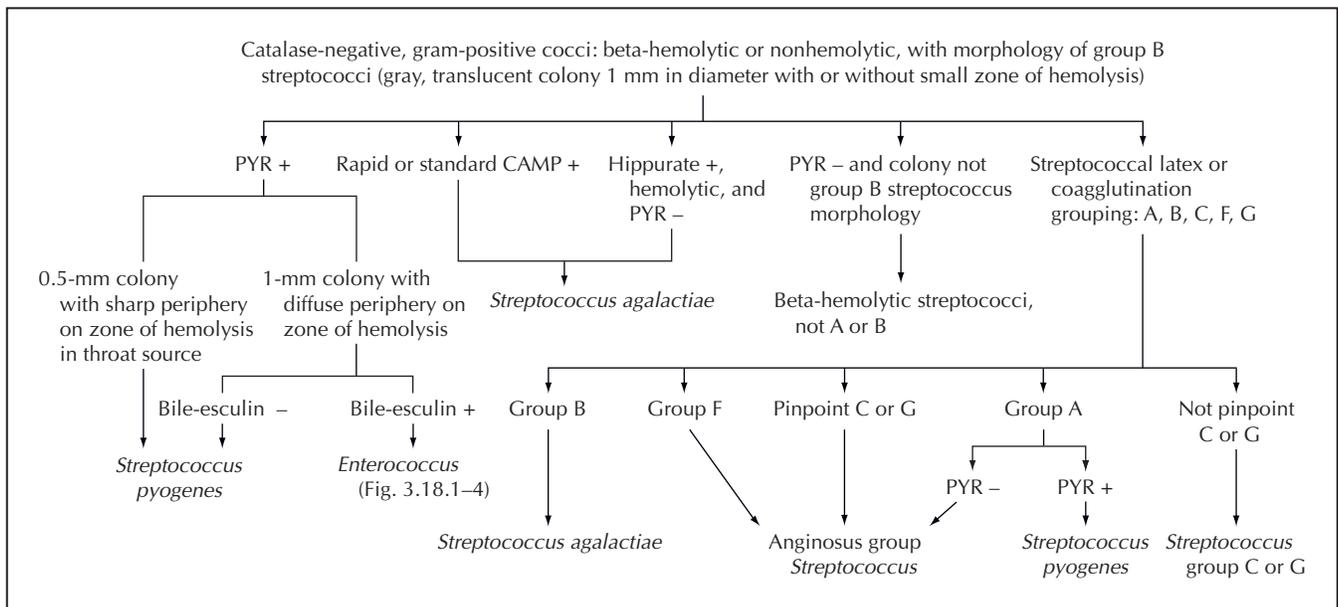

Figure 3.18.1-2 Flowchart for identification of catalase-negative, gram-positive cocci, either beta-hemolytic or nonhemolytic, with morphology of group B streptococci.

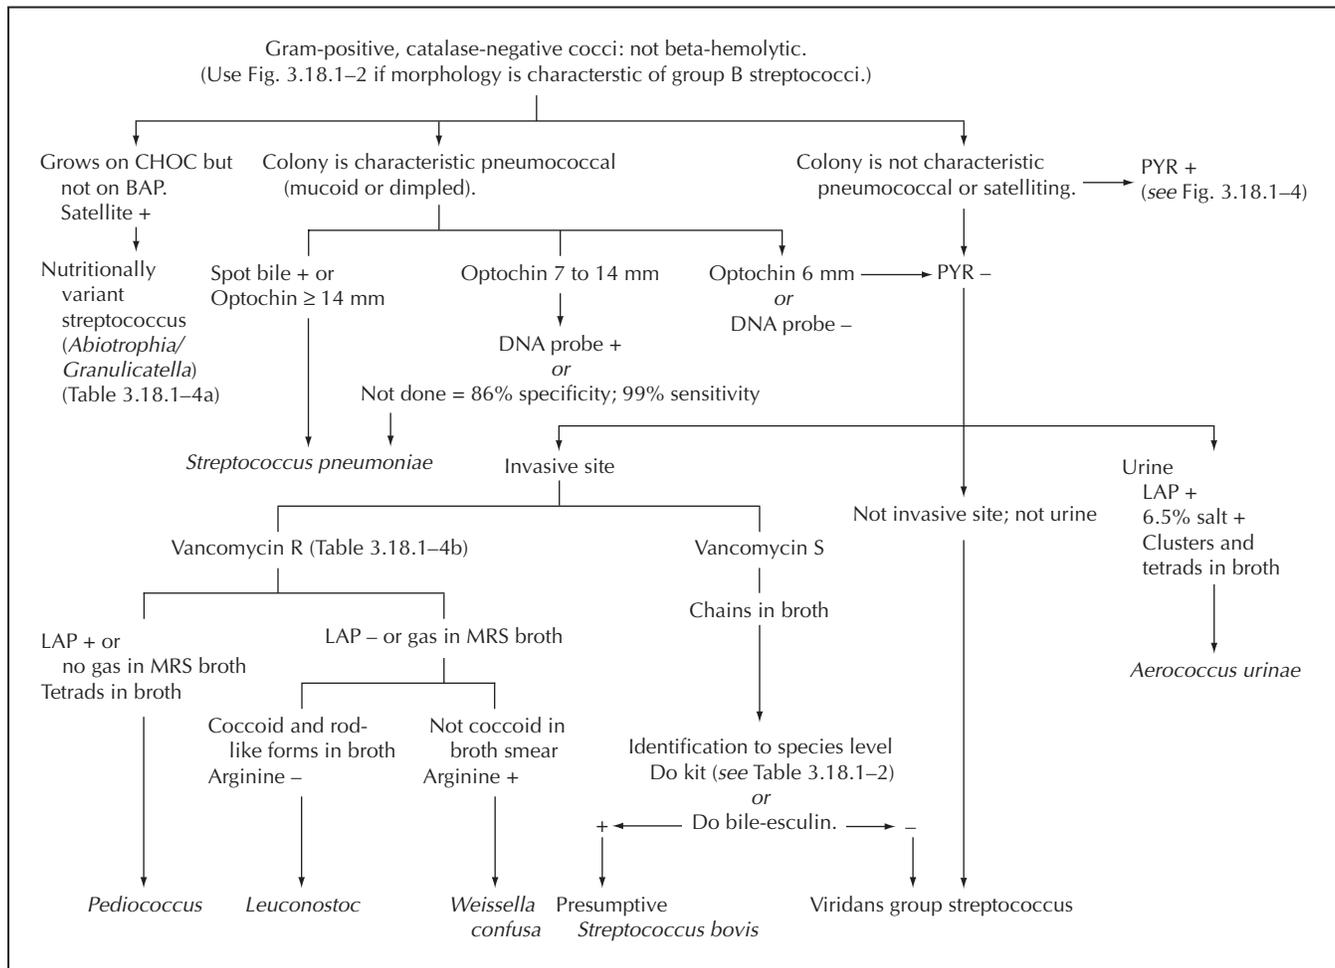

Figure 3.18.1-3 Flowchart for identification of gram-positive, catalase-negative, cocci that are not beta-hemolytic. R, resistant; S, susceptible.

VI. LIMITATIONS

- A. A number of gram-positive cocci are either coagulase or agglutination positive but are not *Staphylococcus aureus*, making identification problematic.
- B. Some staphylococci are catalase-negative. See the aminolevulinic acid (ALA) test for options.
- C. Streptococci are increasingly difficult to identify to the species level, even with commercial kits. The LAP test is important to at least confirm the genus of streptococci or enterococci.
- D. Gram-positive rods are most difficult to identify. Every laboratorian should be able to recognize *Listeria monocytogenes*, *Erysipelothrix rhusiopathiae*, *Bacillus cereus*, *Arcanobacterium haemolyticum*, and *Gardnerella vaginalis* and be able to presumptively recognize *Bacillus anthracis* and *Corynebacterium diphtheriae*. Some other *Corynebacterium* species are identified using a commercial kit. For other gram-positive rods of significance, a reference laboratory is usually needed.

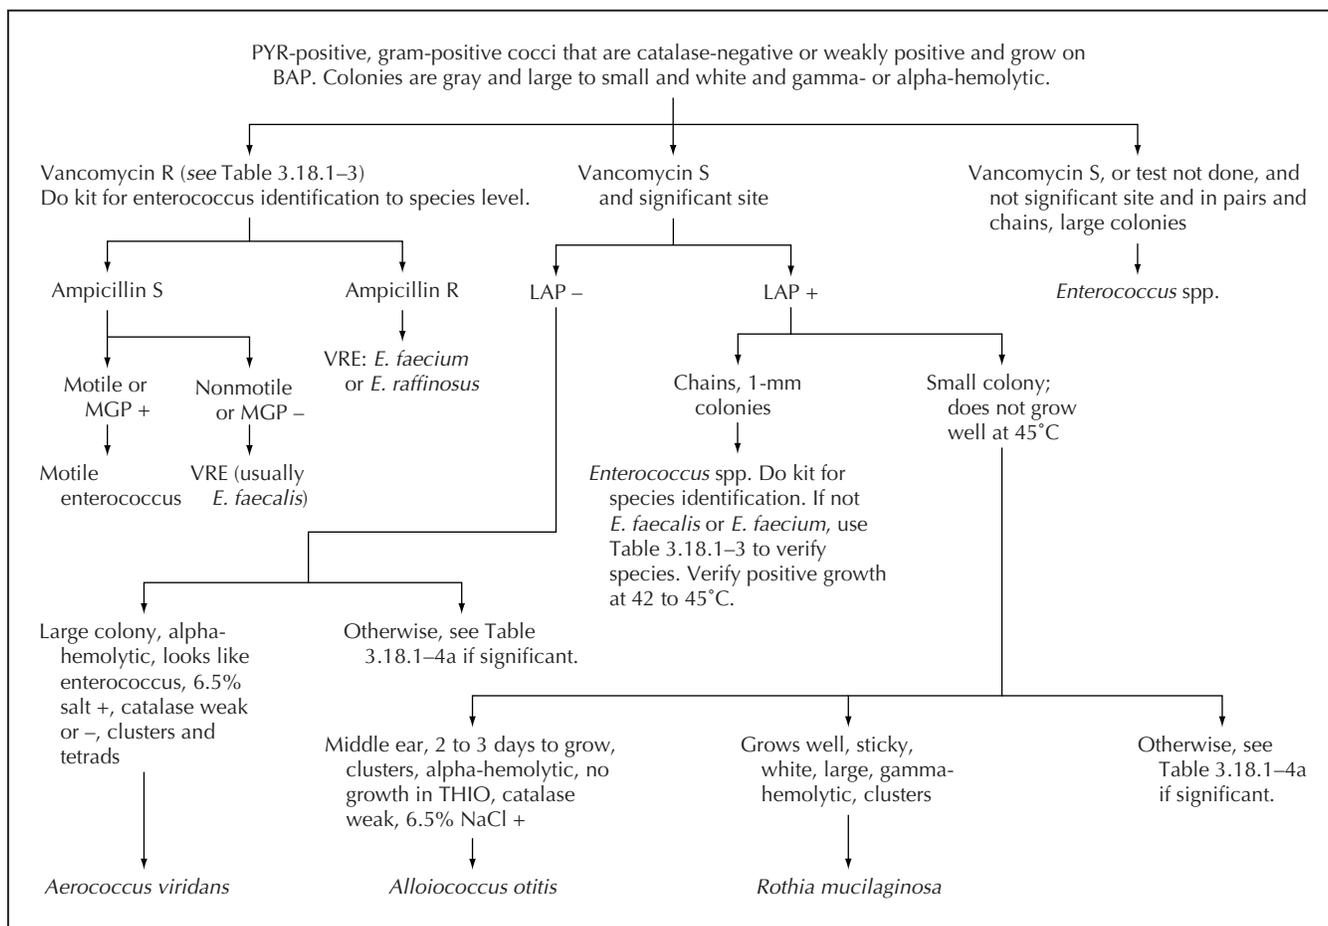

Figure 3.18.1-4 Flowchart for identification of PYR-positive, catalase-negative, gram-positive cocci. R, resistant; S, susceptible; VRE, vancomycin-resistant enterococci; MGP, methyl- α -D-glucopyranoside.

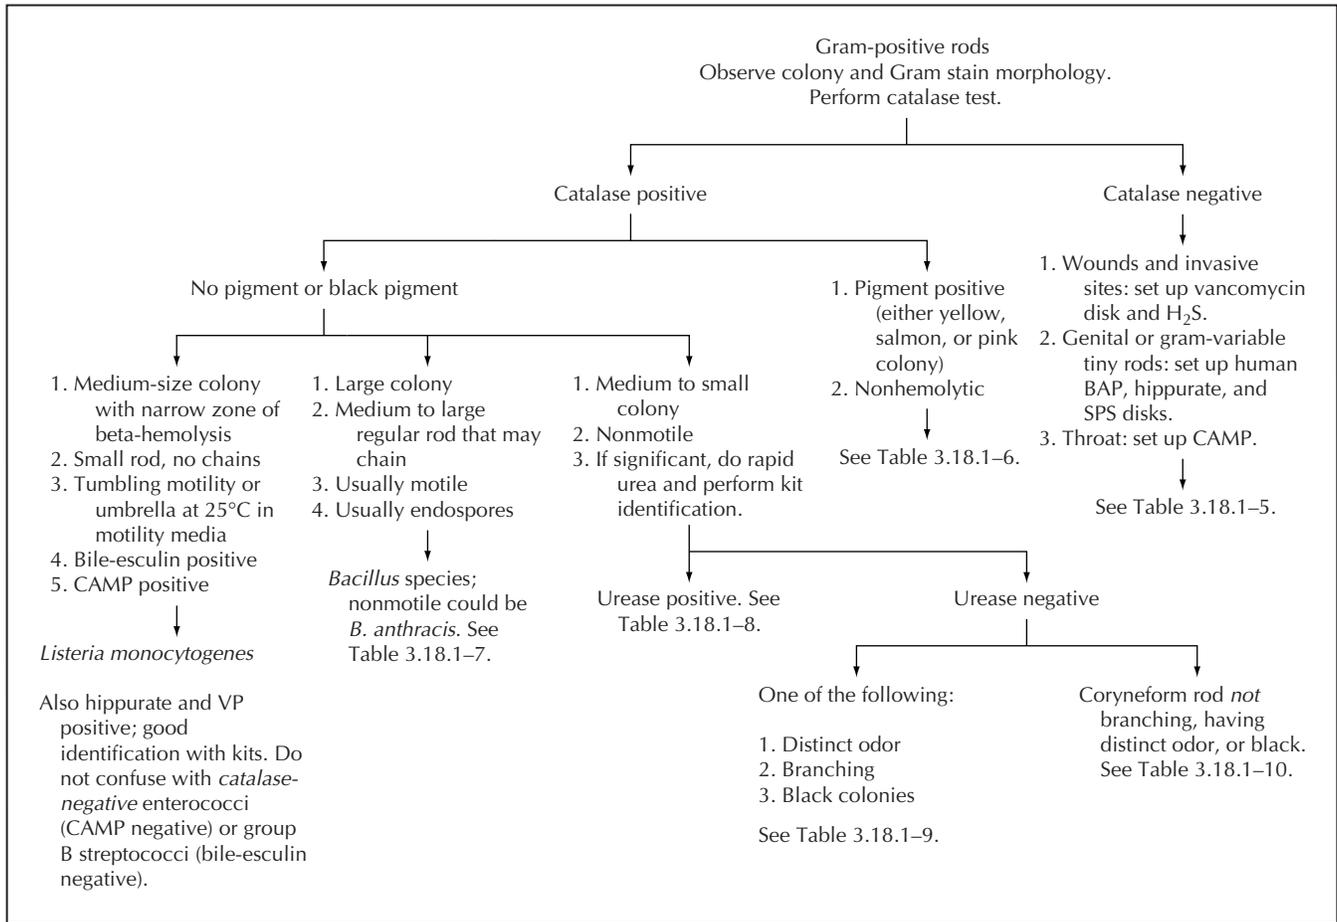

Figure 3.18.1-5 Guide to distinguish genera and significant species of gram-positive rods. VP, Voges-Proskauer. (Refer to section 6 for aerobic actinomycetes.)

Table 3.18.1–1 Key biochemical reactions of the common and/or significant gram-positive cocci that are catalase positive with large white to yellow colonies^a

Organism(s)	Selected characteristic(s)	Slide coag	SAG	Tube coag	Bacit (0.04 U)	Poly B (300 U)	PYR ^b
<i>Rothia mucilaginosa</i>	Adherent, sticky				S	R	V
<i>Micrococcus</i> group ^c	Often yellow				S	S	V
<i>S. aureus</i>	VP +	V	+	+	R	R	–
<i>S. intermedius</i> (dogs)	VP –	V	V	+	R	S	+
<i>Staphylococcus delphini</i> (dolphins)	VP –	–	NA	+	R	NA	NA
<i>Staphylococcus hyicus</i> (pigs)	VP –	–	NA	V	R	R	–
<i>S. lugdunensis</i>	Ornithine +	V	V	–	R	R	+
<i>S. schleiferi</i>	Ornithine –	+	V	– ⁺	R	S	+
<i>S. saprophyticus</i>	Urine; novo R; nonhemolytic	–	V	–	R	S	–
<i>Staphylococcus epidermidis</i>	Nonhemolytic	–	–	–	R	R	–
<i>S. haemolyticus</i>	Urease –, VP +, DNase –	–	–	–	R	S	+
<i>Staphylococcus caprae</i>	Urease +, DNase +	–	–	–	R	S	+
Other coagulase-negative staphylococci	Novo V, urease V; nonhemo- lytic or delayed hemolysis	–	V	–	R	S	V

^a Symbols and abbreviations: +, greater than 90% of strains positive in 48 h; –, greater than 90% of strains negative; V, results are between 90 and 10% positive; –⁺, most strains are negative but rare positive strains exist; NA, not applicable or available; R, resistant; S, susceptible; Bacit, bacitracin; Poly B, polymyxin B; coag, coagulase; SAG, staphylococcal protein A or clumping factor agglutination; VP, Voges-Proskauer; Novo, novobiocin. Data are from references 1, 6, 12, 15, 16, 19, 23, and 30. Catalase can be weak for *Rothia*.

^b PYR data are for broth test. Weak positive results with *S. aureus* ATCC 29213 and ATCC 25923 occur with the disk test, suggesting that this test is unreliable to separate *S. aureus* from *S. intermedius* (M. York, personal communication).

^c Includes related taxa. The genus *Micrococcus* has been divided into additional genera, including *Kytococcus* and *Kocuria*.

Table 3.18.1–2 Separation of the common groups of viridans group streptococci (PYR-negative, LAP-positive, 6.5% NaCl-negative cocci in chains)^a

Group	Species	VP	ARG	MAN	SOR	Esculin	Glucans	Hemolysis and comments
Mutans	<i>S. mutans</i> , <i>S. sobrinus</i> , <i>S. rattii</i>	+	–	+	+	V	+, puddles and droplets	α, β. Sometimes dry and adherent. <i>S. sobrinus</i> can be sorbitol negative; <i>S. rattii</i> is arginine positive.
Salivarius	<i>S. salivarius</i> , <i>S. vestibularis</i>	+	–	–	–	+	+, mucoid, firm	α, γ. <i>S. vestibularis</i> is α, VP and esculin variable, and glucan negative
Bovis	I	+	–	+	–	+	+, watery, spreads	γ. Bile-esculin positive (3). Taxonomic revisions suggest that human <i>S. bovis</i> I isolates be renamed as <i>S. gallolyticus</i> , and biotypes II/2 and II/1 have proposed species names <i>S. pasteurianus</i> and <i>S. infantarius</i> , respectively (3, 4, 10, 27)
	II/1	+	–	–	–	+	+, watery, spreads	
	II/2	+	–	–	–	+	–	
Anginosus (“ <i>S. milleri</i> ”)	<i>S. anginosus</i> , <i>S. constellatus</i> , <i>S. intermedius</i>	+	+	– ⁺	–	+ [–]	–	α, β, γ. <i>S. constellatus</i> is divided into subspecies <i>constellatus</i> and <i>pharyngis</i> . All species are esculin positive, except that <i>S. constellatus</i> subsp. <i>constellatus</i> is esculin variable (28).
Mitis	<i>S. sanguis</i> , <i>S. parasanguis</i> , <i>S. gordonii</i> , <i>S. cristatus</i>	–	+	–	V	+ [–]	V, hard, adheres to agar	α. <i>S. cristatus</i> may be arginine and esculin negative. <i>S. parasanguis</i> may be esculin negative. <i>S. sanguis</i> may be sorbitol positive.
	<i>S. mitis</i> , <i>S. oralis</i>	–	–	–	–	– ⁺	V	α. Can be penicillin resistant. <i>S. oralis</i> can be esculin positive.

^a Abbreviations: ARG, hydrolysis of arginine; MAN, acid production from mannitol; SOR, acid production from sorbitol; +[–], most strains positive but rare negative strains exist. See Table 3.18.1–1, footnote *a* for other abbreviations and symbols. Strains do not always produce glucans; test is only useful if positive. Commercial kits for identification of streptococci are helpful to resolve variable reactions. Data are extrapolated from reference 35. Also see references 7, 10, 25, and 28.

Table 3.18.1-3 Common species of enterococci and related PYR-positive cocci in chains^a

Organism	Motility ^b	Pigment ^c	MGP	Arginine dihydrolase	Arabinose	Mannitol	Lactose	Raffinose	Ribose	Sorbitol	45°C growth	Vancomycin
<i>E. avium</i>	-	-	V	-	+	+	+	-	+	+	+	S

<i>E. dispar</i>	-	-	+	+	-	-	+	+	+	-	-	S

^a All species grow well on BAP and in 6.5% NaCl and are PYR, bile-esculin, and LAP positive. PYR-negative species *E. cecorum*, *E. columbae*, and *E. saccharolyticus* are not included and have not been isolated from humans. PYR-positive strains *E. malodoratus*, *E. pseudoavium*, *E. asini*, and *E. sulfureus* (H₂S⁺) also are not listed since they have not been isolated from humans. *E. gilvus* and *E. pallens* have been described to occur in humans but are extremely rare. Abbreviations: MGP, methyl- α -D-glucopyranoside; D, different reactions in references. See footnote *a* to Tables 3.18.1-1 and 3.18.1-2 for other abbreviations and symbols. Table adapted from references 11, 26, and 33. Also see references 20, 21, and 32.

^b Motility is done in 0.5 ml of BHI or TSB incubated at 30°C for 2 h.

^c Pigment (yellow) is observed by swabbing a blood agar plate incubated at 35°C in 5% CO₂ for 24 to 48 h and observing swab for bright yellow color (+).

^d Lactose-negative asaccharolytic *E. faecalis* exists.

Table 3.18.1–4a Biochemical reactions of PYR-positive, catalase-negative or weakly positive, gram-positive cocci (excluding *Streptococcus pyogenes*)

Genus or species	Phenotypic characteristics ^a								
	Gram stain	CAT	LAP	NaCl	10°C	45°C	Colony on BAP	Hemolysis	Bile-esculin
<i>Enterococcus</i> (some motile)	CH	–	+	+	+	+	Large	α, γ, β	+
<i>Lactococcus</i>	CH	–	+	V	+	–	Large	α, γ	+
<i>Vagococcus</i> (motile)	CH	–	+	+	+	–	Large	α, γ	+
<i>Abiotrophia/Granulicatella</i>	CH	–	+	–	–	–	Satellite	α, γ	–
<i>Globicatella</i>	CH	–	–	+	–	–	Small	α	V
<i>Dolosicoccus</i>	CH	–	–	–	–	–	Small	α	NA
<i>Aerococcus viridans</i>	CL/T	–, W	–	+	–	–	Large	α	V
<i>Helcococcus kunzii</i>	CL/T	–	–	V	–	–	Tiny	γ	–
<i>Gemella</i>	CL/T/CH	–	V	–	–	–	Tiny, 48 h to grow	α, γ	–
<i>Facklamia</i> (hippurate +)	CL/CH	–	+	+	–	–	Small	γ	–
<i>Alloiococcus otitis</i>	CL/T	W, +	+	+	–	–	Tiny, 72 h to grow	α	NA
<i>Ignavigranum</i> (hippurate –)	CL/CH	–	+	+	–	–	Satellite (V) or small	γ	–
<i>Rothia mucilaginosa</i>	CL	–, W, +	+	–	NA	NA	Sticky	γ	V
<i>Dolosigranulum</i>	CL/T	–	+	+	–	–	Small	γ	NA

^a CAT, catalase production; NaCl, growth in broth containing 6.5% NaCl; 10°C and 45°C, growth at 10 and 45°C, respectively (for the latter, use campylobacter incubator if heat block not available). Abbreviations for cell arrangement in Gram stain: CL, clusters; T, tetrads; CH, chains; W, weak. Large colonies are approximately 1 mm; small colonies are about the size of viridans group streptococci. See Table 3.18.1–1, footnote *a*, for other abbreviations and symbols. Tables adapted from references 9, 17, 22, and 25. Also see reference 6.

Table 3.18.1–4b Biochemical reactions of PYR-negative, catalase-negative gram-positive cocci

Genus or species	Phenotypic characteristics ^a						
	Gram stain	LAP	NaCl	Van	Arginine	45°C	MRS
<i>Leuconostoc</i>	CH, rods	–	V	R	–	–	+
<i>Weissella confusa</i>	CH, rods	–	V	R	+	+	+
<i>Pediococcus</i>	CL/T	+	V	R	–	V	–
<i>Streptococcus</i>	CH	+	–	S	–	V	–
<i>Aerococcus urinae</i>	CL/T	+	+	S	–	–	–

^a Van, vancomycin; MRS, gas production in MRS broth. See footnote *a* to Table 3.18.1–4a and Table 3.18.1 for other abbreviations.

Table 3.18.1-5 Catalase-negative, gram-positive rods that can grow aerobically, including cocci that can be confused with rod forms^a

Organism(s)	H ₂ S	Vancomycin	Hemolysis	Hippurate	Motility	Nitrate	Esculin	Gram stain morphology
<i>Weissella</i> spp.	–	R	Alpha	–	–	NA	+	Small, short GPR; gas in MRS broth (22)
<i>Erysipelothrix rhusiopathiae</i>	+	R	Alpha	–	–	–	–	Has two cell forms; the long-chaining form can be confused with <i>Lactobacillus</i> , and the short form can be confused with <i>Actinomyces</i> or even <i>Enterococcus</i> (PYR positive)
<i>Lactobacillus</i> spp.	–	R	Alpha	–	–	V	V	Most lactobacilli are long regular-chaining rods. Some are C shaped.
<i>Arcanobacterium haemolyticum</i>	–	S	Beta	–	–	–	–	Branching, which can be rudimentary; reverse-CAMP positive, lecithinase positive, gelatin negative
<i>Arcanobacterium pyogenes</i>	–	S	Beta	+	–	–	–	Branching, which can be rudimentary; reverse-CAMP negative, lecithinase negative, gelatin positive
<i>Arcanobacterium bernardiae</i>	–	S	V	V	–	–	–	Reverse-CAMP negative, gelatin negative; does not branch; not beta-hemolytic on human blood. Kits can misidentify as <i>Gardnerella</i> .
<i>Gardnerella vaginalis</i>	–	S	–	+ ⁻	–	–	NA	SPS sensitive; beta-hemolytic on human blood
<i>Bifidobacterium</i> spp.	–	S	–	+	–	–	+	Some are aerotolerant; can look like <i>Actinomyces</i> or <i>Gardnerella</i> ; not beta-hemolytic on human blood
<i>Actinomyces israelii</i>	–	S	–	NA	–	+	+	Branching, which can be rudimentary; anaerobic kits will identify; urease negative
<i>Actinomyces</i> spp.	–	S	–	V	–	V	V	Not all species show branching; <i>A. naeslundii</i> and others are urease positive. Some colonies of <i>A. meyerii-odontolyticus</i> group turn red after 1 wk.
Aerotolerant <i>Clostridium</i>	–	S	–	NA	V	+ ⁻	+	Forms spores; medium to large regular rod; grows slowly compared to <i>Bacillus</i> ; anaerobic kits will identify

^aData from references 2, 5, 8, and 24. Once *G. vaginalis*, *Arcanobacterium*, *Weissella*, and *E. rhusiopathiae* are ruled out, either call “Anaerobic gram-positive rod” or do anaerobic identification kit. GPR, gram-positive rods; SPS, sodium polyanethol sulfonate. See footnote a to Tables 3.18.1-1 and 3.18.1-2 for other abbreviations and symbols. See Table 3.18.1-9 for catalase-positive *Actinomyces*.

Table 3.18.1–6 Catalase-positive, usually yellow- or pink-pigmented gram-positive rods^a

Organism(s)	Motility	Fermentation	Nitrate	Urease	Esculin	Gelatin	Glucose	Comment
<i>Cellulosimicrobium/Cellulomonas (Oerskovia)</i> spp.	+	+	+/V	–	+	+	+	Subsurface or surface hyphae/pseudohyphae may be present.
<i>Microbacterium (Aureobacterium)</i> spp.	+ ⁻	V	V	V	+ ⁻	V	+	
<i>Exiguobacterium acetylicum</i>	+	+	V	–	+	V	+	Golden yellow to orange
<i>Leifsonia aquatica</i>	V	–	V	–	V	V	+	Previously called “ <i>Corynebacterium aquaticum</i> ”
<i>Corynebacterium falsenii</i>	–	W	V	W	V	NA	W	Yellow after 72 h
<i>Corynebacterium lipophiloflavum</i>	–	+	–	W	–	–	–	Lipophilic, rarely isolated
<i>Corynebacterium mucifaciens</i>	–	–	–	–	–	–	+	Slightly to deep yellow mucoid colonies, CAMP negative
<i>Rhodococcus equi</i>	–	–	V	+	–	–	–	Mucoid in 48 h, usually pink after 4–7 days, can be yellowish, CAMP positive. Can be acid fast. Important pathogen.

^a If motile and yellow or positive for esculin and/or gelatin, report as “Motile coryneform, not *Corynebacterium* spp.” If of clinical significance, use kit (e.g., Coryne API or RapID Coryne) or send to reference laboratory. Other yellow *Corynebacterium* spp. (*C. aurimucosum*, *C. falsenii*, and *C. sanguinis*) are rarely isolated or associated with human disease. Data are from references 13, 14, 29, and 31; also see section 6. See footnote *a* to Tables 3.18.1–1, 3.18.1–2, and 3.18.1–3 for abbreviations and symbols.

Table 3.18.1–7 Large, regular catalase-positive, gram-positive rods that usually produce spores and are usually motile^a

Organism(s)	Diam of cell usually above 1 μm	Motility ^b	Beta-hemolysis	Lecithinase	Penicillin	Large colony at 24 h	Sticky, tenacious colony at 24 h
<i>B. anthracis</i>	+	–	–	+	S ^b	+	+
<i>B. cereus</i>	+	+	+	+	R	+	–
<i>Bacillus thuringiensis</i>	+	+, V	+	+	R	+	–
<i>Bacillus mycoides</i>	+	–	W	+	R	+	–
<i>Bacillus megaterium</i>	+	+, V	V	–	S	+	–
Other <i>Bacillus</i> spp. and related groups ^c	–	+, V	– ⁺	–	V	V	V

^a *B. cereus*, *B. thuringiensis* (insect pathogen used in horticulture), *B. mycoides* (rhizoids or hairy projections in agar), and *B. anthracis* are included in the *B. cereus* group. If organism is motile with spores, penicillin resistant, hemolytic, with cells greater than 1 μm in diameter, and/or lecithinase positive, report as “*Bacillus cereus* group, not *B. anthracis*.” Otherwise, if organism is motile, with spores, but nonhemolytic and/or lecithinase negative, report as “*Bacillus*, not *B. anthracis* or *B. cereus*.” Data are from references 18 and 34. Spores can be induced by growing on urea, bile-esculin agar, or an agar plate with vancomycin disk or at 45°C. Spores can be proved by heating broth culture to 80°C for 10 min and subculturing to BAP. Viable colonies indicate that spores survived the heating. See Table 3.18.1–1, footnote *a*, for other abbreviations and symbols.

^b Submit any nonmotile, spore-forming strain to designated higher reference laboratory to rule out *B. anthracis*, regardless of the penicillin susceptibility.

^c *Kurthia* (diameter, 0.8 to 1.2 μm) organisms are motile and nonhemolytic and do not produce spores (13).

Table 3.18.1-8 Urease-positive *Corynebacterium* spp. of clinical importance^a

Organism	Nitrate	Urease	Pyrazinamidase	Glucose	Sucrose	Lipophilism	CAMP reaction
<i>C. glucuronolyticum</i>	V	V	+	+	+	–	+
<i>C. pseudotuberculosis</i> ^b	V	+	–	+	V	–	Reverse +
<i>C. ulcerans</i> ^b	–	+	–	+	–	–	Reverse +
<i>C. pseudodiphtheriticum</i> ^c	–	+	+	–	–	–	–
<i>C. riegelii</i> ^d	–	+	V	–	–	–	–
<i>C. urealyticum</i> ^e	–	+	+	–	–	+	–
<i>C. amycolatum</i>	V	V	+	+	V	–	–
CDC group F1	V	+	+	+	+	+	–

^a Data are from references 13 and 14. Other urease-positive or -variable species of less clinical significance include *C. durum*, *C. falsenii*, *C. singulare*, *C. sundsvallense*, and *C. thomssenii*, which are CAMP and reverse-CAMP negative, are not lipophilic, and ferment glucose. See Table 3.18.1-1, footnote a, for abbreviations and symbols.

^b Submit to reference laboratory for diphtheria toxin testing. *C. pseudotuberculosis* is associated with sheep handlers.

^c Respiratory pathogen; not able to acidify maltose, ribose, or trehalose.

^d *C. riegelii* is rarely isolated but has been found in urine and other body sites (13). It is able to acidify maltose.

^e Urinary pathogen; multiresistant to antimicrobials.

Table 3.18.1-9 Catalase-positive, urease-negative, gram-positive rods, excluding *Corynebacterium* spp. and yellow- or pink-pigmented rods^a

Organism(s)	Fermentation	Nitrate	Esculin	Gelatin	Glucose	CAMP	Gram stain or colony appearance
<i>Actinomyces neuii</i>	+	V	–	–	+	+	Nonhemolytic, slight branching
<i>Actinomyces viscosus</i>	+	+	–	NA	+	–	
<i>Propionibacterium avidum/granulosum</i>	+	–	V	V	+	+	Beta-hemolytic, branching
<i>Turicella otitidis</i>	–	–	–	–	–	+	Large rod, branching; ear pathogen CAMP-positive <i>C. auris</i> and <i>C. fermentans</i> have similar reactions
<i>Brevibacterium</i> spp.	–	V	–	+	–	–	Some yellowish, distinct odor
<i>Dermabacter hominis</i>	+	–	+	+	+	–	Cocci rods, distinct odor Lysine +, arginine –, ornithine +
<i>Rothia</i> spp.	+	+	+	V	+	–	Some branching, some black pigmented; if sticky, refer to Tables 3.18.1-1 and 3.18.1-4a for <i>R. mucilaginosus</i> (previously <i>Stomatococcus mucilaginosus</i>) (6).

^a Usually irregular rods. Identify only if clinically significant, but all can be pathogens (13, 14). The important tests are fermentation (use Andrade’s base or cysteine Trypticase agar), CAMP, and Gram stain, with careful reading of Gram stain morphology. Coryneform identification kits can be helpful. For abbreviations and symbols, see Table 3.18.1-1, footnote a.

Table 3.18.1–10 Urease-negative *Corynebacterium* spp. of clinical importance^a

Organism(s)	Nitrate	Urease	Pyrazinamidase	Alkaline phosphatase	Glucose	Maltose	Sucrose	Lipophilism	CAMP	Comment(s)
<i>C. accolens</i>	+	–	V	–	+	–	V	+	–	
CDC group G ^b	V	–	+	+	+	V	V	+	–	Fructose positive
<i>C. jeikeium</i> ^b	–	–	+	+	+	V	–	+	–	Fructose negative
<i>C. afermentans</i>	–	–	V	+	–	–	–	V	V	One subspecies is lipophilic.
<i>C. macginleyi</i>	+	–	–	+	+	–	+	+	–	Found in eye specimens.
<i>C. diphtheriae</i> ^c	+	–	–	–	+	+	–	–	–	<i>C. diphtheriae/belfanti</i> is nitrate negative; <i>C. diphtheriae/intermedius</i> is lipophilic.
<i>C. propinquum</i>	+	–	V	V	–	–	–	–	–	
<i>C. amycolatum</i> ^b	V	V	+	+	+	V	V	–	–	Dry colony, O/129 R, a common species of human resident microbiota; can be misidentified as <i>C. xerosis</i> .
<i>C. minutissimum</i>	–	–	+	+	+	+	V	–	–	O/129 S, DNase positive, PYR positive
<i>C. striatum</i>	+	–	+	+	+	–	V	–	V	O/129 S
<i>C. xerosis</i>	V	–	+	+	+	+	+	–	–	Creamy colony, O/129 S, LAP positive

^a Other species that are rare are not listed (see references 13 and 14), including some CAMP test-positive species. Some *Corynebacterium* organisms have black-pigmented colonies. For identification of species in this table, the combination of CAMP test, lipophilism, O/129 disk, and commercial kits for corynebacteria should be used if identification is clinically important. For abbreviations and symbols, see footnote *a* to Tables 3.18.1–1 and 3.18.1–9.

^b Multiresistant to antimicrobials.

^c Submit to reference laboratory for diphtheria toxin testing.

3.18.2

Identification of Gram-Negative Bacteria

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The gram-negative bacteria are a heterogeneous group of organisms consisting of numerous families, genera, and species, many of which cause serious disease and endotoxic shock. The accurate, rapid identification of gram-negative rods and diplococci provides timely, meaningful treatment and diagnosis of disease. Lack of identification or recognition of a serious pathogen can have long-term effects on the cure and spread of disease. The figures and tables that follow are designed to rapidly determine the agent of infection and to provide guidance in order to avoid misidentification of serious pathogens.

The algorithms presented include a combination of rapid tests for identification, some of which are based on NCCLS guidelines for rapid identification (12) and others of which are based on established references on identification of gram-negative rods (6, 8, 11, 13, 14; G. L. Gilardi, unpublished identification tables). The use of commercial automated and manual multitest systems (kits) is encouraged when colony morphology and a few rapid tests do not provide a definitive identification. Commercial kit systems do an excellent job of identifying most pathogens with minimal work, and they should be a part of any laboratory's identification system. Deciding when to use a commercial system and which system to use for identification is key to success in providing the identification in a timely manner. In addition, knowing the limitations of the databases of the kit systems can be helpful in deciding when to pursue the identifi-

cation further using the tests listed in the tables that follow. Commercial kit systems are presented in Tables 3.16–1 and 3.16–2 and are also reviewed elsewhere (5, 11). These references should be consulted when deciding which kits to purchase and what are the limitations of the databases. In the algorithms presented here, specific manufacturers' kits are not presented.

The great majority of gram-negative strains found in clinical specimens are either *Escherichia coli* or *Pseudomonas aeruginosa*. The identification schemes that follow include rapid identification of these two pathogens, when they produce typical colony morphologies and reactions. The figures also show the identification of many of the gram-negative rod agents of bioterrorism in less than 2 h (refer to section 16). The figures and tables are designed to prevent misidentifications of agents of bioterrorism, as well as many other gram-negative rods which cause life-threatening infections.

The figures that follow include rapid tests (oxidase, indole, and catalase) that lead the user to the appropriate table or definitive identification, when combined with colony morphology. Most are performed in 2 min. The figures are designed to do the minimum amount of work to arrive at a good identification or lead to the appropriate table or kit, without doing tests that are not helpful. For that reason, the figures may not include all of the options at each step, because the observance of one colony morphology may lead to performing a certain test, while the lack of

that morphology may suggest a different test. The figures send the reader to tables which include many organisms that may not be clinically significant. These organisms are listed to avoid misidentifications and to provide biochemical reactions for identification, should they be isolated from a significant site. Finally, the reader is referred to other texts (11, 14) for a more extensive list of tests when the minimal tests indicate what microorganism is suspected but other testing might be helpful to confirm the identification.

An example of using the figures may be helpful. If a nonpigmented respiratory isolate did not grow on MAC but grew at 48 h on BAP, Fig. 3.18.2–3 indicates performing Gram stain, indole, catalase, and oxidase. If the catalase is positive and the oxidase and indole are negative, the figure indicates testing with a polymyxin B disk and consulting Table 3.18.2–5. In Table 3.18.2–5 there are only five microorganisms listed that are oxidase negative or variable, and only one of those is a respiratory coccobacillus. In our case, the Gram stain showed the coccobacillary morphology. A positive rapid (2-h) urea test will complete a preliminary identification of *Bordetella parapertussis*. Inoculation to Mueller-Hinton (MH) agar with a polymyxin B disk for observation of the brown pigment and susceptibility to polymyxin B would be confirmatory and rule out the rare possibility of *Burkholderia mallei*, the agent of glanders (potential bioterrorist agent). However, the report would have already been communicated to

the caregiver for appropriate treatment and isolation techniques. Thus, *B. parapertussis* was identified to the species level in less than 2 h with three <1-min tests, a Gram stain, and one 2-h biochemical test.

To have performed a commercial identification system on this isolate would have delayed the final identification and resulted in needless cost and erroneous results, since this pathogen is not in the da-

tabases of commonly used identification systems. The user is encouraged to follow the charts to arrive at appropriate testing and rapid reporting, often without the need for using more expensive commercial kits.

II. MICROORGANISMS

- A. Gram-negative rods or cocci as determined by Gram stain
- B. Assumed gram-negative rods because of colony morphology or growth on MAC or EMB

III. REAGENTS AND SUPPLIES

▣ **NOTE:** Procedures for methods for biochemical tests are listed in procedures 3.17.1 through 3.17.48. To the extent that tests are available in kits, it is not necessary to stock the separate tests.

A. Minimum useful for most laboratories

1. Catalase (3 and 30%) (procedure 3.17.10)
2. Indole (spot, Kovács', and Ehrlich's) (procedure 3.17.23)
3. Oxidase test reagent (procedure 3.17.39)
4. Polymyxin B (300-U) (or colistin [10-μg]) and penicillin (10-U) disks (procedure 3.17.4)
5. MH agar
6. Butyrate disks (procedure 3.17.7)
7. δ-Aminolevulinic acid (ALA) test (procedure 3.17.3)
8. Pyrrolidonyl-β-naphthylamide (PYR) (procedure 3.17.41)
9. Triple sugar iron agar (TSI) or Kligler's iron agar (KIA) (procedure 3.17.25)
10. Urea—rapid method preferred (procedure 3.17.48)
11. Motility medium—wet mount may suffice (procedure 3.17.31)
12. Kit for *Neisseria* identification (see procedure 3.9.3 for options)
13. Kit(s) for identification of enteric and nonfermenting, gram-negative rods and fastidious other gram-negative rods (Tables 3.16–1 and 3.16–2)

B. Desired for large-volume and reference laboratories and for those laboratories that provide service to cystic fibrosis patients

1. 4-Methylumbelliferyl-β-D-glucuronide (MUG) (procedure 3.17.34)
2. Andrade's glucose broth with rabbit serum (procedure 3.17.9)
3. MH agar with 4% salt (procedure 3.17.43)
4. O/129 150-μg disks (procedure 3.17.36)
5. Acetamide or F and P agar for *Pseudomonas* (procedures 3.17.1 and 3.17.17)
6. Gelatin (procedure 3.17.18)
7. Lysine, ornithine, arginine decarboxylase-dihydrolase broth (Møller's) (procedure 3.17.15)
8. OF medium (procedure 3.17.9)
9. Nitrate medium (procedure 3.17.35)
10. Nitrite medium (procedure 3.17.35)
11. DNase (procedure 3.17.16)
12. Esculin (procedure 3.17.5)
13. Phenylalanine deaminase (PDA) (procedure 3.17.40)
14. Sugar fermentation media or commercial kit with sugar fermentation tests for fastidious microorganisms (procedure 3.17.9)

ANALYTICAL CONSIDERATIONS

IV. PROCEDURE

- A. Observe colony morphology on BAP, CHOC, and MAC or EMB.
- B. Perform oxidase from BAP or CHOC.
 - ▣ **NOTE:** To avoid misidentifications, do not skip this step. Omit only for obvious spreading *Proteus* or satelliting colonies.

IV. PROCEDURE (*continued*)

- C. If microorganism is not growing on MAC, perform Gram stain and catalase test.
- ☑ **NOTE:** With rare exceptions, organisms that grow on MAC are catalase-positive, gram-negative rods.
- D. Follow Fig. 3.18.2-1 if the organism is a diplococcus.
- E. Proceed to Fig. 3.18.2-2 if the organism is a gram-negative rod that does not grow on BAP.
- F. Perform spot indole test on gram-negative rods that are growing on BAP. For organisms that grow poorly on MAC, performing the indole test with Kovács' reagent may be necessary. For organisms that are yellow, perform the tube indole test with Ehrlich's method.
- ☑ **NOTE:** *To avoid misidentifications, do not skip this step.*
- G. Proceed to Fig. 3.18.2-3 for microorganisms that grow on BAP but do not grow or grow poorly on MAC.
1. In order to determine if a gram-negative rod ferments glucose, inoculate TSI or KIA.

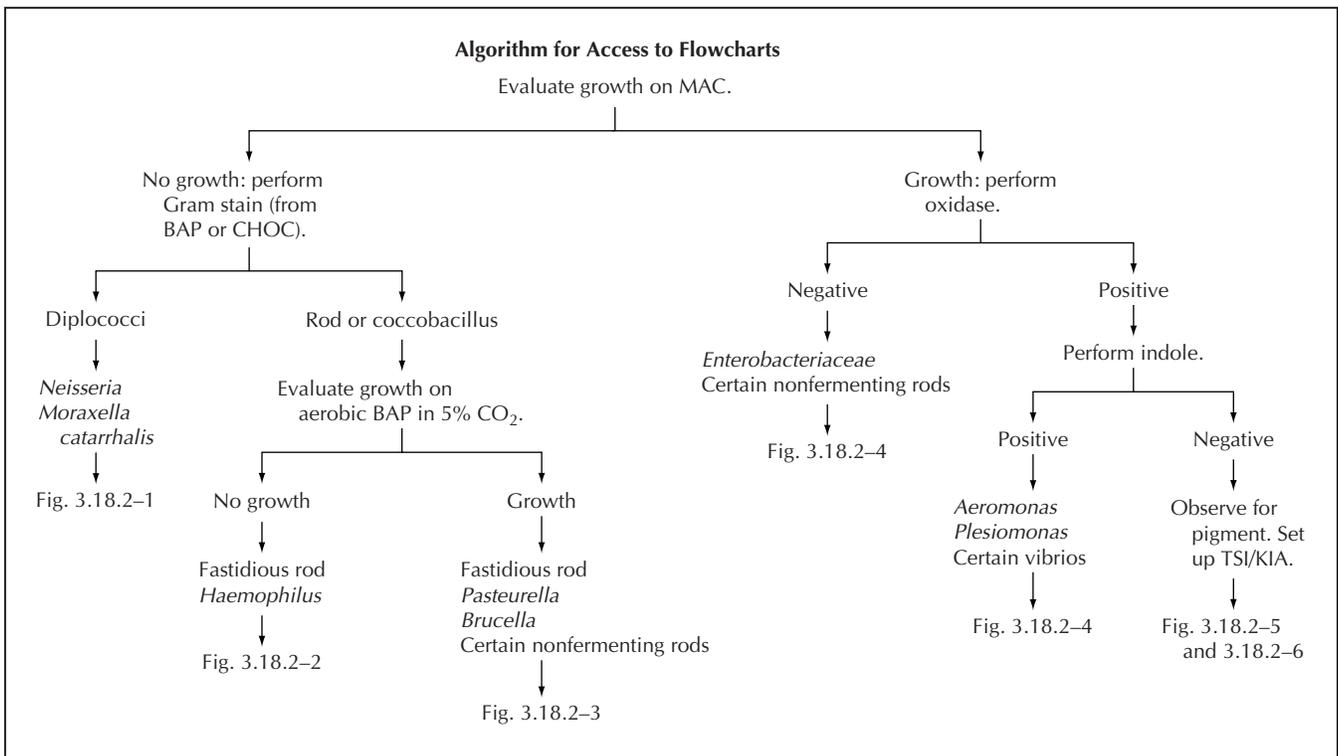

☑ **NOTE:** Many organisms that do not grow on MAC will not show fermentation in OF media, which leads to erroneous identifications. Users may skip this step if they have the experience to recognize that a specific colony morphology represents a suspected nonfermenting rod. For example, many technologists can recognize colonies of *P. aeruginosa* or *Stenotrophomonas maltophilia* and go directly to Fig. 3.18.2-6.
 2. To see if a nonfermenting rod is an oxidizer, inoculate OF medium or use a commercial test system designed to identify nonfermenting rods.
- H. Follow Fig. 3.18.2-4 to identify organisms that grow on MAC and are either oxidase negative or oxidase positive and indole positive.
- I. Go to Fig. 3.18.2-5 and 3.18.2-6 sequentially to identify oxidase-positive, indole-negative rods or oxidase-negative, nonfermenting rods that grow on MAC.
- J. Observe plates at 48 h for colonies that were not present the first day of incubation. This step is particularly important for respiratory specimens.

POSTANALYTICAL CONSIDERATIONS**V. REPORTING AND INTERPRETATION OF RESULTS**

- A. Follow tables and kit identifications to report genus and species as appropriate without delay.
- B. Significant organisms are noted in the flowcharts to alert the user. Less significant microorganisms can be reported with minimal testing (e.g., yellow pseudomonad).

VI. LIMITATIONS

Because many tests are not 100% positive or negative for a particular strain, it is desirable that more than one positive reaction be used in the confirmation of an identification.

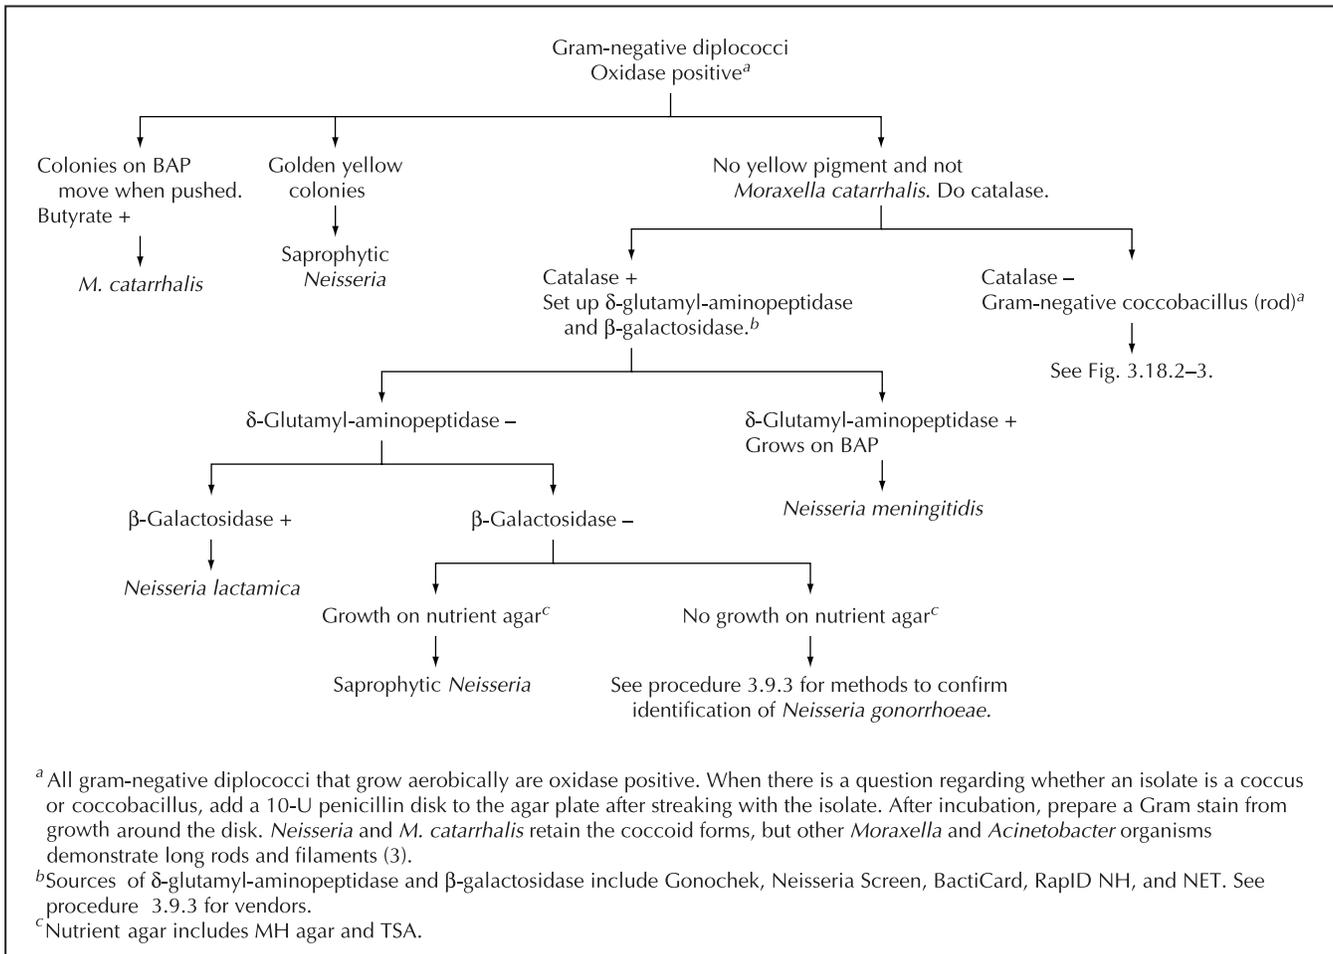

Figure 3.18.2-1 Identification scheme for gram-negative diplococci; also see Table 3.18.2-1.

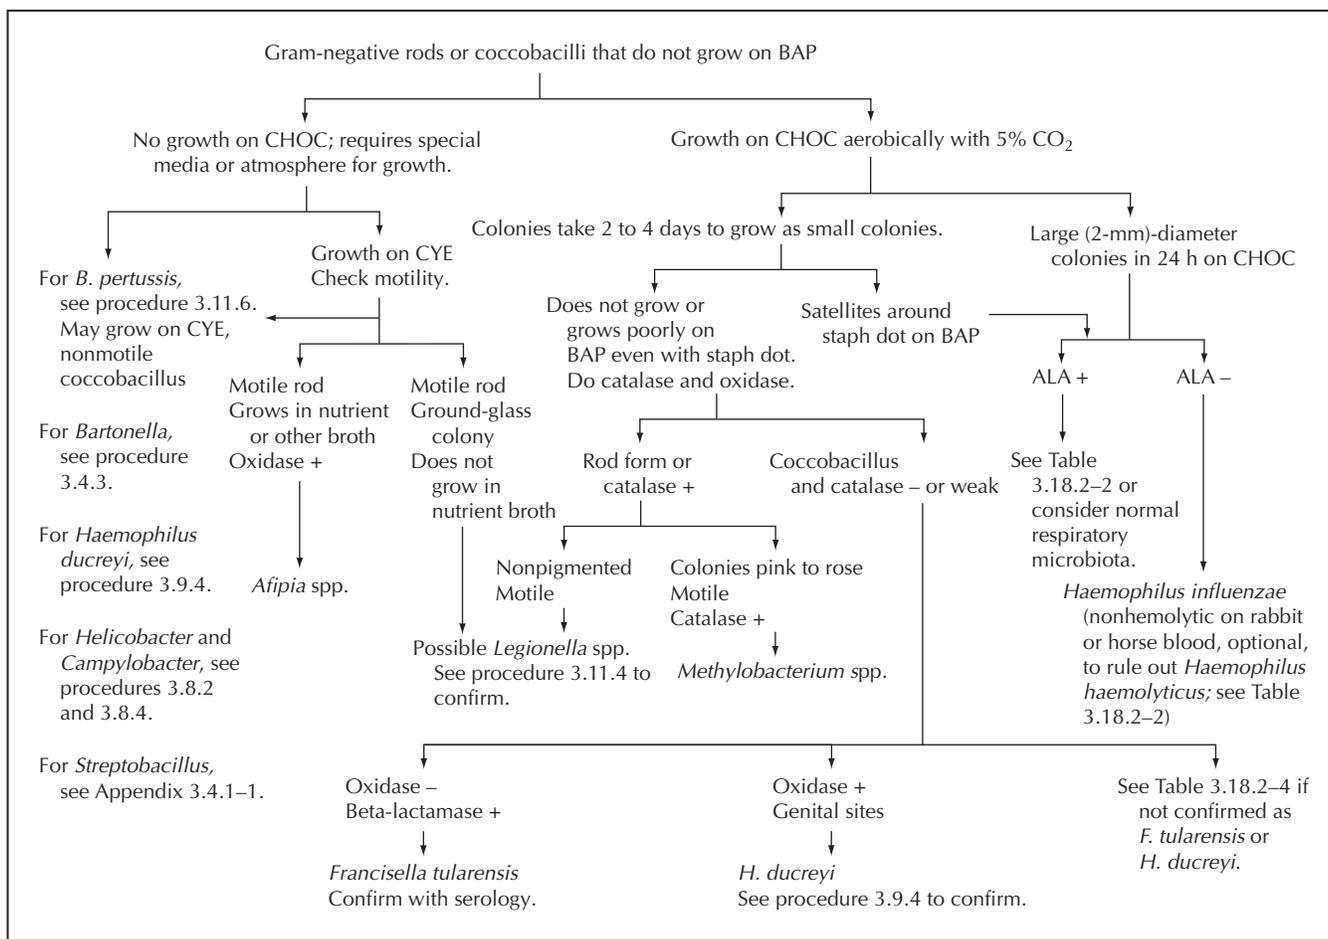

Figure 3.18.2-2 Identification scheme for gram-negative rods that do not grow on BAP aerobically in 5% CO₂. CYE, charcoal-yeast extract agar.

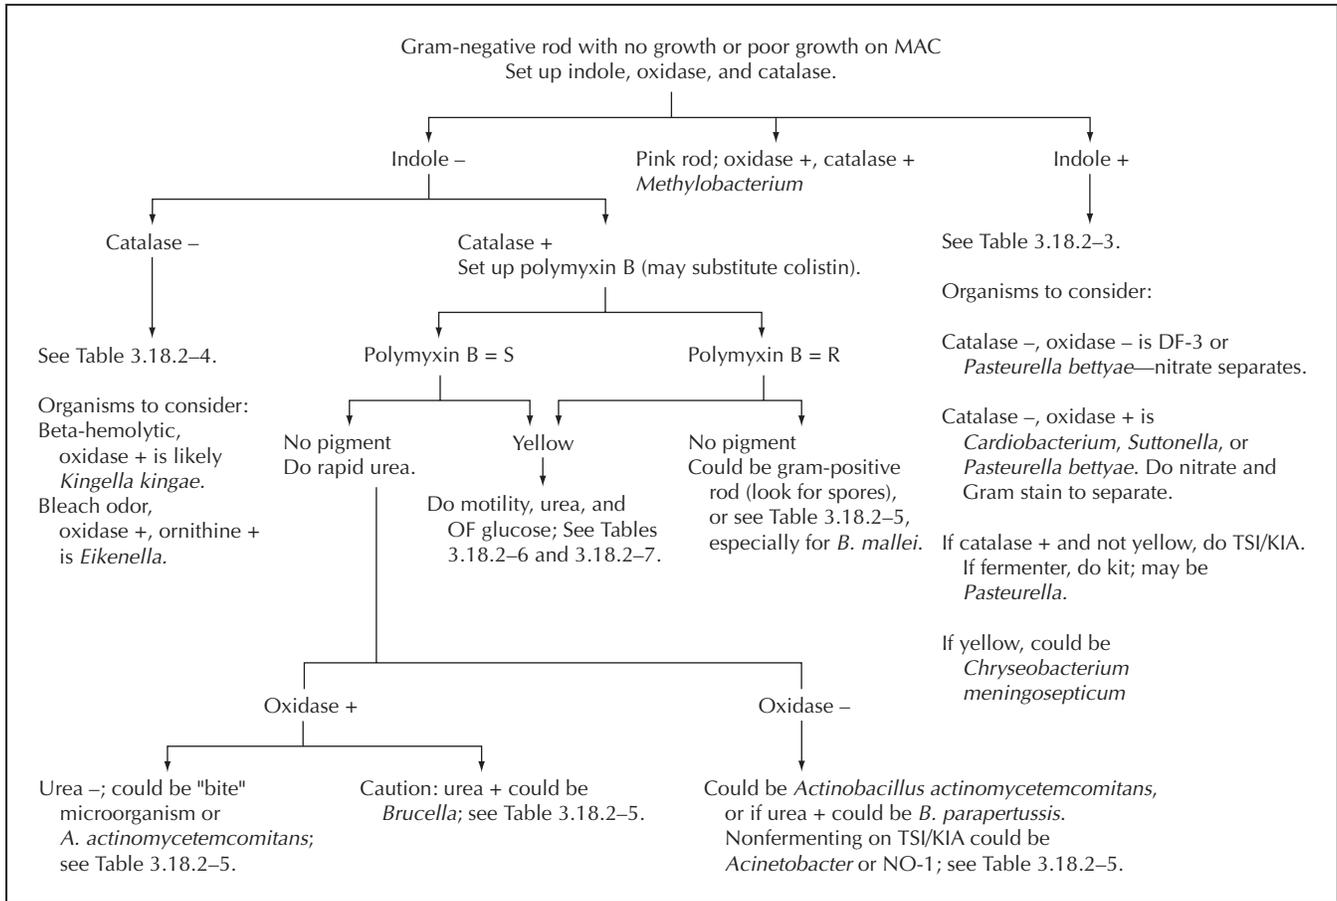

Figure 3.18.2-3 Identification scheme for gram-negative rods that grow on BAP with 5% CO₂ but do not grow well on MAC in 48 h.

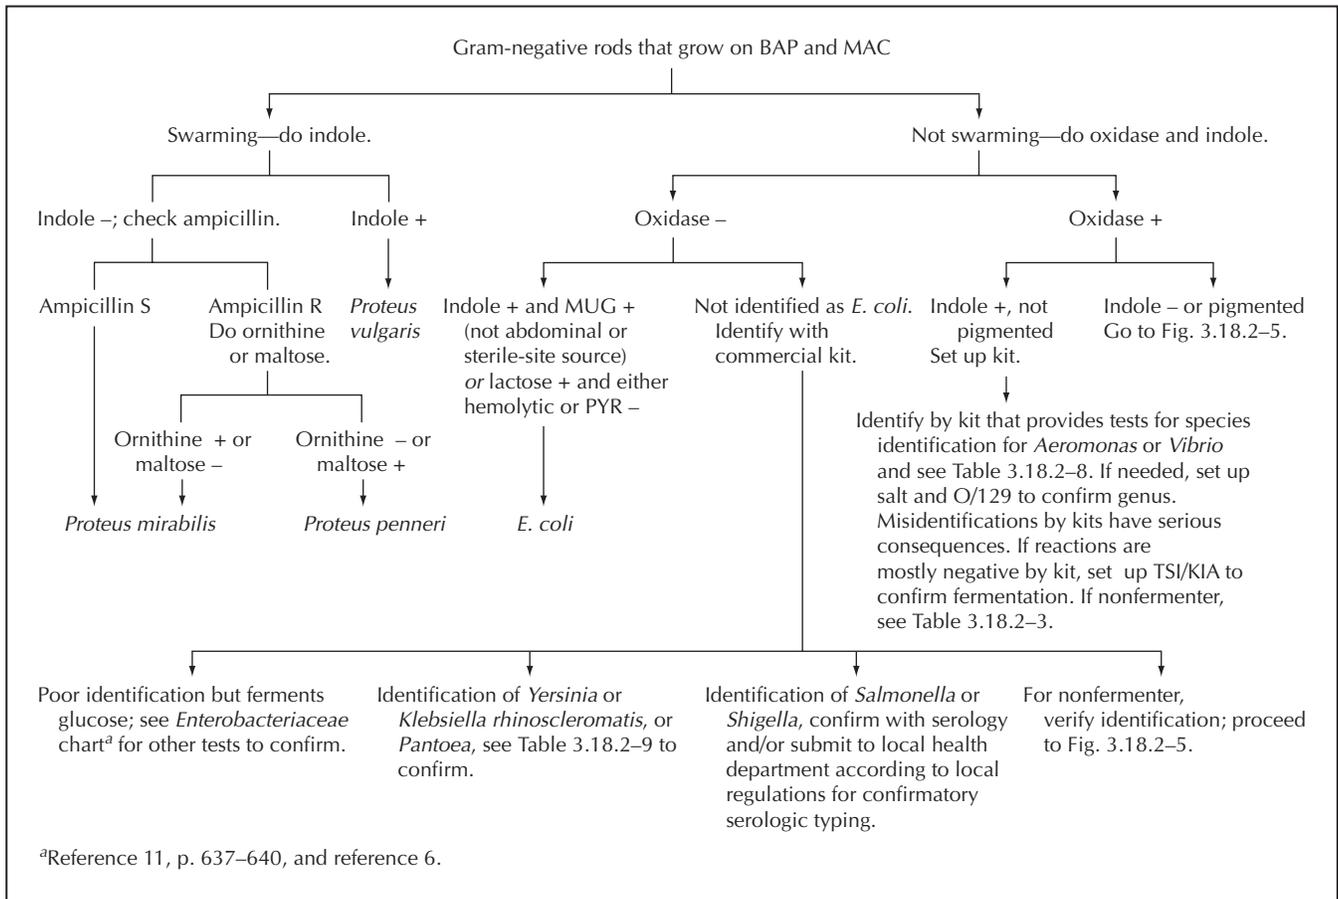

Figure 3.18.2-4 Identification scheme for gram-negative rods that grow on BAP and MAC.

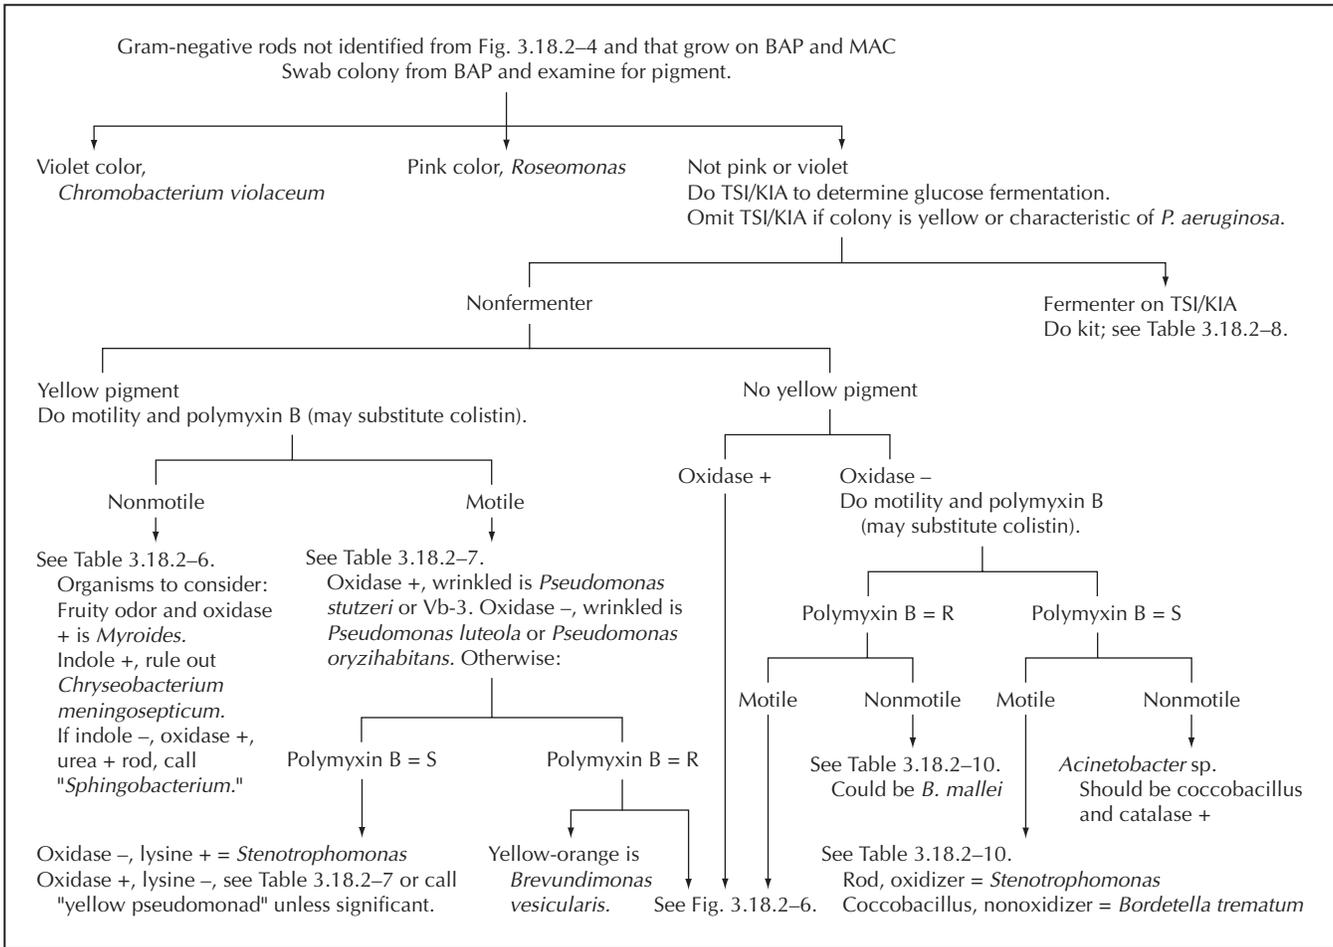

Figure 3.18.2-5 Identification scheme for gram-negative rods that grow well on BAP and MAC and are not identified from Fig. 3.18.2-4.

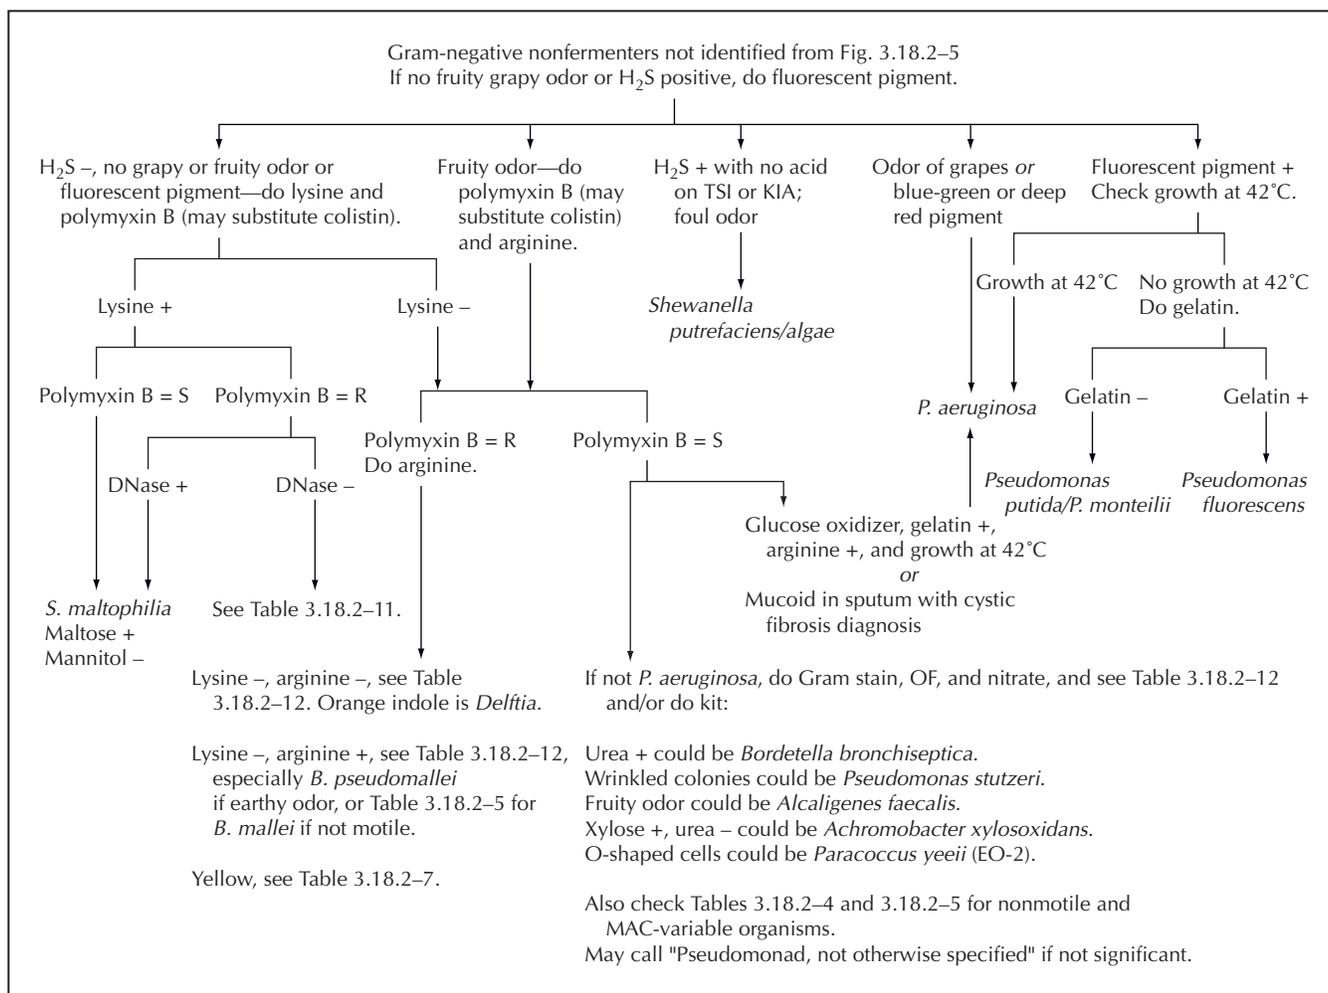

Figure 3.18.2-6 Identification scheme for gram-negative rods that grow on BAP and MAC and are not identified by Fig. 3.18.2-4 and 3.18.2-5.

Table 3.18.2–1 Biochemical reactions of *Neisseria* and related oxidase-positive diplococcus and rods that may grow on Thayer-Martin or similar selective agar^{a,b}

Organism(s)	Superoxol, 30% H ₂ O ₂	Growth on basic agar media at 35°C ^d	Colistin 10-µg disk	Glucose	Maltose	Lactose, ONPG, or BGAL	Sucrose	PRO	GLUT	Butyrate ^e
<i>Neisseria gonorrhoeae</i>	4+	–	R	+ ⁻	–	–	–	+	–	–
<i>Neisseria meningitidis</i>	2–4+	V	R	+	+ ⁻	–	–	V	+	–
<i>Neisseria lactamica</i>	2+	+	R	+	+	+	–	+	–	–
<i>Neisseria cinerea</i> ^c	2+	+	V	V	–	–	–	+	–	–
<i>Neisseria flavescens</i> ^c	2+	+	S	–	–	–	–	+	–	–
<i>Neisseria elongata</i> ^c	V	+	S	–	–	–	–	V	–	–
Other nonpathogenic neisseriae ^c	2+	+	V	+	+	–	V	V	V ^d	–
<i>Moraxella catarrhalis</i>	2–4+	+	V	–	–	–	–	V	–	+
<i>Kingella denitrificans</i>	–	+	R	+	–	–	–	+	–	–

^a Abbreviations for tests: PRO, prolyl iminopeptidase; ONPG, *o*-nitrophenyl-β-D-galactopyranoside; BGAL, β-galactosidase; GLUT, β-glutamyl-aminopeptidase. Reactions are from package inserts, the website <http://www.CDC.gov/ncidod/dastlr/gcdir/neident/index.html>, and references 4, 9 and 15. Polymyxin B can be substituted for colistin; alternatively, resistance to these agents can be determined by growth or lack of growth on Thayer-Martin or other selective agar with colistin or polymyxin B. Results for sugars are in cysteine Trypticase agar.

^b Abbreviations and symbols for results: +, greater than 90% of strains positive in 48 h; –, greater than 90% of strains negative; V, results are between 90 and 10% positive; +⁻, most strains are positive but a few are known to be negative, resulting in critical misidentifications if other tests are not also performed; R, 90% of strains resistant or no zone around disk; S, 90% of strains susceptible or zone around disk.

^c Does not usually grow on selective media for *N. gonorrhoeae*. *N. subflava* and *N. flavescens* colonies are yellow; *N. subflava* is the only species other than *N. meningitidis* to be GLUT positive.

^d Nutrient or MH agar or TSA without blood at 35°C.

^e See procedure 3.17.7. Do not read after time period in package insert, as this delay may result in false-positive reactions. Many *Moraxella* spp. and *Acinetobacter* spp. are butyrate positive. Isolate must be a diplococcus for identification of *M. catarrhalis* to be accurate.

Table 3.18.2–2 Biochemical reactions of *Haemophilus* species that satellite on BAP^a

Organism	Satellite (V factor)	ALA	Lactose ^c	Urea	Indole	Ornithine	Hemolysis ^b	Catalase
<i>H. influenzae</i>	+	–	–	V	V	V	–	+
<i>H. haemolyticus</i>	+ ^b	–	–	+	V	–	+	+
<i>H. parahaemolyticus</i>	+ ^b	+	–	+	–	–	+	+
<i>H. parainfluenzae</i>	+	+	–	V	V	V	–	V
<i>H. paraprothophilus</i>	+	+	+	–	–	–	–	–

^a Data for table from reference 14, p. 218–219. See footnote *b* of Table 3.18.2–1 for abbreviations and symbols.

^b Hemolysis demonstrated on horse, sheep, or rabbit blood agar. Note that hemolytic strains may grow on BAP without staphylococcal dot even though they require V factor.

^c Test is performed in 1% lactose in phenol red broth base (BD Diagnostic Systems) supplemented with hemin and NAD (10 mg of each per liter; Sigma Chemical Co.) (reference 11, p. 628).

Table 3.18.2-3 Differential biochemical reactions for indole-positive, gram-negative rods that grow poorly on MAC in 48 h^a

Organism	MAC	Oxidase	Catalase	Nitrate	Glucose	Mannitol	Maltose	Urea	Other differential trait(s)
<i>Dysgonomonas capnocytophagoides</i> (DF-3)	–	–	–	–	F ^s	–	+	–	Small rod, acid on slant and in butt of TSI, fecal pathogen
<i>Pasteurella bettyae</i>	V	V	–	+	F, gas	–	–	–	Rod, genital sites, acid on slant and in butt of TSI
<i>Cardiobacterium hominis</i>	–	+	–	–	F ^s	+ or (+)	+ or (+)	–	Pleomorphic rod; sorbitol +, alkaline phosphatase –
<i>Suttonella indologenes</i>	–	+	V	–	F	–	+ or (+)	–	Plump rod; sorbitol –, alkaline phosphatase +; rare
<i>Pasteurella dagmatis</i>	–	+	+	+	F, gas	–	+	+	Decarboxylase – ^d
Bisgaard's taxon 16	V	V	+	+	F	–	+	–	Decarboxylase –
<i>Pasteurella stomatis</i>	–	+	+	+	F	–	–	–	Decarboxylase –
<i>Pasteurella pneumotropica</i>	V	+	+	+	F	–	+	+	Ornithine +
<i>Pasteurella multocida</i>	–	+	+	+	F	+	–	–	Ornithine +; from cat bites
<i>Pasteurella canis</i>	–	+	+	+	F	–	–	–	Ornithine +
<i>Bergeyella zoohelcum</i>	–	+	+	–	n-o	–	–	+	Arginine +; rod from animal bites; polymyxin B = R
<i>Weeksella virosa</i>	–	+	+	–	n-o	–	–	–	Light yellow, decarboxylase –, polymyxin B = S
CDC group II-g	+	+	+	–	n-o	–	–	–	Reduces nitrite
CDC groups II-c, II-e, II-h, II-i	–	+	+	–	O	–	V	–	Rarely isolated
<i>Balneatrix alpica</i> ^b	–	+	+	+	O	(+)	+	–	Yellow, esculin –, motile, polymyxin B = S
<i>Chryseobacterium gleum/Chryseobacterium indologenes</i> ^c	V	+	+	V	O	–	+	V	Deep yellow, esculin +, polymyxin B = R
<i>Chryseobacterium meningosepticum</i> ^c	V	+	+	–	O	+	+	–	Yellow V, esculin +, polymyxin B = R

^a Indole is done with Kovács at 48 h directly on plate. For yellow colonies, Ehrlich's method may be needed. CDC group II-g grows on MAC but is a non-glucose oxidizer. See Table 3.18.2-8 for indole-positive, fermenting rods that grow on MAC. Data are from reference 14. (+), greater than 90% of strains positive in 3 to 7 days; F, glucose fermenting in TSI or KIA or Andrade's glucose broth or other sugar fermentation medium; n-o, nonoxidizer in glucose OF medium and no reaction in fermentation medium; O, oxidizer in glucose OF medium; F^s, addition of rabbit serum to Andrade's or other glucose fermentation medium may be required to demonstrate fermentation; gas, gas from either glucose or nitrate, depending on the test. Results for carbohydrates are in OF medium for oxidizers and Andrade's or rapid sugar agar for fermenters. See footnote b to Table 3.18.2-1 for other abbreviations and symbols.

^b All strains except *Balneatrix alpica* are nonmotile.

^c See Table 3.18.2-6 to separate from *Empedobacter brevis*, which is yellow and indole positive and grows on MAC.

^d Decarboxylase – indicates negative reaction for lysine, arginine, and ornithine.

Table 3.18.2-4 Gram-negative rods that grow on BAP but are catalase negative or weak, with poor growth on MAC in 48 h^a

Organism	MAC	Catalase	Oxidase	Nitrate	Indole	Glucose	Xylose	Mannitol	Sucrose	Maltose	Urea	Other differential trait(s)
<i>Leptotrichia</i>	-	-	-	-	-	F	-	-	+	+	-	Long filamentous rods, grows poorly
<i>Streptobacillus moniliformis</i>	-	-	-	-	-	F	-	-	-	+	-	Needs 20% ascitic fluid, blood, or serum to grow; pleomorphic forms; arginine +
<i>Capnocytophaga ochracea</i> (DF-1) and related species	-	-	-	V	-	F	-	-	+	V	-	Gliding motility, esculin V, tapered ends, yellow
<i>Dysgonomonas capnocytophagoideis</i> (DF-3)	-	-	-	-	V	F ^s	V	-	V	V	-	Cocci bacilli, acid on slant and in butt of TSI/KIA, esculin V
<i>Bordetella holmesii</i>	V	V	-	-	-	n-o	-	-	-	-	-	Cocci rod, brown pigment on MH agar, nonhemolytic
<i>Haemophilus aphrophilus</i>	-	-	V	+	-	F, gas	-	-	+	+	-	Tiny rod, acid on slant and in butt of TSI/KIA, esculin -
<i>Pasteurella bettyae</i>	V	-	V	+	+	F, gas	-	-	-	-	-	Rod, genital sites, acid on slant and in butt of TSI
<i>Kingella kingae</i>	-	-	+	-	-	F	-	-	-	+	-	Beta-hemolytic, nitrite V
<i>Moraxella bovis</i>	-	V	+	-	-	n-o	-	-	-	-	-	Beta-hemolytic
<i>Brevundimonas vesicularis</i>	V	V	+	-	-	O	V	-	-	+	-	Half the strains are yellow, motile, polymyxin B = R
<i>Simonsiella muelleri</i>	-	V	+	V	-	F	-	-	-	+	-	"Roll of coins" smear, beta-hemolytic, rarely isolated
<i>Neisseria elongata</i>	-	V	+	V	-	n-o	-	-	-	-	-	Often nitrite +; polymyxin B = S
<i>Eikenella corrodens</i>	-	-	+	+	-	n-o	-	-	-	-	-	Ornithine + is definitive; odor of bleach, can be yellow
<i>Paracoccus yeii</i> (EO-2), <i>Psychrobacter</i> spp.	V	V	+	+	-	O	+	-	-	V	V	Cocci rod but large cells with vacuoles and mucoic colony is <i>Paracoccus yeii</i>
<i>Kingella denitrificans</i>	-	-	+	+	-	F	-	-	-	-	-	Grows on Thayer-Martin; polymyxin B = R
<i>Cardiobacterium hominis</i>	-	-	+	-	+	F ^s	-	(+)	V	V	-	Slender rod; sorbitol +; alkaline phosphatase -
<i>Suttonella indologenes</i>	-	V	+	-	+	F	-	-	+	V	-	Plump rod; sorbitol -, alkaline phosphatase +; rarely isolated

^a All are nonmotile except *B. vesicularis*. Data are from reference 14. See footnote b to Table 3.18.2-1 and footnote a to Table 3.18.2-3 for abbreviations and symbols.

Table 3.18.2-5 Biochemical differentiation of non-yellow-pigmented, gram-negative rods that are catalase-positive and indole-negative but do not grow well on MAC^a

Organism(s)	MAC	Oxidase	Urea ^b	Nitrate	Glucose	Arginine	Other differential trait(s)
<i>Bordetella parapertussis</i>	–	–	+	–	n-o	NA	Coccobacilli, brown pigment on MH agar, beta-hemolytic
CDC group EO-5	–	–	W	–	O	–	Coccobacilli; 20% are yellow
CDC group NO-1	V	–	–, W	+	n-o	–	Rod; from dog and cat bites. <i>Acinetobacter</i> organisms that fail to grow on MAC are coccoid and nitrate –.
<i>Actinobacillus actinomycetemcomitans</i>	–	V	–	+	F, gas V	–	Tiny rod; esculin –; acid slant and butt in TSI; sucrose fermentation –.
<i>Burkholderia mallei</i>	V	V	V	+	O	+	Coccobacilli, hazardous; resistant to polymyxin B; citrate –
<i>Pasteurella gallinarum</i>	V	+	–	+	F	–	Rod, acid slant and butt in TSI; sucrose +
CDC group EF-4b	V	+	–	+	O	–	Reduces nitrite with no gas; no reaction in TSI; from dog and cat bites
CDC group EF-4a	V	+	–	+, gas	F	V	May reduce nitrite with no gas; 73% acid in butt of TSI; from dog and cat bites
<i>Capnocytophaga canimorsus/cynodegmi</i> (DF-2)	–	+	–	–	F ^s	+	Rod; gliding motility, ONPG +; from dog and cat bites
<i>Pasteurella haemolytica</i>	V	+	–	+	F	–	Acid slant and butt in TSI; beta-hemolytic
<i>Methylobacterium</i> spp.	V	+	V	V	n-o, O	NA	Vacuolated rod pink in 72 h; grows faster on CHOC; motile
<i>Actinobacillus</i> spp. (animal)	V	+	+	+	F	–	Acid slant and butt in TSI
<i>Brucella</i> ^b	V	+	+	+	O	NA	Coccoid tiny cells; work in safety cabinet
<i>Paracoccus yeeii</i> (EO-2)	V	+	V	+	O	NA	Coccoid but large cells with vacuoles; mucoid colony
<i>Psychrobacter immobilis</i>	V	+	V	V	n-o, O	NA	Coccoid; may have rose-like odor
<i>Psychrobacter phenylpyruvicus</i>	V	+	+	V	n-o	NA	Coccoid, PDA +, nitrite –, 6.5% salt +
<i>Oligella ureolytica</i>	V	+	+	+, gas V	n-o	NA	Coccoid, PDA +, motile
<i>Oligella urethralis</i>	V	+	–	–	n-o	NA	Coccoid, PDA +, nitrite +
<i>Moraxella</i> spp.	V	+	–	V	n-o	NA	Coccoid, thick cells
<i>Neisseria weaveri</i>	V	+	–	–	n-o	–	Rod; PDA V, nitrite +; Gilardi rod group 1 similar, except nitrite – and PDA +

^a For indole-positive strains, see Table 3.18.2-3. All strains nonmotile, except as noted, but even with those, motility is difficult to demonstrate. See Table 3.18.2-4 for catalase-variable rods. Data are from references 11, 13, and 14 and from G. L. Gilardi, unpublished identification tables. W, weak reaction; NA, not applicable or available. See footnote *b* to Table 3.18.2-1 and footnote *a* to Table 3.18.2-3 for other abbreviations and symbols.

^b Urea-positive, oxidase-positive coccobacilli are presumed to be *Brucella* until proven otherwise.

Table 3.18.2-6 Biochemical characteristics of the nonmotile, yellow, nonfermenting, gram-negative rods that are catalase positive^a

Organism(s)	MAC	Oxidase	Yellow	Indole	Urea	Polymyxin B	Nitrate	Glucose	Mannitol	Sucrose	Maltose	Esculin	DNase	Other differential trait(s)
<i>Weeksella virosa</i>	-	+	Pale	+	-	S	-	n-o	-	-	-	-	-	Penicillin = S

<i>Pseudomonas oryzae</i> <i>zihabitans</i>	+	-	+	S	V	-	O	+	V	+	-	-	Wrinkled colonies; PYR +
<i>Pseudomonas stutzeri</i>	+	+	Pale, V	S	V	+, gas	O	V	-	+	-	-	Wrinkled colonies; PYR -
<i>Pseudomonas mendocina</i> (Vb-2)	+	+	+	S	V	+, gas	O	-	-	-	-	+	Colonies buttery
CDC group Vb-3	+	+	+	S	V	+, gas	O	V	-	+	-	+	Wrinkled colonies
<i>Balnearia alpica</i>	-	+	Pale	S	-	+	O	(+)	-	+	-	-	Indole +, PDA +
<i>Acidovorax</i> spp.	V	+	+ -	NA	+	+	O	V	-	-	-	V	Rarely isolated
<i>Sphingomonas paucimobilis</i>	- +	V	Deep	V	-	-	W	-	+	+	+	-	Motility better by wet mount; vancomycin = S
O-1	- +	V	+	NA	V	-	O, n-o	-	-	-	+	-	Rarely isolated
O-2	-	+	Orange	NA	V	V	O, n-o	-	(+)	(+)	V	V	Rarely isolated
<i>Agrobacterium</i> yellow group	- +	+	+	V	(+)	-	O, n-o	-	(+)	+	V	-	Catalase +
<i>Brevundimonas vesicularis</i>	V	+	Orange	R	-	-	W	-	-	+	+	-	Catalase V, PYR -, vancomycin = S

^a Motility is best at 22°C. All are indole negative except *Balnearia*. Data are from references 10, 11, 13, and 14 and from G. L. Gilardi, unpublished identification tables. - +, most strains are negative but a few are known to be positive. See footnote b to Table 3.18.2-1 and footnote a to Tables 3.18.2-3 and 3.18.2-5 for other abbreviations and symbols.

Table 3.18.2–8 Characteristics of the common pathogenic oxidase-positive, glucose-fermenting rods that grow on MAC and are not yellow pigmented^a

Organism	Oxidase	Indole	Lactose	Sucrose	Lysine	Arginine	Ornithine	O/129 ^b		Growth on ^c :	
								10 µg	150 µg	MH agar	MH agar + 4% salt
<i>V. cholerae</i>	+	+	–	+	+	–	+	S	S	V	V
<i>V. mimicus</i>	+	+	– ⁺	–	+	–	+	S	S	V	V
<i>V. parahaemolyticus</i>	+	+	–	–	+	–	+	R	V	–	+
<i>V. vulnificus</i>	+	+	– ⁺	– ⁺	+	–	V	S	S	+	V
<i>V. alginolyticus</i>	+	– ⁺	–	+	+	–	V	R	V	V	+
<i>V. fluvialis</i>	+	– ⁺	–	+	–	+	–	R	V	–	+
<i>Aeromonas</i>	+	– ⁺	V	V	– ⁺	– ⁺	– ⁺	R	R	+	–
<i>Plesiomonas</i>	+	+	–	–	+	+	+	R, S	S	+	–
<i>Chromobacterium violaceum</i> ^d	V	V	–	V	–	+	–	NA	NA	+	–

^a 1% Salt may be required for sugar and decarboxylase reactions. All strains ferment glucose on TSI or KIA. CDC group II-g grows on MAC and is indole positive but is a non-glucose oxidizer; see Table 3.18.2–3. Data are from references 1, 8, 11, and 14. See footnote *b* to Table 3.18.2–1 and footnote *a* to Tables 3.18.2–5 and 3.18.2–7 for abbreviations and symbols.

^b Resistant *V. cholerae* strains have been isolated in India. Confirmation of arginine-negative *Aeromonas* may be needed to prevent misidentifications. Testing with O/129 is key to prevention of misidentification of *V. fluvialis* and *V. vulnificus* as *Aeromonas* spp.

^c Data on file at University of California, San Francisco. The importance of using both media is to get growth on at least one plate in order to observe the O/129 and other disk susceptibility and to observe that *Aeromonas* and *Plesiomonas* do not grow with salt added. Some *Vibrio* organisms do not grow on MH agar without salt added, and some do not grow with 4% salt.

^d The combination of polymyxin B resistance and indole positivity is associated with nonpigmented strains. The combination of sucrose negativity and growth on MH agar separates this organism from *V. fluvialis*. *C. violaceum* is lysine, maltose, and mannitol negative, which separates it from *Aeromonas*.

Table 3.18.2–9 Differentiation of *Yersinia pestis* from similar bacteria^a

Organism	Lysine	Ornithine	Urea ^b	Motility at:		Glucose	ONPG	Mannitol	Rhamnose	Other differential trait(s)
				35°C	25°C					
<i>Yersinia pestis</i>	–	–	5%	–	–	+	V	+	1%	VP – at 25°C
<i>Yersinia pseudotuberculosis</i>	–	–	+	–	– ⁺	+	V	+	70%	VP – at 25°C
<i>Yersinia enterocolitica</i>	–	+	+, (+)	–	+	+	+	+	–	VP + at 25°C
<i>Klebsiella rhinoscleromatis</i>	–	–	–	–	–	+	–	+	+	Sucrose +
<i>Pantoea agglomerans</i> group	–	–	V	V	V	+	+	+	+	Citrate +
<i>Shigella</i> spp.	–	V	–	–	–	+	V	V	– ⁺	Serology

^a Reactions of *Yersinia* are faster at room temperature. Data are from references 2 and 6. See footnote *b* to Table 3.18.2–1 and footnote *a* to Tables 3.18.2–3 and 3.18.2–7 for abbreviations and symbols.

^b Use rapid urea test method to increase sensitivity. See procedure 3.17.48.

Table 3.18.2-10 Biochemical reactions of non-glucose-fermenting, gram-negative rods that are catalase positive, oxidase negative, or delayed and grow well on MAC within 48 h^a

Organism(s)	Motility	Pigment	Polymyxin B	Lysine	Glucose	Urea	Nitrate	Arginine	Mannitol	Maltose	Other differential trait(s)
<i>Burkholderia gladioli</i> / <i>Pandoraea</i>	+	Variable yellow	R	-	O (O)	V	V	-	V	V	Rod; see Table 3.18.2-11 for species identification; DNase -
<i>Stenotrophomonas maltophilia</i>	+	Variable yellow	V	+	O	-	V	-	-	+	Rod; DNase +, PYR -
<i>Pseudomonas oryzae</i> - <i>bitans/luteola</i>	+	Yellow	S	-	O	V	V	V	+	+	Wrinkled colonies; PYR +
<i>Burkholderia mallei</i>	-	-	R	-	O	V	+	+	V	V	Coccobacilli, hazardous; MAC and oxidase V, citrate -; no growth at 42°C
<i>Acinetobacter</i> spp. Saccharolytic	-	-	S	-	O	-	-	V	-	NA	Coccobacilli; most are <i>A. baumannii</i> , the only one that grows at 42°C
Asaccharolytic	-	-	S	-	n-o	-	-	V	-	-	Coccobacilli; not all grow on MAC; nitrate negativity and rod shape separates them from NO-1
<i>Bordetella trematum</i>	+	-	NA	-	n-o	-	V	-	-	-	Coccobacilli
<i>Roseomonas</i> spp.	V	Pink	R	NA	n-o	+	V	NA	-	-	Coccoid, mucoid, delayed positive oxidase; does not absorb long-wave UV light

^a Reactions from references 10 and 14 and from G. L. Gilardi, unpublished identification tables. All strains are catalase positive. For oxidase-negative, yellow-pigmented organisms, see Table 3.18.2-7. See footnote b to Table 3.18.2-1 and footnote a to Tables 3.18.2-3 and 3.18.2-5 for abbreviations and symbols.

Table 3.18.2-11 Characteristics of *Burkholderia cepacia* complex and related polymyxin B-resistant organisms^a

Organism(s)	Catalase	Oxidase ^c	Oxidation of:										Lysine decarboxylase	Ornithine decarboxylase	ONPG	PYR

The Anaerobic Bacteriology section in this edition retains several authors from the first edition, though I have modified some procedures to include new media, supplies, reagents, or identification systems. In addition, some procedures have been significantly modified to include cost-effective current methods, tests, and organisms.

I thank and acknowledge the significant contributions of Cynnthia Reischelderfer and Jean Siders, procedure authors from the first edition of CMPH who have not continued with this edition. I have chosen to delete from this edition the procedures on prerduced anaerobically sterilized biochemicals (procedure 2.6 of the first edition) and GLC (procedure 2.7), techniques no longer in general use by most clinical laboratories. However, these procedures on anaerobe identification written by Jean A. Siders remain the “gold standard.” Readers should consult the first edition for this information.

Finally, I dedicate the procedure (4.12) on anaerobic cocci to the memory of Perkins B. Poon, who was a dedicated clinical laboratory scientist, a role model for many of us, and a wonderful friend. Perkins died 20 June 1999.

Anaerobic bacteria cause a variety of infections in humans, including appendicitis, cholecystitis, otitis media, dental and oral infections, endocarditis, endometritis, brain abscesses, myonecrosis, osteomyelitis, peritonitis, empyema, salpingitis, septic arthritis, liver abscesses, sinusitis, wound infections following bowel surgery or trauma, perirectal and tuboovarian abscesses, and bacteremia (1, 4, 5). Many reports associate 50 to 60% of important infections with anaerobic bacteria (1–5).

Anaerobic bacteria are overlooked or missed unless the specimen is properly collected and transported to the laboratory and then subjected to appropriate proce-

dures for isolation, including the use of specialized media supplemented with growth factors. Anaerobes vary in their sensitivity to oxygen: a brief exposure (10 min) to atmospheric oxygen is enough to kill some organisms (4). They also vary in their nutritional requirements, but most isolates require vitamin K (menadione) and hemin for growth. Proper collection, media, and incubation are vital to the recovery of anaerobes.

When a clinician knows anaerobes have been isolated, that knowledge helps the clinician to determine whether to treat empirically, whether identification of the bacteria is required in selective speci-

mens, and how to guide the patient's therapy (1).

This section outlines practical procedures that can be used to establish the presence of clinically important anaerobes. Procedures are presented for proper collection and transport; specimen types appropriate for culture, processing, incubation, and isolation; and methods of initial characterization of anaerobes from properly collected specimens. Identification methods and a listing of the salient features of commonly recovered anaerobes are included, as well as cost-effective procedures for workup and identification.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Proper collection of specimens—to avoid contaminating them with normal microbiota—and prompt transport to the laboratory for processing are extremely important. Isolating anaerobes from clinical specimens, determining the numbers of anaerobes in the specimen, and establishing the clinical significance all depend on proper collection and transport of the specimen. The laboratory director or su-

pervisor must provide the clinical staff with guidelines for the optimal amount and type of specimen required for anaerobic culture and must stress the need to transport the properly collected specimen to the laboratory without delay. Patient care units, clinics, and emergency rooms must be supplied with appropriate collection devices and complete instructions for their use. The clinician, in turn, must pro-

vide information regarding specific source, clinical impression, special status of patient, or unusual suspected organisms. Good communication between the clinical microbiology laboratory and the clinical staff will ensure the collection and transport of the best possible specimen for anaerobic culture (1, 2).

II. SPECIMEN

Observe standard precautions.

A. Specimen collection (Table 4.2–1)

1. The best specimen for anaerobic culture is obtained by using a needle and syringe.
2. Tissue samples and biopsy samples are also very good specimens for anaerobic culture.
3. The least desirable specimen is collected by swab. Generally the specimen volume when collected by a swab is small, reducing the probability of isolating organisms, and many organisms adhere to the fibers of the swab, which reduces the opportunity of recovering organisms (1, 2, 4, 5). If collecting a specimen by swab is unavoidable, then collect as much specimen as possible, use a commercially available anaerobe swab system (*see* Table 4.2–1), and use special care to sample the active site of infection to prevent contamination.

B. Specimen transport (*see* Appendix 4.2–1 for a partial list of suppliers)

1. Transport time depends on the volume and nature of the specimen. Large volumes of purulent material and large pieces of tissue maintain the viability of anaerobes for many hours. Swabs (when necessary) and small volumes of aspirated material, biopsy samples, or curettings should be transported in an anaerobic transport device (Table 4.2–2). Suggested transport times relative to specimen volumes and methods of collection are listed in Table 4.2–3.
2. Avoid extremes of heat or cold. *If delays are unavoidable, hold the specimen at room temperature until processing.*
3. Do not transport material for culture in the needle and syringe. Needle transport is very unsafe because there is always the risk of a needle stick injury, and syringe transport poses a risk because the specimen may be expelled

Table 4.2–1 Acceptable specimens for anaerobic culture

Site	Acceptable specimens	Unacceptable specimens
Head and neck	Abscess aspirate obtained by needle and syringe after surface decontamination Biopsy material surgically obtained Anaerobic swab surgically obtained when aspiration is not feasible	Throat or nasopharyngeal swabs Gingival swabs Superficial material collected with swabs
Lungs	Transtracheal aspirate Material from percutaneous lung puncture Biopsy material surgically obtained Bronchoscopic specimen obtained by protected brush Thoracotomy specimen Anaerobic swab surgically obtained	Expectorated sputum Induced sputum Endotracheal aspirate Bronchoscopic specimens not specially collected
Central nervous system	Abscess aspirate obtained by needle and syringe Biopsy material surgically obtained Anaerobic swabs surgically obtained	Aerobic swabs
Abdomen	Peritoneal fluid obtained by needle and syringe Abscess aspirate obtained by needle and syringe Bile Biopsy material surgically obtained Anaerobic swab surgically obtained	Aerobic swabs
Urinary tract	Suprapubic aspirate	Voided urine Catheterized urine
Female genital tract	Culdoscopy specimens Endometrial aspirate obtained by suction or protected collector Abscess aspirate obtained by needle and syringe Biopsy material surgically obtained Anaerobic swabs surgically obtained IUD ^a for <i>Actinomyces</i> species or <i>Eubacterium nodatum</i>	Vaginal or cervical swabs
Bone and joint	Aspirate obtained by needle and syringe Biopsy material surgically obtained Anaerobic swab surgically obtained	Superficial material collected with swabs
Soft tissue	Aspirate obtained by needle and syringe Biopsy material surgically obtained Aspirate from sinus tract obtained by needle and small plastic catheter Deep aspirate of open-wound margin obtained through decontaminated skin Deep aspirate of surface ulcer obtained through decontaminated skin	Superficial material collected from skin surface or edges of wound
Stomach and small bowel	Only for workup of blind-loop or malabsorption syndrome	
Large bowel	Only for culture or toxin assay for suspected involvement of <i>Clostridium difficile</i> or <i>Clostridium botulinum</i> , <i>Anaerobiospirillum succiniciproducens</i> , and other etiologic agents	

^a IUD, intrauterine device.**II. SPECIMEN** (continued)

during transport, creating a threat to personnel and the environment (1). Transfer aspirated material to an anaerobic transport vial. Large volumes of purulent material may be transported in a sterile screw-cap tube.

- Place tissue samples, biopsy samples, or curettings into an anaerobic transport device or a sterile tube or petri dish. Place all of this into a sealable

Table 4.2–2 Anaerobic specimen transport devices

Specimen type	Transport system	Commercially available systems ^a
Aspirated material	Vial or tube with anaerobic atmosphere and agar base with indicator system	Port-A-Cul tube or vial (BD) Anaerobic Transport Medium (Anaerobe Systems) A.C.T. transport tube (Remel)
Tissue, biopsy material, or curettings	Bag systems that act by removing molecular oxygen or tube systems that permit material to be added	Bio-Bag (type A) (BD Biosciences) Anaerobic Transport System (Anaerobe Systems) A.C.T. transport tube (Remel) AnaeroGen (Oxoid) AnaeroPouch (Mitsubishi) Venturi Transystem (Copan) Port-A-Cul widemouthed jar (BD Biosciences)
Specimen collected on swabs	Tube with anaerobic atmosphere and agar base with indicator system, or tube with anaerobic atmosphere and reduced transport medium	Anaerobic Transport System (Anaerobe Systems) A.C.T. transport tube (Remel) Port-A-Cul (BD Biosciences) Venturi Transystem Vi-Pak Amies (Copan Diagnostics)

^a Partial list of suppliers.

II. SPECIMEN (continued)

plastic bag (Becton Dickinson [BD], Oxoid, Mitsubishi) that generates an anaerobic atmosphere. Large pieces of tissue can be transported in a wide-mouthed anaerobic transport device or in a sterile tube or jar.

- If specimens must be collected by swab, transport swabs in a tube containing anaerobic transport medium (*see* Table 4.2–2).

C. Collection methods

1. Abscess

Aspirate material with needle and syringe after the surface of intact tissue is disinfected with a povidone-iodine wash that remains on the surface for at least 1 min. When needle use is contraindicated, aspirate material through a flexible plastic catheter or directly into the syringe with no needle.

Table 4.2–3 Suggested transport times for certain specimen volumes and collection methods

Specimen type	Optimal time for transport to laboratory	Additional comment(s)
Aspirated material		
Very small vol (<1.0 ml)	≤10 min	Transport small vol of aspirated material in anaerobic transport vial whenever possible for best possible results.
Small vol (~1.0 ml)	≤30 min	
Large vol (>2.0 ml)	≤2–3 h	
In anaerobic transport device	≤2–3 h	Transport large vol of purulent material; large pieces of tissue; or aspirated material, tissue, biopsy material, or curettings in an anaerobic transport medium or container. These specimens can generally be accepted for anaerobic culture with good results even after a delay of 8–24 h. Include comment regarding transport delay in report when these cultures are processed.
Tissue or biopsy material		
In sterile container	≤30 min	
In anaerobic bag or transport device	≤2–3 h	
Anaerobic swabs		
In tube with moist anaerobic atmosphere	≤1 h	
In anaerobic transport medium	≤2–3 h	

II. SPECIMEN (*continued*)

2. Sinus tract or deep-wound drainage
Aspirate material with a small flexible plastic catheter and syringe after proper disinfection of the skin surface, or collect curettings of material from deep within the tract or wound.
3. Decubiti and other surface ulcers
Results on specimens from decubiti and other surface ulcers can be very misleading unless special precautions are utilized. Analysis should be performed only on specimens from punch biopsy, on aspirated material obtained by needle and syringe after thorough and proper disinfection of the surface area, or on small curettings of material from deep tissue at the wound margin. Swabs from decubiti and other surface ulcers are never appropriate for anaerobic culture.
4. Pulmonary specimens
Collect lung tissue, transtracheal aspirate, percutaneous aspirate, transcutaneous aspirate, and bronchial brushings via double-lumen catheter. The use of shielded catheters to obtain specimens from pulmonary sources is essential to obtain proper specimens; otherwise the laboratory will be working up and identifying normal respiratory microbiota and providing useless information to the physician. Bronchial washings and other respiratory specimens not obtained via double-lumen catheters are not appropriate for anaerobic culture.
5. Female genital tract specimens
 - a. Disinfect the cervical opening by swabbing it with povidone-iodine.
 - b. Sample the upper genital tract by using a double-lumen collector and self-contained transport system. The Pipelle system obtains cellular material from the uterine wall by suction, and the AccuCulShure uses a double-lumen collector that reduces the potential of contamination (1, 2). Specimens collected by laparoscopy, culdocentesis, or surgery are appropriate for anaerobic culture.
 - c. Culture intrauterine devices anaerobically for *Actinomyces* species or *Eubacterium nodatum*.
6. Urinary tract
Obtain material via suprapubic bladder tap.
7. Other situations
In some cases, when aspiration or biopsy is not feasible (e.g., animal bite wounds), an anaerobic swab may be used for anaerobic culture. Anaerobic swabs are the least desirable specimen for a number of reasons, including small volume of specimen, greater chance of contamination with normal microbiota, excessive dryness, bacterial adherence to cotton fibers, and poor Gram stain quality. Studies have shown poor recovery of anaerobic organisms from some swab transport systems beyond 24 h (3, 4, 5). If a swab must be used, a swab using polyurethane adsorbing material instead of cotton, with two swabs (one for culture and the other for smear), may provide a useful alternative. An aspirate or biopsy sample or even a very small sliver of tissue may often be a better specimen than a swab for anaerobic culture.

ANALYTICAL CONSIDERATIONS**III. PROCESSING SPECIMENS FOR ANAEROBIC CULTURE****A. Visual examination**

Gross inspection of the specimen may provide information about the nature and quality of the specimen. Characteristics to note include blood, purulence, necrotic tissue, foul odor, and sulfur granules.

III. PROCESSING SPECIMENS FOR ANAEROBIC CULTURE (continued)

Include QC information on reagent container and in QC records.

Observe standard precautions.

B. Specimen preparation

1. Vortex grossly purulent specimens in the anaerobic transport vial to ensure even distribution of microorganisms.
2. Grind bone or tissue with approximately 1 ml of liquid medium (THIO or chopped meat) to make a thick paste. Grind the materials in an anaerobic chamber, when possible, to minimize aeration.
3. Wring out swabs in 0.5 ml of liquid medium (THIO or chopped meat), and then treat them as a liquid specimen. Alternatively, plant swabs directly onto appropriate media, but this option is less desirable because the loss of organisms on each medium will result in a poorer specimen for Gram stain.
4. Centrifuge large volumes of nonpurulent material. Use the sediment to inoculate the media and to prepare the Gram stain.

C. Inoculation of media

1. Media for anaerobic culture (see procedure 4.3 for more information)
 - a. Brucella agar with 5% sheep blood supplemented with vitamin K and hemin for the isolation of most organisms.
 - b. Phenylethyl alcohol (PEA)-sheep blood agar for the inhibition of enteric and certain other facultatively anaerobic gram-negative bacilli that may overgrow the anaerobes. PEA also reduces the spreading or swarming characteristic of some anaerobes.
 - c. Kanamycin-vancomycin-laked blood agar for the selection of pigmented *Prevotella* and other *Bacteroides* spp.
 - d. *Bacteroides* bile esculin agar for the selection and presumptive identification of *Bacteroides fragilis* group organisms and *Bilophila wadsworthia*. *Fusobacterium mortiferum/varium* group organisms may also occasionally grow on this medium.
 - e. Chopped meat broth or THIO (supplemented with vitamin K and hemin).
 - f. Freshly prepared or prerduced anaerobically sterilized (PRAS) media are preferred. PRAS media have a prolonged shelf life and are superior to commercial media that have been reduced 24 h before use (1, 2). Further descriptions of media used for anaerobic culture are given in procedure 4.3.
2. Inoculation procedure
 - a. Transfer the prepared specimen onto the appropriate aerobic and anaerobic media, liquid medium, and a slide for Gram stain. Use 1 drop of purulent material per plate, 2 or 3 drops of nonpurulent material per plate, 0.5 to 1.0 ml of specimen on the bottom of the liquid medium, and 1 drop of specimen spread evenly on a glass slide.
 - b. When swabs are used, inoculate the nonselective plates first. If two swabs are available, use one for medium inoculation and one for Gram stain preparation.
3. Incubation

When inoculated media cannot be placed immediately into an anaerobic atmosphere, it would be best to batch process the specimens so that multiple specimens will be inoculated and placed into the anaerobic environment at once. Holding the clinical specimen in an appropriate transport device and batch processing the inoculation to media is preferred to processing specimens one at a time and leaving them in holding jars until time permits to place them at once in an anaerobic environment (either bags, jars, or an anaerobic chamber; see procedure 4.5). The viability of anaerobes can be maintained for hours in a good anaerobic specimen collection device.

IV. MICROSCOPIC EXAMINATION

- A.** A direct smear can be gently heat fixed or fixed in absolute methanol for 1 min and then stained by standard Gram stain procedure and reagents. Alternatively, use basic fuchsin in place of safranin to enhance the staining of some gram-negative anaerobes.
- B.** Gram stain reveals the types and relative numbers of microorganisms and host cells present and serves as a QC measure for the adequacy of anaerobic techniques. Correlation of specimen type with bacterial morphology on the Gram stain can provide the clinician with rapid presumptive information about the identity of the bacteria present. (See procedures 4.10, 4.11, and 4.12 for additional Gram stain clues.)
1. Large gram-positive rods with boxcar-shaped cells and no spores usually indicate *Clostridium perfringens*. Some *C. perfringens* cells may appear gram negative but may have the same morphology as the gram-positive cells within the same microscopic field (See procedure 4.11 on anaerobic gram-positive bacilli and additional Gram stain clues.)
 2. Gram-negative coccobacillary forms suggest pigmented *Prevotella* group or *Porphyromonas* group.
 3. Thin gram-negative bacilli with tapered ends suggest *Fusobacterium nucleatum*.
 4. Pleomorphic pale-staining gram-negative bacilli suggest *Bacteroides* spp.
 5. Very small gram-negative cocci suggest *Veillonella* spp.
 6. See procedures 4.10 and 4.11 for additional Gram stain clues.
- C.** Results of the Gram stain may indicate the need for additional media or special stains. Aspirated material from a lung nodule, for example, may reveal long, thin, branching gram-positive bacilli. These bacilli suggest the possibility of *Actinomyces* or *Nocardia* spp. The addition of a modified Kinyoun acid-fast stain may quickly provide useful information for the clinician.
- D.** Techniques such as phase-contrast microscopy or dark-field examination have been used to demonstrate spirochetes.

4.3

Culture Media for Anaerobes

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The choice of media for use in the anaerobic bacteriology laboratory is important for the success of anaerobic bacteriology. The media must contain appropriate nutrients and supplements needed by clinically significant anaerobes. A combination of enriched, nonselective, selective, and differential media should be used for the initial processing, isolation, and presumptive identification of anaerobic bacteria from

clinical specimens (Fig. 4.3–1 and Tables 4.3–1 and 4.3–2) (1–3). Anaerobes have a wide range of nutritional needs; most, however, require hemin and vitamin K. Some studies suggest that freshly prepared, properly stored, highly enriched media are essential for recovery of anaerobes (4, 7), while another study has shown that prereduced anaerobically sterilized (PRAS) media best support the growth of

anaerobes (6). Recent studies have suggested that using media containing oxyrase may be another alternative (9, 10). Media that have been exposed to air contain oxidized products that may delay or inhibit the growth of many anaerobes. The ideal media for use in anaerobic bacteriology, therefore, are those that have had limited exposure to oxygen.

II. SPECIMEN

The proper specimen for primary culture of anaerobes should be free of normal microbial contamination. Such contamination must be avoided to ensure proper interpretation of results and to prevent the identification of organisms that are not clinically significant. An aspirated fluid or tissue is best (*see* procedure 4.2).

III. MATERIALS

Include QC information on reagent container and in QC records.

- A. The following may be employed. These media are available in dehydrated form and are prepared according to the manufacturer's directions. See Appendix 4.3–1. Commercially prepared enriched primary agar media are available from suppliers (*see* Appendix 4.3–2).
 1. Enriched all-purpose medium for primary growth, e.g., brucella, CDC, Columbia, or Schaedler agar (1–3, 8)
 2. Kanamycin-vancomycin-laked blood agar (KVLB or LKV) (2, 3, 8)
 3. Phenylethyl alcohol agar (PEA) or Columbia nalidixic acid agar (1, 4, 9)
 4. *Bacteroides* bile esculin agar (BBE) (2, 3, 8)
 5. Cycloserine-cefoxitin fructose agar (CCFA) (2, 3, 8)
 6. Egg yolk agar (EYA) (1–3, 8)
 7. Broths
 - a. THIO (thioglycolate) supplemented with vitamin K₁ (menadione) (0.1 µg/ml), hemin (5 µg/ml), and a marble chip or sodium bicarbonate (1 µg/ml)
 - b. Chopped meat-carbohydrate or chopped meat-glucose
- B. See Table 4.3–1 and Appendix 4.3–1 to this procedure for composition, purpose, interpretation, limitations, and recommended QC organisms for each medium.
- C. If these media are purchased, they should be as fresh as possible to ensure their ability to cultivate anaerobes. PRAS media will provide a longer shelf life and will not have developed harmful oxidized products (6). Media containing oxyrase (9, 10) may be another alternative.
- D. If media are prepared in the laboratory, they should be as fresh as possible (24 to 48 h) when used (1, 4, 7).
- E. A scheme for the recommended primary processing of clinical specimens for anaerobes is given in Fig. 4.3–1 and Table 4.3–2, and their general use is shown in Table 4.3–1.

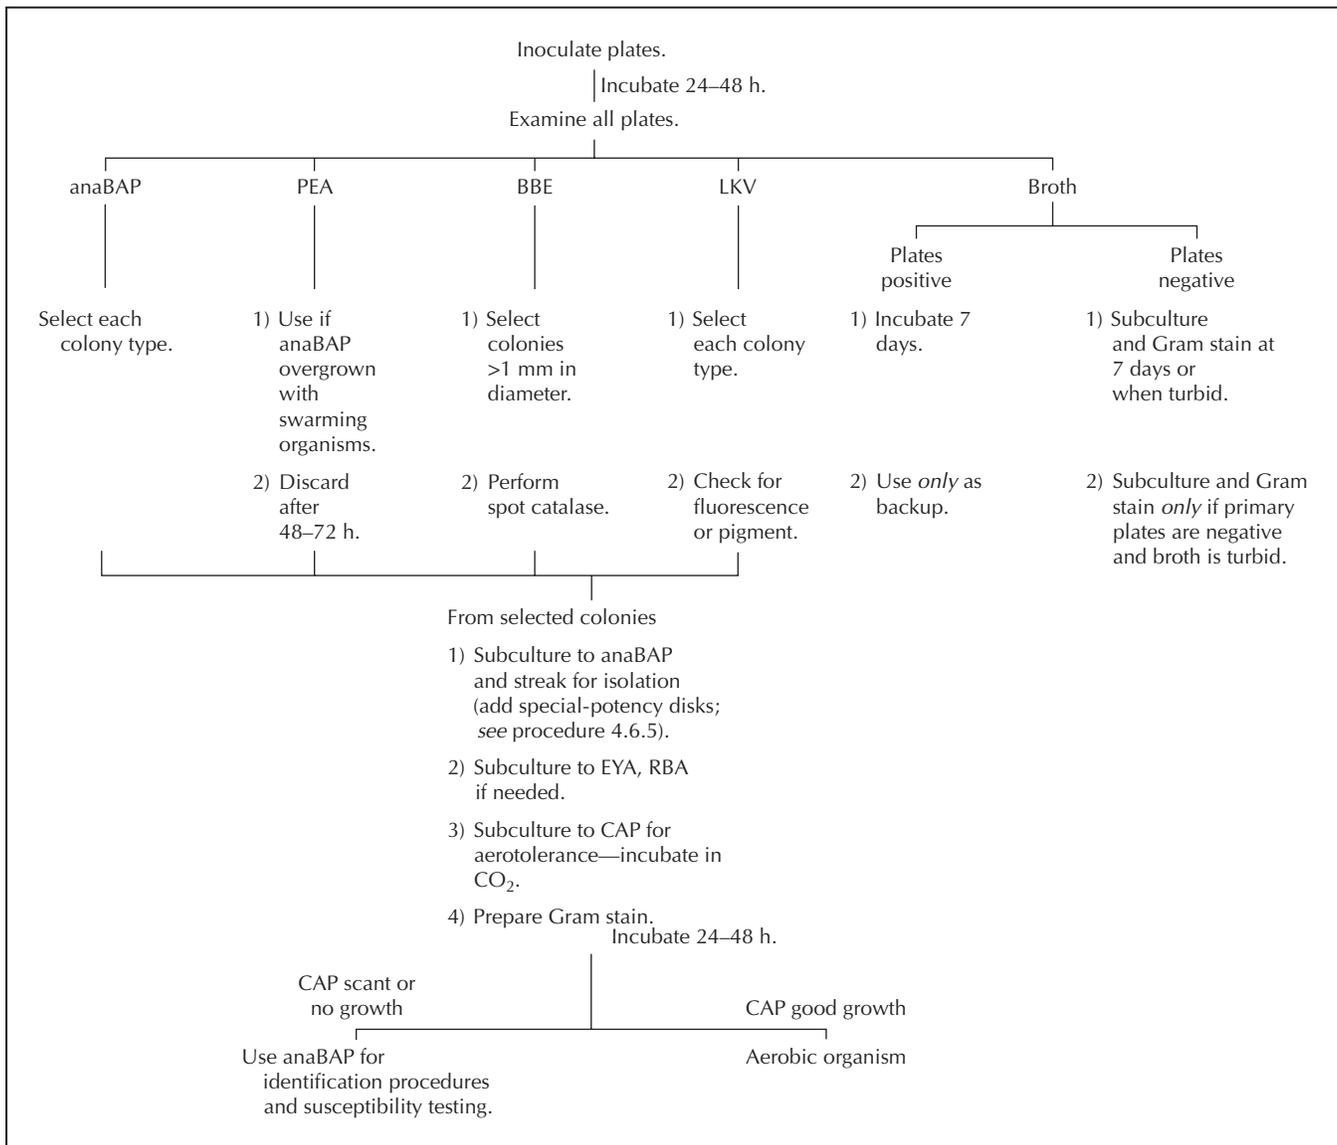

Figure 4.3–1 Flowchart for processing primary anaerobic culture plates. anaBAP, anaerobic blood agar plate; CAP, chocolate agar plates; RBA, rabbit blood agar.

ANALYTICAL CONSIDERATIONS

IV. PROCEDURE

Observe standard precautions.

- A. Inoculate a properly obtained clinical specimen onto the medium, and streak to obtain isolated colonies. The primary enriched medium may be inoculated directly with clinical material or from a broth that has been previously inoculated with clinical material. Immediately incubate anaerobically at 35°C. (See procedure 4.5 for anaerobic incubation techniques.)
- B. Examine initially at 24 h if incubating plates in an anaerobic chamber or at 48 h if incubating plates in an anaerobic jar or anaerobic pouch. Additional periods of incubation may be necessary to recover some anaerobes (Table 4.3–1).

Table 4.3–1 Anaerobic media and their uses

Medium ^a	Purpose	Interpretation	Limitations	QC organisms
BHI blood agar Brucella blood agar CDC anaerobe agar Columbia blood agar TSA blood agar Schaefer blood agar	General all-purpose enriched primary media ^b that allow growth of all clinically significant anaerobes	Observe initially in 24 h if incubation systems permit. Determine if organism is an anaerobe by aerotolerance testing. Hold medium 5–7 days before completing report.	You must perform Gram stain and aerotolerance test. Aerobes will grow on medium.	<i>Clostridium perfringens</i> ATCC 13124 (growth) <i>Bacteroides fragilis</i> ATCC 25285 (growth) <i>Fusobacterium nucleatum</i> ATCC 25586 (growth) <i>Peptostreptococcus anaerobius</i> ATCC 27337 (growth) (Also consider <i>Porphyromonas levii</i> ATCC 29147 [growth and pigment]) <i>Fusobacterium necrophorum</i> ATCC 25286 (growth)
KVLB or LKV	Rapid isolation and selection of <i>Bacteroides</i> species and <i>Prevotella</i> spp. and earlier detection of pigment-producing strains of <i>Prevotella</i> spp.	Growth is presumptive; <i>Bacteroides</i> spp., <i>Prevotella</i> spp., or <i>Fusobacterium mortiferum</i> . Note: <i>Porphyromonas</i> spp. will not grow.	You must perform Gram stain and aerotolerance test. Yeast cells and other kanamycin-resistant organisms may grow on this medium.	<i>Bacteroides fragilis</i> ATCC 25285 (growth) <i>Clostridium perfringens</i> ATCC 13124 (no growth) <i>Escherichia coli</i> ATCC 25922 (no growth)
PEA	Inhibits facultative gram-negative rods and inhibits <i>Proteus</i> from swarming. Also prevents certain clostridia from swarming. Pigment-producing <i>Prevotella</i> and <i>Porphyromonas</i> spp. may pigment first on PEA.	Most gram-positive and gram-negative anaerobes will grow on PEA. Growth may be considered presumptive evidence of anaerobic organisms, but further testing is required.	Examine at 24–48 h. Additional time may be necessary for some slower-growing anaerobes. You must perform Gram stain and aerotolerance test.	<i>Bacteroides fragilis</i> ATCC 25285 (growth) <i>Proteus mirabilis</i> ATCC 12453 (inhibition of swarming and growth) <i>Escherichia coli</i> ATCC 25922 (no growth)
BBE	Rapid selection, isolation, and presumptive identification of <i>Bacteroides fragilis</i> group. Also allows growth and presumptive identification of <i>Bilophila wadsworthia</i> .	Supports growth of bile-resistant <i>Bacteroides fragilis</i> group organisms, which grow and form brown to black colonies. <i>Bilophila wadsworthia</i> produces small, transparent colonies with a black dot in the center (“fish eyes”).	Some strains of <i>Fusobacterium mortiferum</i> , <i>Klebsiella pneumoniae</i> , enterococci, and yeasts may grow to limited extents on this medium. Some anaerobic organisms that should grow on BBE may be inhibited, so inoculate nonselective medium also. You must perform Gram stain and aerotolerance test. <i>Bacteroides vulgatus</i> may not form black colonies or discolor medium.	<i>Bacteroides fragilis</i> ATCC 25285 (growth, black colonies) <i>Fusobacterium necrophorum</i> ATCC 25286 (no growth) <i>Escherichia coli</i> ATCC 25922 (no growth)

(continued)

Table 4.3–1 Anaerobic media and their uses (*continued*)

CCFA	Selective and differential medium for recovery and presumptive identification of <i>Clostridium difficile</i>	<i>Clostridium difficile</i> produces yellow ground glass colonies, and original pink agar turns yellow in vicinity of colonies.	Colonial morphology and Gram stain should be consistent with those of <i>Clostridium difficile</i> . Additional identification methods should be used.	<i>Clostridium difficile</i> ATCC 9689 (growth) <i>Bacteroides fragilis</i> ATCC 25285 (no growth) <i>Escherichia coli</i> ATCC 25922 (no growth)
EYA	For use when <i>Clostridium</i> spp. are suspected or when proteolytic enzyme (lecithinase or lipase) may be useful for identification of anaerobic isolate	Positive lecithinase reaction is indicated by opaque zone (white) in medium around bacterial growth. Positive lipase is indicated by iridescent sheen on surface of bacterial growth of agar. Proteolysis is indicated by total clearing around bacterial growth.	Lipase is observed under oblique light. It is best not to use all the plate so that lecithinase activity can be compared with portion of EYA acting as negative control.	<i>Clostridium perfringens</i> ATCC 13124 (positive lecithinase) <i>Fusobacterium necrophorum</i> ATCC 25286 (positive lipase) <i>Bacteroides fragilis</i> ATCC 25285 (growth but no proteolytic activity-negative control)
THIO supplemented with vitamin K ₁ , hemin, and marble chip or sodium bicarbonate Chopped meat-carbohydrate Chopped meat-glucose	General enrichment broth media that support growth of most anaerobes; provide backup source of culture material if anaerobic environment fails, for enrichment for small numbers, or when growth is inhibited.	Incubate at 35°C until there is growth on primary plates. If primary plates have no growth, incubate liquid medium for at least 7 days and subculture.	Examine and Gram stain broth only if plating medium reveals no growth or if chamber, jar, or pouch is not functioning. Never rely on broth cultures exclusively for isolation of anaerobes. Some anaerobes may be inhibited by metabolic products or acids produced from more rapidly growing facultative anaerobes.	<i>Bacteroides fragilis</i> ATCC 25285 (growth) <i>Clostridium perfringens</i> ATCC 13124 (growth) <i>Peptostreptococcus anaerobius</i> ATCC 27337 (growth) <i>Escherichia coli</i> ATCC 25922 (growth)

^a See Appendix 4.3–1 for formulas of commonly used media.

^bAll media for anaerobes should contain vitamin K and hemin.

POSTANALYTICAL CONSIDERATIONS

V. LIMITATIONS OF THE PROCEDURE

- A. The clinical specimen must be obtained properly and transported to the laboratory in a suitable anaerobic transport container (*see* procedure 4.2).
- B. The microbiologist must be able to verify QC of the medium and determine whether the anaerobic environment (chamber, jar, or anaerobic pouch) is indeed anaerobic.
- C. The microbiologist must perform aerotolerance testing on each isolate recovered from the primary enriched medium to ensure that the organism is an anaerobe (*see* procedure 4.4).

Table 4.3–2 Recommended primary medium setup

Medium ^a	Organisms inhibited	Organisms that grow
Brucella blood agar	None	All
PEA	Facultative anaerobic organisms; prevents swarming of <i>Clostridium</i> and <i>Proteus</i> spp.	Almost all anaerobes; a few organisms occasionally do not grow
BBE	Most aerobes and anaerobes, except for <i>Bacteroides fragilis</i> group, <i>Bilophila wadsworthia</i> , and some <i>Fusobacterium</i> spp.	<i>Bacteroides fragilis</i> group, <i>Bilophila wadsworthia</i> , some <i>Fusobacterium</i> spp.
LKV	All gram-positive and gram-negative facultative anaerobes and many gram-positive and gram-negative anaerobes, including most <i>Fusobacterium</i> spp., <i>Bacteroides ureolyticus</i> group, and <i>Porphyromonas</i> spp.	<i>Bacteroides</i> spp., some <i>Fusobacterium</i> spp., and pigmented and nonpigmented <i>Prevotella</i> spp.
Broth		
Enriched THIO	None	All
Chopped meat-carbohydrate	None	All
Chopped meat-glucose	None	All

^a These and all media for isolation of anaerobes should contain vitamin K₁ and hemin.

APPENDIX 4.3-1

Formulas of Media for Anaerobes

General all-purpose media

A. BHI blood agar

BHI agar (BBL, Difco, Inolex)	26.0 g
agar	2.5 g
distilled water	1,000 ml

Suspend the ingredients in the water, and dissolve them by boiling. Autoclave for 15 min at 121°C and 15 lb/in², cool to about 45°C, and aseptically add 5% defibrinated animal blood. Mix well. Dispense into petri dishes. Final pH is approximately 7.4.

B. Brucella formulation (BBL, Difco, Inolex)

Polypeptone	23.0 g
glucose	1.0 g
yeast extract	2.0 g
sodium chloride	5.0 g
hemin (1% solution)	10.0 ml
vitamin K ₁ (1% solution)	1.0 ml
L-cystine	0.4 g
agar	15.0 g
distilled water	1,000.0 ml

Suspend the ingredients in the water, and dissolve them by boiling. Autoclave for 15 min at 121°C and 15 lb/in², cool to about 45°C, and aseptically add 5% defibrinated animal blood. Mix well. Dispense into petri dishes. Final pH is 7.0 ± 0.2.

C. CDC anaerobe agar

TSA (BBL)	40.0 g
agar	5.0 g
yeast extract	5.0 g
hemin	5.0 mg
L-cystine	400.0 mg
vitamin K ₁ stock solution	1.0 ml
distilled water	1,000.0 ml

Suspend the ingredients in the water, and dissolve them by boiling. Autoclave for 15 min at 121°C and 15 lb/in², cool to about 45°C, and aseptically add 5% defibrinated animal blood. Mix well. Dispense into petri dishes. Final pH is 7.5.

D. Columbia agar base

Polypeptone (BBL) or Pantone (Difco) ..	10.0 g
Biosate (BBL) or Bitone (Difco)	10.0 g
Myosate (BBL) or tryptic digest of beef	
heart	3.0 g
cornstarch	1.0 g
sodium chloride	5.0 g
agar	13.5 g
distilled or demineralized water	1,000.0 ml

Suspend the ingredients in the water, and dissolve them by boiling. Autoclave for 15 min at 121°C and 15 lb/in², cool to about 45°C, and aseptically add 5% defibrinated animal blood. Mix well. Dispense into petri dishes. Final pH is 7.3 ± 0.2.

E. TSA

Trypticase	15.0 g
Phytone	5.0 g
sodium chloride	5.0 g
agar	15.0 g
distilled water	1,000.0 ml

Suspend the ingredients in the water, and dissolve them by boiling. Autoclave for 15 min at 121°C and 15 lb/in², cool to about 45°C, and aseptically add 5% defibrinated animal blood. Mix well. Dispense into petri dishes. Final pH is 7.3.

APPENDIX 4.3–1 (continued)

F. Schaedler blood agar (per liter of deionized water) (BBL, Difco, Inolex)

casein peptone	5.70 g
soy peptone	1.00 g
meat peptone	2.50 g
yeast extract	3.00 g
glucose	2.80 g
hemin	0.01 g
L-cystine	0.40 g
Tris	3.00 g
sodium chloride	5.70 g
dipotassium phosphate	0.80 g
vitamin K ₁	0.01 g
agar	15.00 g
sheep blood	50.00 ml

Suspend the ingredients in the water, and dissolve them by boiling. Autoclave for 15 min at 121°C and 15 lb/in², cool to about 45°C, and aseptically add 5% defibrinated animal blood. Mix well. Dispense into petri dishes. Final pH is 7.6 ± 0.2 at 25°C.

KVLB or LKV

Trypticase peptone	23.0 g
glucose	1.0 g
yeast extract	2.0 g
sodium chloride	5.0 g
hemin (1% solution)	10.0 ml
vitamin K ₁ (1% solution)	1.0 ml
L-cystine	0.5 g
agar	15.0 g
kanamycin	100.0 mg
vancomycin	7.5 mg
sheep blood (laked)	45.5 ml
distilled water	1,000.0 ml

Treat as described for Schaedler blood agar. Mix well. Dispense into petri dishes. Final pH is 7.0 ± 0.2.

PEA (BBL, Difco, Inolex)

Trypticase peptone	23.0 g
glucose	1.0 g
yeast extract	2.0 g
sodium chloride	5.0 g
hemin (1% solution)	10.0 ml
vitamin K ₁ (1% solution)	1.0 ml
L-cystine	0.4 g
agar	15.0 g
sheep blood	50.0 ml
phenylethyl alcohol	2.7 ml
distilled water	1,000.0 ml

Treat as described for Schaedler blood agar. Mix well. Dispense into petri dishes. Final pH is 7.0 ± 0.2.

BBE (BBL, Difco)

TSA	40.0 g
oxgall	20.0 g
esculin	1.0 g
ferric ammonium citrate	0.5 g
hemin solution (5 mg/ml)	2.0 ml
gentamicin solution (40 mg/ml)	2.5 ml
distilled water	1,000.0 ml

Adjust pH to 7.0, heat to dissolve, dispense into 100-ml bottles, autoclave at 121°C for 15 min, and cool to 50°C. Mix well. Dispense into petri dishes. Final pH is 7.0 ± 0.2.

APPENDIX 4.3-1 (continued)

***Clostridium difficile* agar (BBL, Difco)**

casein peptone	18.0 g
glucose	1.0 g
BHI-meat peptone	8.0 g
dipotassium phosphate	2.5 g
sodium chloride	5.5 g
yeast extract	2.0 g
fructose	6.0 g
neutral red	30.0 mg
cycloserine	500.0 mg
cefoxitin	16.0 mg
agar	15.0 g

Treat as described for Schaedler blood agar. Mix well. Dispense into petri dishes. Final pH is 7.4 ± 0.2 at 25°C.

EYA (BBL, Difco)

casein meat peptone	40.0 g
glucose	2.0 g
disodium phosphate	5.0 g
monopotassium phosphate	1.0 g
sodium chloride	2.0 g
magnesium sulfate	0.1 g
hemin	5.0 mg
egg yolk enrichment	100.0 ml
agar	20.0 g

Treat as described for Schaedler blood agar. Add the egg yolk enrichment to the autoclaved base. Mix, and then dispense into petri dishes. Final pH is 7.4 ± 0.2 at 25°C.

Liquid broths**A. THIO medium without indicator**

peptone	20.0 g
L-cystine	0.25 g
glucose	6.0 g
sodium chloride	2.5 g
sodium thioglycolate	0.5 g
sodium sulfite	0.1 g
agar	0.7 g
distilled water	1,000.0 ml

Dispense 10 ml per tube. Autoclave for 15 min at 121°C and 15 lb/in². Final pH is 7.2.

B. Enriched THIO

Enriched THIO is prepared by adding to freshly prepared autoclaved medium (or to previously prepared medium that has been boiled for 10 min and then cooled) vitamin K₁ solution (0.1 µg/ml), sodium bicarbonate (1 mg/ml), and hemin (5 µg/ml). Rabbit or horse serum (10%) or Fildes enrichment (5%) may also be added.

C. Chopped-meat–glucose broth

lean ground beef	500.0 g
distilled water	1,000.0 ml
sodium hydroxide (1 N)	25.0 ml
Trypticase	30.0 g
yeast extract	5.0 g
K ₂ HPO ₄	5.0 g
L-cystine	0.5 g
hemin (1% solution)	0.5 ml
vitamin K ₁ (1% alcohol solution)	0.1 ml
glucose	3.0 g

Dispense 5 ml into screw-cap tubes. Autoclave for 15 min at 121°C and 15 lb/in².

D. Chopped-meat–carbohydrate broth

To the above chopped-meat–glucose formula add the following:

maltose	1.0 g
cellobiose	1.0 g
starch	1.0 g

Dispense 5 ml into screw-cap tubes. Autoclave for 15 min at 121°C and 15 lb/in².

4.4

Examination of Primary Culture Plates for Anaerobic Bacteria

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The goal of processing primary culture plates is to isolate significant anaerobic organisms present in the original specimen for identification and when susceptibility testing is indicated. The original Gram stain of the specimen is critical. At that time all morphological types should be carefully described and recorded. When evaluating culture plates, all morphotypes observed in the original Gram stain should match.

It is important to remember that anaerobic culture media permit facultatively anaerobic bacteria to grow. All bacterial isolates must be subjected to aerotolerance testing before being designated anaerobes (see Fig. 4.4–1).

Special precautions must be taken to avoid exposure of culture plates to oxygen

during examination. Even a 10-min exposure will kill some oxygen-sensitive anaerobes (*Fusobacterium* spp., *Porphyromonas* spp., and anaerobic cocci). In addition, reduced culture media will become oxidized when exposed to air, making the media unsuitable for isolation of fastidious anaerobes.

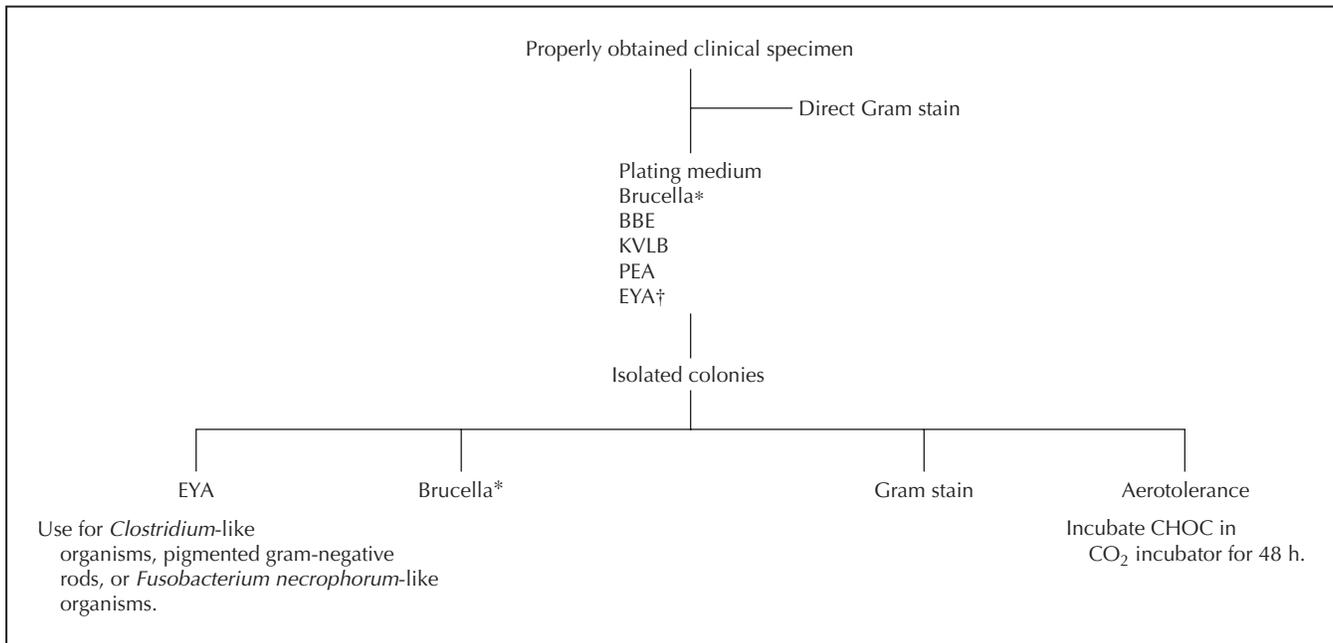

Figure 4.4–1 Procedure for the examination of primary culture plates for anaerobes. Symbols: *, use any other suitable enriched primary media that contain vitamin K and hemin and that allow good growth of anaerobes; †, use EYA if clostridia are suspected from Gram stain or from nature of clinical specimen. KVLB, kanamycin-vancomycin-laked blood agar.

II. MATERIALS

Include QC information on reagent container and in QC records.

A. Reagents

1. Gram stain reagents
2. Absolute methanol stored in a screw-cap amber bottle
3. Special-potency antimicrobial agent disks (Anaerobe Systems, Becton Dickinson [BD], Hardy, PML, Remel) (*see* procedure 4.6 for details of disks to add and a list of manufacturers)
 - colistin 10 µg
 - kanamycin 1,000 µg
 - vancomycin 5 µg
4. Nitrate disk (Anaerobe Systems, BD, Hardy, PML, Remel)
Nitrate A and nitrate B reagents, zinc powder (*see* procedure 4.6 for details)
5. Sodium polyanethol sulfonate disk (Anaerobe Systems, BD, Hardy, PML, Remel) (*see* procedure 4.6 for details)
6. 15% H₂O₂
7. *p*-Dimethylaminocinnamaldehyde (Anaerobe Systems, BD, Hardy, PML, Remel) (*see* procedure 4.6 for details)

B. Supplies

1. Clean glass microscope slides
2. Inoculating loops (sterile wooden applicator sticks may be substituted for loops). Platinum loops should be used in place of Nichrome loops.

3. Anaerobic BAP (anaBAP) (*see* procedure 4.3 for manufacturers)
4. CHOC plates (CAP) for aerotolerance testing
5. Egg yolk agar (EYA) plates for lipase and lecithinase testing
6. Rabbit blood agar (RBA) for enhancement of pigment production (optional)
7. Selective media: *Bacteroides* bile esculin (BBE), laked blood-kanamycin-vancomycin (LKV), and phenylethyl alcohol agar (PEA)
8. Other media for special circumstances are available from Anaerobe Systems, BD, Hardy, PML, or Remel.
9. Equipment (*see* procedure 4.5 for incubation techniques). The choice of one of the three anaerobic incubation systems listed depends upon volume and space limitations.
 - a. Anaerobic bags or pouches (*see* procedure 4.5)
 - b. Anaerobic jars (*see* procedure 4.5)
 - c. Anaerobic chambers (Coy, Forma, Sheldon, Toucan) (*see* procedure 4.5)
 - d. Stereoscopic microscope (7× to 15×) or hand lens (8×)
 - e. UV light, 366-nm wavelength (Wood's lamp)

III. QUALITY CONTROL

Include QC information on reagent container and in QC records.

QC of media, reagents, disks, equipment, appropriate organisms, etc., is discussed in procedure 4.3 and elsewhere. Abbreviations used are also listed in that procedure.

ANALYTICAL CONSIDERATIONS

IV. PROCEDURE

See Fig. 4.4–1 for a flowchart of a procedure for the examination of primary culture plates for anaerobes.

- A. Perform the initial plate examination 24 h after plate inoculation if an anaerobic chamber is used. Delay this first examination until 48 h after inoculation if anaerobic jars or bags are used.
- B. Carefully examine the anaBAP with a stereoscopic microscope or hand lens. Record a detailed description of each colony type, noting such characteristics as pitting, swarming, hemolysis, pigment, “greening” of the medium, etc. These colony characteristics can provide valuable clues to the identity of the isolates when used in conjunction with rapid identification tests and Gram stain (*see* Table 4.4–1 for anaerobic organism clues and use of supplemental media).
- C. Select a single, well-isolated colony of each morphological type observed. Touch each colony with a loop or sterile stick, subculture it onto anaBAP and CAP, and make a smear for Gram stain.

Table 4.4–1 Anaerobic organism clues from primary culture plates, and use of supplemental media

Colony morphology	Possible identification	Supplemental medium
Agar pitting	<i>Bacteroides ureolyticus</i> group	
Black or tan pigmentation	<i>Porphyromonas</i> spp. or pigmented <i>Prevotella</i> spp.	EYA for lipase (<i>Prevotella intermedia</i>)
Brick red fluorescence	<i>Porphyromonas</i> spp. or pigmented <i>Prevotella</i> spp. (<i>Porphyromonas gingivalis</i> does not fluoresce)	EYA for lipase (<i>Prevotella intermedia</i>)
Chartreuse fluorescence (gram-negative rod)	<i>Fusobacterium</i> spp.	EYA for lipase
Chartreuse fluorescence (gram-positive rod)	<i>Clostridium difficile</i> or <i>Clostridium innocuum</i>	CCFA
Double zone of beta hemolysis	<i>Clostridium perfringens</i>	EYA for lecithinase
“Fried egg”	<i>Fusobacterium necrophorum</i> , <i>Fusobacterium varium</i>	EYA for lipase, BBE for bile growth
“Greening” of medium	<i>Fusobacterium</i> spp.	EYA for lipase
Large with irregular margin	<i>Clostridium</i> spp.	EYA for proteolytic activity
“Medusa-head”	<i>Clostridium septicum</i>	PEA
“Molar tooth”	<i>Actinomyces</i> spp.	
Pink to red colony (gram-positive rod)	<i>Actinomyces odontolyticus</i>	
Speckled or “bread-crumbs”	<i>Fusobacterium nucleatum</i>	
Swarming growth	<i>Clostridium septicum</i> , <i>Clostridium sordellii</i> <i>Clostridium tetani</i>	PEA to prevent swarming

IV. PROCEDURE (*continued*)**1. anaBAP**

- a. Streak the subcultured organism in four quadrants to obtain isolated colonies.
- b. If the organism is gram negative, add special-potency kanamycin, vancomycin, and colistin antimicrobial agent disks to first quadrant of this plate. Add a nitrate disk to the second or third quadrant.
- c. If the organism is a gram-positive coccus, add nitrate and sodium polyanethol sulfonate disks (from Anaerobe Systems, BD, Hardy, PML, or Remel) only. The addition of special-potency antimicrobial agent disks does not help in further characterization of gram-positive organisms.
- d. If the organism is a gram-positive rod, add a nitrate disk only. The addition of special-potency antimicrobial agent disks does not help in further characterization of gram-positive organisms.
- e. Incubate anaerobically at 35 to 37°C for 24 to 48 h. Table 4.4–2 outlines results to expect with special-potency antimicrobial agent disks. Refer to procedure 4.10 for further details on identification of gram-negative organisms and procedure 4.11 for further details on identification of gram-positive organisms.

2. CHOC

- a. Divide this plate into quadrants, and subculture four organisms onto each plate.
- b. Incubate at 35 to 37°C in a 5% CO₂ environment for 24 to 48 h to detect slow-growing aerobic organisms such as *Capnocytophaga*, *Actinobacillus*, and *Eikenella* spp.

Include QC information on reagent container and in QC records.

Table 4.4–2 Special-potency antimicrobial agent disks for the identification of anaerobic bacteria^a

Organisms	Response ^b to:		
	Kanamycin, 1,000 µg	Vancomycin, 5 µg	Colistin, 10 µg
Gram-positive organisms	V	S ^c	R
<i>Bacteroides fragilis</i> group	R	R	R
<i>Bacteroides ureolyticus</i> group	S	R	S
<i>Fusobacterium</i> spp.	S	R	R
<i>Porphyromonas</i> spp.	R	S ^d	R
<i>Prevotella</i> spp.	R	R	V
Gram-negative cocci	S	R	S

^a Adapted with permission from P. Summanen, E. J. Baron, D. M. Citron, C. Strong, H. M. Wexler, and S. M. Finegold, *Wadsworth Anaerobic Bacteriology Manual*, 5th ed., 1993, Star Publishing Co., Belmont, Calif.

^b R, resistant; S, susceptible; V, variable.

^c Exceptions: rare strains of *Lactobacillus* spp. and *Clostridium* spp. may be vancomycin resistant.

^d *Porphyromonas* spp. are vancomycin susceptible but fluoresce or are pigmented.

IV. PROCEDURE (continued)

- c. Use only CHOC for aerotolerance testing. *Haemophilus* spp. will grow anaerobically on BAP and therefore will be mistaken for anaerobic gram-negative rods if CHOC is not used.
- d. Some authorities have suggested performing aerotolerance testing in multiple environments (ambient air, CO₂, microaerophilic environment) on problem isolates. This is not necessary for identification of the most commonly isolated anaerobes but may be considered for isolates when their exact atmospheric requirement is difficult to determine.

3. Gram stain

- a. Air dry the smear. It is preferred not to heat fix the slide as heat can distort the morphology of many anaerobes. Fix smears by flooding the slide with absolute methanol. Methanol should also be used when fixing smears prepared from colonies.
- b. Drain the methanol from the slide after 1 min, and then immediately begin your normal Gram stain procedure. Complete the Gram stain according to standard procedure.

D. Examine selective media such as PEA, BBE, and LKV (see procedure 4.3 for media, manufacturers, and usage and Table 4.3–1 for QC organisms to use on these media).

1. Pick any colonies on PEA that are different from the colonies isolated on the anaBAP. The PEA plate may be used in place of the anaBAP if the culture is overgrown with swarming *Clostridium* spp., *Proteus* spp., or other organisms. PEA may also provide earlier detection of pigmented anaerobic organisms (see procedure 4.6).
2. Pick all the different colonies growing on BBE that are >1 mm in diameter. Record the esculin hydrolysis reaction (black = positive), and perform a spot catalase test on each colony type.
3. Pick all colony types isolated on LKV. Check organisms for pigment or fluorescence by exposing the plate to UV (366-nm) light. Subculture organisms onto RBA to enhance pigment production (optional).
4. Process organisms isolated from selective media using the schema described for isolates from the anaBAP. Subculture onto anaBAP and CHOC, and add appropriate disks according to Gram stain reaction.

E. Use of supplemental media (EYA, RBA, BBE, etc.) can aid in the rapid identification of anaerobic organisms (see Table 4.4–1). These media provide evidence of lipase and/or lecithinase production (EYA), pigmentation (RBA), abil-

Include QC information on reagent container and in QC records.

IV. PROCEDURE (continued)

ity to grow in the presence of 20% bile (BBE), and other useful characteristics. Divide the supplemental plates into quadrants, and subculture four organisms to a plate. Use Table 4.4–1 to select supplemental media on the basis of colony morphology and to provide anaerobic organism clues.

F. Broth culture

1. No growth on original plates
 - a. Examine the broth culture daily for evidence of growth.
 - b. Prepare a Gram stain, and subculture onto anaBAP, PEA, BBE, LKV, and CAP as soon as growth is apparent. Use the addition of broth *only* as a backup; i.e., subculture only when anaerobic systems fail or when primary plates are negative but the broth is turbid.
 - c. Incubate negative broth cultures for 7 days, examine visually, and discard appropriately.
 - d. Refer to procedure 4.3 for medium and broth usage (Fig. 4.3–1).
2. Growth on original plates

If there is growth on the primary plates, subculture of the backup broth is generally not helpful and can lead to needless duplication. If, on the other hand, *Actinomyces* is suspected, the backup broth can be occasionally helpful to recover this slow growing organism, which may not grow readily on solid media.
3. Subsequent plate examination
 - a. Incubate primary anaBAP for 5 to 7 days. Examine the primary plates at 24- to 48-h intervals, depending on the type of anaerobic environment employed. Isolate and perform aerotolerance tests on any new colony types that appear.
 - b. Pigmented *Prevotella* spp., *Porphyromonas* spp., and *Actinomyces* spp. commonly appear after 2 to 3 days of incubation. Examine the primary anaBAP for fluorescent and pigmented organisms. Use the stereoscope to check for the characteristic “molar tooth” colonies of *Actinomyces* spp.
 - c. *Bilophila wadsworthia* commonly appears after 3 to 4 days of incubation, generally first observed from the BBE medium. This organism appears as small, translucent colonies with a black center and can resemble “fish eyes.”
 - d. Discard PEA and BBE plates after 4 days of incubation. These media lose their selective properties upon incubation because of evaporation and antibiotic degradation. Secondary growth will occur as these media lose selectivity.

POSTANALYTICAL CONSIDERATIONS

V. REPORTING RESULTS

Appendix 4.4–1 is an example of a reporting worksheet.

4.5

Incubation Techniques for Anaerobic Bacteriology Specimens

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

This procedure describes the various environmental methods and incubation conditions used for anaerobic bacteriology specimens once a properly selected, collected, and transported specimen arrives in the laboratory. Ideally, the specimen is processed immediately on arrival in the laboratory and incubated under anaerobic

conditions to prevent further exposure to oxygen. Refer to procedure 4.2 for collection procedures, to procedure 4.3 for anaerobic media, and to procedure 4.4 for processing and inoculation techniques.

In general, growing cultures must not be exposed to oxygen until after 48 h of incubation, since anaerobes are most sen-

sitive to oxygen during the log phase of growth. One of the obvious advantages of using an anaerobic chamber is that technologists can inspect inoculated media without removing them from the anaerobic environment of the chamber at any time.

II. SPECIMENS

It is imperative that these cultures be handled in a biosafety hood.

Observe standard precautions.

All primary bacteriology specimens should be collected, processed, inoculated, and incubated according to the techniques described in section 2 of this handbook and in procedures 4.2 to 4.4. When preparing specimens for culture, observe standard precautions at all times. All steps in the processing of a specimen should be conducted either in an anaerobic chamber or in a laminar-flow safety hood.

A good transport system and a good specimen (fluid or tissue) permit the laboratory to batch inoculate and incubate plates at convenient times throughout the day without jeopardizing the recovery of anaerobes.

ANALYTICAL CONSIDERATIONS

III. INCUBATION OF SPECIMENS

Observe standard precautions.

Immediately place inoculated plates into an anaerobic environment, and incubate them at 35 to 37°C for 48 h. If you are using an anaerobic chamber, inoculated plates may be examined at 24 h. Some anaerobes require a longer incubation depending on their growth requirements. *Monitor the incubator temperature daily.*

Alternatively, some laboratories may use a holding system (a jar, box, or small chamber) to store uninoculated plates or inoculated plates under near-anaerobic conditions until they are placed into an anaerobic chamber or jar. The holding system is constantly flushed with a light flow of oxygen-free gas (nitrogen is preferred, since carbon dioxide may change the pH of the medium). Inoculated plates should not remain in the holding jar for extended periods (i.e., not longer than 1 h) at room temperature. The holding jar should remain as anaerobic as possible, and care should be taken to minimize convection currents whenever freshly inoculated plates are added to the jar. These holding systems are often used to collect a sufficient number of inoculated plates before the final anaerobic system used in the laboratory is set up. However, a holding jar may not be needed if the laboratory batch inoculates specimens periodically throughout the day.

IV. INCUBATION SYSTEMS

Include QC information on reagent container and in QC records.

The choice of incubation systems is influenced by cost, the number of anaerobic cultures performed, and space limitations. The anaerobic environment is monitored with a methylene blue strip or resazurin indicator (Becton Dickinson, Hardy, PML, Remel). These indicators, initially blue and pink (respectively), become colorless with low concentrations of oxygen. *Monitor the indicator strip daily.* Alternatively, monitor the anaerobic system with biological indicators by incubating a plate freshly inoculated with a fastidious anaerobe such as *Fusobacterium nucleatum* ATCC 25586, *Porphyromonas levii* ATCC 29147, or *Clostridium novyi* type B ATCC 25758. The most common choices of anaerobic incubation systems are the following.

A. Anaerobic chamber

See Appendix 4.5–1 at the end of this procedure for manufacturers.

1. Anaerobiosis is maintained in a gastight box or chamber by a gas mixture containing 80 to 90% nitrogen (N_2), 5% hydrogen (H_2), and 5 to 10% carbon dioxide (CO_2) and by using a palladium catalyst. Usually the systems have a positive pressure inside the chamber. The catalyst reduces oxygen to water, thus removing atmospheric oxygen from the device. Carbon dioxide is included because many anaerobes require it for growth.

■ **NOTE:** Do not exceed 5% hydrogen because of hazardous conditions.

2. Add anaerobic indicator or biological indicator to chamber interior. Place indicator in empty petri dish to prevent drying.
3. Humidity is controlled by the absorption of water formed in the catalytic conversion with silica gel crystals. In other chambers, humidity is controlled with a “cold spot” that condenses excess humidity and allows the water formed to be removed through a drain.
4. Change catalyst daily.
5. Plates are incubated at 35 to 37°C and can be examined at any time within the chamber (generally at 24 to 48 h).

B. Anaerobic bag or pouch

See Appendix 4.5–1 for manufacturers.

1. Pouch systems exist that create anaerobic conditions with a sachet that absorbs atmospheric oxygen without the generation of hydrogen, without the addition of water, and without requiring a catalyst. A methylene blue or resazurin indicator strip is used to monitor anaerobic conditions.

■ **NOTE:** The resulting carbon dioxide level produced in these systems is generally higher than 10%.

2. Other bag or pouch systems generate gas to create anaerobic conditions. An envelope or ampoule containing reagents either is crushed or has water added to it to begin a chemical reaction that provides an atmosphere of 80 to 90% N_2 , 5% H_2 , and 5 to 10% CO_2 . A new catalyst should be used *each time* to convert hydrogen and oxygen to water. A resazurin or methylene blue indicator strip is used to monitor anaerobic conditions.
3. Activate the generating envelope, ampoule, or sachet, add an anaerobic indicator, and seal the bag or pouch. Incubate the bag at 35 to 37°C in a standard incubator for 48 h. This prevents exposure of smaller colonies to oxygen.
4. Remove the plates from the bag to examine them and work up the organisms as quickly as possible.
5. Reseal bag and pouches and use a new generating envelope, ampoule, or sachet.

C. Anaerobic jars

See Appendix 4.5–1 for a list of manufacturers.

1. Place inoculated plates into a self-contained jar containing a catalyst; a gas-generating system (usually an envelope, ampoule, or sachet) providing an

IV. INCUBATION SYSTEMS

(continued)

- atmosphere of 80 to 90% N₂, 5% H₂, and 5 to 10% CO₂; and an anaerobic indicator. If a sachet is employed, hydrogen is not produced and a catalyst is not required (*see* item IV.B above). Add an anaerobic indicator to the jar.
2. Close the jar, and incubate it at 35 to 37°C in a standard incubator.
 3. Incubate the plates for 48 h before opening the jar. This prevents exposure of smaller colonies to oxygen.
 4. The catalyst, composed of palladium-coated alumina pellets, should be fresh or rejuvenated each time prior to use unless a catalyst is included in the gas pack envelope or a waterless anaerobic generating system is used.
 5. Remove the plates from the bag or jar to examine them and work up the organisms as quickly as possible.
 6. Reseal jar and use a new generating envelope, ampoule, or sachet.

POSTANALYTICAL CONSIDERATIONS

V. PROCEDURE NOTES

- A. A clinical laboratory that receives very few requests for anaerobic culture (one per day) and/or receives a rare anaerobic specimen after normal laboratory hours may consider the use of anaerobic bags or pouches. Bags and pouches are convenient and easy to use, but they are the most expensive way of producing an anaerobic environment (about \$6.00 per bag).
- B. A clinical laboratory that receives perhaps three or four specimens per day for anaerobic culture may consider the use of anaerobic jars. Anaerobic jars may be most economically employed if the laboratory batches the processing of specimens at convenient times rather than using one jar for one specimen. If the laboratory receives a specimen at odd times after jars have been closed, perhaps the new specimen may be incubated in a pouch or bag and then after 48 h included in an anaerobic jar.
- C. For a laboratory that may receive perhaps five or more specimens per day, the most economical way of producing an anaerobic atmosphere is by using an anaerobic chamber. The laboratory would need to consider the initial expense and the space required for the chamber. The ability to examine cultures at 24 h and report the presence of anaerobes earlier using an anaerobic chamber may also be a patient care benefit for the hospital. Many laboratories, however, find that jars work well for them even if they may receive 5 to 10 specimens for anaerobic culture per day. These decisions depend upon the daily operation of the laboratory and financial considerations.

4.6

RAPID DISK, SPOT TESTS, AND OTHER METHODS FOR THE IDENTIFICATION OF ANAEROBES

4.6.1

Introduction

Rapid disk, spot tests, and other methods described in this procedure provide a cost-effective system for the identification of anaerobes. Many of the tests described cost less than \$0.25 each to perform (*see*

Appendix 4.6–1 for a summary of tests used for the rapid identification of anaerobes).

Depending upon the source, the type of isolate recovered, the type of patient, and

the needs of the physician, the tests described in this procedure are adequate to permit a rapid presumptive identification of the isolate which may be sufficient in some situations for patient care.

4.6.2

Spot Indole Test

I. PRINCIPLE

The indole test is important in the grouping and identification of anaerobic bacteria. Indole is split from tryptophan by certain organisms possessing the enzyme tryptophanase. The indole test specifically detects indole and is based on the formation of a colored adduct complex when

indole reacts with the aldehyde group of the test reagent (*p*-dimethyl-aminocinnamaldehyde [DMACA]). To perform the test, the growth medium must contain tryptophan (BAP or egg yolk agar [EYA]).

II. SPECIMEN

- A. The specimen for the spot indole test consists of a 24- to 48-h pure culture on an agar medium that contains sufficient tryptophan, such as brucella blood agar or EYA.
- B. Do not use a plate that also contains a nitrate disk, because the nitrate disk may cause a false-negative indole result.
- C. Since the enzyme that degrades tryptophan diffuses into the agar, only pure cultures of the test organism can be present. For example, a few colonies of a common contaminant, *Propionibacterium acnes*, or another indole-producing organism can cause an erroneous result.

III. MATERIALS

Include QC information on reagent container and in QC records.

A. Reagents

Perform and record QC as required. Include expiration date on label.

1. Prepare DMACA as follows.
 - DMACA (Sigma-Aldrich)1 g
 - hydrochloric acid (10%, vol/vol)100 ml
- a. DMACA is carcinogenic, so use gloves, and work in a fume hood when preparing the reagent.
- b. Dissolve DMACA in the hydrochloric acid solution in a glass flask.
- c. Store refrigerated (4 to 6°C) in a dark bottle, and label "Indole re-

agent DMACA," with the date of preparation and an expiration date of 2 months.

2. DMACA is also available commercially (Anaerobe Systems, Becton Dickinson [BD], Hardy, PML, Remel; see Appendix 4.6-2 for addresses).

B. Supplies

1. Filter paper
2. Clean empty petri dish or glass slide
3. Wooden sticks or bacteriological loops

IV. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- A. Check the spot indole reagent when it is prepared and monthly thereafter.
- B. Test *Escherichia coli* ATCC 25922 and *Pseudomonas aeruginosa* ATCC 27853 as described below under item V. The results of the test should show the following.
 1. *E. coli*: indole positive
 2. *P. aeruginosa*: indole negative
- C. Record the results on a QC log (see Appendix 4.6-3 for a sample QC sheet).

V. PROCEDURE

- A. Place a piece of filter paper (no. 1 Whatman) in petri dish cover, or place a small piece of filter paper on the surface of a glass slide.
- B. Moisten paper with reagent. Paper should be saturated but not dripping wet.
- C. Remove several colonies from agar with a wooden stick or loop, and rub them on the filter paper. When testing anaerobic bacteria, it is best to use a heavy inoculum, because the reaction may be fairly weak.
- D. You can perform several tests on a single filter paper while it is wet.

Caution: Do not use a plate that has a nitrate disk on it: a positive nitrate test can interfere with the spot indole test by causing a false-negative result.

VI. RESULTS**A. Indole positive: development of a blue or green color on the filter paper around the inoculum within 30 s**

The dark-pigmented organisms may give a greenish color. In addition, the color development may be masked by the pigment, so examine the filter paper with care.

B. Indole negative: no color change or pinkish color

Color development after 30 s should be disregarded.

4.6.3

Nitrate Disk Reduction Test

I. PRINCIPLE

Nitrate can be reduced to nitrite and other reduction products by organisms possessing the enzyme nitrate reductase. Certain anaerobic bacteria are capable of reducing nitrate, and testing for it is useful in determining the species of anaerobic organisms and in grouping them. The presence of nitrites can be demonstrated by naph-

thylamide and sulfanilic acid reagents, which form a red diazonium dye when reacting with nitrite. If the organism is capable of reducing nitrite further, the test for nitrite will give a negative result. Therefore, all negative results must be confirmed by the addition of metallic

zinc. Zinc catalyzes the reduction of nitrate to nitrite, and the development of a red color after zinc is added indicates the presence of residual nitrates and confirms a negative reaction. If no color develops, nitrate was reduced beyond nitrite (positive test).

II. SPECIMEN

The specimen is any isolated colony on primary or subculture plates.

III. MATERIALS

Include QC information on reagent container and in QC records.

A. Reagents

Perform and record QC as required. Include expiration date on label.

1. Nitrate disks

- a. Combine the following in a flask.

potassium nitrate 30 g
sodium molybdate dihydrate 0.1 g
distilled water 100 ml

- b. After dissolving these, sterilize by filtration (0.22- μ m-pore-size filter).

- c. Dispense 20- μ l quantities of the solution onto sterile 1/4-in. filter paper disks that are spread inside empty, sterile petri dishes. Allow the disks to dry at room temperature for 72 h before collecting them in storage containers (e.g., glass vials).

- d. Store at room temperature. Label with expiration date of 1 year.

2. Nitrate reagents

a. Nitrate A

sulfanilic acid 0.5 g
glacial acetic acid 30 ml
distilled water 120 ml

b. Nitrate B

1,6-Cleve's acid (5-amino-2-naphthalene sulfonic acid) 0.2 g
glacial acetic acid 30 ml
distilled water 120 ml

- (1) Dissolve the ingredients of each solution in distilled water in separate containers.

- (2) Store refrigerated (4 to 6°C) in dark bottles, and label "Nitrate A" and "Nitrate B," with date of preparation and expiration date of 3 months.

3. Disks and reagents are also commercially available (disks and reagents from Anaerobe Systems, Becton Dickinson, Hardy, PML, and Remel) (*see* Appendix 4.6-2).

4. Zinc

B. Supplies

1. Clean empty petri dish or glass slide
2. Dropper bottles or pipettes

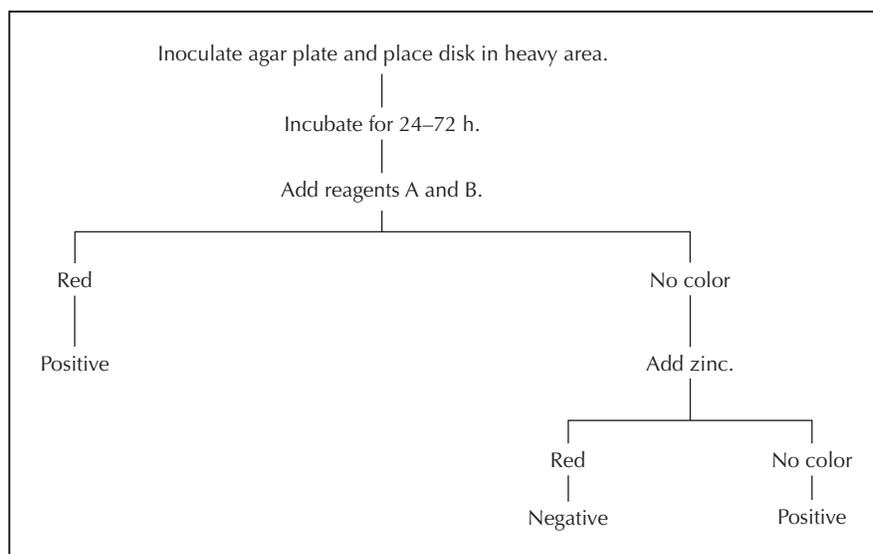

Figure 4.6.3-1 Flowchart for nitrate disk reduction test.

IV. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- A. Check the disks and reagents when they are prepared and monthly thereafter.
- B. Inoculate *Escherichia coli* ATCC 25922 and *Acinetobacter lwoffii* ATCC 43498 on BAP, and test as described below under item V. The results should show the following.
 1. *E. coli*: nitrate positive, development of red color
 2. *A. lwoffii*: nitrate negative, no color change; after addition of zinc, development of red color
- C. Record the results on a QC log (see Appendix 4.6-3 for a sample QC sheet).

V. PROCEDURE

See Fig. 4.6.3-1 for a flowchart of these procedures.

- A. Inoculate organism on brucella or other nonselective anaerobic BAP.
 - B. Place the nitrate disk on the most heavily inoculated area.
 - C. Incubate anaerobically for 24 to 72 h at 35 to 37°C until heavy growth occurs around the disk.
 - D. Remove the disk from the surface of the plate, and place it in a clean petri dish or on a slide.
 - E. Add 1 drop each of nitrates A and B. If no color develops within 5 min, add a pinch of zinc dust or zinc granules to the disk and wait 5 min.
- ☑ **NOTE:** See procedure 4.6.2 for limitation of a positive nitrate disk reaction causing a false-negative spot indole test.

VI. RESULTS

- A. Positive reaction: development of red or pink color after the reagents are added *or* no color development after zinc is added
- B. Negative reaction: no color development after the reagents are added *and* development of red color after zinc is added
- C. *Hint:* The red color of a positive test may be difficult to distinguish from the red color of the anaerobic BAP. Tilting the plate to allow the red liquid to flow to the edge improves detection.

4.6.4

Catalase Test

I. PRINCIPLE

Some anaerobic bacteria possess catalase, an enzyme that decomposes hydrogen peroxide (H_2O_2) into oxygen and water. When a catalase-positive organism is emulsified with H_2O_2 , it releases oxygen,

which is detected by the formation of bubbles. A 15% solution of H_2O_2 instead of the conventional 3% is preferred for anaerobic bacteria.

II. SPECIMEN

The specimen should show adequate growth on primary plates or subculture plates. Since RBCs contain some catalase, it is recommended that a medium without blood, such as egg yolk agar, be used.

III. MATERIALS

A. Reagent

H_2O_2 , 15% (Anaerobe Systems; see Appendix 4.6-1)
Store in a dark bottle, and keep refrigerated (4 to 6°C) when not in use.

B. Supplies

1. Clean empty petri dish or glass slide
2. Wooden sticks or loops

IV. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- A. Test hydrogen peroxide before using it and every day of use thereafter.
- B. Test *Staphylococcus aureus* ATCC 25923 and *Streptococcus pyogenes* ATCC 19615 as described below under item V. The results should be as follows.
 1. *S. aureus*: strong positive reaction
 2. *S. pyogenes*: negative reaction
- C. Record the results on a QC log (see Appendix 4.6-3 for a sample QC sheet).

V. PROCEDURE

- A. Touch the center of a pure colony with a loop or sterile wooden stick, and transfer the sample onto the surface of a clean, dry glass slide or petri dish. If you are testing growth from blood-containing medium, avoid carryover of the agar.
- B. Add 1 drop of 15% hydrogen peroxide to the smear. Do not introduce a platinum loop into the drop, because this may cause a false-positive reaction.
- C. Observe for immediate bubbling.
- D. An alternative is to add 1 drop of 15% hydrogen peroxide directly to the growth on a medium that does not contain blood and then observe for bubble formation.

VI. RESULTS**A. Positive reaction: immediate bubbling of the hydrogen peroxide****B. Negative reaction: no bubbling**

Formation of rare bubbles after 20 to 30 s is considered a negative catalase test.

Precaution: Some bacteria may possess enzymes other than catalase that can decompose hydrogen peroxide.

4.6.5

Identification by Using Special-Potency Disks

I. PRINCIPLE

Special-potency disks of vancomycin (5 µg), kanamycin (1,000 µg), and colistin (10 µg) are used as an aid in determining the Gram stain reaction of anaerobes as well as in preliminary categorization of some anaerobic genera and species (Table 4.6.5–1). In general, gram-positive organ-

isms are resistant to colistin and susceptible to vancomycin, while most gram-negative organisms are resistant to vancomycin. This difference is especially useful with some clostridia that consistently stain gram negative.

II. SPECIMEN

The specimen is any isolated colony on primary or subculture plates.

III. MATERIALS

Include QC information on reagent container and in QC records.

A. Reagents

Perform and record QC as required. Include expiration date on label.

- Special-potency antimicrobial agent disks are commercially available (Anaerobe Systems, Becton Dickinson, Hardy, PML, Remel; See Appendix 4.6–1).

vancomycin 5 µg
kanamycin 1,000 µg
colistin 10 µg

- Store a small supply of disks (one carton each) in a tight container with desiccants in a refrigerator.

- Store the stock supply at –20°C.

- Brucella or other anaerobic BAP

B. Supplies

- Single-disk dispenser or forceps
- Ruler (divided into millimeters)

Table 4.6.5–1 Identification by means of special-potency antimicrobial agent disks^a

Organisms	Response ^b to:		
	Kanamycin, 1,000 µg	Vancomycin, 5 µg	Colistin, 10 µg
Gram positive	V	S ^c	R
Gram negative	V	R	V
<i>Bacteroides fragilis</i> group	R	R	R
<i>Bacteroides ureolyticus</i> group	S	R	S
<i>Fusobacterium</i> spp.	S	R	R
<i>Porphyromonas</i> spp.	R	S ^d	R
<i>Prevotella</i> spp.	R	R	V
<i>Veillonella</i> spp.	S	R	S

^a Adapted with permission from P. Summanen, E. J. Baron, D. M. Citron, C. Strong, H. M. Wexler, and S. M. Finegold, *Wadsworth Anaerobic Bacteriology Manual*, 5th ed., 1993, Star Publishing Co., Belmont, Calif.

^b R, resistant; S, susceptible; V, variable.

^c Exceptions: rare strains of *Lactobacillus* spp. and *Clostridium* spp. may be vancomycin resistant.

^d *Porphyromonas* spp. are vancomycin susceptible but fluoresce or are pigmented.

IV. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- A. Test special-potency antimicrobial agent disks by lot when initially received and weekly thereafter.
- B. Test *Bacteroides fragilis* ATCC 25285, *Clostridium perfringens* ATCC 13124, and *Fusobacterium necrophorum* ATCC 25286 as described below under item V. The results should show the following.
 1. *B. fragilis*: resistant to all three antimicrobial agents
 2. *F. necrophorum*: resistant to vancomycin and susceptible to kanamycin and colistin
 3. *C. perfringens*: susceptible to vancomycin and kanamycin and resistant to colistin
- C. Record the results on a QC log (*see* Appendix 4.6–3 for a sample QC sheet).

V. PROCEDURE

- A. Allow the container with disks to reach room temperature before opening it.
- B. Subculture the isolate on a BAP. To ensure an even, heavy lawn of growth, streak the first quadrant back and forth several times. Streak the other quadrants to yield isolated colonies.
- C. Place the three antimicrobial agent disks on the first quadrant well apart from each other.
- D. If you have several organisms to test, first streak all the plates and then add the disks to them at the same time.
- E. Incubate the plate(s) anaerobically for 48 to 72 h at 35 to 37°C.
- F. Examine for zones of inhibition of growth around the disks.

VI. RESULTS

- A. **Susceptible: zone of inhibition of ≥ 10 mm**
- B. **Resistant: zone of inhibition of < 10 mm**

SUPPLEMENTAL READING

4.6.6

Sodium Polyanethol Sulfonate Disk for Differentiation of Anaerobic Cocci

I. PRINCIPLE

Sodium polyanethol sulfonate (SPS), a commonly used anticoagulant, inhibits certain bacteria, such as *Peptostreptococcus anaerobius* and the aerobic *Gardner-*

ella vaginalis. Paper disks impregnated with 5% SPS can be used as a tool for differentiating *P. anaerobius* from other anaerobic cocci.

II. SPECIMEN

The specimen is any isolated colony of anaerobic gram-positive cocci on primary or subculture plates.

III. MATERIALS

Include QC information on reagent container and in QC records.

A. Reagents

Perform and record QC as required. Include expiration date on label.

1. SPS disks

- Combine the following in a flask.

SPS5 g
distilled water100 ml

- After dissolving SPS, sterilize the mixture by filtration (0.22- μ m-pore-size filter).

- Dispense 20 μ l onto sterile 1/4-in.-diameter filter paper disks that are spread inside empty, sterile petri dishes. Allow these

to dry for 72 h at room temperature.

- Store the disks at room temperature, and label with an expiration date of 6 months.

- SPS disks are also commercially available (Anaerobe Systems, Becton Dickinson, Hardy, PML, Remel; see Appendix 4.6-1). Store as indicated by the manufacturer.

3. Brucella or other anaerobic BAP

B. Supplies

- Single-disk dispenser or forceps
- Ruler (divided into millimeters)

IV. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- Test each lot upon receipt and monthly thereafter.

- Test *P. anaerobius* ATCC 27337 and *Peptostreptococcus asaccharolyticus* ATCC 29745 as described below under item V. The results should show the following.

- P. anaerobius*: susceptible to SPS
- P. asaccharolyticus*: resistant to SPS

- Record the results on a QC log (see Appendix 4.6-3 for a sample QC sheet).

V. PROCEDURE

- Allow the container with disks to reach room temperature before use.
- Subculture the isolate on a BAP. To ensure an even, heavy lawn of growth, streak the first quadrant back and forth several times. Streak the other quadrants to yield isolated colonies.
- Place the SPS disk on the first quadrant.
- If you have several organisms to test, first streak all the plates and then add the disks to them at the same time. You can use one plate for up to four tests.
- Incubate the plate(s) anaerobically for 48 to 72 h at 35 to 37°C.
- Examine for a zone of inhibition of growth around the disk.

VI. RESULTS**A. Susceptible: zone of inhibition of ≥ 12 mm**

P. anaerobius usually gives a very large zone of inhibition (≥ 16 mm), whereas other anaerobic cocci that appear susceptible to SPS give smaller zones. To presumptively identify *P. anaerobius*, you must also consider the Gram stain, typical colonial morphology, and odor. Some strains of *Peptostreptococcus micros* may be susceptible or partially susceptible to SPS. Examine the Gram stain for the small cell size of *P. micros* and chaining characteristics of *P. anaerobius*.

B. Resistant: zone of inhibition of < 12 mm

4.6.7

Bile Test/*Bacteroides* Bile Esculin Agar for Differentiation of Anaerobic Gram-Negative Rods

I. PRINCIPLE

Bacteroides fragilis group organisms, *Fusobacterium mortiferum*, and *Fusobacterium varium* are clinically significant anaerobic gram-negative bacilli that are capable of growing in the presence of

bile. Thus, the ability to grow in the presence of 20% bile (equal to 2% oxgall) is a key reaction in separating *B. fragilis* group from other anaerobic gram-negative bacilli as well as in differentiating

bile-resistant fusobacteria. Besides inoculating a bile-containing medium, such as *Bacteroides* bile esculin agar (BBE), the test can also be performed with disks impregnated with 20% bile.

II. SPECIMEN

The specimen is any isolated colony on primary or subculture plates.

III. MATERIALS

Reagents

- A. **Bile disks** (Anaerobe Systems, Becton Dickinson, Hardy, PML, Remel; see Appendix 4.6–1)
- B. **Brucella or other anaerobic BAP**

IV. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- A. Test each lot upon receipt and monthly thereafter.
- B. Test *B. fragilis* ATCC 25285 and *Prevotella melaninogenica* ATCC 25845 as described below under item V. The results should show the following.
 - 1. *B. fragilis*: resistant to the bile disk
 - 2. *P. melaninogenica*: susceptible to the bile disk
- C. Record the results on a QC log (see Appendix 4.6–3 for a sample QC sheet).

V. PROCEDURE

- A. Allow the container with disks to reach room temperature before use.
- B. Subculture the isolate on a BAP. To ensure an even, heavy lawn of growth, streak the first quadrant back and forth several times. Streak the other quadrants to yield isolated colonies.
- C. Place the bile disk on the second quadrant.
- D. If you have several organisms to test, first streak all the plates and then add the disks to them at the same time. You can use one plate for up to four tests.
- E. Incubate the plate(s) anaerobically for 48 to 72 h at 35 to 37°C.
- F. Examine for any zone of inhibition of growth.

VI. RESULTS

- A. **Susceptible: zone of inhibition present**
- B. **Resistant: no zone of inhibition present**

4.6.8

Fluorescence

I. PRINCIPLE

Fluorescence is manifested because specific molecules exposed to UV light (366 nm) absorb energy and become excited. As electrons subsequently return to their original lower-energy states, they emit photons at a different wavelength. The presence and color of fluorescing colonies can aid in the rapid detection and presumptive identification of certain anaerobic bacteria (see Table 4.6.8–1).

II. SPECIMEN

- A. The specimen is any isolated colony on primary plates or any colony on subculture plates containing blood. Prolonged incubation (>72 h) is often required to produce fluorescing pigment for the black- or brown-pigmented *Porphyromonas* spp. and *Prevotella* spp. The use of laked blood or rabbit blood in medium has been found to enhance pigment production.
- B. Use the sample itself (tissue, fluid, etc.).
- C. The test can be done at the infected body site of a patient.

III. EQUIPMENT

- A. Long-wave (366-nm) UV light source (UVP, Inc.; see Appendix 4.6–2)
- B. Viewing cabinet (UVP, Inc.)

IV. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- A. Test pigmented *Prevotella* spp. on anaerobic BAP used in your laboratory for fluorescence.
- B. Subculture *Prevotella melaninogenica* ATCC 25845 and *Bacteroides fragilis* ATCC 25285 onto BAP, incubate them anaerobically for 48 h at 35 to 37°C, and test them as described below under item V. The results should show the following.
 1. *P. melaninogenica*: (brick) red fluorescence
 2. *B. fragilis*: no fluorescence
- C. Record the results on a QC log (see Appendix 4.6–3 for a sample QC sheet).

Table 4.6.8–1 Fluorescence of anaerobic bacteria

Organism(s)	Color of fluorescence
<i>Porphyromonas asaccharolytica</i> , <i>Porphyromonas endodontalis</i>	Red ^a
<i>Porphyromonas gingivalis</i>	None
Pigmented <i>Prevotella</i> spp.	Red ^a
Nonpigmented gram-negative bacilli	No fluorescence or pink, orange, or yellow
<i>Fusobacterium</i> spp.	Chartreuse
<i>Veillonella</i> spp.	Red
<i>Eubacterium lentum</i>	Red
<i>Clostridium difficile</i>	Chartreuse
<i>Clostridium innocuum</i>	Chartreuse

^a Fluorescence disappears when black pigment has developed.

V. PROCEDURE

- A.** Expose the culture plate, patient sample, or infected body site to the UV light source in the dark by using a UV viewing cabinet or by darkening the room.
- 1.** When examining colonies on a plate, take the cover off and hold the plate close to the light source. Keep moving the plate until you find the optimal angle for best fluorescence.
 - 2.** When examining slow-growing organisms such as *Eubacterium lentum* and *Veillonella* spp., look at the heaviest growth area for fluorescence. The fluorescence of *Veillonella* spp. fades rapidly in air, so examine the specimen within 15 min after it is exposed to air.
- B.** Wait 10 to 15 s for the fluorescence to occur.
- C.** Note the presence and color of fluorescence.

VI. RESULTS

- A. Positive: distinct color detected with UV light**
Brick red fluorescence is the only reliable color for presumptive identification of *Porphyromonas* spp. and pigmented *Prevotella* spp.
- B. Negative: no fluorescence**

SUPPLEMENTAL READING

4.6.9

Lipase Test

I. PRINCIPLE

Fats in egg yolk agar (EYA) are broken down by the enzyme lipase to produce glycerol and fatty acids. The fatty acids appear as a surface iridescent layer that covers the colony and may extend beyond the edge of the colony.

II. SPECIMEN

- A. The specimen for the lipase tests consists of a 24- to 48-h pure culture from a primary enriched medium such as brucella agar.
- B. Perform aerotolerance testing on the isolate to ensure that the organism is an anaerobe.

III. MATERIALS

- A. Use commercially prepared EYA plates (Anaerobe Systems, Becton Dickinson [BD], Hardy, PML, Remel).
- B. Alternatively, prepare media by using EYA emulsion (BD, Hardy, PML, Remel, Oxoid). Follow the manufacturer's instructions.

IV. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- A. Check the egg yolk medium for lipase activity when it is prepared or when each shipment or lot is received.
- B. *Fusobacterium necrophorum* ATCC 25286 is positive.
- C. *Bacteroides fragilis* ATCC 25285 is negative.
- D. Record the results on a QC log (see Appendix 4.6-3 for a sample QC sheet).

V. PROCEDURE

- A. Inoculate a portion of egg yolk medium with the organism to be tested.
- B. It is best to inoculate the portion of egg yolk medium heavily and then streak to obtain isolated colonies.
 - **NOTE:** Do not inoculate the whole plate; leave a portion to act as a negative control.
- C. Incubate the plate under anaerobic conditions for 24 to 48 h.

VI. RESULTS

- A. Examine egg yolk medium plates for an iridescent and multicolored layer on top of the colonies.
- B. It may be necessary to hold plates at an angle to adequately view the iridescent multicolored layer. This is a positive test.
- C. Hold plates for 48 h. Some rare organisms may require 72 h of incubation to exhibit results. After 72 h of incubation, however, egg yolk medium plates may produce irregular test results.

4.6.9.1

4.6.10

Lecithinase Test

I. PRINCIPLE

Bacterial lecithinase splits lecithin into water-insoluble diglycerides, resulting in an opaque halo surrounding a colony.

II. SPECIMEN

- A. The specimen for the lecithinase tests consists of a 24- to 48-h pure culture from a primary enriched medium such as brucella agar.
- B. Perform aerotolerance testing on the isolate to ensure that the organism is an anaerobe.

III. MATERIALS

- A. Use commercially prepared egg yolk agar (EYA) plates (Anaerobe Systems, Becton Dickinson [BD], Hardy, PML, Remel).
- B. Alternatively, prepare media by using EYA emulsion (BD, Hardy, PML, Remel, Oxoid). Follow the manufacturer's instructions.

IV. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- A. Check the egg yolk medium for lecithinase activity when it is prepared or when each shipment or lot is received.
- B. *Clostridium perfringens* ATCC 13124 is positive.
- C. *Bacteroides fragilis* ATCC 25285 is negative.
- D. Record the results on a QC log (see Appendix 4.6–3 for a sample QC sheet).

V. PROCEDURE

- A. Inoculate a portion of egg yolk medium with the organism to be tested.
- B. It is best to inoculate *only a portion* of egg yolk medium heavily and then streak to obtain isolated colonies.
 - ☑ **NOTE:** Do not inoculate the whole plate; leave a portion to act as a negative control.
- C. Incubate the plate under anaerobic conditions for 24 to 48 h.

VI. RESULTS

- A. Examine egg yolk medium plates for a white opacity in the medium that surrounds the colony and extends beyond the edge of growth. The white opaque edge is very sharp and very even. This is a positive test.
- B. A positive test may take 48 h for some organisms.

SUPPLEMENTAL READING

MacFaddin, J. F. 2000. *Biochemical Tests for Identification of Medical Bacteria*, 3rd ed. Lippincott Williams & Wilkins, Philadelphia, Pa.

4.6.11

Pigment Production

I. PRINCIPLE

Some species of *Prevotella* and *Porphyromonas* produce a dark pigment that causes their colonies to become brown to black. *Prevotella* spp. produce black-brown protoporphyrin, but pigmentation of incubated colonies may be delayed for 4 days or even more, whereas the pigment of *Porphyromonas* spp. is protoheme that may appear within 4 days of incubation but may also be delayed for as long as 2 weeks.

II. SPECIMEN

- A. The specimen for pigment production tests consists of a pure culture from a primary enriched medium such as brucella agar.
- B. Plated media containing laked blood or rabbit blood are frequently used to enhance pigmentation.
- C. Perform aerotolerance testing on the isolate to ensure that the organism is an anaerobe.

III. MATERIALS

Use commercially prepared anaerobic agar plates (BBL, Hardy, PML, Remel, BAP, or use laked BAP or rabbit blood Oxoid).

IV. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- A. Check the BAP or other medium for pigment production when it is prepared or when each shipment or lot is received.
- B. *Prevotella melaninogenica* ATCC 25845 is positive.
- C. *Bacteroides fragilis* ATCC 25285 is negative.
- D. Record the results on a QC log (*see* Appendix 4.6–3 for a sample QC sheet).

V. PROCEDURE

- A. Examine colonies from anaerobic plates for brown to black pigment.
- B. Some strains may produce pigment in 4 to 6 days; others may take up to 2 weeks.
- C. Colonies initially appear tan and then darken.
- D. Pigmented *Prevotella* spp. and *Porphyromonas* spp. (except for *Porphyromonas gingivalis*) produce brick red fluorescence under a Wood's lamp (366 nm) at 2 to 3 days before they become pigmented. Brick red fluorescence results can substitute for pigment production.
- E. In most clinical laboratory situations it is not necessary to hold primary plates longer than 7 days to detect pigment production, since other methods (*see* procedure 4.6.5, Identification by Using Special-Potency Disks, or procedure 4.6.8, Fluorescence) can be used to help identify pigmented *Prevotella* spp. and *Porphyromonas* spp.

VI. RESULTS

- A.** Black pigment is positive.
B. The absence of black pigment is negative.

4.6.12

Urease Test

I. PRINCIPLE

Some organisms have the ability to split urea into two molecules of ammonia by the enzymatic action of urease, resulting in alkalinity, which causes the indicator phenol to change from yellow to red.

II. SPECIMEN

- A. The specimen for the urease test consists of a 24- to 48-h pure culture from a primary enriched medium such as brucella agar.
- B. Perform aerotolerance testing on the isolate to ensure that the organism is an anaerobe.

III. MATERIALS

- A. Use commercially available urea broth (BBL, Hardy, PML, Remel) son, Hardy, PML, Key Scientific Products, Remel).
- B. Alternatively, use commercially available rapid urea disks (Becton Dickinson, Hardy, PML, Key Scientific Products, Remel).

IV. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- A. Intense pink throughout the disk or broth is positive.
- B. *Bacteroides ureolyticus* ATCC 33387 is positive.
- C. *Bacteroides fragilis* ATCC 25285 is negative.
- D. Record the results on a QC log (see Appendix 4.6–3 for a sample QC sheet).

V. PROCEDURE

- A. Inoculate urea broth or urea disk with organism to be tested.
- B. Incubate urea broth under anaerobic conditions for 1 h.
- C. If you use a urea disk, heavily inoculate the disk. Observe any reaction for 1 h. Most positive reactions will become pink in 15 min.
- D. Follow the manufacturer's instructions.

VI. RESULTS

- A. A positive test is the rapid formation of a pink color.
- B. A negative test is no color change in the expected time frame.

4.6.13

Appendixes to Procedure 4.6

APPENDIX 4.6-1

Summary of tests used for the rapid identification of anaerobes^a

Test	Principle	Reagent(s)	Results	Control organisms	Expected result(s)
Special-potency disks	Special-potency disks are used as an aid in determining the Gram stain reaction of anaerobes as well as in preliminary categorization of some genera and species. Susceptible zones, ≥ 10 mm; resistant zones, ≤ 10 mm	Vancomycin, 5 μ g Kanamycin, 1,000 μ g Colistin, 10 μ g	See Table 4.6.5-1 for details. In general, gram-positive organisms are resistant to colistin and susceptible to vancomycin, while most gram-negative organisms are resistant to vancomycin, except for <i>Porphyromonas</i> spp.	<i>Bacteroides fragilis</i> ATCC 25285 <i>Fusobacterium necrophorum</i> ATCC 25286 <i>Clostridium perfringens</i> ATCC 13124	Resistant to all three antibiotics Resistant to vancomycin; susceptible to kanamycin and colistin Resistant to colistin; susceptible to vancomycin and kanamycin
Spot indole test	Indole is split from tryptophan by certain organisms. It is used in grouping and identifying many anaerobic bacteria.	<i>p</i> -Dimethyl-aminocinnamaldehyde. To perform test, ensure that media contain tryptophan, such as blood agar or egg yolk medium. Use a small piece of filter paper.	Positive indole, development of a blue or green color on filter paper within 30 s. A negative test is no color change or pinkish color.	<i>Escherichia coli</i> ATCC 25922 <i>Pseudomonas aeruginosa</i> ATCC 27853	Indole positive Indole negative
Nitrate disk reduction test	Nitrate can be reduced to nitrite and other reduction products by organisms possessing the enzyme nitrate reductase. The nitrate test is useful for separating <i>Bacteroides ureolyticus</i> grp organisms from <i>Fusobacterium</i> grp organisms, which have similar special-potency disk results. <i>B. ureolyticus</i> grp organisms are nitrate positive and <i>Fusobacterium</i> grp organisms are nitrate negative.	Nitrate disks are commercially available. Nitrate A and B reagents and zinc	See Fig. 4.6.3-1 for details. A positive reaction is indicated by the development of a red or pink color after the reagents are added. A negative reaction is indicated by no color development after the reagents are added and development of a red color after zinc is added.	<i>E. coli</i> ATCC 25922 <i>Acinetobacter lwoffii</i> ATCC 43498	Nitrate positive, red color Nitrate negative, no color change

(continued)

APPENDIX 4.6–1 (continued)

Summary of tests used for the rapid identification of anaerobes^a (continued)

Catalase test	Some anaerobic bacteria possess catalase, an enzyme that decomposes hydrogen peroxide into oxygen and water.	A 15% solution of hydrogen peroxide is preferred.	A positive reaction is indicated by immediate bubbling; a negative reaction is indicated by no bubbling. Formation of bubbles after 20 s is considered a negative test.	<i>Staphylococcus aureus</i> ATCC 25923 <i>Streptococcus pyogenes</i> ATCC 19615	Catalase positive Catalase negative
SPS disk test	SPS is used for the differentiation of anaerobic cocci.	SPS disks are commercially available.	<i>Peptostreptococcus anaerobius</i> produces a large zone (≥ 12 mm) around the SPS disk. <i>Peptostreptococcus micros</i> may produce small zones around the SPS disk (≤ 10 mm).	<i>P. anaerobius</i> ATCC 27337 <i>Peptostreptococcus asaccharolyticus</i> ATCC 29745	Susceptible to SPS Resistant to SPS
Bile test	<i>B. fragilis</i> , <i>Fusobacterium mortiferum</i> , <i>Fusobacterium varium</i> , and <i>Bilophila wadsworthia</i> are capable of growing in the presence of bile (bile resistant). This is a key reaction in separating <i>B. fragilis</i> grp organisms from many other anaerobic gram-negative rods.	Bile disks are commercially available, or use BBE agar plates, which are also commercially available.	A positive test (bile resistance) is indicated by growth around bile disks or growth on BBE agar plates.	<i>B. fragilis</i> ATCC 25285 <i>Prevotella melaninogenica</i> ATCC 25845	Resistant to bile Susceptible to bile
Fluorescence	Some anaerobic organisms are capable of fluorescing when exposed to UV light. The presence and color of fluorescing colonies can aid in the rapid detection and identification of certain anaerobic bacteria.	Use any isolated colony from plates containing blood. Prolonged incubation, of >72 h, is necessary. Use a long-wave UV light source (366 nm).	A positive test is a distinct color detected with UV light from blood agar plates. See Table 4.6.8–1 for use as an aid in the presumptive identification of certain anaerobic bacteria.	<i>P. melaninogenica</i> ATCC 25845 <i>B. fragilis</i> ATCC 25285	Brick red fluorescence No fluorescence
Esculin	To determine the ability of an organism to hydrolyze the glycoside esculin to esculetin. Esculetin reacts with an iron salt to form a dark-brown or black complex.	Use commercially prepared BBE agar plates, or use esculin broth.	A positive esculin test is the presence of black to brown color. A positive test on BBE agar is a black colony.	<i>B. fragilis</i> ATCC 25285 <i>Bacteroides vulgatus</i> ATCC 29327	Black, positive esculin No black, esculin negative

Summary of tests used for the rapid identification of anaerobes^a (continued)

Lipase	Free fats in EYA are broken down by the enzyme lipase to produce glycerol and fatty acids. The fatty acids appear as a surface iridescent layer that covers the colony and may extend beyond the edge of colony.	Use commercially prepared EYA plates, or prepare media by using EYA media.	Examine egg yolk medium plates for an iridescent and multicolored layer on top of the colonies. This is a positive test; it may take 48 h.	<i>F. necrophorum</i> ATCC 25286 <i>B. fragilis</i> ATCC 25285	Lipase positive, multicolored layer Lipase negative, no color on top
Lecithinase	Bacterial lecithinase splits lecithin to insoluble diglycerides, resulting in an opaque halo surrounding a colony on a medium containing egg yolk.	Use commercially prepared EYA plates, or prepare media by using EYA media.	Examine egg yolk medium plates for a white opacity in the medium that surrounds the colony and extends beyond the edge of growth. This is a positive test.	<i>C. perfringens</i> ATCC 13124 <i>B. fragilis</i> ATCC 25285	Lecithinase positive Lecithinase negative
Pigment production	Some anaerobic gram-negative rods, namely, <i>Porphyromonas</i> spp. and some <i>Prevotella</i> spp., produce a dark pigment that causes their colonies to become brown to black.	Use commercially prepared anaerobic BAP, or use laked BAP plates or rabbit blood agar plates.	Examine colonies from anaerobic plates for brown to black pigment. Some strains may produce pigment in 4 to 6 days; others may take up to 2 weeks. A brown to black pigment is a positive test.	<i>P. melanogenica</i> ATCC 25845 <i>B. fragilis</i> ATCC 25285	Black pigment No black pigment
Urease	To determine the ability of an organism to split urea. Hydrolysis of urea by the enzyme urease releases ammonia, the alkalinity of which causes the indicator phenol to change from yellow to red.	Use commercially available urea broth, or use commercially available rapid urea disks.	A color change from pale yellow to dark bright pink represents a positive test for urea hydrolysis.	<i>B. ureolyticus</i> ATCC 33387 <i>B. fragilis</i> ATCC 25285	Urease positive, pink color Urease negative, no color change

^a Abbreviation: grp, group.

4.7

Microbiochemical Systems for the Identification of Anaerobes

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Microbiochemical systems of identification rely on the metabolic breakdown of substrates and the production of end products during the growth of the isolated organism. Two commercially packaged systems have been widely used for anaerobic

identification: the API 20A (bioMérieux, Inc.) and the Minitek (BD Biosciences) (1–8). These kits are used when species identification is needed. The API 20A uses 15 carbohydrates; its indicator system of

bromocresol purple turns yellow at a pH of 6.8. The Minitek system offer a wide choice of carbohydrates; its indicator system of phenol red turns yellow at pH 5.2 (Table 4.7–1).

II. SPECIMEN

The ideal specimens for analysis are colonies grown for 24 to 48 h on brucella-BAP or another medium suitably enriched for growing anaerobes (*see* procedure 4.3).

III. MATERIALS

- A. API 20A or Minitek (*see* Appendix 4.7–1 for addresses)
- B. Manufacturer-recommended inoculation fluid (Lombard-Dowell)
- C. Pasteur pipette
- D. Anaerobic jar, anaerobic pouch, or anaerobic chamber (*see* procedure 4.5)
- E. Accompanying reagents
- F. Mineral oil
- G. Incubator, 35 to 37°C

ANALYTICAL CONSIDERATIONS

IV. PROCEDURE

The instructions below serve only as a general guide; it is imperative that you follow the manufacturer's packaged directions for each of the microbiochemical systems. The microtube systems require growth of the organism for substrate degradation.

Table 4.7–1 Characteristics of microbiochemical systems^a

Parameter	Minitek ^b	API 20A ^c
No. of tests	20	21
Inoculum source	Plate	Plate
McFarland turbidity (in 5 ml)	No. 5	No. 3
Diluent	Provided	Provided
Incubation time	48 h	24 h
Database	Codebook, computer assisted	Codebook

^a Adapted from reference 2 with permission of Elsevier.

^b BD Biosciences.

^c bioMérieux, Inc.

IV. PROCEDURE (continued)

- A. Suspend enough colonies from a 24- to 48-h culture from a nonselective medium to make a turbid suspension equivalent to a McFarland no. 3 standard for the API 20A and a McFarland no. 5 standard for the Minitek.
- B. The Minitek Anaerobe Identification Panel uses paper disks impregnated with various biochemical substrates. Dispense the disks into the wells of the disposable plastic plate provided. Then use a Pasteur pipette to dispense the required amount of McFarland suspension into each well. The Minitek system offers a wide choice of biochemical tests with microtray plates and disks saturated with various substrates.
- C. For the API 20A, use a Pasteur pipette to dispense the suspension into each cupule of the strip provided. The urea and indole require an oil overlay. The API 20A strip contains 16 carbohydrates and tests for indole, urea, gelatin, esculin, and catalase.
- D. Incubate the Minitek plate for 48 h or the API 20A strip for 24 h in an anaerobic jar, anaerobic pouch, or anaerobic chamber at 35°C.
- E. After incubation, add the required reagents according to the manufacturer's directions, and read the reactions. *Precaution: Color reactions may be difficult to interpret because of reduction of the indicator.* The color reactions in these systems are not always clear-cut (shades of brown [API 20A] and shades of yellow-orange [Minitek]) and make interpretation of test results difficult. In this situation, neither system should be relied on for identification. The agreement of final identification between prereduced anaerobically sterilized biochemicals plus GLC and these microtube systems demonstrates that neither system is adequate for identification of many anaerobes without using other tests as well (3–5, 8). Various anaerobes reduce the indicator to colorless, straw yellow, muddy green-yellow, or pale purple. If these changes occur, add additional indicator to each carbohydrate cupule before reading the reactions.
- F. Use the numerical identification system from the package to obtain a code number.
- G. Compare the code number obtained with the code numbers in the manufacturer's database book to identify the organism. If there is no match, follow the manufacturer's recommendation. Calling the computer center of the manufacturer or repeating the test may be necessary.

V. QUALITY CONTROL

Include QC information on reagent container and in QC records.

Each manufacturer recommends specific QC procedures (Table 4.7–2). Record the results on a QC log (see Appendix 4.6–3 for a sample QC sheet).

Table 4.7–2 Recommended QC strains

System	Organism	ATCC no.
API 20A	<i>Clostridium histolyticum</i>	19401
	<i>Bacteroides ovatus</i>	8483
	<i>Propionibacterium acnes</i>	11827
	<i>Clostridium sordellii</i>	9714
	<i>Clostridium perfringens</i>	13124
Minitek	<i>Clostridium perfringens</i>	13124
	<i>Bacteroides ovatus</i>	8483
	<i>Veillonella parvula</i>	10790
	<i>Clostridium sordellii</i>	9714

POSTANALYTICAL CONSIDERATIONS

VI. LIMITATIONS OF THE PROCEDURE

- A. Laboratories using either of these microbiobiochemical systems must use only the identification tables or numerical systems provided by the manufacturer.
- B. Microbiochemical systems work with the hardy saccharolytic organisms; however, poor performance is noted with slow growers and with fastidious (*Porphyromonas* spp.) and asaccharolytic (*Fusobacterium nucleatum*, *Peptostreptococcus* spp.) organisms (3–8).
- C. The indole reaction is frequently false negative, and some anaerobes reduce the pH indicator.
- D. Both the API 20A and the Minitek should be supplemented with several tests, such as bile tolerance, egg yolk medium, catalase (lipase and lecithinase), motility, and special-potency antimicrobial agent disk susceptibility for complete identification (3–8).
- E. Some saccharolytic organisms reduce the indicators or produce color reactions that are difficult to interpret.

4.8

Rapid Enzymatic Systems for the Identification of Anaerobes

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Rapid identification of anaerobes can be accomplished with commercially available microsystems for the detection of preformed enzymes within a few hours following inoculation (2–6, 8, 9, 11–14, 16–18), eliminating the need for growth of the isolates. The systems allow the identification and differentiation of many species

not identified by conventional microbiological systems. The systems and their characteristics are listed in Table 4.8–1. All systems require only 4 h of aerobic incubation after inoculation with a turbid culture suspension (no. 3 to no. 4 McFarland standard). A database and numerical identification profile are provided for each sys-

tem. A study comparing the IDS Rapid-ANA with the API 20A and with conventional prereduced anaerobically sterilized (PRAS) biochemicals demonstrated 96% correct identification of fresh clinical isolates (24 to 48 h) (1, 6, 16, 17).

Other systems, not discussed here, are also available.

II. SPECIMEN

The ideal specimen consists of isolated colonies grown for 24 to 48 h on brucella BAP or another suitably enriched nonselective medium for growing anaerobes. *Schaedler agar is not recommended because the extra glucose in the medium interferes with enzyme production (15, 19). However, the Crystal Anaerobe ID kit does have a separate database that allows the use of Schaedler agar (3).*

III. MATERIALS

- A. Anaerobe ANI Card and Rapid ID 32A (bioMérieux, Inc.), Rapid Anaerobe ID (Dade MicroScan, Inc.), Crystal Anaerobe ID kit (BD Biosciences), or RapID-ANA (Remel, Inc.) (2–4, 8, 9, 16, 17) (see Appendix 4.8–1 for addresses)
- B. Recommended inoculation fluid
- C. Pasteur pipette, if required by system
- D. 35°C aerobic incubator *without carbon dioxide*

IV. QUALITY CONTROL

Include QC information on reagent container and in QC records.

Each manufacturer recommends specific QC procedures (Table 4.8–1).

ANALYTICAL CONSIDERATIONS

V. PROCEDURE

- A. Suspend enough colonies from a 24- to 48-h culture from a nonselective medium to make a turbid suspension equivalent to a McFarland no. 3 to no. 4 standard. Each test kit has its own medium and McFarland requirements (Table 4.8–1).
- B. Once the suspension is prepared, inoculate the panel within 15 min. For some organisms, growth from two plates is necessary to achieve a McFarland no. 4 standard.

Table 4.8–1 Characteristics of rapid identification systems

Parameter	Rapid ID 32A ^a	RapID-ANA II ^b	Anaerobe panel ^c	Anaerobe ANI Card ^d	Crystal Anaerobe ID kit ^e
No. of tests	29	18	24	28	29
Inoculum source	Plate (use only Columbia blood agar)	Plate	Plate	Plate	Plate
Inoculum age	24–48 h	24–72 h	24–48 h	24–48 h	24–72 h
McFarland turbidity	No. 4 in 3.0 ml	No. 3 in 1.0 ml	No. 3 in 3.0 ml	No. 3 in 1.5 ml	No. 4 in 2.3 ml
Diluent	Suspension medium (purchased)	Provided	Sterile deionized H ₂ O	Sterile saline	Provided

^a bioMérieux, Inc., Hazelwood, Mo.^b bioMérieux, Inc., Hazelwood, Mo.^c Remel, Inc., Lenexa, Kans.^d BD Biosciences, Sparks, Md.^e Dade MicroScan, Inc., West Sacramento, Calif.**V. PROCEDURE** (continued)

- C.** Incubate in a standard aerobic 35°C incubator for 4 h. *Precaution: Do not incubate in CO₂.*
- D.** After incubation, add the required reagents (Table 4.8–1). The development of specific colors in the chromogenic tests indicates a positive reaction. Read the reactions, and record as either positive or negative.

V. PROCEDURE (*continued*)

- E. To interpret the results of the test, use the numerical identification system from the package to obtain a code number.
- F. Compare the code number obtained with the code numbers in the manufacturer's database book to identify the organism. Careful adherence to interpretation of colors is important for correct identification of the isolate.

VI. RESULTS

- A. Glucose *ortho*- or *para*-nitrophenyl compounds are colorless. If an enzyme is present, hydrolysis produces *ortho*- and *para*-nitrophenyl, yielding a yellow color.
- B. Arylamidase or aminopeptidase hydrolyzes amino acids, forming naphthylamines. The action of the peptidases on the cinnamaldehyde complexes forms a pink to purple pigment (15, 19).
- C. Indoxy phosphate is cleaved by phosphatases and releases indoxyl, which is oxidized to form indigo blue.
- D. Tetrazolium is reduced by the organism to form a red formazan precipitate.
- E. Many of the systems use conventional biochemicals such as urea, trehalose, and indole. Some authors (10) have reported differences in the detection of indole formation when different reagents are used.

POSTANALYTICAL CONSIDERATIONS**VII. LIMITATIONS OF THE PROCEDURE**

- A. Specific medium requirements differ from manufacturer to manufacturer; however, systems generally do not use media containing glucose because the sugar suppresses glycolytic activity.
- B. Rapid enzymatic test kits should be used in conjunction with other conventional information such as Gram stain, colonial morphology, and organism growth requirements. Special-potency antimicrobial agent disks and other presumptive tests can be very useful in verifying identification and Gram stain reaction. All aggregate reactions must be considered.
- C. *Interpretation of colors produced can be difficult but is critical for obtaining accurate reproducible results.*
- D. Organisms that have been sequentially transferred for long periods may demonstrate aberrant reactions and incorrect identification. Organisms that have not been recently subcultured may demonstrate aberrant results.
 - **NOTE:** The inoculum size is critical to obtain correct results; refer to the manufacturer's instructions.
- E. Advantages of rapid enzymatic systems
 1. Systems do not require growth to obtain an identification.
 2. Incubation is in a standard non-carbon dioxide incubator.
 3. Identification in 4 h is possible.
 4. Systems are good for fastidious anaerobic organisms and are not dependent on saccharolytic activity.
 5. Many isolates can be identified without the expense of PRAS biochemicals.
- F. Disadvantages of rapid enzymatic systems
 1. Anaerobic bacteria of nonclinical origin have not been fully characterized by these systems (14).
 2. Some anaerobic organisms from the oral cavity have not been fully characterized by these systems (18).
 3. Identification systems are limited by their databases and may not include recent taxonomic changes.
 4. Some reactions are difficult to interpret.

4.9.1

Introduction

Many anaerobic isolates may be identified to the genus and species levels using a variety of preformed-enzyme tests or other rapid biochemical tests. In some instances, tests for identification beyond the level that can be attained with the various spot tests described in procedure 4.6 are

needed. Presumptive or definitive identification of anaerobes is possible by using individual biochemical tests or a combination of preformed enzymatic manifestations.

Rapid biochemical tests are individual tests that may need to be performed when

system approaches such as those described in procedure 4.6 are used. See Appendix 4.9–1 for a summary of rapid biochemical tests for the identification of anaerobes. See Appendix 4.9–2 for a list and addresses of manufacturers of rapid biochemical tests.

4.9.2

Alkaline Phosphatase

I. PRINCIPLE

Hydrolysis of 4-nitrophenyl phosphate by alkaline phosphatase releases free 4-nitrophenol, which is yellow. This test may be used to distinguish between the indole-positive species *Peptostreptococcus hydrogenalis* and *Peptostreptococcus asaccharolyticus*.

II. MATERIALS

A. Reagents

1. Wee-Tabs (Key Scientific Products)
2. Alkaline phosphatase is available in commercial identification kits (*see* procedure 4.8).

3. Enzymatic tablets (Pro-Lab Diagnostics)

B. Supplies

1. Loop or wooden applicator stick
2. Disposable petri dish
3. Glass slide

III. QUALITY CONTROL

Include QC information on reagent container and in QC records.

A. Organisms

1. Positive control: *P. hydrogenalis*
2. Negative control: *P. asaccharolyticus*

B. Performance frequency

1. Perform QC test with each new lot of substrate or reagent.
2. Perform QC test each day the test is performed.
3. Record the results on a QC log (*see* Appendix 4.6–3 for a sample QC sheet).

IV. PROCEDURE

- A. Use an actively growing (48- to 72-h) culture on an agar plate medium that does not contain carbohydrates.
- B. Prepare a heavy suspension of organisms (>2.0 McFarland turbidity) in 0.25 ml of saline.
- C. Add tablet, vortex the suspension, and incubate at 37°C for a maximum of 4 h.

V. RESULTS

- A. **Positive: yellow color**
- B. **Negative: no color or very pale yellow**

VI. LIMITATIONS AND PRECAUTIONS

- A. This test is only part of the overall scheme for the identification of some anaerobes.
- B. Further biochemical characterization may be necessary for specific identification.
- C. Insufficient inoculum may give false-negative results.
- D. Allowing the test to react less or significantly longer than 4 h may lead to uninterpretable results.

SUPPLEMENTAL READING

- Key Scientific Products.** 2001. Technical insert. Key Scientific Products, Round Rock, Tex.
1993. *Wadsworth Anaerobic Bacteriology Manual*, 5th ed. Star Publishing Co., Belmont, Calif.
- Summanen, P., E. J. Baron, D. M. Citron, C. A. Strong, H. M. Wexler, and S. M. Finegold.**

4.9.3

Glutamic Acid Decarboxylase

I. PRINCIPLE

The glutamic acid decarboxylase test is used to determine the enzymatic ability of an organism to decarboxylate glutamic acid to form an amine, with resulting alkalinity. Glutamic acid decarboxylase is a rapid test for presumptive identification of

most of the *Bacteroides fragilis* group, *Clostridium perfringens*, *Clostridium sordellii*, *Clostridium baratii*, *Eubacterium limosum*, and 53% of *Peptostreptococcus micros* strains.

II. MATERIALS

- A. Glutamic acid tube (GDC tube [Remel, Inc.] or conventional tube)
- B. Microbiological loop
- C. Standard 35°C aerobic incubator

III. QUALITY CONTROL

Include QC information on reagent container and in QC records.

A. Organisms

1. Positive control: *B. fragilis*
2. Negative control: *Fusobacterium nucleatum*

B. Performance frequency

1. Perform QC test with each new lot of substrate or reagent.
2. Perform QC test each day the test is performed.
3. Record the results on a QC log (see Appendix 4.6–3 for a sample QC sheet).

IV. PROCEDURE

- A. Pick up a heavy inoculum (heavy visible paste) from a fresh pure culture of the anaerobe to be tested.
- B. Stab the inoculum in several spots at the very top of the medium, and then macerate it well throughout the upper one-fourth of the medium by moving the loop in and out of the medium several times.
- C. Do not inoculate the agar in the butt of the tube.
- D. Incubate aerobically at 35°C.
- E. Examine at 30 min and 1 h if desired. Incubate tests for 4 h before a final negative determination.

V. RESULTS

- A. A positive test for glutamic acid decarboxylase is indicated by an alkaline shift of the indicator from green to deep blue.
- B. No change or a light to medium blue is considered negative.

VI. LIMITATIONS AND PRECAUTIONS

- A. This test is only part of the overall scheme for identification and provides a high probability for presumptive identification of the *B. fragilis* group, *C. perfringens*, and *C. sordellii*.
- B. Further biochemical characterization may be necessary for specific identification.

VI. LIMITATIONS AND PRECAUTIONS (*continued*)

- C. When testing the *B. fragilis* group, negative tests cannot be expressed as “not *B. fragilis* group,” since approximately 40% of *Bacteroides distasonis* and 55% of *Bacteroides vulgatus* strains are negative.
- D. Many *Fusobacterium* strains give intermediate reactions.
- E. Only a distinct deep blue color should be considered positive.
- F. Too light an inoculum may yield false-negative results.
- G. After prolonged standing, the test may be difficult to read owing to the presence of an indistinct yellowish-purple color. Compare with an uninoculated tube.

SUPPLEMENTAL READING

- Remel, Inc.** 1999. Technical insert. Remel, Inc., Lenexa, Kans.

4.9.4

L-Alanyl-Alanylaminopeptidase

I. PRINCIPLE

Hydrolysis of L-alanyl-alanylaminopeptide by alanylaminopeptidase releases beta-naphthylamine, which complexes with paradimethylaminocinnamaldehyde

in the presence of acetic acid to produce a pink to purple color. This procedure may be used as a rapid test to separate *Fusobacterium* species from *Bacteroides* species.

II. MATERIALS

A. Reagents

1. L-Alanyl-L-alanylaminopeptidase disk (ALN Disk; Remel, Inc.)
2. Paradimethylaminocinnamaldehyde reagent
3. Enzymatic tablets (Pro-Lab Diagnostics)

B. Supplies

1. Deionized water
2. Loop or wooden applicator stick
3. Disposable petri dish
4. Glass slide

III. QUALITY CONTROL

Include QC information on reagent container and in QC records.

A. Organisms

1. Positive control: *Bacteroides fragilis*
2. Negative control: *Fusobacterium mortiferum*

B. Performance frequency

1. Perform QC test with each new lot of substrate or reagent.
2. Perform QC test each day the test is performed.
3. Record the results on a QC log (see Appendix 4.6–3 for a sample QC sheet).

IV. PROCEDURE

- A. Place disk on slide or petri dish lid, and moisten slightly with water.
- B. Rub visible inoculum onto ALN Disk with loop or wooden applicator stick, and allow to react for 2 min.
- C. Add 1 drop of cinnamaldehyde reagent, and look for color change in 30 s.

V. RESULTS

- A. Red to pink is positive for possible *Bacteroides* species.
- B. The absence of color change is negative for *Fusobacterium* species.

VI. LIMITATIONS AND PRECAUTIONS

- A. This test is only part of the overall scheme for the identification of some anaerobes.
- B. The organism tested must be an anaerobic gram-negative rod.
- C. Cultures older than 3 days should be subcultured before the test is performed.
- D. Further biochemical characterization may be necessary for specific identification.
- E. Insufficient inoculum may give false-negative results.
- F. Allowing the test to react for less or significantly longer than 30 s may lead to uninterpretable results.

Remel, Inc. 2001. Technical insert. Remel, Inc., Lenexa, Kans.

4.9.5

L-Proline-Aminopeptidase

I. PRINCIPLE

Hydrolysis of L-proline-beta-naphthylamide by proline aminopeptidase releases beta-naphthylamine, which complexes with paradimethylaminocinnamaldehyde

in the presence of acetic acid to produce a pink to purple color.

This test is used to screen for the presumptive identification of suspected col-

onies of *Clostridium difficile* on selective media. Proline-aminopeptidase may also be used as a rapid test in the differentiation of other anaerobic organisms.

II. MATERIALS

A. Reagents

1. L-Proline-beta-naphthylamide disk (PRO Disk, Remel, Inc.; Key Scientific, Pro-Lab Diagnostics)
2. Paradimethylaminocinnamaldehyde reagent

B. Supplies

1. Deionized water
2. Loop or wooden applicator stick
3. Disposable petri dish
4. Glass slide

III. QUALITY CONTROL

Include QC information on reagent container and in QC records.

A. Organisms

1. Positive control: *C. difficile*
2. Negative control: *Clostridium perfringens*

B. Performance frequency

1. Perform QC test with each new lot of substrate or reagent.
2. Perform QC test each day the test is performed.
3. Record the results on a QC log (*see* Appendix 4.6–3 for a sample QC sheet).

IV. PROCEDURE

- A. Place disk on slide or petri dish lid, and moisten slightly with water.
- B. Rub visible inoculum (heavy) onto disk with loop or wooden applicator stick.
- C. Allow to react for 2 min or up to 5 min.
- D. Add 1 drop of cinnamaldehyde reagent, and look for color change in 30 s.

V. RESULTS

- A. Color change (red to pink) within 30 s means that the organism may be *C. difficile*.
- B. The absence of color change means that the organism is not *C. difficile*.

VI. LIMITATIONS AND PRECAUTIONS

- A. This test is only part of the overall scheme for the identification of some anaerobes.
- B. The test organism must be an anaerobic gram-positive rod.
- C. Further biochemical characterization may be necessary for specific identification.
- D. An insufficient inoculum may give false-negative results.
- E. Allowing the test to react for less or significantly longer than 30 s may lead to uninterpretable results.

SUPPLEMENTAL READING

Remel, Inc. 2001. Technical insert. Remel, Inc., Lenexa, Kans.

4.9.5.1

4.9.6

4-Methylumbelliferone Derivative Substrates

I. PRINCIPLE

Preformed enzyme (glucosidase) links to a fluorescent substrate (4-methylumbelliferone) to yield rapid determination of enzymatic activity. In the presence of the glucosidase enzyme, the derivative sub-

strate 4-methylumbelliferyl releases 4-methylumbelliferone, a fluorescent compound easily detected by long-wave (360-nm) UV light.

II. MATERIALS

- A. 4-Methylumbelliferone glucoside substrate (Sigma-Aldrich, Inc.)
- B. Glucosidase substrates suspended in distilled water to a concentration of 4 mM

- C. Substrates frozen in snap-cap tubes (12 by 75 mm)

III. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- A. Use known negative and positive controls for each substrate.
- B. Perform QC test with each new lot of substrate or reagent.
- C. Perform QC test each day the test is performed.
- D. Record the results on a QC log (*see* Appendix 4.6–3 for a sample QC sheet).

IV. PROCEDURE

- A. If derivative substrates are frozen, thaw and suspend in 20 μ l of 1 M sodium phosphate buffer (pH 5.0).
- B. Add enough solution to soak a Whatman no. 2 filter paper strip.
- C. Allow solution spot to dry for 10 min.
- D. Smear a heavy loopful of bacteria (24 to 48 h of incubation) directly on the substrate, and incubate the filter paper strip at 37°C for 15 min.
- E. Examine the filter paper strip under a long-wavelength handheld lamp.

V. RESULTS

- A. The hydrolytic product of enzymatic action on the glucoside derivative produces an immediate light blue fluorescence under a Wood's lamp.
- B. Light blue fluorescence under a Wood's lamp (365 nm) is positive; no color is negative.

VI. LIMITATIONS AND PRECAUTIONS

- A. A light inoculum will yield false-negative results.
- B. The buffer must be acidic. An alkaline buffer will yield false-positive results.
- C. Observe in a dark room to avoid false-negative results.

4.9.7

Combination Enzymatic Tablets for Nitrophenol, Aminopeptidase, and Methylumbelliferyl Substrates

I. PRINCIPLE

Some bacteria may produce enzymes which hydrolyze various chromogenic substrates, producing a positive test. Combination tablets allowing two or more enzymatic tests to be performed in a single

tube can be used to detect enzymatic activity based upon a color change or to detect other substrates producing 4-methylumbelliferone enzymatically from methylumbelliferyl substrates, leading to fluo-

rescent end products when exposed to a Wood's lamp. These test systems are a convenient and economical way to achieve identification of some anaerobes.

II. MATERIALS

A. Reagents

1. Tablets can be purchased containing two or more test substrates in various predetermined combinations (see manufacturer for choice of combination tablets and substrates available; Wee-Tabs, Key Scientific Products, Round Rock, Tex.).
2. Individual tablets may be purchased from Pro-Lab Diagnostics.

3. Peptidase reagent (cinnamaldehyde)

B. Supplies

1. Microbiological loop or sterile swab
2. Sterile distilled water
3. Long-wave UV light (Wood's lamp, 366 nm)

III. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- A. Each lot of disks should be tested with organisms of known reactivity prior to use.
- B. See manufacturer's insert for QC organism recommendations.
- C. Test each new lot of peptidase reagent.
- D. Perform QC test each day the test is performed.
- E. Record the results on a QC log (*see* Appendix 4.6–3 for a sample QC sheet).

IV. PROCEDURE

- A. Add at least 0.25 ml but not more than 0.5 ml (about 5 drops) of distilled water to tablet.
- B. Inoculate heavily from fresh 24-h growth from anaerobic BAP. The heavier the inoculum, the better (>2.0 McFarland turbidity).
- C. Incubate for at least 2 h at 37°C.

V. RESULTS

Read and interpret in the exact sequence listed below.

- A. Nitrophenol tests (glucosidase): observe for an immediate bright yellow color indicating a positive test.
- B. 4-Methylumbelliferone: observe the tube for fluorescence by holding under a long-wave UV lamp. An immediate blue-green fluorescence indicates a positive test.
- C. Aminopeptidase: perform the aminopeptidase test last by adding 2 drops of peptidase reagent. A dark red within 15 min indicates a positive test.

VI. LIMITATIONS AND PRECAUTIONS

- A. These tests may be only part of an overall identification scheme for some anaerobes.
- B. Further biochemical characterization may be necessary for specific identification of some anaerobic bacteria.
- C. Insufficient inoculum and organisms older than 24 h may give false-negative results.
- D. Allowing the test to react for less or significantly more time than manufacturer's recommendations may lead to uninterpretable results.
- E. The glucosidase test must be read first, followed by the 4-methylumbelliferone test and then the aminopeptidase test. This sequence must be followed for reliable results.

Appendixes to Procedure 4.9

APPENDIX 4.9-1

Summary of single or combination rapid enzymatic tests for anaerobes

Test	Principle	Reagents	Results
Alkaline phosphatase	Hydrolysis of 4-nitrophenyl phosphate by alkaline phosphatase releases free 4-nitrophenol, which is yellow. Used to help identify anaerobic gram-positive cocci.	Alkaline phosphatase in kits or in individual tablets	A yellow color within 4 h is positive; no color is negative.
Glutamic acid decarboxylase	Enzymatic action on glutamic acid by a specific decarboxylase releases an amine indicated by a dark blue color. Used for the presumptive identification of <i>Bacteroides fragilis</i> group and some <i>Clostridium</i> spp.	Glutamic acid tube, commercially available	A positive test for glutamic acid decarboxylase is indicated by a color shift from green to dark blue; no change is negative.
L-Alanyl-alanylaminopeptidase	Hydrolysis of L-alanyl-alanylaminopeptide releases β -naphthylamine, which complexes with cinnamaldehyde to produce a pink to purple color. Used to separate <i>Fusobacterium</i> spp. from <i>Bacteroides</i> spp.	ALN Disk, commercially available	A positive test is indicated by a pink to purple color in 30 s. A negative test is indicated by no color change.
L-Proline-aminopeptidase	Hydrolysis of L-proline- β -naphthylamine releases β -naphthylamine, which complexes with cinnamaldehyde to produce a pink to purple color. Used to presumptively identify <i>Clostridium difficile</i> .	PRO Disk, commercially available	A positive test is indicated by a pink to purple color in 30 s. A negative test is indicated by no color change.
4-Methylumbelliferone derivative substrates	A glucosidase is linked to a fluorescent substrate, 4-methylumbelliferone, to yield rapid determination of enzymatic activity as indicated by fluorescence when viewed with a Wood's lamp.	4-Methylumbelliferone glucoside substrate, commercially available, and 360-nm UV light	An immediate light blue fluorescence when viewed with a Wood's lamp is positive. A negative test is no color.
Combination glucosidase naphthylamide tablets	Combination tablets in which two or more enzymatic tests can be performed in a single tube. Some substrates may also be linked to 4-methylumbelliferone to permit detection of fluorescent end products.	Glucosidase/naphthylamine/methylumbelliferone commercially available tablets	A positive glucosidase is indicated by bright yellow within 2 h; a positive peptidase is indicated by red within 15 min; 4-methylumbelliferone shows a blue-green fluorescence immediately.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The anaerobic gram-negative bacteria are part of the microbiota of the mouth, upper respiratory tract, intestinal tract, and urogenital tract (3, 12, 16). Many taxonomic changes have been instituted based on molecular biology considerations. Newly separated genera have led to reclassifications in this group that will continue (1, 4, 5, 8, 10, 13, 14, 17, 18). These changes have made understanding current taxonomy more difficult for all parties; clinical decisions still require accurate, timely identification of organisms by the clinical laboratory.

This procedure describes characteristics of and identification methods for the clinically important members of the anaerobic gram-negative bacilli, including *Bacteroides* spp., *Porphyromonas* spp., *Prevotella* spp., *Fusobacterium* spp., *Campylobacter* spp., *Sutterella*, and *Bilophila*. Anaerobic gram-negative bacilli are the most commonly encountered anaerobes in clinical specimens, with *Bacteroides fragilis* isolated more frequently than any other anaerobe (3, 12, 16).

Initial differentiation of anaerobic gram-negative bacilli is based on cell and

colony morphology, motility, pigment production, fluorescence under long-wave UV light, susceptibility to special-potency antimicrobial agent disks and other disk and spot tests, and rapid enzyme testing. Definitive species identification currently requires additional biochemical testing and analysis of metabolic end products by GLC or fatty acid analysis (6, 8, 9). Communication with the patient's physician is crucial to determine the extent of workup required.

II. ISOLATES

Identification of anaerobic gram-negative bacilli requires isolation of the organism in pure culture. Follow the directions in procedure 4.4 for details on how to obtain a pure culture of the isolate to be identified and how to confirm that the isolate is an anaerobe. Establish that the isolate is a gram-negative bacillus by Gram stain reaction; see other sections in this handbook for identification of other types of isolates. The following steps will aid in identification.

- A. Place special-potency antimicrobial agent disks of kanamycin (1,000 µg), vancomycin (5 µg), and colistin (10 µg) on a brucella BAP or another enriched medium for isolates that are gram-negative bacilli or coccobacilli (7, 16). See procedures 4.3, 4.4, and 4.6 for other media and procedures.
- B. Add a nitrate disk (Anaerobe Systems, Becton Dickinson [BD], Hardy, PML, Remel) to a heavily inoculated section (*see* procedure 4.6).
- C. Using the results obtained with special-potency antimicrobial agent disks, refer to Fig. 4.10–1 for directions to the appropriate follow-up chart and to determine the tests needed for identification. Use the pure-culture growth on the brucella BAP to perform additional tests.

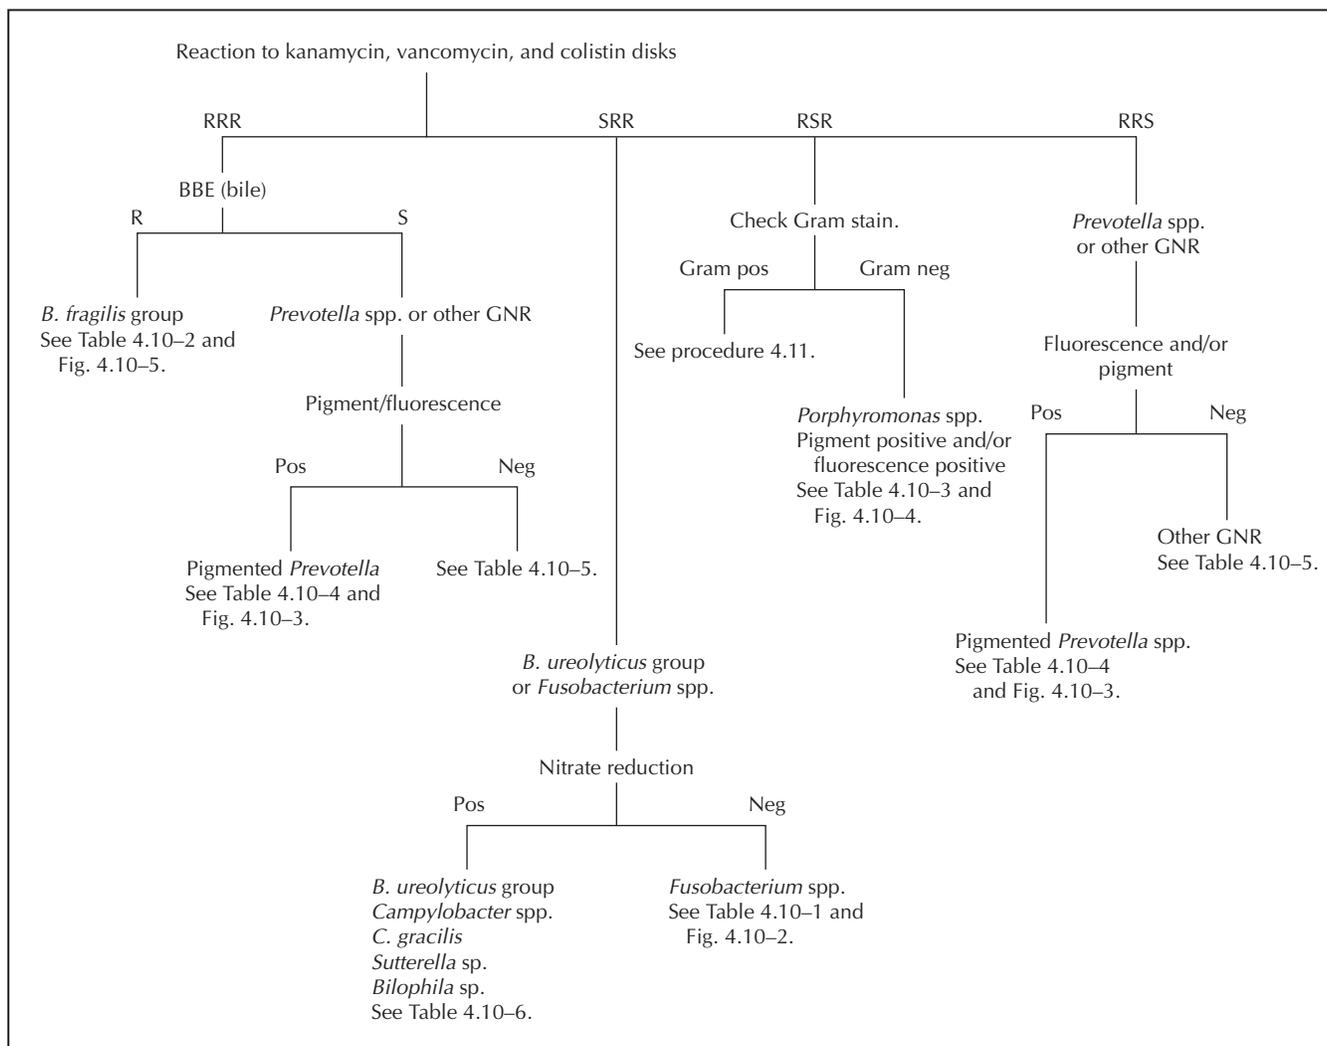

Figure 4.10-1 Reaction to kanamycin, vancomycin, and colistin disks. Pos, positive; Neg, negative; GNR, gram-negative rods; R, resistant; S, susceptible.

ANALYTICAL CONSIDERATIONS

III. CELL AND COLONY MORPHOLOGY

(See Appendix 4.10-1.)

A. Gram stain morphology

- The steps taken to identify anaerobic isolates depend on the Gram stain reaction, yet anaerobic organisms often have a variable stain. Any unclear reaction may be resolved by use of one or all of the following.
 - Use a young culture (log-phase growth) grown on medium with small or no amounts of carbohydrates.
 - Alter Gram stain procedure by use of methanol instead of heat to fix smear (see procedure 4.4); use basic fuchsin as a counterstain (12, 16).
 - Use buffered Gram stain reagents (see procedure 4.4).
 - Reduce the acetone concentration in the decolorizer solution (300 ml of acetone, 700 ml of 95% ethanol) (6, 7, 12, 16).
- Most *Bacteroides* spp. do not display unique morphology on Gram stain. They appear as pale, filamentous, pleomorphic, gram-negative rods with or without vacuoles and irregular staining (see Appendix 4.10-1).

III. CELL AND COLONY MORPHOLOGY

(continued)

3. The pigmented *Prevotella* spp. and *Porphyromonas* spp. tend to stain as pale coccobacilli (see Appendix 4.10–1).
4. Cell morphology may be a significant differentiating factor for some *Fusobacterium* spp.
 - a. *Fusobacterium nucleatum* is a thin, pale, gram-negative rod with tapering ends (fusiform). Other *Fusobacterium* spp. may be differentiated from *F. nucleatum* on the basis of indole reaction, lipase, and bile (Fig. 4.10–2 and Table 4.10–1). Caveat: The needle-shaped morphology is shared with the microaerophilic, indole-negative *Capnocytophaga* spp.
 - b. Other *Fusobacterium* spp. (see Appendix 4.10–1 and Table 4.10–1) tend to be pleomorphic on Gram stain. *Fusobacterium mortiferum* (and sometimes *Fusobacterium necrophorum*) displays more bizarre and extremely pleomorphic forms, with filaments, round bodies, and swollen areas.
5. *Bacteroides ureolyticus*, *Campylobacter gracilis*, other anaerobic *Campylobacter* spp., *Bilophila*, and *Sutterella* are thin gram-negative rods with rounded ends (12, 16).

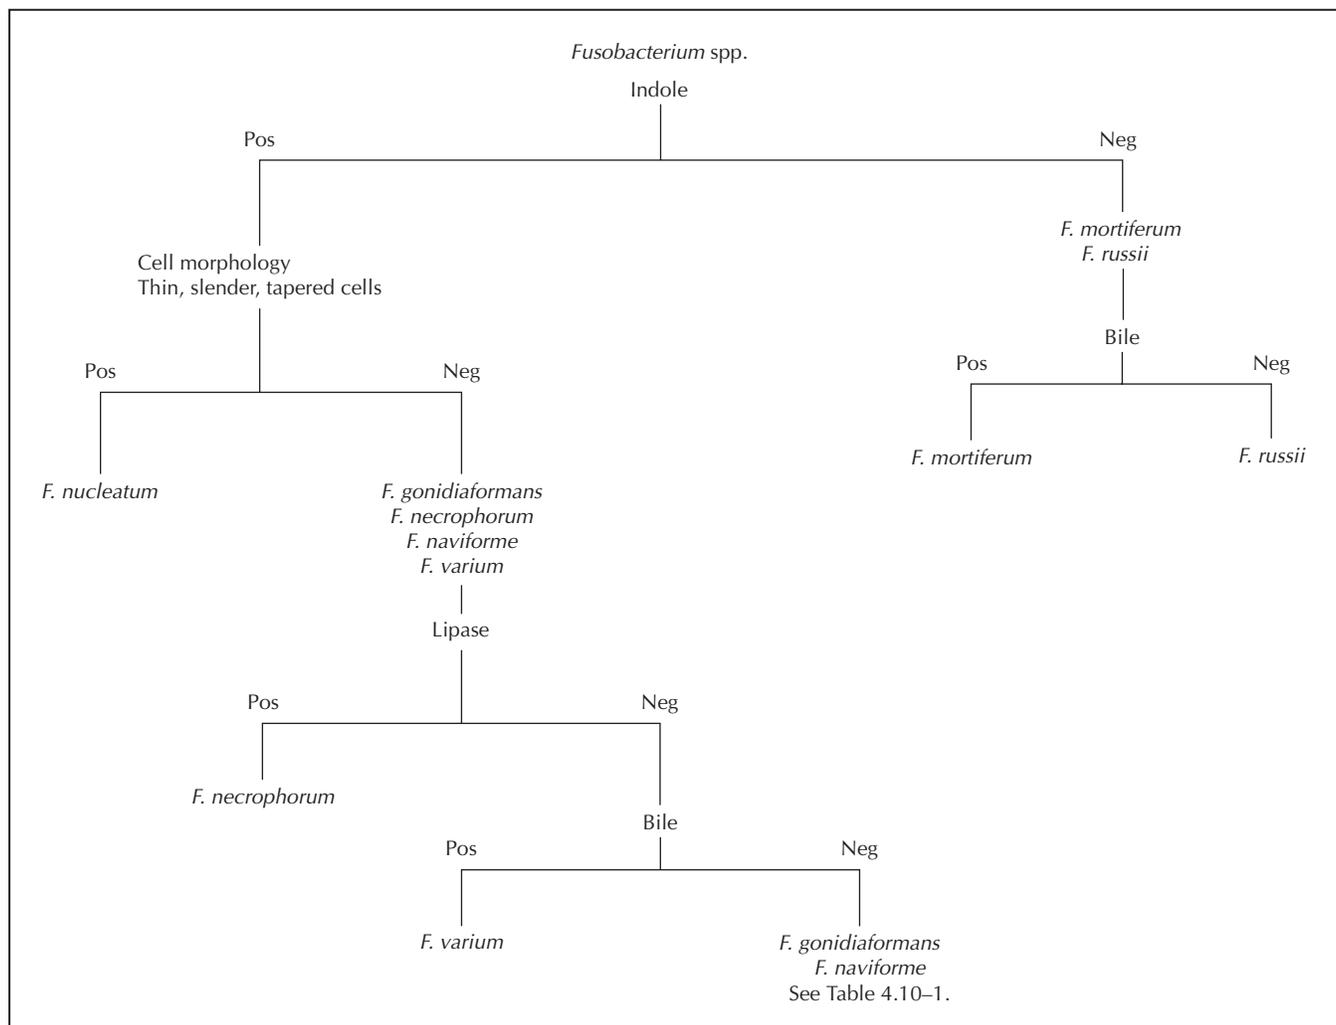

Figure 4.10–2 Identification of *Fusobacterium* spp. Pos, Positive; Neg, negative.

Table 4.10–1 Characteristics of *Fusobacterium* spp.^a

Species	Cell morphology	Colony morphology	Indole	Growth in 20% bile	Esculin	Lipase
<i>F. nucleatum</i>	Thin, tapered ends	Breadcrumblike, speckled	+	–	–	–
<i>F. gonidiaformans</i>	Gonidial forms	Smooth	+	–	–	–
<i>F. necrophorum</i>	Round ends (bizarre); large	Umbonate, greening	+	– ^{+b}	–	+ [–]
<i>F. naviforme</i>	Boat shaped	Mottled	+	–	–	–
<i>F. varium</i>	Round ends	Smooth (“fried egg”)	+ [–]	+	–	–

<i>F. russii</i>	Round ends	Smooth	–	–	–	–

^a +, positive; –, negative; +[–], most strains positive, some negative; –⁺, most strains negative, some positive.

^b Different subspecies; adapted from reference 12.

III. CELL AND COLONY MORPHOLOGY (continued)

B. Colony morphology (see Appendix 4.10–1)

1. Anaerobic gram-negative bacilli display a variety of colony morphologies, some of which are characteristic of certain species. Presumptive identification can sometimes be made on the basis of colony morphology and Gram stain results.

a. Record the colony description, such as size, shape, and unusual characteristics (pitting, spreading, hemolysis, “breadcrumblike” or “fried-egg-like” appearance, iridescence, pigments, UV reactions) (see procedure 4.4).

b. Perform aerotolerance testing on all colony types prior to proceeding with other tests (see procedure 4.4).

c. Note growth characteristics on enriched and differential primary isolation media (see procedure 4.4).

2. *B. fragilis* group

In general, on enriched primary media, *B. fragilis* group organisms form colonies that are 2 to 3 mm in diameter, circular, convex, and gray to gray-white (shiny, silver-like). A *Bacteroides* bile esculin (BBE) plate may be included for primary isolation and will select for those species able to grow in the presence of 20% bile and to hydrolyze esculin (Table 4.10–2 and Appendix 4.10–1).

Table 4.10–2 Characteristics of the *Bacteroides fragilis* group^a

Species	Growth in 20% bile	Indole	Catalase	Esculin hydrolysis	Arabinose	Cellobiose	Rhamnose	Salicin	Sucrose	Trehalose	Xylan	Alpha-fucosidase
<i>Bacteroides caccae</i>	+	–	–	+	+	+	+	–	+	+	–	+
<i>Bacteroides distasonis</i>	+	–	+	+	–	+	V	+	+	+	–	–
<i>Bacteroides eggerthii</i>	+	+	–	+	+	–	+	–	–	–	+	–
<i>Bacteroides fragilis</i>	+	–	+	+	–	+	–	–	+	–	–	+
<i>Bacteroides merdae</i>	+	–	–	+	–	V	+	+	+	+	–	–

<i>Bacteroides stercoris</i>	+	+	–	+	–	+	+	–	+	–	V	V
<i>Bacteroides thetaiotaomicron</i>	+	+	+	+	+	+	+	–	+	+	–	+
<i>Bacteroides uniformis</i>	+ ^w	+	–	+	+	+	–	+	+	–	V	+
<i>Bacteroides vulgatus</i>	+	–	–	–	+	–	+	–	+	–	–	+

^a +, positive; –, negative; +^w, most strains positive, some weakly positive; W, weak; V, variable.

III. CELL AND COLONY MORPHOLOGY

(continued)

- a. Black colonies on BBE that are >1 mm in diameter and Gram stain as pale, pleomorphic, gram-negative rods can be presumptively identified as belonging to the *B. fragilis* group.
 - b. *Bacteroides vulgatus* produces >1-mm-diameter colonies on BBE but usually does not hydrolyze esculin (Table 4.10–2).
 - c. Some non-*B. fragilis* group organisms are resistant to bile. *Bilophila wadsworthia*, *F. mortiferum/varium*, *Enterococcus* spp., and some members of the family *Enterobacteriaceae* will grow on BBE medium. However, these organisms generally do not produce >1-mm colonies, so evaluate carefully any growth on BBE.
3. *B. ureolyticus* group organisms (*B. ureolyticus*, *C. gracilis*, *Campylobacter* spp., and *Sutterella*) produce colonies that are small and translucent or transparent and may produce greening of the agar. Three colony morphologies exist: smooth and convex, pitting, and spreading. All three colony types may appear in the same culture (12, 16).
 - a. It may be necessary to subculture colonies of each morphology to resolve questions of pleomorphism.
 - b. Pitting (corroding) is usually best detected if the surface of the agar is inspected at a 30 to 45° angle.
 - c. Ability to corrode agar and spread can be medium dependent and may be enhanced by using moist, fresh media or pre-reduced anaerobically sterilized (PRAS) media.
 - d. Colony variants may produce multiple forms (pitting, spreading, convex). Improper methods of maintaining stock cultures may cause pure isolates to revert to producing multiple colony types.
 - e. *B. ureolyticus* group colonies are usually much smaller and more translucent than those of fusobacteria (see Appendix 4.10–1).
 4. *Fusobacterium* species (Fig. 4.10–2 and Table 4.10–1)
 - a. Along with its distinctive cell morphology, *F. nucleatum* possesses three different characteristic colony forms: breadcrumb, speckled, and smooth. The colony sizes vary from <0.5 to 2 mm, and the colors vary from white (breadcrumb) to gray and gray-white (4, 7, 16). The agar surrounding *F. nucleatum* colonies becomes greenish upon exposure to air.
 - b. *F. necrophorum* produces umbonate colonies with greening of the agar. Strains that are lipase positive can also be beta-hemolytic.
 - c. *F. mortiferum/varium* produces fried-egg colonies (translucent with opaque centers and irregular borders) on the surface of the agar (distinct from *Chlamydia*).
 - d. *Capnocytophaga* spp. (not obligate anaerobes) produce iridescent or speckled, flat, spreading colonies with fingerlike projections and yellow centers.

IV. PIGMENTATION AND FLUORESCENCE

Include QC information on reagent container and in QC records.

A. Pigmentation (see procedure 4.6)

1. Use of primary medium containing 5% laked sheep blood (also laked rabbit blood) enhances production of pigment by pigmented *Prevotella* spp. and *Porphyromonas* spp. Organisms that fluoresce brick red or produce brown to black colonies on blood-containing medium are placed into pigmented *Prevotella* spp. or *Porphyromonas* spp.
2. Pigmentation usually occurs within 4 days but may be delayed, taking as long as 21 days for some isolates (8, 10, 15, 16). Pigmentation begins as light tan to brown and then darkens upon incubation.
3. Note the degree of pigmentation; it may be useful in differentiating this group from other groups. *Porphyromonas* spp. tend to produce dark brown to black

IV. PIGMENTATION AND FLUORESCENCE (continued)

colonies (Table 4.10–3), while some pigmenting *Prevotella* spp. do not develop pigmentation as dark (Table 4.10–4). *Prevotella bivia*, although not usually considered a part of the pigmented group, may produce pigment upon prolonged incubation (see Table 4.10–5).

Table 4.10–3 Characteristics of *Porphyromonas* spp.^a

IV. PIGMENTATION AND FLUORESCENCE (continued)

4. It is generally not practical in a clinical laboratory to hold primary plates beyond 7 days to detect delayed pigment production, particularly when brick red fluorescence is usually detected in 48 to 72 h.

B. Long-wave UV fluorescence (see procedure 4.6)

1. Test all primary plates with growth or any suspicious colonies for fluorescence by exposure to long-wave UV light (Wood's lamp, 366 nm) in order to recognize black-pigmented *Prevotella* spp. and *Porphyromonas* spp. (except for *Porphyromonas gingivalis*) before a distinct pigment develops (Fig. 4.10-3 and 4.10-4, and Tables 4.10-3 and 4.10-4) (15). Usually brick red fluorescence can be observed in 48 to 72 h, whereas pigment production may often take 4 to 5 days.
2. Some nonpigmented anaerobic gram-negative organisms can fluoresce a variety of shades of pink, orange, and chartreuse. Therefore, only those isolates that fluoresce brick red can be presumptively identified as pigmented *Prevotella* spp. or *Porphyromonas* spp. (see Tables 4.6-2 and 4.10-3) (see also procedure 4.6).
 - a. *Fusobacterium* spp. can fluoresce chartreuse (yellow-green).
 - b. *Veillonella* spp. can fluoresce red (but not brick red). Differentiation is easily achieved by Gram stain.
 - c. *P. gingivalis* may lack the ability to fluoresce but will produce black colonies, so note both pigmentation and fluorescence (Table 4.10-3).

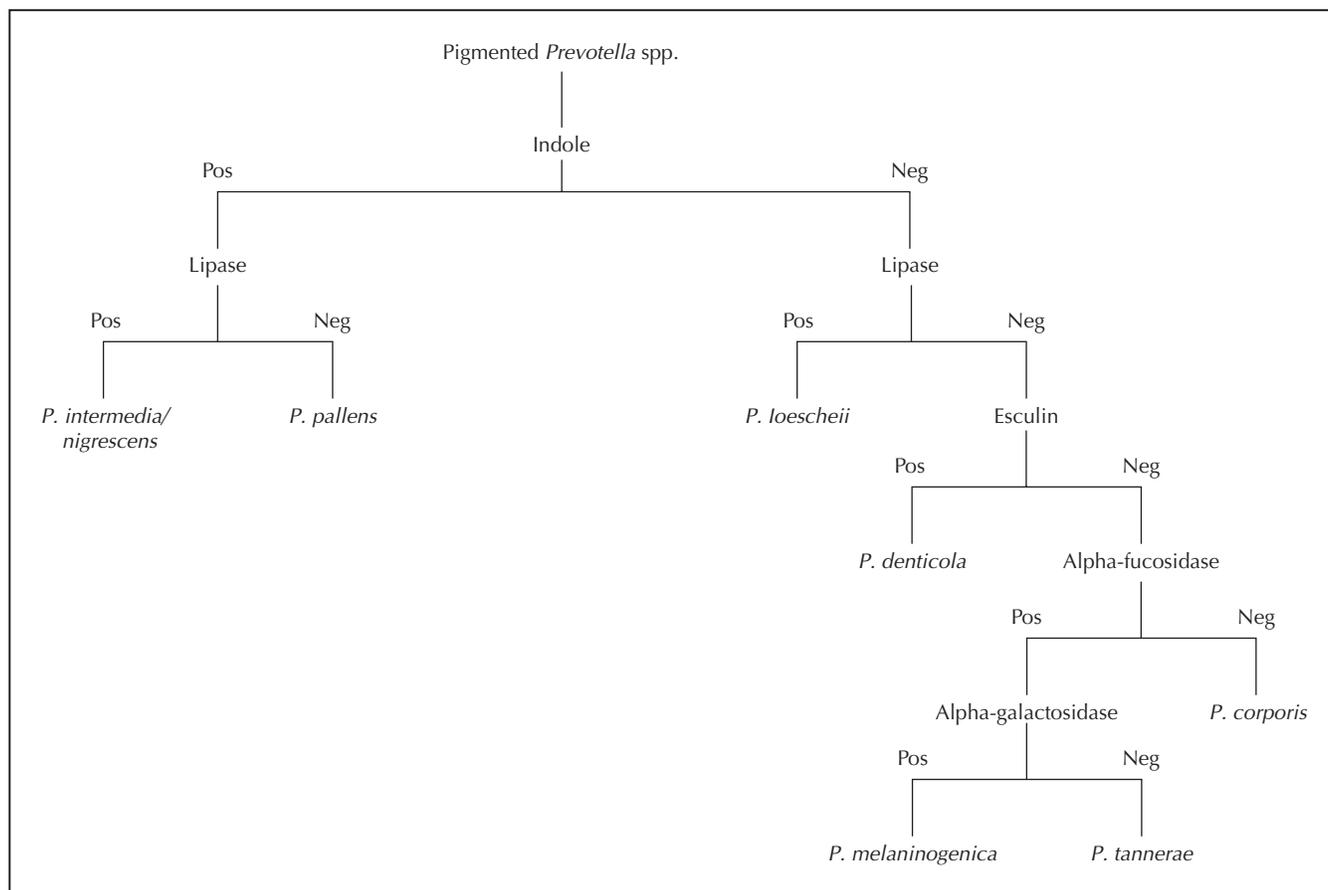

Figure 4.10-3 Identification of pigmented *Prevotella* spp. Pos, positive; Neg, negative.

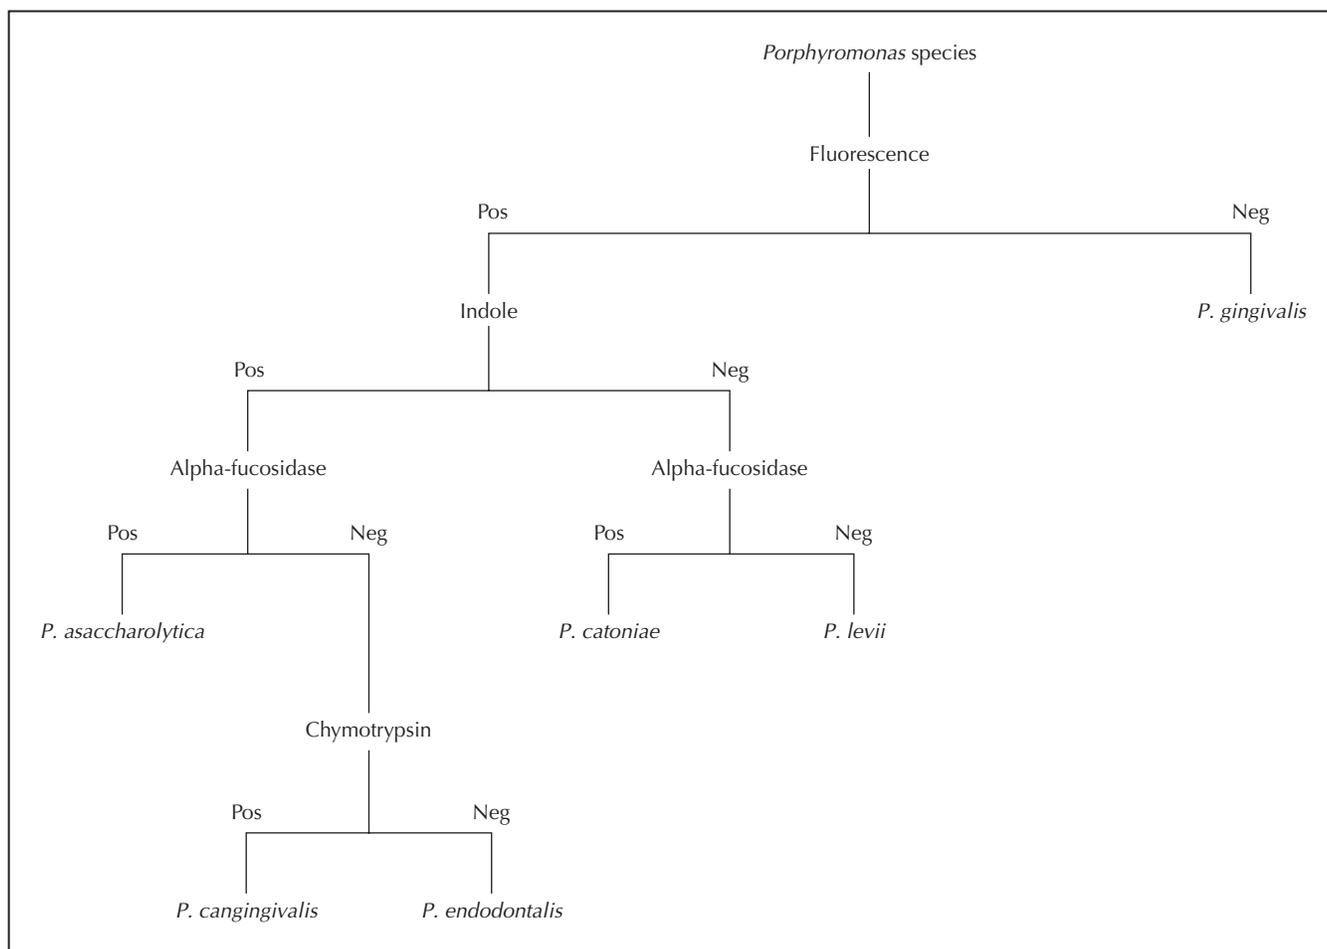

Figure 4.10–4 Identification of *Porphyromonas* spp. Some *Porphyromonas* spp. of animal origin that may be recovered from bite infections are not listed. Pos, positive; Neg, negative.

IV. PIGMENTATION AND FLUORESCENCE (continued)

- d. If colonies are too old (>5 days), they lose their ability to fluoresce by direct exposure to UV light (4–6, 15). A preparation of 5 to 10 pigmented colonies emulsified in absolute methanol (1 ml) in a glass test tube can be exposed to UV light to test for fluorescence and may increase the likelihood of a positive result (15).

V. MOTILITY

Most significant clinical isolates fall into the “gram-negative nonmotile” classification. However, if there is any difficulty in identifying an isolate or if the Gram stain shows helical or curved rods, perform either a flagellum stain or a motility test (7, 12, 16). Determine motility as follows.

- A. Use wet-mount examination and dark-field or phase-contrast microscopy of young broth cultures (3 h old). The addition of formate and fumarate may be necessary.
- B. Use Todd-Hewitt broth partially solidified with 0.3% agar. Incubate 3 to 6 days; observe for diffuse growth away from stab.
- C. Use Columbia broth supplemented with 1% soluble starch (BD), 2% rabbit serum, and 0.24% agar (12). Incubate for 3 to 6 days.

V. MOTILITY (continued)

- D. Dark-field or phase-contrast microscopy is preferred, since these semisolid-medium motility tests are time-consuming and difficult to interpret. However, many clinical laboratories may not have a dark-field or phase-contrast microscope.

VI. RAPID PRESUMPTIVE IDENTIFICATION TESTS

Include QC information on reagent container and in QC records.

Use rapid tests to rule out or confirm presumptive identifications based on Gram stain and colony morphology (see procedure 4.4 for additional information). When typical morphology (cell and colony) is apparent and is combined with rapid tests, the resulting preliminary identification may be useful until more exhaustive tests are completed or are needed by clinician (see procedures 4.6 to 4.9 for an explanation).

A. Special-potency antimicrobial agent disks

Determine susceptibility to special-potency antimicrobial agent disks (vancomycin, 5 µg; kanamycin, 1,000 µg; and colistin, 10 µg) (see procedure 4.6). These disks are used as an aid in determining the Gram stain reaction and in separating different gram-negative species and genera (16).

1. *B. fragilis* group organisms can be identified by the special-potency antimicrobial agent disk pattern showing resistance to all three disks and resistance to 20% bile or on BBE agar (Fig. 4.10–1 and Table 4.10–2).
2. *B. ureolyticus* group organisms are susceptible to kanamycin and colistin and resistant to vancomycin special-potency disks. These organisms reduce nitrate and are nitrate reductase positive (Fig. 4.10–1).
3. *Fusobacterium* spp. are susceptible to kanamycin and colistin and resistant to vancomycin special-potency disks. These organisms are nitrate reductase negative (Fig. 4.10–1).
4. *Porphyromonas* spp. are resistant to kanamycin and colistin and susceptible to vancomycin special-potency disks (Fig. 4.10–1).
5. *Prevotella* spp. are resistant to kanamycin and vancomycin special-potency disks and vary in their susceptibility to colistin. *Prevotella* spp. may have a disk pattern typical of the *B. fragilis* group (resistance to the three antimicrobial agent disks), but these organisms do not grow in 20% bile (Fig. 4.10–1).

B. Spot indole (see procedure 4.6 for use of spot indole)

1. Some species of the *B. fragilis* group (see Table 4.10–2 and Fig. 4.10–5) can be differentiated by spot indole (16).
2. *F. nucleatum* is differentiated from other *Fusobacterium* spp. and from *Capnocytophaga* spp. (microaerophiles) by typical cell morphology, its ability to produce indole, and other tests (see Fig. 4.10–2 and Table 4.10–1).
3. An indole- and lipase-positive coccobacillus that forms black-pigmented colonies or fluoresces red under UV light is identified as belonging to the *Prevotella intermedia/nigrescens* group (Table 4.10–4).
4. An indole-positive, lipase-positive, pleomorphic gram-negative rod that produces beta-hemolytic colonies on blood agar is *F. necrophorum* (see Table 4.10–1 and Fig. 4.10–2).
5. *Precaution: Indole is diffusible, so the spot indole test should be performed only on plates with pure cultures (see procedure 4.6).*

C. Nitrate and urease (see procedure 4.6 for use of nitrate and urea disk tests)

1. A thin, gram-negative bacillus with rounded ends that is resistant to vancomycin and susceptible to both kanamycin and colistin should be tested for nitrate reduction. Place a nitrate disk (Anaerobe Systems, BD, Hardy, Remel) on the anaerobic BAP along with special-potency antimicrobial agent disks (see procedure 4.6).

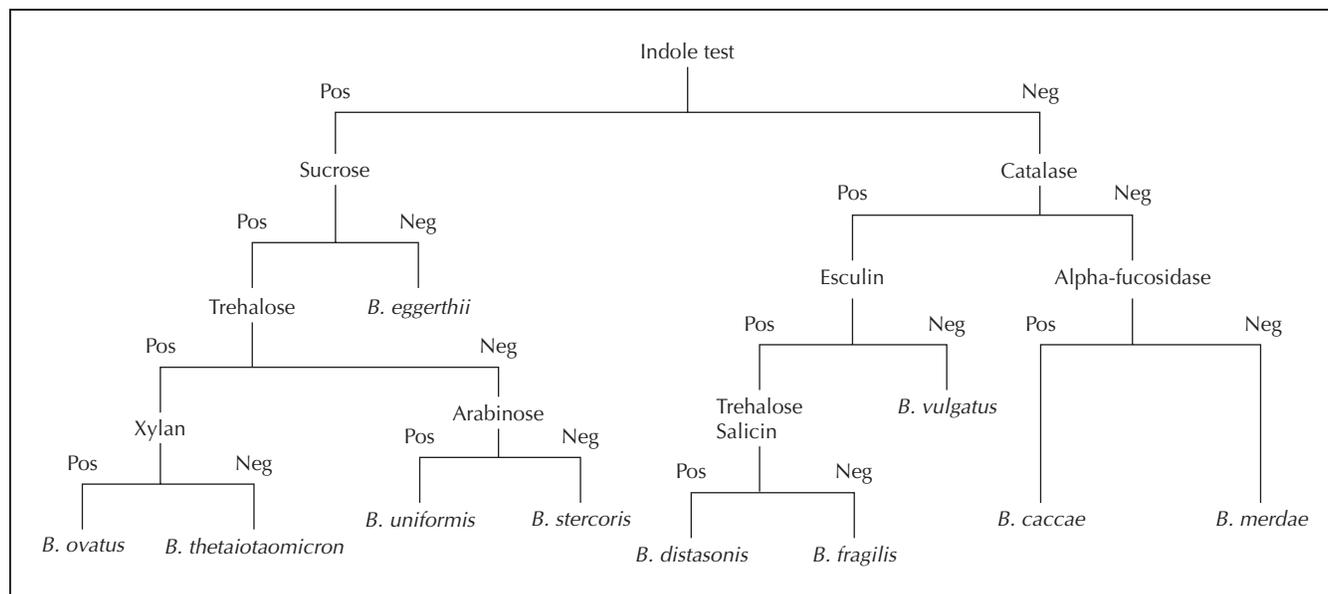

Figure 4.10-5 Identification of the *Bacteroides fragilis* group. Pos, positive; Neg, negative.

VI. RAPID PRESUMPTIVE IDENTIFICATION TESTS (continued)

- The agar-pitting *B. ureolyticus* group organisms resemble some of the less frequently isolated *Fusobacterium* spp. in cell morphology and special-potency disk pattern but are easily differentiated by the ability to reduce nitrates (Fig. 4.10-1 and Table 4.10-6).
- Nitratase-positive, corroding isolates that are urease positive and have the proper patterns of susceptibility to special-potency disks are identified as *B. ureolyticus* (Fig. 4.10-1 and Table 4.10-6). A rapid urea test using sterile urea broth or a urea disk can give a positive result in 15 to 30 min (see procedure 4.6).
- C. gracilis* is nonmotile and urease negative and thus can be differentiated from *B. ureolyticus* (Table 4.10-6).
- B. wadsworthia*, which phenotypically resembles *B. ureolyticus*, is nitrate and urease positive but grows in 20% bile (or on BBE agar) and has a strong catalase reaction (2) (Table 4.10-6).
- Sutterella wadsworthensis* is nitrate positive but is urea negative and catalase negative, allowing for differentiation from *B. wadsworthia* (see Table 4.10-6).
- Small, gram-negative cocci that have colonies fluorescing red (not brick red) under UV light and are nitrate positive are *Veillonella* spp.

Table 4.10-6 Characteristics of *B. ureolyticus*, *Campylobacter* spp., *Bilophila wadsworthia*, and *Sutterella wadsworthensis*^a

Species	Agar pitting	Growth in 20% bile	Catalase	Motility	Urease	Growth stimulated by formate-fumarate ^b
<i>B. ureolyticus</i>	+	-	- ⁺	-	+	+
<i>Bilophila wadsworthia</i>	-	+	+	-	+ ⁻	-
<i>Campylobacter</i> spp.	V	-	-	+ ⁻	-	+
<i>C. gracilis</i>	V	-	-	-	-	+
<i>Sutterella wadsworthensis</i>	V	+ ^c	-	-	-	+

^a +, positive; -, negative; +⁻, most strains positive, some negative; -⁺, most strains negative, some positive; V, variable.

^b Addition of formate-fumarate to broth to determine stimulation of growth.

^c Resistant to bile disk, sensitive to BBE and bile broth.

VI. RAPID PRESUMPTIVE IDENTIFICATION TESTS

(continued)

D. Bile (see procedure 4.6 for use)

1. The ability to grow in the presence of bile is an important characteristic in the primary identification of many anaerobic gram-negative organisms. Use of a primary-isolation BBE plate, bile broth, or bile disk plate provides a quick means of separating organisms that grow on bile.
2. *B. fragilis* group organisms are resistant to bile; other *Bacteroides* spp. may be resistant (see Fig. 4.10-1 and 4.10-5 and Tables 4.10-2 and 4.10-5).
3. Some *Fusobacterium* spp. grow on bile (Table 4.10-1 and Fig. 4.10-2). A kanamycin-sensitive, bile-tolerant organism should be identified as a *Fusobacterium* sp. (either as *F. mortiferum* or *F. varium*). Some bile-resistant strains of *F. necrophorum* may also be lipase positive and require additional testing (see procedures 4.8 and 4.9).
4. *B. wadsworthia* grows in 20% bile and forms small colonies on BBE in 3 to 4 days that are clear with black centers, resembling "fish eyes" (2) (Table 4.10-6).
5. *S. wadsworthensis* is tolerant to the bile disk but is urease and catalase negative (Table 4.10-6).

☑ **NOTE:** An unusual characteristic of *S. wadsworthensis* is that it apparently does not grow in 20% bile broth or on BBE medium.

E. Lipase

1. Lipase (egg yolk agar plate) (see procedure 4.6) can be combined with rapid tests to aid identification of pigmented *Prevotella* spp., *Porphyromonas* spp., and *Fusobacterium* spp.
2. An indole- and lipase-positive coccobacillus that produces black-pigmented or brick red fluorescent colonies is identified as a member of the *P. intermedia/nigrescens* group (Table 4.10-4).
3. A lipase-positive, indole-negative pigmented gram-negative rod may be identified as *Prevotella loescheii* (Table 4.10-4).
4. An indole- and lipase-positive isolate with a fusobacterium special-potency antimicrobial agent disk pattern is identified as *F. necrophorum* (Table 4.10-1). Lipase-positive strains of *F. necrophorum* will usually be beta-hemolytic (16).

F. Other rapid tests, spot tests, or enzymatic tests

Other rapid tests, spot tests, or enzymatic tests may be helpful in the identification of anaerobic gram-negative rods (see procedure 4.6 for more information) (11, 12, 16).

POSTANALYTICAL CONSIDERATIONS

VII. DEFINITIVE IDENTIFICATION

Use the appropriate figure or table to determine additional tests required for identification of an isolate (see also procedures 4.7 to 4.9). The definite identification of some species requires certain additional biochemical tests beyond the scope of this procedure, such as PRAS biochemicals, metabolic end product analysis, genetic analysis, and/or whole-cell fatty acid profiling by GLC (see CMPH 2.6 and 2.7 and references 6, 12, and 16). Even in some research or reference laboratories, a number of anaerobic gram-negative strains will not be identified completely. Clinicians usually want to know if anaerobes are present. The choice of antimicrobial agents is usually empirical. Persistent resistance to therapy may lead to requests for antimicrobial susceptibility testing. Periodic antimicrobial profiles of the most common anaerobic isolates should be conducted and broadcast to the medical community.

APPENDIX 4.10-1

Gram stain and colony morphology of common anaerobic gram-negative rods^a

Organism	Gram stain morphology	Colony morphology
<i>Bacteroides fragilis</i> group	Gram-negative coccobacilli or straight rods with variable length. Some cells are pleomorphic or contain vacuoles.	Circular, entire, gray to white, 2- to 3-mm-diam colony that is shiny and smooth on primary blood agar media. Good growth on BBE: >1.0-mm-diam colonies that are circular, entire, and convex, usually surrounded by a dark gray zone or brown to blackening of medium caused by esculin hydrolysis. <i>Bacteroides vulgatus</i> grows on BBE but is esculin negative.
<i>Bacteroides ureolyticus</i> group	Gram-negative coccobacilli or short rods. Some cells are in filaments.	Circular to slightly umbonate; some are gray-white; others produce spreading or swarming growth that forms a depression in the agar. Pitting is best observed if the plate surface is at a 45° angle.
<i>Bilophila wadsworthia</i>	Gram-negative, pleomorphic to straight, short rods.	Small gray colonies within 3 to 4 days on BAP. Growth on BBE: clear colonies with black centers, "fish eye."
<i>Fusobacterium</i> spp.	Gram-negative uneven staining, pleomorphic, coccoid, and rod-shaped cells. Some cells have rounded ends.	Circular, flat to convex colonies with >1-mm diam. Usually gray-white translucent to shiny colony.
<i>Fusobacterium necrophorum</i>	Gram-negative fairly large cells, usually pleomorphic. Rounded-end cells.	Circular, convex colonies with >1- to 2-mm diam. Gray-white to shiny translucent colonies.
<i>Fusobacterium nucleatum</i>	Pale staining, thin gram-negative cells with sharply pointed or tapered ends; spindle-shaped rods; some may have swellings.	Small colonies, usually with <1-mm diam. Circular to slightly irregular; some strains produce rough breadcrumb colonies. Some strains have "flecked" or "ground-glass" appearance. Most strains when exposed to oxygen produce greenish discoloration of the blood agar under the colony.
<i>Porphyromonas</i> spp.	Short gram-negative rods; some shorter spherical cells are seen.	Small colony, circular, convex, light gray after 48 h; 6 to 10 days is required for black color. No growth on LKV.
<i>Prevotella</i> spp. (pigmented or non-pigmented)	Gram-negative rods, some short; some coccobacillus forms.	Circular, convex colony with about 1- to 2-mm diam. Gray to slightly shiny. Growth on LKV. Some species form a brown-tan to black pigment in 5 to 10 days.

^a LKV, laked kanamycin-vancomycin agar.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Anaerobic gram-positive bacilli of human clinical relevance are divided into two distinct groups: one genus of sporeformers (*Clostridium* spp.) and five genera of non-sporeformers (*Actinomyces*, *Bifidobacterium*, *Eubacterium*, *Lactobacillus*, and *Propionibacterium*). Another gram-positive nonsporeforming bacillus, *Mobiluncus*, is not commonly recovered from clinical specimens and its pathogenicity is not well understood (4). The anaerobic gram-positive bacilli are part of the normal microbiota of the oral cavity, gastrointestinal and genitourinary tracts, and skin.

Currently there are known to be 130 species of clostridia. Fortunately for the

clinical microbiologist, the percentage of clostridial isolates commonly recovered in properly collected specimens is relatively small (1, 2, 4). *Clostridium perfringens* is the most common clostridial isolate, followed by *Clostridium clostridioforme*, *Clostridium innocuum*, and *Clostridium ramosum* (2, 4, 5). *Clostridium* species can cause acute, severe, or chronic infections. Some *Clostridium* spp. are highly pathogenic or toxigenic, while others are rarely pathogenic. Some species are resistant to antimicrobial agents. The nonsporeformers are infrequently clinically significant and they cause chronic disease. *Many of*

these nonsporeformers are resistant to metronidazole (1).

Identification of the anaerobic gram-positive bacilli can be a challenge for the clinical microbiologist (1–5). In many instances the use of prereduced anaerobically sterilized (PRAS) biochemicals, GLC, and fatty acid analysis is necessary. A great source of confusion is the fact that many *Clostridium* spp. and occasionally the nonsporeforming genera can stain gram negative. The use of the special-potency antimicrobial agent disks can help resolve this problem (*see procedure 4.6*).

II. SPECIMEN

- A. Pure isolates of anaerobic gram-positive bacilli on brucella agar with 5% sheep blood or on other enriched media are used for various tests, for inoculum preparation, and for biochemical identification systems (*see procedures 4.6, 4.8, and 4.9*).
- B. Perform aerotolerance testing.
- C. There are a few aerotolerant strains of clostridia (*Clostridium tertium*, *Clostridium carnis*, *Clostridium histolyticum*, and an infrequent strain of *C. perfringens*), as well as a few aerotolerant strains of nonsporeforming bacilli (*Actinomyces* spp., *Lactobacillus* spp., and *Propionibacterium* spp.). Additional testing to determine their physiological requirements for oxygen may be necessary (3, 4).

III. MATERIALS

Include QC information on reagent container and in QC records.

- A. **Reagents, media, and supplies**
 1. PRAS brucella agar with 5% sheep blood supplemented with vitamin K and hemin or other suitable enriched agar media (*see procedure 4.3*)
 2. CHOC plates
 3. PRAS egg yolk agar plates
 4. PRAS chopped meat-carbohydrate
 5. Identification disks: nitrate
 6. Special-potency antimicrobial agent disks: kanamycin, 1,000 µg; vancomycin, 5 µg; colistin, 10 µg

ANALYTICAL CONSIDERATIONS

IV. PROCEDURE

A. Day 1

1. Pick colony of anaerobic gram-positive rod from brucella sheep blood agar or other suitably enriched media and subculture to the following.
 - a. Chopped meat-carbohydrate for spore test and GLC (if necessary) and as a backup medium
 - b. Egg yolk agar for detection of lipase and lecithinase
 - c. Brucella sheep blood agar with nitrate, kanamycin, vancomycin, and colistin disks
 - d. CHOC in CO₂ for aerotolerance
2. Gram stain colony for specific characteristics and record results (see Appendix 4.11-1, Fig. 4.11-1, and Table 4.11-1).
 - a. If organism is pleomorphic and diphtheroidal, do indole and catalase tests. If both tests are positive, report *Propionibacterium acnes*.
 - b. If cells are large, gram-positive bacilli arranged in pairs as “boxcars” and if the colony produces a double zone of hemolysis on blood agar, report as *C. perfringens* (1 to 2 h of refrigeration will develop the zone of hemolysis).
 - c. If spores are seen and the cells are not large boxcar type, report *Clostridium* sp. but not *C. perfringens*.
3. Wet mount for motility
Nonmotile anaerobic gram-positive rods are *C. perfringens*, *C. ramosum*, *C. innocuum*, and nonsporeformers (exceptions are *Lactobacillus* and rare *Eubacterium* spp.).
4. Catalase
Propionibacterium and *Actinomyces viscosus* are positive.

B. Day 2 (or when adequate growth is achieved)

1. Examine brucella sheep blood agar plate.
 - a. Record results with kanamycin, vancomycin, colistin, and nitrate disks.
 - b. Record colonial morphology (see Appendix 4.11-1).
 - c. Record odor. *Clostridium difficile* smells of horse barn, and *P. acnes* has a strong odor of tryptophan.
2. Examine egg yolk agar plate.
Record lecithinase and/or lipase reaction (Fig. 4.11-2).
3. Stain chopped meat-carbohydrate.
 - a. Gram stain, and look for spores. If spores are present, record their presence and locations.
 - b. Spore stain can also be used (4).

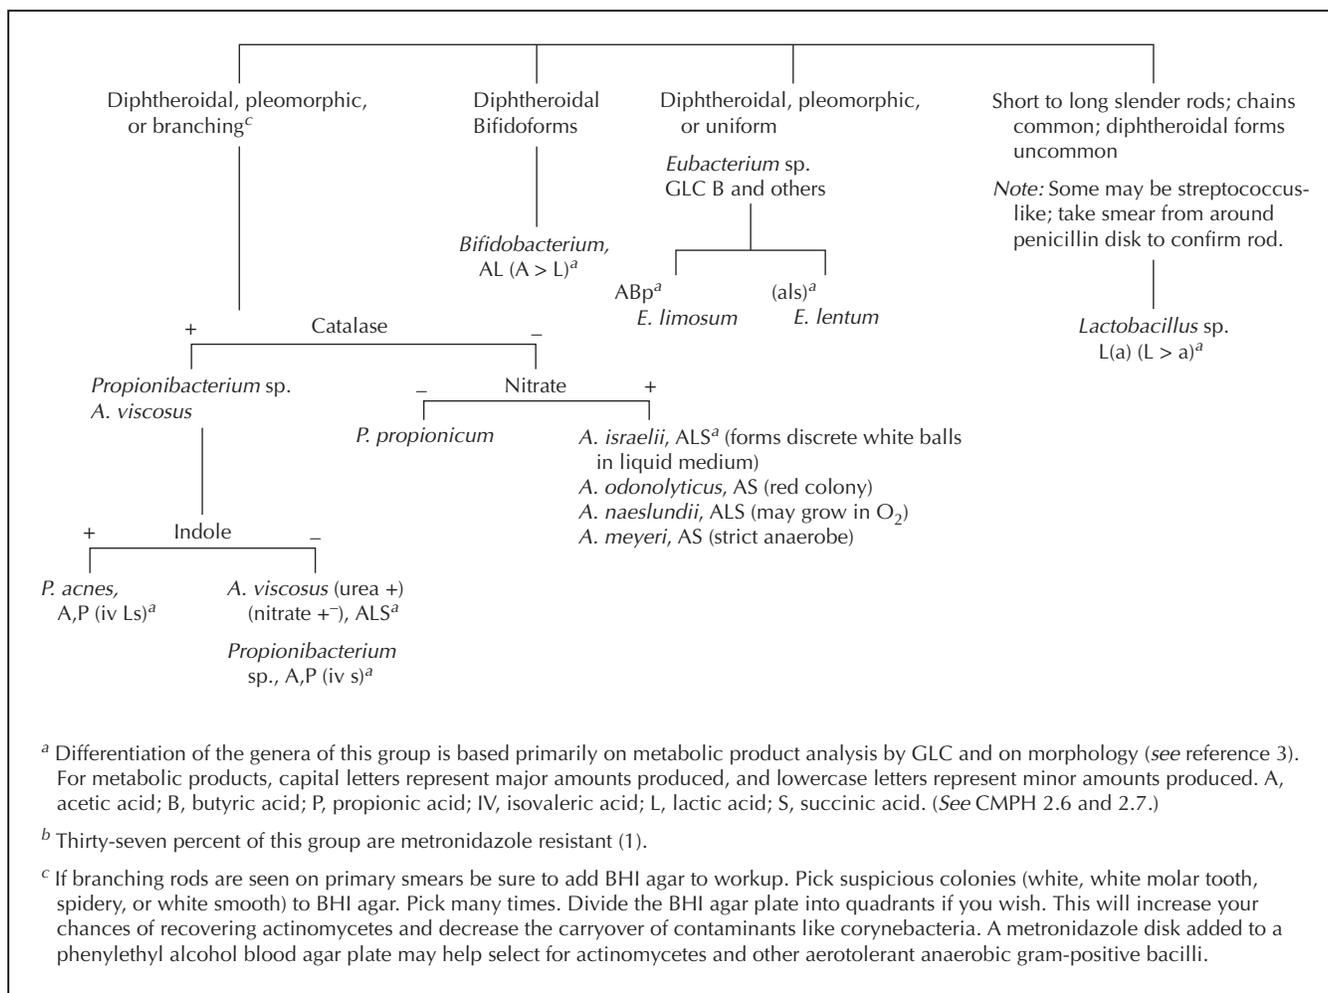

Figure 4.11-1 Non-spore-forming (i.e., no spores detected) gram-positive rods.^{a,b}

IV. PROCEDURE (continued)

4. Perform indole, fluorescence, and urea tests. Use cycloserine cefoxitin fructose agar (CCFA) as needed (see procedure 4.3).
5. Observe for swarming. *Hint:* This can be difficult at times to confirm. Drag loop or stick on medium to observe for presence of growth.

C. Days 3 to 5

Perform spore test if needed (2, 3, 5).

V. IDENTIFICATION

A. Clostridium spp.

See Appendix 4.11-1 and Fig. 4.11-3 for Gram stain and colonial characteristics of species. See Table 4.11-1 for cost-effective identification tips for commonly isolated Clostridium spp.

1. Vegetative cells rod shaped, can vary from coccoid to filamentous
2. Obligate anaerobes (majority)
Exceptions (will grow on CHOC in air) are C. carnis, C. histolyticum, and C. tertium.
3. Gram positive (most)
Exceptions (sometimes appear as gram negative) are Clostridium clostridioforme, C. ramosum, and Clostridium tetani (by time of spore formation).

Table 4.11–1 Cost-effective identification tips for the commonly recovered *Clostridium* spp.

Species	Spore location ^a	Swarming	Indole	Lecithinase	Fluorescence	Double zone of hemolysis	Urease	Yellow colonies, on CCFA	Gram stain morphology
<i>C. perfringens</i>	Not seen	–	–	+	–	+	–	–	Boxcar; spores not seen
<i>C. clostridioforme</i>	ST	–	–	–	–	–	–	–	Usually gram negative; football-shaped cells
<i>C. innocuum</i>	T	–	–	–	+, chartreuse	–	–	–	Small cells, terminal spores
<i>C. ramosum</i>	T	–	–	–	+, red	–	–	–	Usually gram negative; thin, round, terminal spores
<i>C. bifermentans</i>	ST	–	+	+	–	–	–	–	Large cells, subterminal spores in chains
<i>C. difficile</i>	ST	–	–	–	+, chartreuse	–	–	+	Long, thin cells; oval spores
<i>C. sordellii</i>	ST	– ^b	+	+	–	–	+	–	Straight cells, central to subterminal spores
<i>C. septicum</i>	ST	+	–	–	–	–	–	–	Long, thin cells; pleomorphic; oval spores

^a +, positive; –, negative; ST, subterminal; T, terminal.

^b *C. sordellii* may form large, spreading colonies.

V. IDENTIFICATION (continued)

4. Motile

Exceptions are *C. perfringens*, *C. ramosum*, and *C. innocuum*.

5. Catalase is generally not produced. If it is produced, it will be weak and in small amounts.

6. Most commonly encountered in infection: *C. perfringens*

7. Since aerotolerant clostridia (*C. tertium*, *C. carnis*, *C. histolyticum*) can show growth on solid media incubated in 5 to 10% CO₂, it is possible to confuse them with certain facultatively anaerobic *Bacillus* species. However, members of the genus *Clostridium* usually form spores only under anaerobic conditions and almost never produce catalase, whereas *Bacillus* species will form spores under aerobic or anaerobic conditions and are catalase positive.

8. Some species are obligate anaerobes, such as *Clostridium haemolyticum* and *Clostridium novyi* type B, and will not grow when exposed to even trace amounts of oxygen.

9. Swarming or spreading clostridia (*C. tetani*, *Clostridium septicum*, *C. sordellii*) can be differentiated by spore location, indole, and urease production.

10. An organism that produces a horse barn smell, produces yellow “ground-glass” colonies on CCFA, and fluoresces chartreuse is *C. difficile*.

11. *C. ramosum* is a thin, gram-variable rod that has a small round or oval terminal spore. It can commonly be misidentified as a gram-negative rod.

Hint: When in doubt, perform special-potency disk procedure and observe for an oval terminal spore often appearing as a blue dot.

B. Gram-positive non-spore-forming bacilli

See Fig. 4.11–1 and Appendix 4.11–1 for more details. These bacilli include *Actinomyces*, *Bifidobacterium*, *Eubacterium*, *Lactobacillus*, and *Propionibacterium* spp.

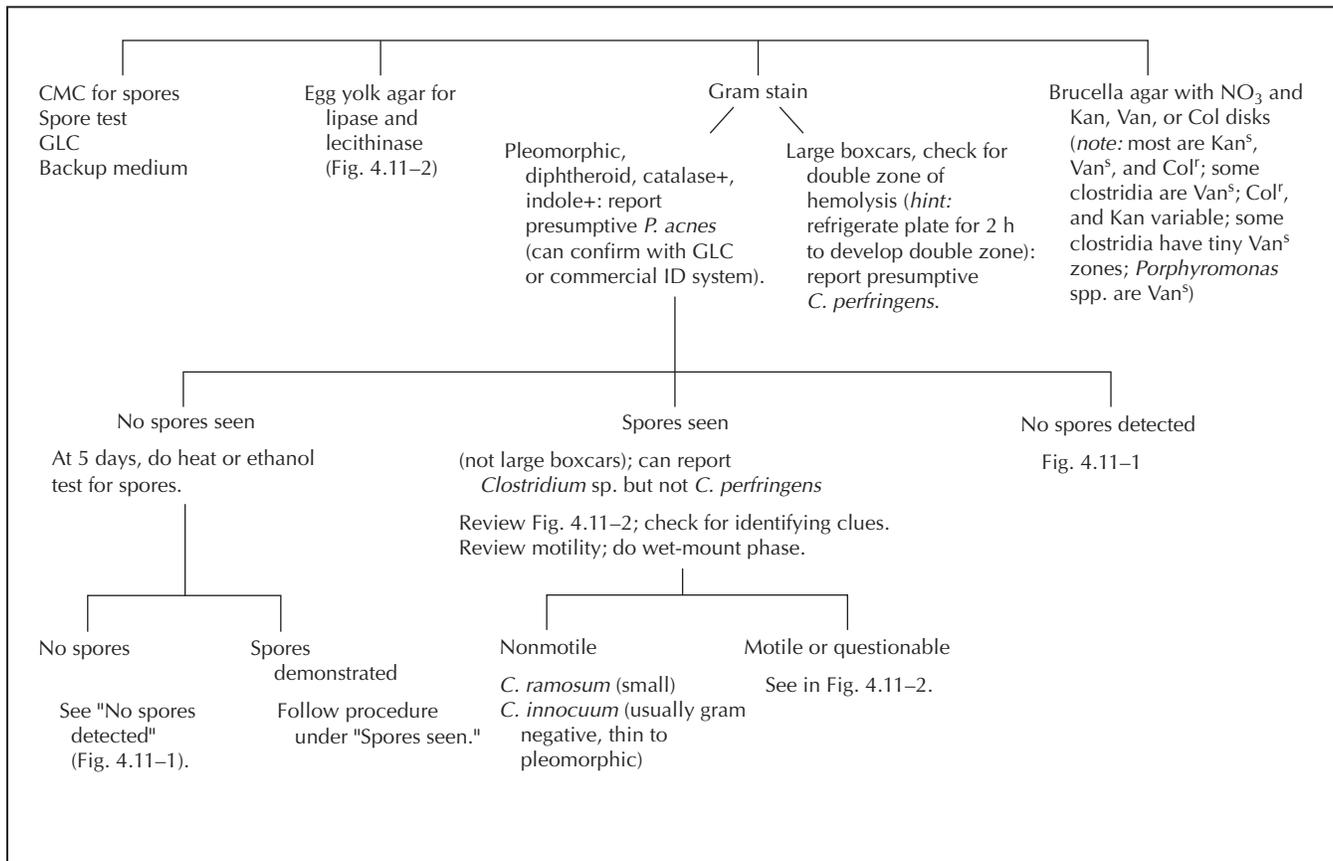

Figure 4.11-3 Procedure for identification of pure-colony anaerobic gram-positive bacillus from brucella or other agar. Refer to previous sections for details on collection, isolation, culture, and examination of plates and on obtaining pure colonies of anaerobic gram-positive rods. CMC, chopped meat-carbohydrate; ID, identification; Kan, kanamycin; Van, vancomycin; Col, colistin; r, resistant; s, susceptible.

V. IDENTIFICATION (continued)

6. A clubbing, palisading, gram-positive bacillus that is indole positive, nitrate positive (usually), and catalase positive is *P. acnes*.
7. A small, straight-sided gram-positive bacillus that is nitrate positive and fluoresces red under UV light (366 nm) is *Eubacterium lentum*.

■ **NOTE:** Other non-spore-forming, anaerobic gram-positive rods may be isolated. At times, they are part of a mixed microbiota in which the other anaerobes and nonanaerobes are usually more important, and at other times, they represent contamination of a specimen with a normal microbiota.

VI. REPORTING RESULTS

- A. Rapid presumptive reporting to the physician can be extremely valuable. In some situations, the identification to the genus and species levels of an anaerobic gram-positive rod may take a number of days because of the time required to detect spores or because slow growers take a long time to form end products for GLC. Therefore, it is essential that preliminary results from rapid tests, Gram stains, etc., be reported as promptly as possible.
- B. Reports of results should include the following.
 1. Organized report form with a clear format
 2. Rapid reporting of Gram stain and other preliminary tests

VI. REPORTING RESULTS
(continued)

3. Legibility on workcards (especially important if more than one technologist is reporting results); clear entries if computer is used
4. Telephone calls to the physician or ward about Gram stains and preliminary results with sterile body fluids or growth in blood cultures, CSF, or any sterile body fluid or tissue
5. Telephone calls to the physician or ward of any abnormal results
6. Documentation of information relayed by telephone
7. Method of flagging abnormal results
8. Interpretation of any results that might be confusing

POSTANALYTICAL CONSIDERATIONS

VII. PROCEDURE NOTES

- A. Confirm aerotolerance testing of isolate. Some *Clostridium* spp. grow aerobically and may be confused with *Bacillus* spp. (see procedure 4.4; more details are within this procedure as well).
- B. Confirm purity of all isolates (see procedure 4.4).
- C. Confirm Gram stain reaction (see procedures 4.2 and 4.4).
- D. Confirm presence of spores. Do not confuse spores with vacuoles. There will be one spore per cell in the same location in every cell. Vacuoles (one or more) appear in various locations within the cell.
- E. Confirm motility. Do not confuse Brownian movement with motility.
- F. Confirm that you have a bacillus. Look at a Gram-stained sample taken from around a penicillin disk on a plate where your organism is growing. A rod elongates and sometimes takes on long, bizarre shapes; cocci remain coccal.

Gram stain and colonial characteristics of anaerobic gram-positive bacilli

Organism	Gram stain characteristics ^a	Colonial characteristics
<i>Actinomyces israelii</i>	Long, thin; some branching, some club shaped	Rough, "molar tooth" after 5-7 days; can be smooth, white; slow growth (note: white, crumblike molar tooth best seen on BHI agar)
<i>A. meyeri</i>	Diphtheroidal; may be branching	Smooth, white (note: strict anaerobe)
<i>A. naeslundii</i>	Long, thin; many short branches	White, smooth or rough, raised irregular; tan pigment on older colonies; rapid growth
<i>A. odonolyticus</i>	Diphtheroidal, branching	Smooth; may have pink-red pigment
<i>A. viscosus</i>	Diphtheroidal, branching	Smooth; rapid growth
<i>P. propionicum</i>	Diphtheroidal, branching	Rough; slow growth
<i>Bifidobacterium dentium</i> (formerly <i>B. eriksonii</i>)	Short, thick, with clubbed or bifurcated ends	White, smooth, glistening, convex with irregular edge; rapid growth; aerotolerant

(continued)

APPENDIX 4.11–1 (continued)

Gram stain and colonial characteristics of anaerobic gram-positive bacilli (continued)

Organism	Gram stain characteristics ^a	Colonial characteristics
<i>Clostridium baratii</i>	Large, with blunt ends; nonmotile; spores (ST) rarely seen	No hemolysis
<i>C. bifermentans</i>	Large, motile, oval (ST) spores in chains	Gray, irregular edge; narrow zone of hemolysis (note: chalk white on egg yolk agar)
<i>C. botulinum</i>	Large, motile, spores (ST)	Variable hemolysis
<i>C. butyricum</i>	Round or blunt ends, motile, large oval (ST) spores	Nondescript
<i>C. cadaveris</i>	Motile, oval (T) spores	
<i>C. clostridioforme</i>	Stains gram negative; elongated with tapered ends; football-shaped cells; spores rarely seen	Small, convex, translucent; mottled or mosaic surface
<i>C. difficile</i>	Relatively long, thin, motile, oval (T) spores readily seen; horse barn or stable odor	Slightly raised; umbonate with filamentous edge; translucent, with crystalline internal speckling; chartreuse fluorescence
<i>C. histolyticum</i>	Pleomorphic, motile, oval (ST) spores	Smooth and rough colonies; rough have flat edges with rhizoids; aerotolerant
<i>C. innocuum</i>	Small, nonmotile spores (T)	White, glossy, raised; chartreuse fluorescence
<i>C. novyi</i>	Medium, motile, oval (ST) spores	Gray, translucent; irregular surface; may swarm; double zone of hemolysis
<i>C. perfringens</i>	Large, blunt square ends; boxcar appearance; spores rarely seen, nonmotile	Gray, opaque; low, flat, somewhat rhizoid; tend to spread but not swarm; double zone of hemolysis
<i>C. ramosum</i>	Frequently gram negative; thin, pleomorphic, in chains with bulges; nonmotile; spores (T) round or oval, rarely seen	Translucent; circular or slightly irregular; entire; convex; red fluorescence
<i>C. septicum</i>	Long, thin, some oval; tend to be pleomorphic, sometimes producing long thin filaments; chain formation common; motile, oval (ST) spores	Medusa head-like growth becomes heavy film that covers plate; flat, gray, glistening, semitranslucent; markedly irregular to rhizoid margins
<i>C. sporogenes</i>	Oval (ST) spores, filamentous in older cultures, motile	Raised gray-yellow center, rhizoid edge; swarms; colonies adhere firmly to agar
<i>C. sordellii</i>	Straight, in singles and pairs; spores central to ST, cause slight swelling of cell; free spores often seen, motile	Translucent to opaque; flat or raised; can have mottled internal structure; swarms or spreads
<i>C. tertium</i>	Large oval (T) spores; sporulates only anaerobically; motile	Small, low, translucent, glossy; aerotolerant
<i>C. tetani</i>	Slender, motile, round (T) spores; tennis racket appearance	Translucent, gray; irregular edge; narrow zone of hemolysis
<i>Eubacterium lentum</i>	Short, coccoidal or diphtheroidal, pleomorphic; in short chains	Smooth, opaque; slightly irregular edge; aerotolerant; red fluorescence
<i>E. limosum</i>	Pleomorphic; in pairs and short chains	Translucent to white; entire edge; aerotolerant
<i>Lactobacillus catenaforme</i>	Pleomorphic; sometimes long, straight, and slender; often in long chains, some strepto-coccuslike	Slightly translucent; entire edge; aerotolerant
<i>Propionibacterium</i> spp.	Pleomorphic; club shaped, pointed ends	White to pink, shiny, opaque; entire edge; aerotolerant

^a Spore location: ST, subterminal; T, terminal.

4.12

Anaerobic Cocci

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The anaerobic cocci are a prominent part of the normal human microbiota of the skin, bowel, oral cavity, upper respiratory tract, and female genital tract. The anaerobic gram-positive cocci are important human pathogens; next to the anaerobic gram-negative bacilli they are the most commonly isolated anaerobes in clinically significant infections (1, 3, 4, 8). Anaerobic cocci are commonly isolated from patients with a wide variety of head and neck infections, including periodontitis, chronic otitis media, chronic sinusitis, brain abscesses, tuboovarian abscesses, perforated appendices, and peritonitis (3). Anaerobic

gram-negative cocci account for a very small percentage of the anaerobic cocci isolated from human specimens (1, 3, 7, 8).

The use of DNA composition, hybridization data, and cellular fatty acid profiles has permitted organisms that at one time were in the genus *Peptococcus* (except for *Peptococcus niger*) to be transferred to the genus *Peptostreptococcus* (2). Parenthetically, based upon genetic characteristics, there has been a recent proposal that *Peptostreptococcus magnus* be reclassified in a new genus, *Finegoldia*, as *Finegoldia magna*, and that *Peptostreptococcus micros* be reclassified in a new genus, *Mi-*

cromonas, as *Micromonas micros* (6). Since at the time of the editing of this handbook these have not been approved officially, they will not be used in this procedure.

Anaerobic cocci can be identified by Gram stain, colony morphology, rapid or spot tests, and various biochemical reactions and commercial systems. In some instances, prereduced anaerobically sterilized (PRAS) biochemicals, GLC, or fatty acid analysis may be necessary (7). Rarely recovered strains, or strains from animal origin, are not described in this procedure.

II. SPECIMEN

- A. Appropriate specimens should be transported to the laboratory using an anaerobic transport system because anaerobic cocci are very susceptible to the toxic effects of oxygen (*see* procedure 4.2).
- B. Pure cultures of anaerobic cocci on brucella agar with 5% sheep blood or on other nonselective enriched media with 5% sheep blood are used for various rapid tests and for the commercially available rapid enzymatic biochemical identification kits (*see* procedures 4.6, 4.8, and 4.9).

III. MATERIALS

Include QC information on reagent container and in QC records.

Reagents, media, and supplies

Perform and record QC as required. Include expiration date on label.

- A. 5% Sheep blood brucella agar supplemented with vitamin K (menadiolone) and hemin
- B. CHOC plates for aerotolerance testing
- C. Disposable loops and needles
- D. Gram stain reagents (*see* procedure 4.4)
- E. Special-potency antimicrobial agent disks: colistin, 10 µg; vancomycin, 5 µg; and kanamycin, 1,000 µg (*see* procedure 4.6)
- F. Identification disks: sodium polyanethol sulfonate (SPS) and nitrate (*see* procedure 4.6)
- G. Spot indole reagents (*see* procedure 4.6)
- H. Rapid biochemical tests and commercial rapid enzymatic biochemical identification kits (*see* procedures 4.8 and 4.9)

ANALYTICAL CONSIDERATIONS

IV. PROCEDURE**A. Day 1**

The first day that workable colonies are seen on the primary brucella agar is considered day 1.

1. Pick one colony from the primary brucella agar, and subculture it to PRAS brucella agar or other suitable media.
2. Streak the first quadrant of the subculture brucella agar to ensure heavy growth. Streak the other quadrants for isolation.
3. If the Gram stain reveals gram-positive cocci, place SPS and nitrate disks. Many anaerobic gram-positive cocci do not always stain as gram-positive cocci; therefore, the addition of the special-potency disks is useful for establishing the true Gram stain reaction of those microorganisms (*see* procedure 4.6).
4. Pick the same colony (*see* step IV.A.1) and subculture it to CHOC for aerotolerance testing. Incubate the plate at 35°C in 5% CO₂ for 24 h.
5. Pick the same colony and make a smear for Gram stain if not previously performed.
6. Document the description of colony morphology, Gram stain reaction, and all work performed on the anaerobe worksheet.
7. If the original colony is too small, the aerotolerance testing and Gram stain can be done on day 3 by using growth from the brucella agar subculture plate.
8. If using bags, pouches, or jars, leave primary isolation plates for 48 h.

B. Day 2

1. Examine the CHOC aerotolerance plate. Growth on CHOC indicates that the organism is not an anaerobe. There is no need to proceed with its anaerobic identification.
2. If there is no growth on the CHOC aerotolerance agar, incubate the plate for another 24 h.
3. Examine the brucella agar if the anaerobic incubation system is a chamber. If there is good growth, proceed to read biochemical tests.

C. Day 3

1. Examine the CHOC again to confirm that the organism is an anaerobe.
2. Examine the brucella agar incubated on day 1. If there is good growth, proceed to read the potency disk results.
3. If the organism is a gram-negative coccus, perform the nitrate test and see Fig. 4.12–1 for presumptive identification (*see* procedure 4.10).
4. If the organism is a gram-positive coccus, read SPS result and nitrate test and proceed according to Fig. 4.12–1 and Table 4.12–1.
5. Perform spot indole and/or rapid urease test if necessary (*see* procedure 4.6).
6. If the organism cannot be identified by rapid tests, proceed to set up rapid biochemical spot tests or rapid enzymatic biochemical kits (*see* procedures 4.8 and 4.9). In some instances the definitive identification of anaerobic gram-positive cocci must be performed using the aid of chromatographic analysis of metabolic fatty acids (5).

V. RESULTS**A. Colony morphology** (*see* Table 4.12–1)

1. Growth of anaerobic cocci is usually slower than that of *Bacteroides* or *Clostridium* spp. Small colonies are not apparent on brucella agar until 48 h of incubation. However, *Peptostreptococcus anaerobius* can produce growth within 24 h of incubation.

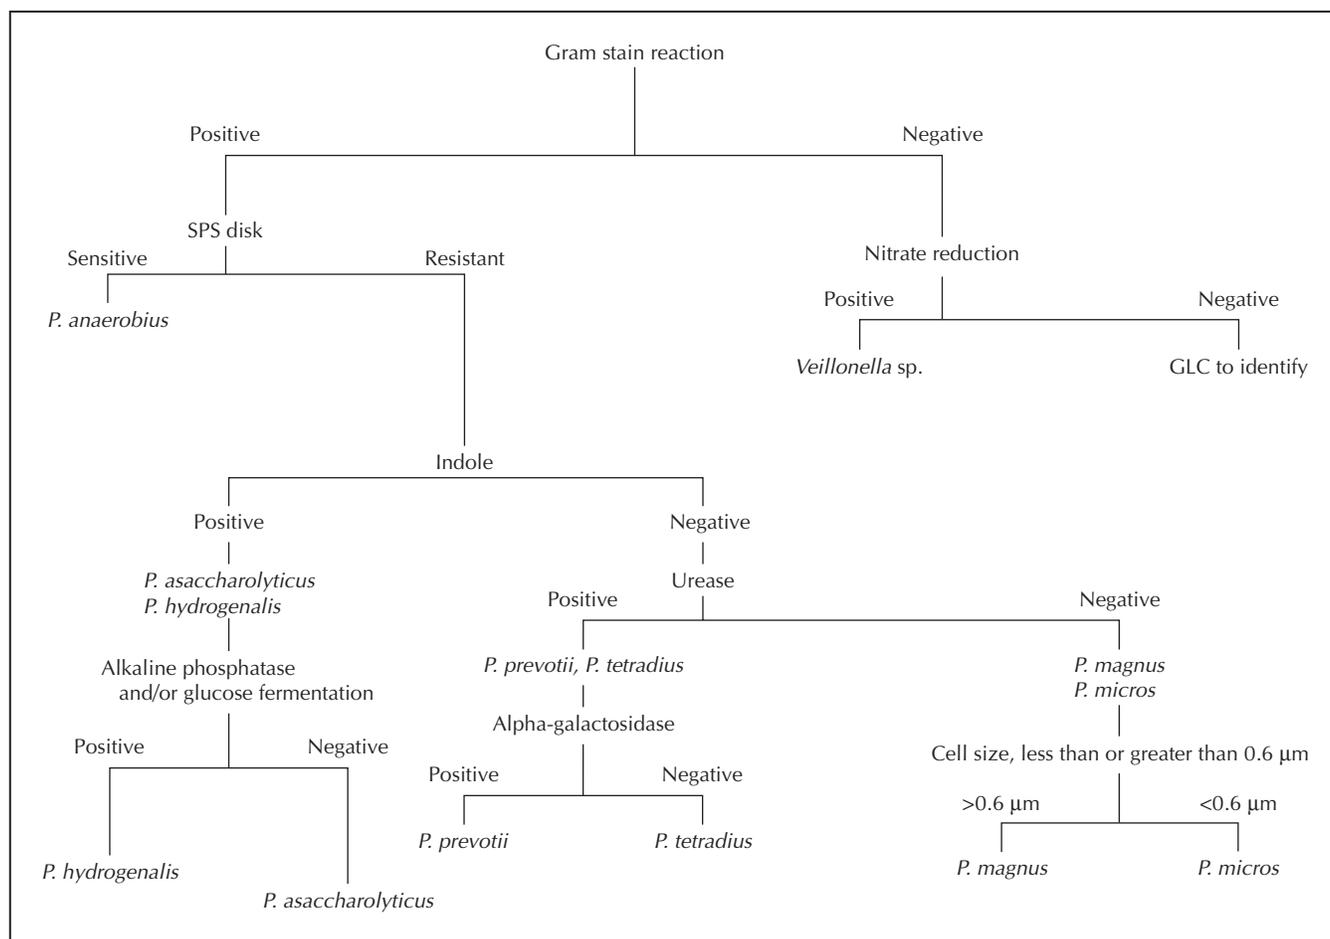

Figure 4.12–1 Flowchart for identification of anaerobic cocci.

Table 4.12–1 Characteristics of commonly recovered *Peptostreptococcus* spp.^a

Species	Indole	SPS	Urease	Glucose fermentation	Alk phos ^{b,c}	Alpha-galactosidase	Gram stain and plate morphology characteristics
<i>P. anaerobius</i>	–	+	–	+	–	–	Cells often in chains, large colonies (>1 mm), nonhemolytic. Pungently sweet odor.
<i>P. asaccharolyticus</i>	+	–	–	–	–	–	Cells in irregular clumps, pairs, or tetrads. Colonies are small, slightly yellow pigment.
<i>P. hydrogenalis</i>	+	–	V	+	+	–	Cells in short chains or masses. Small colonies, nonhemolytic.
<i>P. magnus</i>	–	–	–	–	V	–	Cells are large (>0.6 μm), in pairs, tetrads, or clusters. Small colonies, nonhemolytic, raised, and smooth.
<i>P. micros</i>	–	–	–	–	+	–	Cells in clusters or short chains. Small colonies, convex, dull color.
<i>P. prevotii</i>	–	–	+	–	– ^w	+	Cells in clumps or tetrads. Small colonies.
<i>P. tetradius</i>	–	–	+	+	–	–	Cells are small, in pairs, tetrads, or short chains. Small colonies.

^a Rarely recovered or animal strains are not listed. +, positive; –, negative; –^w, most strains are negative, with some weak; V, variable.

^b Tested by API Zym, Rosco, and Wee-Tabs.

^c Alk phos, alkaline phosphatase.

V. RESULTS (*continued*)

2. Colonies of gram-positive cocci are small, convex, grayish white, and opaque. The edge of the colony is entire, and the surface may appear stippled or pockmarked. Colony diameter is usually <0.5 to 2 mm. Other specific clues are as follows.
 - a. Colonies of *P. magnus* are minute to 0.5 mm in diameter, raised, dull, smooth, and nonhemolytic.
 - b. Colonies of *P. micros* are minute to 1 mm, convex, and dull.
 - c. Colonies of *P. anaerobius* are usually somewhat larger (1 mm) and on good media can appear in 24 h. The colonies are nonhemolytic, gray to white, shiny, and opaque. Often the colonies have a pungently sweet (cantaloupe-like) odor.
 - d. Colonies of *Peptostreptococcus asaccharolyticus* are minute to 2 mm and may have a slightly yellow pigment on blood agar.
3. *Veillonella* spp., the most commonly isolated gram-negative cocci, produce small, convex, translucent to transparent colonies with entire edges. These colonies may show red fluorescence under long-wave UV light (Wood's lamp, 366 nm).

B. Gram stain morphology (*see* Table 4.12-1)

1. There are no unique microscopic characteristics to differentiate anaerobic cocci from facultatively anaerobic cocci. Some peptostreptococci may resemble staphylococci microscopically. The presence of staphylococcal forms on direct Gram stain with no staphylococci recovered aerobically may suggest a *Peptostreptococcus* sp. (1, 4, 7, 8).
2. Microscopically, the gram-positive cocci are usually more consistent, although some coccobacillary forms exist and other clues may be helpful.
 - a. Anaerobic gram-positive cocci do not always stain as gram-positive cocci.
 - b. *Peptostreptococcus productus* and *P. anaerobius* may be elongated and resemble gram-positive coccobacilli.
 - c. *P. magnus* has cells that are 0.7 to 1.2 μm in diameter and appear in a tightly packed arrangement or in masses.
 - d. *P. micros* has cells that are smaller, 0.3 to 0.7 μm in diameter, and that usually form short chains. Generally, *P. magnus* and *P. micros* can often be differentiated on the basis of cell size.
 - e. *P. anaerobius* has cells that are 0.5 μm in diameter and that are often elongated and in long chains.
 - f. *P. asaccharolyticus* has cells that are 0.5 to 1.5 μm in diameter and are arranged in pairs, tetrads, or irregular clumps.
 - g. *Peptostreptococcus prevotii* has cells that are 0.6 to 0.9 μm in diameter that occur in tetrads, irregular groups, and occasionally in short chains of 6 to 8 cells.
3. *Veillonella* spp. are <0.5 μm in diameter and are usually seen in clusters or masses and occasionally as diplococci.

C. Special-potency disks (*see* procedure 4.6)

1. If the Gram stain reaction of the organism is difficult to interpret, gram-positive anaerobes can be separated from gram-negative anaerobes by their susceptibility to the vancomycin special-potency antimicrobial agent disk and their resistance to the colistin special-potency antimicrobial agent disk. The susceptibility pattern is the opposite for gram-negative anaerobes.
2. Susceptibility to SPS is a unique characteristic of *P. anaerobius*.
■ **NOTE:** *P. micros* may produce small zones around SPS disk (*see* procedure 4.6).

D. Spot indole (*see* procedure 4.6)

P. asaccharolyticus and *Peptostreptococcus hydrogenalis* are spot indole positive (*see* Fig. 4.12-1 and Table 4.12-1 for separation). *P. asaccharolyticus* is alkaline phosphatase negative, whereas *P. hydrogenalis* is positive for alkaline phosphatase. *Peptostreptococcus indolicus* is also indole positive and alkaline

V. RESULTS (continued)

phosphatase positive, but it is rarely isolated from clinical specimens and is not described in this procedure (7, 8).

E. Rapid nitrate and urease tests (see procedure 4.6)

1. *Veillonella parvula*, the only anaerobic gram-negative coccus of clinical significance, reduces nitrate (1, 7, 8).
2. Most clinically significant anaerobic gram-positive cocci are nitratase negative (4, 5).
3. *P. prevotii* and *Peptostreptococcus tetradius* can both produce urease. These organisms can be separated by glucose fermentation and alpha-galactosidase. *P. prevotii* is glucose fermentation negative and alpha-galactosidase positive, whereas *P. tetradius* is glucose fermentation positive and alpha-galactosidase negative (see Table 4.12-1).

F. Rapid enzymatic biochemical identification (see procedure 4.8)

1. Rapid spot and commercially available enzymatic tests can be used to complete the identification if the tests described above fail to identify the organism. Depending upon the clinical need, in most instances a report of *Peptostreptococcus* spp., or a presumptive report using Fig. 4.12-1, may be satisfactory.
2. Many of the commercial identification systems described in procedure 4.8 can be used to identify strictly anaerobic *Streptococcus* spp. and other anaerobic gram-positive cocci which are not described in this procedure.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. Send a preliminary report to the physician as soon as the rapid-testing results are available. In some situations, the identification of the anaerobic isolate may be complete by this time.
- B. Send the preliminary or final report to the physician after results from further tests, if necessary, are available.
- C. Anaerobic isolates that cannot be identified by rapid tests and commercial rapid enzymatic identification systems may be reported as *Peptostreptococcus* or *Veillonella* spp. Consult with the requesting physician about the anaerobes recovered to ensure that results are clinically significant before pursuing definitive identification. Depending upon clinical need and specimen source, a presumptive or group level identification may be satisfactory for the physician to initiate therapy.
- D. Appendix 4.12-1 is an example of a report form.

5.1

Disk Diffusion Test

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

A standardized inoculum of bacteria is swabbed onto the surface of a Mueller-Hinton agar (MHA) plate. Filter paper disks impregnated with antimicrobial agents are placed on the agar. After overnight incubation, the diameter of the zone of inhibition is measured around each disk. By referring to the tables in the NCCLS disk diffusion standard (1), a

qualitative report of susceptible, intermediate, or resistant is obtained.

The NCCLS describes a standard method for disk diffusion testing of non-fastidious bacteria. The NCCLS also describes standardized procedures for testing *Haemophilus influenzae*, *Neisseria gonorrhoeae*, *Streptococcus pneumoniae*, and *Streptococcus* spp. The procedures for

these bacteria are similar to those for non-fastidious bacteria; however, the test media are supplemented with nutrients that will support the growth of these fastidious organisms. Any bacterium not addressed by the NCCLS in the disk diffusion standard should be tested by an MIC method if testing is required.

II. SPECIMEN

Prepare inoculum from four or five isolated colonies of similar colony morphology.

- A. For log-phase-growth inoculum: use colonies grown for 1 or 2 days on nonselective or selective (e.g., MAC) medium.
- B. For direct colony suspension inoculum: use colonies grown overnight on nonselective medium (e.g., BAP or CHOC).
- C. Subculture stock, frozen, or lyophilized isolates two times prior to testing.

III. MATERIALS

Include QC information on reagent container and in QC records.

A. Media and reagents

- 1. Agar plates (150 or 100 mm; depth, approximately 4 mm)
Store at 2 to 8°C.
 - a. MHA
 - b. MHA with 5% sheep blood (BMHA)
 - c. *Haemophilus* test medium (HTM)
 - d. GC agar base with defined supplements
- 2. Nutrient broth (e.g., Mueller-Hinton, TSB) or 0.9% NaCl (3.0- to 5.0-ml aliquots)
Store at 2 to 30°C.
- 3. Antimicrobial disks
Store with desiccant at -14 to 8°C.
 - a. To maintain activity of beta-lactam class antimicrobial agents, store at -14°C or below in a frost-free freezer. Once opened, discard after 1 week of refrigeration.

- b. Cefaclor, imipenem, and clavulanic acid combinations are the most labile drugs tested. Improved stability may be achieved by storing frozen until the day of testing.

B. Supplies

- 1. Sterile cotton tipped swabs
- 2. Sterile plastic pipettes
- 3. McFarland 0.5 turbidity standard

C. Equipment

- 1. Forceps
- 2. Ruler, template, or sliding caliper
- 3. Movable light source
- 4. Black nonreflecting surface (e.g., sheet of black paper or black counter surface)
- 5. Vortex mixer
- 6. 35°C ambient-air incubator; CO₂ incubation for some organisms (see Appendix 5.1-3)
- 7. Multidisk disk dispensing apparatus and container (optional)

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. QC strains** (*see* appendixes to this procedure for QC of specific fastidious organisms)
1. *Escherichia coli* ATCC 25922
 2. *Staphylococcus aureus* ATCC 25923
 3. *Pseudomonas aeruginosa* ATCC 27853
 4. *E. coli* ATCC 35218
 5. *Enterococcus faecalis* ATCC 29212
- B. Monitoring accuracy**
1. Test QC strains by following routine procedure, and record results in QC notebook. Record lot numbers and expiration dates of disks and agar. *See* Appendix 5.1-1.
 2. Compare to expected results (*see* NCCLS QC tables [1]). Note any out-of-control result and document; proceed with corrective action, if necessary.
- C. Daily QC testing**
1. Unless 30-day proficiency has been documented to reduce frequency of testing to weekly (*see* item IV.D), monitor performance of the test system by testing appropriate QC strains each day susceptibility testing is performed on patient isolates.
 2. QC testing is in control if, for each antimicrobial agent-organism combination, no more than 1 out of 20 consecutive results is outside acceptable range.
 3. If any more than 1 of 20 results is out of control, proceed with corrective action.
- D. Weekly QC testing**
1. Frequency of QC testing
 - a. QC testing can be reduced from daily to weekly providing a laboratory can document proficiency in performing this test by performing QC daily (or each day patient tests are performed) until results from 20 consecutive test days have been obtained.
 - b. Proficiency in performing QC testing is confirmed if for each antimicrobial agent-organism combination no more than 1 of 20 results are outside accuracy limits. Weekly QC testing may then be initiated.
 - c. If 2 or 3 results of the 20 are out of control, continue testing for a total of 30 days. If no more than 3 of 30 results are outside accuracy limits, proficiency is demonstrated, and weekly testing can be initiated.
 2. Weekly QC testing is in control if *all* zones are within specified accuracy limits. If any result is out of control, proceed with corrective action (*see* item IV.E).
 3. Document proficiency each time a new antimicrobial agent is added to testing protocols.
 - Save records documenting proficiency indefinitely.
 4. Perform QC testing each time a new lot or new shipment of agar or disks is put into use.
- E. Corrective action**
1. Out-of-control result due to obvious error (e.g., use of wrong disk, contamination, incorrect organism tested, inadequate incubation conditions, etc.) that can be easily corrected: record reason for out-of-control result and retest the same day. If the repeated result is in range, no further action is needed.
 2. Out-of-control result not due to obvious error
 - a. Test the involved antimicrobial agent(s)-QC strain combination for five consecutive test days. Record all results.

IV. QUALITY CONTROL*(continued)*

- b.** For each antimicrobial agent-QC strain combination, if all of the five zone diameters are within the acceptable QC range, weekly testing may be resumed.
- c.** If the problem is not resolved (at least one zone diameter is outside the accuracy control limits), continue daily QC testing until the problem is resolved.
- d.** Investigate possible procedural problems (e.g., review measurement of zones, standardization of inoculum, storage and expiration dates of reagents, incubation conditions, equipment, and maintenance and purity of control strain).
- e.** In order to return to weekly testing, satisfactory performance for another 20 or 30 consecutive days must be documented (as described in item IV.D. 1.b and c above).
- f.** During corrective action, carefully evaluate whether patient reports will be affected. It may be necessary to use an alternate test method until the problem is resolved.
- g.** See Appendix 5.1–2 for additional information regarding corrective action. (Refer to procedure 5.13 for maintenance of QC strains and additional measures for verifying results for bacteria isolated from patients.)

V. PROCEDURE

See Appendix 5.1–3 for summary of testing conditions for various organisms and Appendixes 5.1–4 to 5.1–7 for special procedures for testing *Haemophilus* spp., *N. gonorrhoeae*, *S. pneumoniae*, and *Streptococcus* spp. and testing for extended-spectrum beta-lactamase (ESBL) production in *E. coli* and *Klebsiella* spp.

- A.** Bring agar plates and canisters of disks to room temperature before use. Agar plates may be removed from refrigerator and placed in a 35°C ambient-air incubator with lids slightly ajar to evaporate excess moisture. Do not leave in incubator for longer than 30 min.
- B.** Inoculum preparation
Using a loop or swab, transfer colonies as follows.
 - 1.** Direct colony suspension method
Pick several colonies from a *fresh* (18- to 24-h) nonselective agar plate to broth or 0.9% NaCl.
 - 2.** Log-phase method
 - a.** Pick four or five isolated colonies to 3.0 to 5.0 ml of broth.
 - b.** Incubate at 35°C for 2 to 8 h until growth reaches the turbidity at or above that of a 0.5 McFarland standard.
 - 3.** For either the log phase or direct colony suspension method, vortex well and adjust turbidity visually with sterile broth or 0.9% NaCl to match a 0.5 McFarland standard (1×10^8 to 2×10^8 CFU/ml). Alternatively, standardize suspension with a photometric device.
 - 4.** Selection of inoculum preparation method
 - a.** Direct colony suspension
 - (1) Use for bacteria that grow slowly or unpredictably in broth.
 - (2) Always use for staphylococci.
 - (3) Use for any organism when fresh (18- to 24-h) growth is available.
 - b.** Log-phase or stationary-phase method
 - (1) Use for nonfastidious rapidly growing bacteria when fresh colonies are not available.
 - (2) If desired, use for nonfastidious rapidly growing bacteria when fresh growth is available.

V. PROCEDURE (*continued*)**C. Inoculation of agar plate**

1. Within 15 min of adjusting turbidity, dip a sterile cotton swab into the inoculum and rotate against the wall of the tube above the liquid to remove excess inoculum.
2. Swab entire surface of agar plate three times, rotating plate approximately 60° between streaking to ensure even distribution. Avoid hitting the sides of the plate to avoid aerosols. Finally, run swab around the edge of the agar to remove any excess moisture.
3. Allow inoculated plate to stand for 3 to 15 min before applying disks.

D. Application of disks

1. Apply disks to agar surface with dispenser or manually with a sterile forceps.
2. Apply gentle pressure with sterile forceps or needle to ensure complete contact of disk with agar (some dispensers do this automatically).
3. Do not place disks closer than 24 mm from center to center.
 - a. No more than 12 disks on 150-mm plate
 - b. No more than 5 disks on 100-mm plate
4. *Do not* relocate a disk once it has made contact with agar surface. Instead, place a new disk in another location on the agar.

E. Incubation

1. Invert plates and incubate within 15 min of disk application.
2. Incubate for 16 to 18 h at 35°C in an ambient-air incubator.
 - a. Incubate all staphylococci that are susceptible to penicillinase-stable penicillins (e.g., oxacillin) or to vancomycin after 16 to 20 h for an additional 4 to 8 h (total of 24 h).
 - b. Incubate all enterococci that are susceptible to vancomycin after 16 to 20 h for an additional 4 to 8 h (total of 24 h).

F. Reading plates

1. Read plates only if lawn of growth is confluent or nearly confluent.
2. Translucent media (MHA, HTM, GC agar)
 - a. Hold inverted plate a few inches above a black nonreflecting surface.
 - b. Illuminate plate with reflected light.
 - c. Use a sliding caliper or ruler held on the back of the plate to measure the diameter of inhibition zone to nearest whole millimeter.
 - d. For staphylococci with penicillinase-stable penicillins (oxacillin, methicillin, nafcillin) and vancomycin and for enterococci with vancomycin
 - (1) Use transmitted light; hold plate between your eye and light source.
 - (2) Examine closely; consider *any* growth as resistant.
3. Opaque media (BMHA)
 - a. Remove cover of agar plate.
 - b. Illuminate plate with reflected light.
 - c. Measure diameter of inhibition zone at agar surface to nearest whole millimeter.
 - d. When testing hemolytic organisms, measure the diameter of the zone of inhibition of growth and not the zone of inhibition of hemolysis.
4. Additional considerations
 - a. With the exception of staphylococci and enterococci, when reading vancomycin or oxacillin zones, always disregard minute colonies visible only by viewing with transmitted light or by examining with a magnifying device.
 - b. Disregard swarming of *Proteus* spp. and measure the edge of the obvious inhibition under the veil of swarming.
 - c. When measuring zones for sulfonamides, trimethoprim, or trimethoprim-sulfamethoxazole, disregard light growth (20% or less of lawn of growth) and measure edge of the more obvious margin of the zone.

V. PROCEDURE (continued)

- d. Discrete colonies growing within the inhibition zone may represent a mixed culture or resistant variants; subculture a single colony from the primary culture plate, reidentify, and retest for susceptibility. If the discrete colonies are still apparent, measure the colony-free inner zone.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

A. Interpretation

Use criteria specified by the NCCLS (1) to interpret the zones of inhibition for each antimicrobial agent.

B. Reporting

Report categorical result as either susceptible (S), intermediate (I), or resistant (R).

Example: *E. coli*

<u>Drug</u>	<u>Result</u>
Ampicillin	R
Cefazolin	S
Piperacillin	I
Gentamicin	S
Trimethoprim-sulfamethoxazole	S

C. Important reporting rules

1. Report methicillin-, oxacillin-, or nafcillin-resistant staphylococci as resistant to all beta-lactam antimicrobial agents (including beta-lactam–beta-lactamase inhibitor combinations, all cepheems, all penicillins, and carbapenems) regardless of results of in vitro susceptibility testing.
2. If test organisms require a nonstandardized method, add notation to report that susceptibility testing has been performed by a nonstandardized method (e.g., small-colony variant of *S. aureus* performed on BMHA, or if CO₂ incubation is used for organisms other than *Haemophilus* spp., *N. gonorrhoeae*, *S. pneumoniae*, or *Streptococcus* spp.).
3. Misleading results

Specific organism-antimicrobial agent combinations should not be reported, since susceptible results could be *dangerously misleading*:

 - a. First- and second-generation cephalosporins and aminoglycosides against *Salmonella* spp. and *Shigella* spp.
 - b. Cephalosporins, trimethoprim-sulfamethoxazole, clindamycin, and aminoglycosides (except for high-level disk testing for aminoglycosides) against enterococci
 - c. Beta-lactams against oxacillin-resistant *Staphylococcus* spp.
 - d. Cephalosporins, penicillins, and aztreonam against ESBL-producing *E. coli* and *Klebsiella* spp.

VII. PROCEDURE NOTES

A. Oxacillin (methicillin)-resistant staphylococci

1. Oxacillin is the recommended penicillinase-stable penicillin for testing, and oxacillin results can represent all penicillinase-stable penicillins (oxacillin, methicillin, and nafcillin and also cloxacillin, dicloxacillin, and flucloxacillin). Testing of oxacillin with staphylococci should be performed in cation-adjusted Mueller-Hinton broth (CAMHB) supplemented with 2% NaCl (other drugs should not be tested in 2% NaCl supplemented CAMHB).

VII. PROCEDURE NOTES*(continued)*

2. Clues to detection of methicillin (oxacillin)-resistant *S. aureus*
 - a. Multiple resistance to other antimicrobial agents (beta-lactams, aminoglycosides, erythromycin, clindamycin, and tetracycline). Recently, strains of oxacillin-resistant *S. aureus* that are not multiply resistant have been encountered among isolates from patients with community-acquired infections and nosocomial infections.
 - b. Presence of haze of growth within the zone of inhibition around an oxacillin, methicillin, nafcillin, or cephalothin disk

B. Materials**1. Disks**

Working supplies of disks (properly stored as described above) can be utilized for at least 1 week; verify acceptability by QC methods

2. Media

- a. Thymidine can interfere with performance of sulfonamides and trimethoprim. Monitor by testing *E. faecalis* ATCC 29212 and trimethoprim-sulfamethoxazole (zone of ≤ 20 mm indicates acceptable performance). Blood components (other than horse blood) contain thymidine and should not be used (except sheep blood for *S. pneumoniae* and *Streptococcus* spp. as described in this procedure).
- b. An increase in the cation content (Ca^{2+} , Mg^{2+}) of the medium results in decreased zone sizes with aminoglycosides and increased zone sizes with tetracycline for *P. aeruginosa*. A decrease in cation content has the opposite effect. Monitor cation content by testing aminoglycosides with *P. aeruginosa* ATCC 27853 and making sure results are within defined QC limits.
- c. Increased zinc ions may cause decreased zone sizes with carbapenems.
- d. Variation in calcium ions affects the results of daptomycin tests.

VIII. LIMITATIONS

- A. This method is standardized only for rapidly growing aerobes, including the *Enterobacteriaceae*, *P. aeruginosa*, *Acinetobacter* spp., *Staphylococcus* spp., and *Enterococcus* spp. Modifications have been made to standardize testing of some fastidious organisms, such as *Haemophilus* spp., *N. gonorrhoeae*, *S. pneumoniae*, and *Streptococcus* spp (see appendixes to this procedure). For other organisms an MIC test is recommended.
- B. Numerous factors can affect results, including inoculum size, rate of growth, formulation and pH of media, incubation environment and length of incubation, disk content and drug diffusion rate, and measurement of endpoints. Therefore, strict adherence to protocol is required to ensure reliable results.
- C. Emergence of resistance
Some bacteria may become resistant during antimicrobial therapy. Performing susceptibility testing on subsequent isolates after 3 or 4 days is recommended for the following.
 1. *Enterobacter*, *Citrobacter*, and *Serratia* for cephalosporins
 2. *P. aeruginosa* for all antimicrobial agents
 3. Staphylococci for quinolones
- D. Additional QA measures
Following recommended QC procedures alone does not guarantee prevention of reporting erroneous results for isolates from patient specimens. A mechanism to flag atypical results is an integral component of an effective QA program. A protocol for verification of unusual results should be included in the susceptibility testing procedures.

APPENDIX 5.1–1

Disk diffusion susceptibility testing QC (*see* p. 5.1.15)

APPENDIX 5.1–2

Troubleshooting guide for disk diffusion susceptibility testing^{a,b}

Aberrant result	Probable cause	Corrective action ^b	Effect on current day's reports
Tetracycline zone too large and clindamycin zone too small with <i>E. coli</i> or <i>S. aureus</i> control strains	pH of medium too low	Adjust pH to 7.2–7.4 before pouring medium. Commercial media should not have pH problems. Get a new lot (incubation in CO ₂ may alter agar surface pH).	<i>Do not</i> report test results until corrective action has been taken and new batch of medium demonstrates acceptable results.
Tetracycline zone too small and clindamycin zone too large with <i>S. aureus</i> or <i>E. coli</i> control strains	pH of medium too high	Adjust pH to 7.2–7.4 before pouring medium. Commercial media should not have pH problems. Get a new lot (incubation in CO ₂ may alter agar surface pH).	<i>Do not</i> report test results until corrective action has been taken and new batch of medium demonstrates acceptable results.
Aminoglycoside zone too small with <i>P. aeruginosa</i> control strain	Ca ²⁺ and/or Mg ²⁺ level too high in medium	Acquire new lot of agar medium that will meet QC criteria.	<i>Do not</i> report aminoglycoside results on <i>P. aeruginosa</i> or <i>Acinetobacter</i> until zone sizes meet QC standard.
Aminoglycoside zone too large with <i>P. aeruginosa</i> control strain	Ca ²⁺ and/or Mg ²⁺ level too low in medium	Acquire new lot of agar medium that will meet QC criteria.	<i>Do not</i> report aminoglycoside results on <i>P. aeruginosa</i> or <i>Acinetobacter</i> until zone sizes meet QC standard.
Zones universally too large on control plates	Inoculum too light	Adjust inoculum to McFarland 0.5 turbidity standard.	Hold results until repeat QC is within limits (6-h reading).
	Nutritionally poor medium	Use only MHA medium.	<i>Do not</i> report until MHA is used.
	Slow-growing organism (not seen with controls)	Use MIC procedure only.	<i>Do not</i> report any slow-grower disk results.
Zones universally too small on control plates	Improper medium depth (too thin)	Use 4- to 5-mm depth	<i>Do not</i> use this batch or lot of medium for testing.
	Inoculum too heavy	Adjust inoculum to 0.5 McFarland standard.	Hold results until repeat QC is within limits (6-h reading).
Methicillin zone decreasing over days or wk with control organisms	Agar depth too thick (minor)	Use 4- to 5-mm depth.	<i>Do not</i> use this batch or lot of medium for testing.
	Methicillin degrading during refrigerator storage	Change methicillin disks or use oxacillin or nafcillin as routine test disk.	Report methicillin only if within QC range.
Carbenicillin zone disappears with <i>Pseudomonas</i> control	Resistant mutant has been selected for testing.	Change <i>Pseudomonas</i> control strain every 2 wk and whenever resistant mutants appear within carbenicillin zone.	Repeat carbenicillin disk only. Read at 6 h. Report other disks as usual.
Single disk result above or below control limit	Error in reading, fuzzy zone edge, transcription error, bad disk	Note error. Recheck reading and ask for second opinion.	Report other disks by following standard protocol. Repeat test for out-of-control disk before reporting actual test results. Read repeat QC at 6 h.
	Disk may not be pressed firmly onto agar surface (bad disks usually demonstrate trend toward being out of control).	Statistically, one may expect occasional out-of-range result. Values usually fall within range on retesting.	
Colonies within zone of inhibition	Mixed culture	Isolate, identify, and retest pure culture only.	<i>Do not</i> report results of this plate.
	Resistant mutants within zone (<i>see</i> carbenicillin above)	Gram stain or do other test to rule out contaminant.	Report as resistant.
Very large zones with anaerobes		<i>Do not</i> use disk agar diffusion procedure to test anaerobes!	
<i>S. aureus</i> from patient resistant to methicillin one day and sensitive the next	<i>May be two different organisms</i> ; temp shift from 37 to 35°C can dramatically alter zone size in this case.	Check testing temp. Test must be performed at 35°C for methicillin (oxacillin or nafcillin) and <i>S. aureus</i> .	Report result obtained at 35°C.
	Low methicillin content in disk	Use new disks.	

APPENDIX 5.1–2 (continued)

Aberrant result	Probable cause	Corrective action ^b	Effect on current day's reports
Zones overlap	Disks too close together	Use no more than 12 disks on a 150-mm plate and 4 to 5 on a 100-mm plate. Place disks no closer than 15 mm to edge of plate.	Repeat test.
Zones indistinct with single colonies noted on plate	Poorly streaked plate, inadequate inoculum	Use properly adjusted inoculum, and repeat test.	Repeat test before reporting.
Zone-within-zone phenomenon	Swarming <i>Proteus</i> sp.	Read wide, distinct zone, and disregard growth that swarmed over	Report <i>Proteus</i> spp. from outer distinct zone.
	Feather edges of zones around penicillin or ampicillin disks usually with beta-lactamase-negative strains of <i>S. aureus</i>	Take half distance from inner zone to outermost zone as measure mark.	Report zone as described under "Corrective action" column.
	Sulfonamides	Disregard growth from disk margin to major inner zone.	Report outer zone
	Beta-lactamase-positive <i>H. influenzae</i> with penicillin or ampicillin	Use inside zone.	Call physician if meningitis.
Indistinct zones with sulfamethoxazole ± trimethoprim or with trimethoprim alone	Thymidine in medium inhibits action of these antimicrobials	Use commercial thymidine-free plates. Disregard small amount of growth within zone as with sulfonamides.	Report as usual if confident of results.

^a Disk diffusion testing is not standardized by the NCCLS for organisms other than those in this table. If testing is required, perform by MIC method. Abbreviations: DCS, direct colony suspension—standardize to McFarland 0.5 turbidity standard; DCS/LPG, direct colony suspension or log-phase growth—standardize to McFarland 0.5 turbidity standard; GC, GC agar with defined supplement; LPG, log-phase growth.

^b All incubation temperatures are 35°C.

^c And other penicillinase-stable penicillins.

APPENDIX 5.1–4

Haemophilus spp.**PREANALYTICAL CONSIDERATIONS**

A. SPECIMEN

Isolated colonies of similar colony morphology grown overnight on CHOC

B. SUPPLEMENTAL MATERIALS

1. CHOC

Store at 2 to 8°C.

2. HTM plates

Store at 2 to 8°C.

3. Photometric standardizing device (e.g., bench top photometer) for 0.5 McFarland turbidity and test tubes that will fit this device

ANALYTICAL CONSIDERATIONS

C. QC STRAINS

1. *H. influenzae* ATCC 492472. *H. influenzae* ATCC 497663. *E. coli* ATCC 35218 (for beta-lactam–beta-lactamase inhibitor combinations)4. Refer to NCCLS *Haemophilus* QC table for acceptable QC ranges (1).

D. PROCEDURE

1. Prepare inoculum by using a direct colony suspension in Mueller-Hinton broth or 0.9% NaCl from a fresh (20- to 24-h) CHOC plate.

2. Use a photometric device to adjust turbidity to match a 0.5 McFarland turbidity standard (1×10^8 to 4×10^8 CFU/ml). This step is recommended to avoid erroneous results due to under- or overinoculation.

3. Without delay, inoculate agar, and apply disks.

4. Because *Haemophilus* spp. show large zones with some drugs (e.g., third-generation cephalosporins), apply no more than nine disks per 150-mm plate or no more than four disks per 100-mm plate.

5. Incubate in 5% CO₂ for 16 to 18 h at 35°C.

E. READING RESULTS

Measure zones of inhibition from back of plate.

POSTANALYTICAL CONSIDERATIONS

F. REPORTING RESULTS

1. Refer to the appropriate NCCLS interpretive table for zone interpretation for *Haemophilus* spp. (1).

2. Only the susceptible interpretation is defined in NCCLS tables for several cephalosporins, carbapenems, aztreonam, macrolides, and fluoroquinolones because no (or very few) resistant strains have been reported to date. Confirm identification and susceptibility results for all isolates which are not susceptible to these agents, save isolate, and submit to a reference laboratory for testing using an NCCLS dilution reference method.

G. NOTES

1. Beta-lactamase-positive *Haemophilus* spp. are resistant to ampicillin and amoxicillin regardless of the MICs.

2. Occasional isolates are beta-lactamase negative and ampicillin resistant. Consider these resistant to amoxicillin-clavulanic acid, ampicillin-sulbactam, cefaclor, cefamandole, cefetamet, cefonicid, cefprozil, cefuroxime, loracarbef, and piperacillin-tazobactam despite in vitro results.

3. For life-threatening *Haemophilus* infections (e.g., meningitis, bacteremia), report only ampicillin, a third-generation cephalosporin, chloramphenicol, and meropenem.

APPENDIX 5.1-5

*Neisseria gonorrhoeae***PREANALYTICAL CONSIDERATIONS**

A. SPECIMEN

Isolated colonies of similar colony morphology grown overnight in 5% CO₂ on CHOC

B. SUPPLEMENTAL MATERIALS

1. CHOC

Store at 2 to 8°C.

2. GC agar base and 1% defined growth supplement (GC medium). Cysteine-free growth supplement is not required for disk testing. Refer to procedure 5.14. Store at 2 to 8°C.

ANALYTICAL CONSIDERATIONS

C. QC STRAIN

1. *N. gonorrhoeae* ATCC 49226

2. Refer to NCCLS *N. gonorrhoeae* QC table for QC ranges (1).

D. PROCEDURE

1. Prepare inoculum by using a direct colony suspension in Mueller-Hinton broth or 0.9% NaCl from a fresh (18- to 24-h) CHOC plate.

2. Adjust turbidity visually to a 0.5 McFarland turbidity standard or use a photometric device.

3. Inoculate agar within 15 min, and apply disks.

4. Apply no more than nine disks per 150-mm plate and four disks per 100-mm plate.

5. Incubate in 5% CO₂ for 20 to 24 h at 35°C.

E. READING RESULTS

Measure zones of inhibition from back of plate.

POSTANALYTICAL CONSIDERATIONS

F. REPORTING RESULTS

1. Refer to the appropriate NCCLS interpretive table for zone interpretations for *N. gonorrhoeae* (1).

2. Only the susceptible interpretation is defined for several cephalosporins because resistant strains have not been reported to date. Confirm identification and susceptibility results for all isolates which are not susceptible to these agents, save isolate, and submit to a reference laboratory for testing using an NCCLS dilution reference method.

G. NOTES

1. *N. gonorrhoeae* organisms with zone diameters of ≤ 19 mm with the 10-U penicillin disk generally are beta-lactamase producers. Beta-lactamase tests are preferred for detecting this plasmid-mediated resistance.

2. *N. gonorrhoeae* organisms with zone diameters of ≤ 19 mm with the 30- μ g tetracycline disk usually indicate plasmid-mediated resistance to tetracycline. Confirm by a dilution MIC test.

3. Strains interpreted as susceptible have a >95% clinical cure rate, whereas those isolates which are intermediate have a lower cure rate, 85 to 95%.

Reference

1. NCCLS. 2003. *Performance Standards for Antimicrobial Disk Susceptibility*, 8th ed. Approved standard M2-A8. NCCLS, Wayne, Pa.

APPENDIX 5.1–6

Streptococcus pneumoniae* and *Streptococcus* spp.*PREANALYTICAL CONSIDERATIONS**

A. SPECIMEN

Isolated colonies of similar colony morphology grown overnight on BAP

B. SUPPLEMENTAL MATERIALS

1. BAP

Store at 2 to 8°C.

2. Agar plates: use BMHA plates. Store at 2 to 8°C.

ANALYTICAL CONSIDERATIONS

C. QC STRAINS

1. *S. pneumoniae* ATCC 49619

2. Refer to NCCLS *S. pneumoniae* and *Streptococcus* QC table for acceptable QC ranges (1).

D. PROCEDURE

1. Prepare inoculum by using a direct colony suspension in Mueller-Hinton broth or 0.9% NaCl from fresh (16- to 18-h) growth on BAP.

2. Adjust turbidity visually to a 0.5 McFarland turbidity standard or use a photometric device.

3. Without delay, inoculate the plate as previously described.

4. Incubate in 5% CO₂ for 20 to 24 h at 35°C.

E. READING RESULTS

1. Remove lid and measure zones of inhibition from top of plate.

2. Only the susceptible interpretation is defined for vancomycin and linezolid for all streptococci and for penicillin, ampicillin, and extended-spectrum cephalosporins for beta-hemolytic streptococci because resistance has not been observed. Confirm identification and susceptibility results for all isolates which are not susceptible to these agents, save isolate, and submit to a reference laboratory for testing using an NCCLS dilution reference method.

POSTANALYTICAL CONSIDERATIONS

F. REPORTING RESULTS

1. Refer to the appropriate NCCLS interpretive table for zone interpretations for *S. pneumoniae* and the separate table for *Streptococcus* spp. (1).

2. Penicillin and *S. pneumoniae* (test 1-μg oxacillin disk to determine penicillin susceptibility)

a. Susceptible: oxacillin zone \geq 20 mm.

Report results for *penicillin*, not *oxacillin*. Penicillin-susceptible pneumococci are also considered susceptible to all other beta-lactam antimicrobial agents which have approved indications for pneumococci, and these drugs need not be tested.

b. Penicillin resistant or intermediate: oxacillin zone \leq 19 mm.

Isolates with zones of \leq 19 mm may occur with penicillin-resistant or intermediate strains or certain susceptible strains. Perform an MIC test with penicillin, meropenem, and either cefotaxime or ceftriaxone on isolates with oxacillin zones of \leq 19 mm.

G. NOTES

1. *S. pneumoniae*

a. Pneumococci may lyse rapidly in liquid (particularly water). Therefore, follow the inoculum preparation procedure described here precisely and inoculate the BMHA plate immediately after standardization of the inoculum suspension.

b. Penicillin-resistant *S. pneumoniae* does not produce beta-lactamase; do not use a beta-lactamase test to predict penicillin resistance.

2. Penicillin and viridans group streptococci

Penicillin (and oxacillin) disk testing is not reliable for viridans group streptococci. Perform penicillin MIC testing on viridans group streptococci isolated from normally sterile body sites (e.g., blood, CSF, bone, etc.).

1. NCCLS. 2003. *Performance Standards for Antimicrobial Disk Susceptibility*, 8th ed. Approved standard M2–A8. NCCLS, Wayne, Pa.

APPENDIX 5.1–7

Extended-Spectrum Beta-Lactamase Testing for *Escherichia coli*, *Klebsiella pneumoniae*, and *Klebsiella oxytoca***PREANALYTICAL CONSIDERATIONS**

A. PRINCIPLE

ESBLs are derived from point mutations in the genes that code for common beta-lactamases such as TEM-1, TEM-2, or SHV-1. In contrast to TEM-1, TEM-2, and SHV-1, ESBLs hydrolyze or inactivate extended-spectrum cephalosporins, aztreonam, and expanded-spectrum penicillins. They do not hydrolyze carbapenems and generally do not hydrolyze cephamycins. ESBLs are blocked by beta-lactamase inhibitors such as clavulanic acid, and laboratory tests for detecting ESBL-producing bacteria are based on this property.

The screening test for ESBL production in *E. coli* and *Klebsiella* spp. utilizes interpretive criteria for certain third-generation cephalosporins and aztreonam that are different from those used for routine testing of *Enterobacteriaceae*. Once an isolate is deemed screen positive and therefore suspicious for ESBL production, a phenotypic confirmatory test is performed. The confirmatory test requires four disk tests: (i) ceftazidime alone, (ii) cefotaxime alone, (iii) ceftazidime plus clavulanic acid, and (iv) cefotaxime plus clavulanic acid. If the zone diameter of either ceftazidime or cefotaxime (or both) in the presence of clavulanic acid is ≥ 5 mm larger than the zone diameter of the respective agent alone, the test is considered positive for ESBL production.

B. SPECIMEN

Colonies as described in item II of procedure 5.1 for routine disk diffusion testing of rapidly growing nonfastidious bacteria

C. SUPPLEMENTAL MATERIALS

1. Materials as stated in item III of procedure 5.1 for routine disk diffusion testing of rapidly growing nonfastidious bacteria
2. Disks for the following agents at the concentrations specified
 - a. Ceftazidime, 30 μg
 - b. Ceftazidime-clavulanic acid, 30/10 μg
 - c. Cefotaxime, 30 μg
 - d. Cefotaxime-clavulanic acid, 30/10 μg

ANALYTICAL CONSIDERATIONS

D. QC STRAINS

1. *Klebsiella pneumoniae* ATCC 700603 (ESBL-producing strain)
2. *E. coli* ATCC 25922
3. Refer to current NCCLS QC and ESBL tables for acceptable QC ranges (1).

E. PROCEDURE

Follow standard disk diffusion testing recommendations for inoculum preparation, inoculation, and incubation as indicated in item V of procedure 5.1.

1. Initial screen test

- a. Perform disk diffusion tests with one or more of the following agents and include the disk concentration listed below. If the zone of inhibition is below that listed (positive screen test), proceed with the ESBL phenotypic confirmatory test.

Antimicrobial agent	Disk potency (μg)	Zone diam (mm) for positive screen
Cefpodoxime	10	≤ 17
Ceftazidime	30	≤ 22
Cefotaxime	30	≤ 27
Ceftriaxone	30	≤ 25
Aztreonam	30	≤ 27

- b. If the screen test is positive, suppress any susceptible results for penicillins, cephalosporins, or aztreonam from the patient report.
- c. If the screen test is negative, consider the isolate ESBL negative.

APPENDIX 5.1–7 (continued)

2. Phenotypic confirmatory test
 - a. Perform a routine disk diffusion test and include four disks at the concentrations listed.
 - (1) Ceftazidime, 30 µg
 - (2) Ceftazidime-clavulanic acid, 30/10 µg
 - (3) Cefotaxime, 30 µg
 - (4) Cefotaxime-clavulanic acid, 30/10 µg
 - b. Measure zones as described above for testing rapidly growing nonfastidious bacteria. See procedures 5.2 and 5.8 for alternative ESBL confirmatory testing methods.

POSTANALYTICAL CONSIDERATIONS

F. REPORTING RESULTS

1. Positive for ESBL production: a ≥ 5 -mm increase in the zone diameter for either ceftazidime or cefotaxime tested in combination with clavulanic acid versus its zone diameter when tested alone
 - a. Demonstration of enhanced activity (≥ 5 -mm increase in the zone diameter) in the presence of clavulanic acid with either one or both pairs of antimicrobial agents is a positive result.
 - b. Report all penicillins, cephalosporins (excluding the cephamycins such as ceftiofur or cefotetan), and aztreonam as resistant, even if the in vitro susceptibility test results are intermediate or susceptible.
2. Negative for ESBL production: a ≤ 5 -mm increase in the zone diameter for either ceftazidime or cefotaxime tested in combination with clavulanic acid versus its zone diameter when tested alone

G. NOTES

1. At least 130 different types of ESBL enzymes have been described for *E. coli* and *Klebsiella* spp. Among the bacteria that produce these, a wide variety of susceptibility profiles may be noted with extended-spectrum beta-lactam antimicrobial agents, including the ESBL test screening agents. Use of more than one screening agent increases the likelihood of detecting the various types of ESBLs.
2. Extended-spectrum beta-lactam resistance in isolates that are screen test positive but confirmatory test negative is generally due to a mechanism other than ESBL production. ESBL screening tests have high specificity for *K. pneumoniae* but low specificity for *E. coli*. Many ESBL screen-positive *E. coli* strains are resistant to extended-spectrum antimicrobial agents due to a resistance mechanism such as hyperproduction of AmpC beta-lactamase. As a screening agent for *E. coli*, cefpodoxime is the most sensitive but the least specific.
3. Generally, the hierarchy of activity of the screening agents in detecting ESBL production is cefpodoxime > ceftazidime > cefotaxime > ceftiofur > aztreonam.
4. The genes for ESBL production are typically located on plasmids, and genes for resistance to other antimicrobial agents are often found on the same plasmid. Consequently, isolates that produce ESBLs often (but not always) demonstrate multiple resistance to other classes of antimicrobial agents (e.g., aminoglycosides, fluoroquinolones, or trimethoprim-sulfamethoxazole).
5. ESBLs do not hydrolyze carbapenems, and ESBL-producing *E. coli* and *Klebsiella* spp. remain susceptible to these antimicrobial agents. Carbapenems are considered the beta-lactams of choice for treating infections due to ESBL-producing bacteria.

H. LIMITATIONS

1. Some organisms with ESBLs may contain other beta-lactamases or other resistance mechanisms (e.g., porin alterations) that can mask ESBL production in the phenotypic confirmatory test, resulting in a false-negative result.
2. Other members of *Enterobacteriaceae* produce ESBLs. However, practical clinical laboratory methods for screening and detection of these isolates have not been determined as yet.

5.2

Broth Microdilution MIC Test

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The broth microdilution MIC method is used to measure (semiquantitatively) the *in vitro* activity of an antimicrobial agent against a bacterial isolate. A sterile plastic tray containing various concentrations of antimicrobial agents is inoculated with a standardized number of test bacteria. After overnight incubation at 35°C, the MIC is determined by observing the lowest concentration of an antimicrobial agent which will inhibit visible growth of the bacterium. MICs obtained are interpreted as susceptible, intermediate, or resistant, based on the criteria listed in the NCCLS MIC standard (1).

For full-range MIC testing, five to eight concentrations representing a therapeutically achievable range for each agent are usually tested. Breakpoint MIC testing represents a modification of microdilution MIC testing in which generally one to three concentrations of each agent are tested and results are reported qualitatively. This enables more agents to be tested per tray.

The NCCLS describes a standard method for broth microdilution MIC test-

ing of nonfastidious bacteria which utilizes cation-adjusted Mueller-Hinton broth (CAMHB). The NCCLS also describes standardized broth microdilution MIC procedures for testing *Haemophilus influenzae*, *Streptococcus pneumoniae*, and *Streptococcus* spp. The procedures for these bacteria are similar to those for nonfastidious bacteria; however, the test media are supplemented with nutrients that will support the growth of these fastidious organisms.

II. SPECIMEN

Prepare inoculum from four or five isolated colonies of similar colony morphology.

- A. Log-phase or stationary-phase growth inoculum
Use colonies grown for 1 or 2 days on nonselective or selective (e.g., MAC) medium.
- B. Direct colony suspension inoculum
Use colonies grown overnight on nonselective medium (e.g., BAP or CHOC).
- C. Subculture stock, frozen, or lyophilized isolates two times prior to testing.

III. MATERIALS

Include QC information on reagent container and in QC records.

A. Media and reagents

1. Prepared broth microdilution trays containing an antimicrobial agent in CAMHB in volumes of 0.1 ml solution per well. Store at -70°C.
2. Nutrient broth (e.g. Mueller-Hinton, TSB) or 0.9% NaCl (3.0- to 5.0-ml aliquots)
Store at 2 to 30°C.
3. BHI broth (0.5-ml aliquots)
Store at 2 to 30°C.
4. Water diluent containing 0.02% Tween 80 dispensed in aliquots of 40 ml in screw-cap tubes
Store at 25°C.
5. BAP
Store at 2 to 8°C.

B. Supplies

1. Sterile cotton tipped swabs
2. Sterile plastic pipettes
3. McFarland 0.5 turbidity standard (McFarland 4.0 standard for stationary-phase inoculum)
4. Sterile disposable plastic multi-pronged inoculator sets (include inoculum reservoir)

C. Equipment

1. Vortex mixer
2. Ambient-air incubator (34 to 35°C), CO₂ incubation for some organisms (see Appendix 5.2-1)

III. MATERIALS (*continued*)

3. Adjustable micropipette and sterile pipette tips
4. Calibrated loop (0.001 ml [1 µl])
5. Viewing device to read inoculated MIC trays after incubation
6. Microdilution tray storage containers (e.g., Tupperware-type containers or plastic bags)
7. Freezer (−70°C; sometimes a −20°C, non-frost-free freezer is acceptable)

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL****A. QC strains** (*see* appendixes to this procedure for QC of specific fastidious organisms)

1. *Escherichia coli* ATCC 25922
2. *Pseudomonas aeruginosa* ATCC 27853
3. *Staphylococcus aureus* ATCC 29213
4. *E. coli* ATCC 35218
5. *Enterococcus faecalis* ATCC 29212

B. Monitoring accuracy

1. Test QC strains by following routine procedures and record results in a QC notebook. Record lot numbers and expiration dates of broth microdilution trays.
2. Compare with expected results listed in the most recent NCCLS standard tables (1). Note any out-of-control result and document; proceed with corrective action, if necessary.
3. Record all results on QC worksheet (Appendix 5.2–2)

C. Additional controls

1. Growth controls
A growth control well must show 3+ to 4+ growth; a purity plate must show good growth without contaminating organisms.
2. The sterility control well should be free of any growth.
3. Inoculum controls
An inoculum count verification plate (checked once per month) should show approximately 50 colonies.

D. Daily QC testing

1. QC testing is in control if, for each drug-organism combination, no more than 1 out of 20 consecutive results is outside acceptable range.
2. If any more than 1 of 20 results is out of control, proceed with corrective action.

E. Weekly QC testing

1. Frequency of QC testing
 - a. QC testing can be reduced from daily to weekly providing a laboratory can document proficiency in performing this test by performing QC daily (or each day patient tests are performed) until results from 20 consecutive days of testing have been obtained.
 - b. Proficiency in performing QC testing is confirmed if for each drug-organism combination no more than 1 of 20 results are outside accuracy limits. Weekly QC testing may then be initiated.
 - c. If 2 or 3 of the 20 results are out of control, continue testing for a total of 30 days. If no more than 3 of 30 results are outside accuracy limits, proficiency is demonstrated, and weekly testing can be initiated.
2. Weekly QC testing is in control if all MICs are within specified accuracy limits. If any result is out of control, proceed with corrective action.

IV. QUALITY CONTROL*(continued)*

3. Document proficiency each time a new drug is added to testing protocols.
 - ☑ Save records documenting proficiency indefinitely.
4. Perform QC testing each time a new lot or new shipment of materials (broth microdilution trays) is put into use.
5. Perform colony counts on QC strains at least once per month.

F. Corrective action

1. Out-of-control result due to obvious error (e.g., contamination, incorrect organism tested, inadequate incubation conditions, etc.) that can be easily corrected: record reason for out-of-control result and retest the same day. If the repeated result is in range, no further action is needed.
2. Out-of-control result not due to obvious error
 - a. Test the panel with the QC strain that demonstrated out-of-control results for five consecutive test days. Record results. It is up to each laboratory to decide whether to record results from all agents tested or just those for the “problematic” agent.
 - b. If all five results for the problematic antimicrobial agent are now within the acceptable QC range, weekly testing may be resumed.
 - c. If the problem is not resolved (at least one MIC is outside the accuracy control limits), continue daily QC testing until the problem is resolved.
 - d. Investigate possible procedural problems (e.g., review reading of MICs, standardization of inoculum, storage and expiration dates of reagents, incubation conditions, equipment, and maintenance and purity of control strain).
 - e. In order to return to weekly testing, satisfactory performance for another 20 or 30 consecutive days must be documented (as described above).
 - f. During corrective action, carefully evaluate whether patient reports will be affected. It may be necessary to use an alternate test method until the problem is resolved. (Refer to procedure 5.13 for maintenance of QC strains and additional measures for verifying results for bacteria isolated from patients.)

V. PROCEDURE

See Appendix 5.2–1 for a summary of testing conditions for various organisms and Appendixes 5.2–3 to 5.2–5 for special procedures for testing *Haemophilus* spp., *S. pneumoniae*, and *Streptococcus* spp. and testing for extended-spectrum beta-lactamase (ESBL) production in *E. coli* and *Klebsiella* spp. See Appendix 5.2–6 for breakpoint MIC panels.

- A. Allow frozen trays to thaw at room temperature.
- B. Inoculum preparation
 1. Using a loop or swab, transfer colonies as follows.
 - a. Direct colony suspension method
Pick several colonies from a fresh (18- to 24-h) nonselective agar plate to broth or 0.9% NaCl.
 - b. Log-phase method
 - (1) Pick four or five isolated colonies to 3.0 to 5.0 ml of broth.
 - (2) Incubate at 35°C for 2 to 8 h until growth reaches the turbidity at or above that of a 0.5 McFarland standard.
 - c. For either the log-phase or direct colony suspension method, vortex well and adjust turbidity visually with sterile broth or 0.9% NaCl to match that of a 0.5 McFarland standard (1×10^8 to 2×10^8 CFU/ml). Alternatively, standardize suspension with a photometric device.

V. PROCEDURE (continued)

d. Stationary-phase method

- (1) Transfer several isolated colonies to 0.5 ml of BHI.
