All cell lines commonly used in diagnostic virology are available commercially. Laboratories may find it more practical to purchase cells already grown as monolayers in tubes. However, in-house preparation of cell cultures allows for the continued use of young, metabolically active cells and control over the quality and sensitivity of the culture system. The ATCC, the national repository for reference cell cultures, is a source of cell lines. Cells from the ATCC have been authenticated as to the species of origin; have been determined to be free of contaminating microorganisms such as mycoplasmas, bacteria, fungi, protozoa, and cytopathic viruses; and are provided in a cryopreserved state for use (3). These cells are seeded into a flask upon receipt by the laboratory and then serially propagated as described in this procedure. Cells from one or two flasks from an early passage should be cryopreserved for future use in the event of contamination or other problems. For

Table 10.3–1 Characteristics of monolayer cell cultures

Culture type	Synonym(s)	Subpassages	Source	Morphology	Examples ^a
Primary		Few ^b	Donor tissue	Epitheliallike	HNK, RMK, RK
Diploid	Semicontinuous	30–50	Monolayer	Fibroblastlike	MRC-5, WI-38, HNF
Heteroploid	Established, transformed, continuous, immortalized	Infinite	Monolayer	Epitheliallike	HEp-2, A-549, HeLa, Vero, McCoy, ML

^a HNK, human neonatal kidney; RMK, rhesus monkey kidney; RK, rabbit kidney; MRC-5 and WI-38, human embryonic lung; HNF, human newborn foreskin; HEp-2, human epidermoid laryngial carcinoma; A-549, human epidermoid lung carcinoma; HeLa, human cervical carcinoma; Vero, African green monkey kidney; McCoy, mouse karyotype; ML, mink lung.

^b May be subpassaged to yield secondary cultures.

10.3.1

II. OBTAINING CELLS FOR CULTURE (continued)

some laboratories, it may be more economical to purchase flasks of cells as needed for preparation of culture tubes, vials, and other vessels rather than serially propagating these cells in the laboratory. Most laboratories continue to purchase primary monkey kidney cells from commercial sources unless alternative cell lines are being used or primate facilities are available.

III. MATERIALS

A. Medium and reagents

■ Indicate the expiration date on the label and in the work record or on the manufacturer's label.

See procedure 10.2 for details on preparation of medium.

1. Cell culture medium

Eagle's minimum essential medium in either Earle's or Hanks' (HBSS) balanced salt solution and containing heat-inactivated (56°C, 30 min) fetal bovine serum (FBS). Growth medium is used for the rapid proliferation of cells and usually contains FBS at a final concentration of 7.5 to 10.0%. Maintenance medium contains only 2% FBS and is used to maintain the cells in a steady state of slow metabolic activity.

2. Enzymes for dissociation of cell monolayers: available commercially as sterile solutions or in powdered form

a. Trypsin-EDTA

Trypsin-EDTA (Versene) is a combination of enzyme and chelating agent most commonly used to dissociate cell monolayers. The mixture is prepared in a balanced salt solution without calcium and magnesium at a final concentration of 0.25% trypsin and 0.02% EDTA. Store reconstituted material at -20°C or lower and lyophilized material at 4°C , observing the manufacturer's expiration date. Once thawed, the trypsin-EDTA can be stored at 4°C for as long as 3 weeks or dispensed in single-use quantities. Avoid repeated freeze-thawing of trypsin-EDTA.

b. Alternative dissociation reagents include trypsin without EDTA, elastase, thermolysin, collagenase, protease, pancreatin (which includes amylase, trypsin, lipase, RNase, and protease), and a nonenzymatic solution containing EDTA, sodium citrate, and glycerol in a balanced salt solution.

3. HBSS or phosphate-buffered saline (PBS) without calcium or magnesium, pH 7.2 to 7.4. HBSS or PBS should be free of divalent cations such as Ca^{2+} and Mg^{2+} , since these ions stabilize bonds between cells and thereby prohibit effective dissociation of cells bound to substrates.

4. Dimethyl sulfoxide (DMSO) for cryopreservation

B. Supplies

1. Sterile plasticware or glassware (e.g., flasks, tubes, pipettes)

a. Sterile disposable plastic pipettes, flasks, and tubes, sterilized and chemically treated to provide a uniform and reproducible substrate for the attachment and growth of cells in monolayers, are commercially available and convenient to use.

b. Glassware must be meticulously cleaned and sterilized to be suitable for cell culture techniques. Processing of glassware requires presoaking of the soiled materials, washing with an appropriate detergent, thorough rinsing with tap and deionized water, and sterilization by dry heat. The cost and convenience of plasticware must be balanced against the time and labor involved in cleaning and sterilizing glassware. Also, *variations in preparation and sterilization of glassware can have significant adverse effects on the growth of cells in culture.*

2. Hemacytometer for cell enumeration

3. Racks designed to hold culture tubes at a 5 to 7° angle

4. Safety pipetting devices, protective clothing, infectious-waste disposal containers, adequate autoclave facilities

5. 0.5% Hypochlorite solution for cleaning work surfaces

6. Cryovials (e.g., Sarstedt, Corning, or Nunc) for freezing cell stocks

III. MATERIALS (*continued*)**C. Equipment**

1. Inverted and standard light microscopes, $\times 100$ to $\times 200$ magnification
2. Class II biological safety cabinet
3. Refrigerator at 2 to 8°C
4. Centrifuge
5. Vacuum source and collection trap containing 0.5% sodium hypochlorite
6. Incubator at 37°C with or without CO₂
The need for CO₂ depends on the use of Earle's balanced salt solution or HBSS and HEPES buffer in the cell culture medium.
7. -70°C freezer
8. Liquid nitrogen storage freezer

IV. QUALITY CONTROL

Cell cultures are extremely fragile and require meticulous care for optimum performance. Appropriate QC procedures and maintenance records should be established for all laboratories performing cell culture work. Cells should be observed routinely for indications of instability or deterioration. Examine the cells both macro- and microscopically for the presence of contaminating microorganisms; look for changes in characteristic cell morphology such as rounding, vacuolization, sloughing, or retraction; examine the medium for abnormal changes in the pH; and check all cell lines for continued susceptibility to viruses known to grow in each cell type.

A. Bacterial and fungal contamination

See Appendix 10.3-1.

B. Mycoplasmal contamination

See Appendix 10.3-2.

C. Contamination with endogenous viruses

Primary monkey kidney cells are often infected with simian virus 5 (SV5) and SV40 and the foamy retroviruses that may produce cytopathic effect or hemadsorption.

V. PROCEDURE**A. Subpassage of stock cell culture flasks**

Cell lines may be kept active and available for seeding of tubes, vials, dishes, and plates by weekly subpassage. Subpassage ("splitting") of cell cultures is normally performed when the cells are at or near confluency.

1. Select flasks with confluent or nearly confluent monolayers for subpassage, and examine each flask prior to use.
2. Remove the medium from the flask by aspiration, and wash the monolayer once with a Ca²⁺- and Mg²⁺-free salt solution (refer to Table 10.3-2 for volume). Gently rock the flask back and forth to wash the residual medium from the cells. *Removal of residual medium is essential since medium components (i.e., serum, Ca²⁺, Mg²⁺) can inactivate the trypsin-EDTA.*
3. Aspirate the wash solution from the flask.
4. Add enough trypsin-EDTA solution to the flask to completely cover the monolayer of cells (refer to Table 10.3-2 for volume). Gently rock the flask back and forth for 10 to 20 s, and remove the solution by aspiration.
5. Add a fresh volume of trypsin-EDTA, and incubate the cell monolayer for 5 min at room temperature or for 2 to 3 min at 37°C.
6. Observe the cells during the incubation. When the cells begin detaching from the surface of the flask, hold the flask with one hand and firmly slap the side of the flask into the palm of your other hand to completely dislodge the cells. *Do not trypsinize cells for longer than needed.*

V. PROCEDURE (continued)

7. Add medium containing serum to the cell suspension as soon as possible to inhibit the enzymatic activity of the trypsin and to stop the action of the chelating agent (refer to Table 10.3–2 for medium volume).
8. Disperse the cells by gently pipetting them up and down enough times to break apart clumps and produce an even suspension.
9. If desired, perform a cell count (*see* Appendix 10.3–3).
10. For preparing new culture vessels, the split ratio method is commonly used in place of cell counting. This ratio is defined as the dilution at which cells will adequately replicate to form monolayers; it determines the number of new cell cultures that can be prepared from each cell suspension. For example, from a cell line having a split ratio of 1:3, the resuspended cells can be divided evenly among three new culture vessels of the same size, nine vessels that are three times smaller, one vessel that is triple in size, and so on. See Table 10.3–3 for the split ratios of commonly used cell lines in diagnostic virology.
11. Determine the number and types of new culture vessels needed, and label the vessels appropriately. Also, be certain to record the cell line used, date subcultured, new subpassage number, and number and types of vessels prepared.
12. Seed the resuspended cells into new culture vessels containing predispensed growth medium to make the final volumes (medium plus cell suspension) indicated in Table 10.3–4. It is recommended that 0.2 to 0.5 ml of medium be added per square centimeter of surface area (2). Make certain that the cell suspension remains completely resuspended during seeding to ensure delivery of the appropriate number of cells to each vessel.

Table 10.3–2 Reagent volumes for trypsinization of monolayer cell cultures

Size of source vessel (cm ²)	Amt (ml) of:		
	Wash reagent ^a	Enzyme ^b	Growth medium ^c
25	5	1	2
75	10	3	6
150	15	5	10

^a PBS or balanced salt solution.^b Trypsin-EDTA (Versene).^c Minimum essential medium with 10% FBS. If a cell count is not going to be performed, resuspend the cells in a volume equal to the split ratio of the given cell line.**Table 10.3–3** Recommended split ratios for commonly used cell lines^a

Cell line ^b	Split ratio
Diploid: MRC-5 and WI-38	1:3–1:4
Heteroploid	
HEp-2	1:6–1:8
A-549	1:6–1:8
ML	1:6–1:8
HeLa	1:5
Vero	1:4
LLC-MK ₂	1:4
BHK-21	1:10
RK-13	1:3

^a Adapted from Bird and Forrester (1).^b LLC-MK₂, rhesus monkey kidney; BHK-21, hamster kidney; RK-13, rabbit kidney. For other cell lines, see Table 10.3–1, footnote *a*.

Table 10.3–4 Surface area, cell yield, and final volume of growth medium for commonly used culture vessels^a

Type of seed vessel	Surface area	Cell yield	Final vol (ml) of growth medium
Plates			
Microtiter (96 well)	32.0 mm ²	~10 ⁵	0.1
12 well	4.5 cm ²	~10 ⁶	2.0
24 well	2.0 cm ²	5.0 × 10 ⁵	1.0
Petri dishes			
30 mm	6.85 cm ²	1.7 × 10 ⁶	2.0
60 mm	21.0 cm ²	5.0 × 10 ⁶	5.0
100 mm	55.0 cm ²	1.4 × 10 ⁷	10.0
Flasks			
25 cm ²	25.0 cm ²	5.0 × 10 ⁶	5.0–8.0
75 cm ²	75.0 cm ²	2.0 × 10 ⁷	15.0–30.0
150 cm ²	150.0 cm ²	6.0 × 10 ⁷	50.0–75.0
Shell vial	1.1 cm ²	3.0 × 10 ⁵	2.0
Culture tube	~3.5 cm ²	~10 ⁶	2.0

^a Adapted from Freshney (2).

V. PROCEDURE (continued)

13. Disperse the cells by gently swirling the vessels.
14. Incubate the vessels at 37°C with or without 5% CO₂ as needed. The caps of the vessels should remain slightly loose or completely tightened during the incubation depending on the buffering system used. Flasks, vials, and plates should be incubated in a flat position and tubes in a slanted position.
15. Observe the cells at 24 h and every other day thereafter for growth, contamination, and changes in the pH of the medium. If necessary, refeed cells with fresh growth medium.
16. When the monolayers are confluent, replace the growth medium with maintenance medium and maintain the cells as described in CMPH 8.5. Subpassage stock flasks of confluent monolayers weekly. Cell cultures of flasks, tubes, vials, or plates for virus growth should be used within 10 days of seeding.

B. Cryopreservation of cell lines

All diploid and continuous cell lines commonly used in the virology laboratory are routinely frozen and stored indefinitely in liquid nitrogen.

1. Use healthy, actively growing cells known to be free of contamination.
2. Follow steps V.A.1 through 8 above.
3. Perform a viable cell count on the cells (*see* Appendix 10.3–3). Freeze cells at high concentrations, usually 10⁶ to 10⁷ viable cells per ml.
4. Prepare freezing medium, which is composed of the growth medium without antimicrobial agents, 10 to 20% FBS, and 10% DMSO. The DMSO need not be sterilized but should be of cell culture quality and handled aseptically. Freezing medium should be freshly prepared.
5. Suspend cells in cold freezing medium to the concentration mentioned above.
6. Aliquot 1 ml of cell suspension into labeled cryovials. Seal the caps tightly.
7. Freeze the cells *slowly* by wrapping them in gauze or cotton and placing them in a styrofoam storage container that is sealed and stored at –70°C overnight.

V. PROCEDURE (*continued*)

8. Remove the vials from the styrofoam container, quickly place them in liquid nitrogen storage boxes or canes, and immediately place them in the vapor phase of liquid nitrogen (-196°C) for long-term storage.
9. Maintain inventory control records describing the cell line frozen, passage level, seed and freeze dates, number of vials frozen, size of source flask(s), and location of vials within the storage vessel.
10. Freeze all cell lines soon after they are received in the laboratory and when they are at low subpassage number.

C. Recovery of cryopreserved cells

1. Obtain a vial of frozen cells from liquid nitrogen storage and *quickly* thaw it by swirling it in a 37°C water bath.
2. Wipe the outside of the vial with 70% alcohol.
3. Transfer the contents of one vial to a flask of the same size as used for the source culture. If viability is expected to be low or if cells have been frozen for more than 1 year, a smaller flask may be used.
4. Slowly (over a period of 2 min) add the cell's growth medium to the flask to gradually dilute the cells and DMSO preservative. *Sudden dilution can cause severe osmotic damage and reduce cell survival.*
5. Incubate the cells at 37°C , and observe them at 24 h for adherence and growth.
6. Refeed cells with growth medium to remove all traces of DMSO and reincubate the cells.
7. Subpassage the flask when monolayer is confluent.

VI. PROCEDURE NOTES

- A. Primary cell lines are normally purchased from commercial sources and are not subpassaged. These cells are refeed with maintenance medium when they are received. The cells are incubated at 37°C until used or for a maximum of 14 days. Maintain inventory records on all cell lines received from commercial sources.
- B. When preparing and maintaining stock flasks of cells, do not use antimicrobial agents in the growth or maintenance medium. Use medium with antimicrobial agents when preparing and maintaining tubes, vials, dishes, or plates. See CMPH 8.19 for details on the preparation of cell culture medium.
- C. The ability to dissociate cells and remove them from the culture vessel surface is dependent on the cell type, confluency of the cells, completeness of serum and medium removal before the addition of trypsin-EDTA, and time elapsed since the cells were last subcultured. The time for trypsin-EDTA treatment may vary accordingly, although it should be kept to a minimum to avoid cell damage.
- D. Once dissociated, cells are resuspended in growth medium for preparation of new culture vessels; delays may lead to cell loss due to adherence of cells to the source flask surface. This may lead to new vessels of lower numbers of cells than anticipated and subsequent delays or total inability to achieve confluent monolayers.
- E. The number of cells used to seed culture vessels can be varied to yield confluent monolayers rapidly, e.g., within 24 h, as for chlamydial cultures, or within 3 to 5 days.
- F. When seeding vessels containing coverslips, remove trapped air bubbles from under the coverslips by gently tapping the bottoms of the vessels.
- G. It is recommended that cultures be refeed with fresh maintenance medium the day before subpassage.

VI. PROCEDURE NOTES (continued)

- H. When preparing tubes of HEP-2 or A-549 cells for the detection of respiratory syncytial virus, seed the cells at a lower density than normal to achieve slightly subconfluent monolayers at the time these cells will be used for detection of this virus. *Syncytium formation by respiratory syncytial virus is best observed in subconfluent monolayers and may not be seen at all if confluent cells are used for specimen inoculation.*
- I. When freezing cells in liquid nitrogen, make certain that the vials have been properly sealed to avoid leaks, and *do not store the vials in the liquid phase because they may violently explode upon removal. The vials can be wrapped with sterile gauze immediately after removal and while opening to protect hands and eyes from flying glass or plastic. Always wear gloves and a protective face mask, and shield the water bath when thawing vials.*
- J. If it is necessary to remove the DMSO when recovering cells from cryopreservation, resuspend the 1.0 ml of thawed cells in 10 ml of growth medium in a 15-ml conical centrifuge tube. Centrifuge the cells at $400 \times g$ for 10 min at room temperature. Then, resuspend the cells in an appropriate amount of growth medium, and transfer them to a new culture vessel.
- K. The use of nonadherent cell cultures and lines is limited to specialized applications. Because these cells do not form monolayers, the use of proteolytic enzymes for subpassage is obviated.

APPENDIX 10.3-1

Detection of Bacterial and Fungal Contamination in Cultured Cells

- A. Macro- and microscopic observation of cell cultures is very helpful in detecting bacterial and fungal contamination. Changes in cell morphology, abnormal shifts in pH, cloudiness of the medium, a decrease in cell growth over time, unusual odors, and direct visualization of microorganisms in the culture are all signs of probable contamination.
- B. Simple procedures such as a Gram stain of sediments from centrifuged supernatant fluid of the culture cells or inoculation of the cell suspension to enriched broth medium (e.g., THIO, TSB, BHI) or agar (e.g., blood and Sabouraud dextrose agar plates) can be beneficial when contamination is suspected. It is recommended that broth medium be inoculated at a ratio of 1:10 and agar medium be inoculated with samples of 0.1 to 1.0 ml. Incubate the inoculated media at appropriate temperatures, and observe for bacterial and fungal growth for 7 to 14 days. Check sterility of all media and reagents prepared in-house for cell culture by placing a volume in broth medium and observing for growth of unwanted microorganisms. Quarantine the materials, and do not use them until sterility is confirmed. All solutions of purchased reagents undergo QC by the suppliers and need not be retested on a routine basis. However, it is prudent to periodically test these reagents for sterility and to check with each manufacturer to determine whether appropriate testing procedures are being performed.

APPENDIX 10.3-1 (continued)

- C. The primary sources of bacterial and fungal contamination are many and can include any of the number of reagents, supplies, and equipment used to perform cell culture. However, it is more likely that a lapse in aseptic technique while using these materials is the origin of the contamination. Cell culture techniques can be easily performed free of contamination but only if laboratory personnel are constantly aware of the consequences of poor technique and if appropriate preventive and QC measures have been established in the laboratory. These should include a system for monitoring and detecting bacterial and fungal contamination and adequate methods for removing the contaminants.
- D. When cell cultures are proven to be contaminated, immediately remove them from the tissue culture area and dispose of them properly. Unless absolutely necessary, do not attempt to treat the cells to eliminate the contaminant(s).

APPENDIX 10.3-2

Detection of Mycoplasmas in Cultured Cells

- A. Contamination with mycoplasmas is difficult to detect without proper testing, and the organism is one of the contaminants most feared by individuals working with cell cultures. Mycoplasmas produce few recognizable gross changes in the cultured cells but can have a profound effect on the growth, metabolic activity, and susceptibility to viral infection of cell lines. They can also produce a cytopathic effect that may be confused with viral cytopathic effect. Generalized deterioration of cells and a rapid drop in the pH of the medium may indicate mycoplasmal contamination. Because mycoplasmas have no cell wall, the medium will not become turbid, as with other bacterial contaminants.
- B. The source of mycoplasmal contamination is thought to be human, bovine, or porcine. Mycoplasmas are routinely found as commensal organisms in the respiratory and genital tracts of almost all humans (e.g., *Mycoplasma orale*, *M. hominis*, *M. buccale*, *M. fermentans*, and *M. salivarium*). Commercial sera produced from animals are the most likely source of the bovine (*M. arginini* and *Acholeplasma laidlawii*) and porcine (*M. hyorhinitis*) mycoplasmas. Although commercial companies routinely check sera, trypsin, and cells for mycoplasmas, it may be beneficial to periodically retest these potential sources of contamination when they are received in the laboratory.
- C. *It is strongly recommended that cultured cells be initially obtained from commercial sources that have tested and verified the cells to be free of mycoplasmas.* Avoid obtaining cell lines from colleagues, or strictly quarantine such cells until they have been appropriately tested for mycoplasmas.
- D. Make certain that cells to be tested for mycoplasmas have been grown in antimicrobial agent-free medium for at least 3 days before testing is initiated and that at least 10^2 to 10^3 cells are used.
- E. Testing should include a culture method and one of the many indirect methods available (1-3). Mycoplasmal detection services are also available through the ATCC and other commercial sources.
- F. A defined schedule of testing for mycoplasmas should be developed in the laboratory. Test cells monthly that are continuously subpassaged, test frozen cells both before and after freezing, test cells obtained from outside sources before use, and check reagents as necessary. Keep a written inventory of the mycoplasmal testing performed.

APPENDIX 10.3-3**Cell Counting with a Hemacytometer**

Cell counting with a hemacytometer can be used to count viable cells in the total cell suspension.

- A. Obtain a Neubauer hemacytometer with coverslip. The hemacytometer has two chambers containing nine identical ruled squares, each measuring 1 by 1 mm. When the coverslip is placed over the chambers, the space between the coverslip and the ruled squares is 0.1 mm. Therefore, the volume of one ruled square is 0.1 mm³, or 10⁻⁴ cm³.
- B. Prepare a dilution of the cell suspension in a balanced salt solution for total cell counts or in a 0.4% solution of trypan blue for viable cell counts. The dilution chosen should provide a cell count of approximately 2 × 10⁵ to 5 × 10⁵ cells per ml. Additional dilution or concentration of the suspension may be necessary to achieve this goal. Thoroughly mix the diluted cells to receive an even suspension without excessive clumping.
- C. With the coverslip in place, transfer 10 μl of diluted cells to each chamber of the hemacytometer by using the V notches provided. The cell mixture will fill the chambers by capillary action.
- D. Place the counting chamber on the stage of a light microscope. Using the low-power objective, focus on the ruled squares, and count all of the cells in the 1-mm² center square and the four 1-mm² corner squares. Do the same for the second chamber. Do not count cells lying outside the borders of the squares. If needed, keep a separate count of viable and nonviable cells.
- E. Divide the total number of viable cells in the 10 squares by 10 to determine the mean count per square. This represents the number of cells per 0.1 mm³. This number is multiplied by 10,000 to determine the number of cells per cubic centimeter. Since 1 cm³ is equivalent to 1 ml, the cell number can now be expressed per milliliter. Adjust the final number by the appropriate dilution factor.
- F. The percentage of viable cells can be determined by dividing the total number of viable cells by the total number of stained and unstained cells and multiplying by 100.
- G. By knowing the total number of viable cells per milliliter and the split ratio of different cell lines, appropriate dilutions of cell suspensions can be made to prepare various types and numbers of culture vessels. It is recommended that concentrations of 100,000 to 300,000 cells per ml be used to seed new culture vessels and that diploid cells be seeded at a higher concentration than heteroploid cells (1).

I. PRINCIPLE

Successful viral culture requires careful attention to the selection, collection, transport, and assessment of specimens. The information contained in this procedure is essential not only to those laboratories performing viral cultures on site but also to those outsourcing specimens. The labora-

tory must provide written guidelines to collection sites (nursing station, clinic, physician's office, and emergency room) detailing cultures that are available and instructions for submitting specimens. Instructions should include laboratory hours of operation and contact person(s); in-

structions for specimen collection, labeling, storage, and transport; source and storage conditions for transport media and containers; information required for adequate testing; turnaround time; reporting procedures and values; and testing limitations.

II. SPECIMEN COLLECTION

For best correlation between viral recovery and disease etiology, the specimen should reflect the target organ whenever possible. For example, isolation of an enterovirus from a throat or rectal swab obtained from an individual with aseptic meningitis is less meaningful than isolation from CSF. Specimens most frequently submitted for viral testing are presented in Table 10.4-1.

A. Timing

Collect specimens as soon after onset of symptoms as possible, because the likelihood of obtaining positive results is generally greatest within the first 3 days after onset of symptoms and diminishes rapidly as the course of infection proceeds in otherwise healthy and immunocompetent individuals. Viruses may be recovered from clinical samples for prolonged periods with disseminated or persistent infections.

Collect autopsy specimens as soon after death as possible.

B. Collection

Specimen collection practices are summarized in Fig. 10.4-1. Refer to Table 10.4-1 for specimen collection guidelines. Collect specimens as aseptically as possible since microbial contamination will interfere with testing. Place each specimen into a separate sterile leakproof container labeled with the patient's name and identification number, the collection site, and the date and time of collection. Collect fluid (e.g., CSF, urine) and bulk (e.g., stool, autopsy tissues) specimens in a sterile, dry, leakproof container.

Collect swab specimens by using sterile Dacron- or rayon-tipped swabs with plastic or aluminum shafts; do not use cotton, calcium alginate (2), or wooden-shafted swabs (9). Use flexible aluminum-shafted, small-tipped swabs for sampling sites (urethra, nasopharynx) for which larger swabs with rigid shafts would be inappropriate. Place swabs, scrapings, and small pieces of tissue into tubes or vials containing viral transport medium (VTM).

Table 10.4–1 Specimen collection^a

Specimen	Collection ^b	Representative virus(es)	Comment(s)
Amniotic fluid	Collect 5–8 ml in a sterile container.		
Blood	Collect 8–10 ml in anticoagulant (sodium citrate, EDTA, or heparin). For pediatric specimens smaller volumes are acceptable, but less than 1–2 ml may be inadequate for testing.	Arboviruses, arenaviruses, CMV, HSV, HIV-1, and other retroviruses	Useful for persistent and disseminated infections in immunocompromised patients and neonates; do not refrigerate if cell separation techniques are to be performed. Do not freeze blood.
Bone marrow	Collect at least 2 ml in anticoagulant (sodium citrate, EDTA, heparin).	CMV	
CSF	Collect 2–5 ml in a sterile container.	CMV, enteroviruses ^c other than poliovirus, HHV-6, HSV, LCMV, mumps virus	CMV: culture useful with polyradiculopathy, but not encephalitis. HSV: culture useful with meningitis or meningoencephalitis, but not encephalitis; useful for some arboviruses.
Gastrointestinal Rectal swab	Insert swab 4–6 cm into rectum, and roll swab against mucosa. Place swab into VTM.	Adenovirus, enteroviruses, ^c CMV, HSV	Not equivalent to stool sample. Useful for proctitis.
Stool	Place 2–4 g (ca. 3 tsp) into a sterile container. Add 8–10 ml of VTM if transport to laboratory is not immediate.	Adenoviruses, enteroviruses, ^c reoviruses	
Genitourinary Cervical swab	Remove exocervical mucus with swab and discard swab. Insert fresh swab at least 1 cm into cervical canal, and rotate swab against surface for 10 s. Place into VTM.	HSV, CMV	Asymptomatic HSV shedding in women: collection of a vulvar swab in addition to a cervical swab may increase viral recovery (12).
Urine	Collect 10–20 ml of midstream clean-voided urine in a sterile container.	Adenoviruses, BK virus, CMV, HSV, mumps virus, rubella virus	Low clinical specificity for CMV disease in immunocompromised individuals.
Lesion swab	Wipe vesicle with saline. Disrupt vesicle, and collect fluid with swab. With same swab, collect cells from base of the lesion. For nonvesicular lesions, collect cells from base of lesion by using a swab premoistened with saline. Place swab into VTM.	Group A coxsackieviruses, echoviruses, HSV, poxviruses, VZV	

Table 10.4-1 (continued)

Specimen	Collection ^b	Representative virus(es)	Comment(s)
Vesicle aspirate	Wipe area with sterile saline. Aspirate fluid from vesicle with a 26- or 27-gauge needle attached to a tuberculin syringe. Immediately rinse the syringe in 1–2 ml of VTM.		Preferred specimen for VZV
Mucosal swab	Swab back and forth across involved surface and place swab into VTM.	Oral: group A coxsackieviruses, HSV. Anogenital: HSV	
Ocular Conjunctival swab	Swab lower conjunctiva with flexible fine-shafted swab pre-moistened with sterile saline. Place swab into VTM.	Adenoviruses, group A coxsackieviruses, CMV, enterovirus type 70, HSV	
Corneal or conjunctival scraping	Place scraping into VTM. Specimen should be obtained only by an ophthalmologist or other trained individual.	Same as for conjunctival swab	
Pericardial fluid	Place at least 2 ml in a sterile container.	Group B coxsackieviruses	
Pleural fluid	Place at least 2 ml in a sterile container.	Group B coxsackieviruses	
Respiratory swabs Nasal	Insert flexible fine-shafted swab into nostril, rotate swab, and let it rest for several seconds to absorb secretions. Place into VTM. Use separate swabs for each nostril; both swabs may be placed into the same transport vial.	Rhinoviruses	Not recommended for other respiratory viruses; prompt inoculation into cell culture is recommended.
Nasopharyngeal	Insert flexible fine-shafted swab through nostril into nasopharynx and rotate the swab gently a few times. Place swab into VTM.	Adenoviruses, CMV, enteroviruses, ^c HSV, influenza virus, measles virus, mumps virus, parainfluenza viruses, RSV, reoviruses, rhinoviruses, rubella virus, VZV	Preferred to pharyngeal swabs for respiratory viruses; prompt inoculation into cell culture is recommended for RSV.
Pharyngeal (throat)	Vigorously swab tonsillar areas and posterior nasopharynx. Use tongue blade to depress tongue to prevent contamination of swab with saliva. Place swab into VTM.	Same as for nasopharyngeal swab	
Respiratory fluids Lower respiratory tract: bronchoalveolar lavage, bronchial wash	Place 8–10 ml in sterile container.	Viruses associated with pneumonia in otherwise healthy (e.g., influenza virus, RSV, adenoviruses) or immunocompromised (e.g., CMV, VZV) patients	

(continued)

Table 10.4–1 Specimen collection^a (continued)

Specimen	Collection ^b	Representative virus(es)	Comment(s)
Nasopharyngeal aspirate	Using mucus collection device, insert appropriate-sized catheter nasally into posterior nasopharynx. Apply suction, using intermittent suction as catheter is withdrawn. Wash aspirate through tubing with 5–8 ml of VTM or sterile saline, and transport material from trap to sterile container.	Same as for nasopharyngeal swab	Preferred upper respiratory tract specimen
Saliva	Collect saliva with one or two swabs from anterior floor of mouth and near Stenson's ducts. Place swabs into VTM.	CMV, mumps virus, rabies virus	
Tissues	Place small samples (e.g., lung biopsy specimen) into VTM to prevent drying. Place larger specimens (1–2 g; e.g., autopsy tissues) into sterile container. Add 8–10 ml of VTM.	Many viruses can be recovered from tissues during disseminated or visceral disease (e.g., CMV, HSV, adenoviruses); arboviruses, rabies virus, HSV, and other viruses associated with encephalitis can be recovered from brain tissue.	An understanding of the pathogenesis of viral infections is essential for selecting appropriate specimens. Autopsy tissues: several organs are usually sampled (liver, lung, spleen) and any organs or tissues for which involvement is suggested by clinical history or pathologic findings (e.g., brain, adrenal glands)

^a Abbreviations: tsp, teaspoons; HHV-6, human herpesvirus type 6; HIV-1, HIV type 1; HSV, herpes simplex virus; LCMV, lymphocytic choriomeningitis virus; VZV, varicella-zoster virus.

^b Use sterile screw-cap containers for fluid (other than blood) and bulk samples. For collection of swab samples, Dacron-tipped plastic- or wire-shafted swabs are recommended; do not use cotton or wooden-shafted swabs.

^c Includes group A and group B coxsackieviruses, echoviruses, enterovirus types 68 to 71, and polioviruses.

II. SPECIMEN COLLECTION

(continued)

VTM prevents specimen drying, maintains viability, and retards the growth of microbial contaminants. Most laboratories use a liquid transport medium, but other types are also used (reviewed in reference 9). Formulations are presented in Appendix 10.4–1.

1. Liquid transport media

VTM typically consists of a protein source such as bovine serum albumin, gelatin, or serum and antimicrobial agents in a buffered salt or sucrose solution. A sucrose-containing medium such as 2-SP is frequently used as a chlamydial transport medium and appears to protect labile viruses and may be particularly useful in situations requiring extended refrigeration or frozen shipment (6, 9). Transport tubes usually contain 2 to 3 ml of medium and small glass beads to facilitate specimen preparation; some sources package collection tubes and swabs together as a convenient collection kit. Use larger volumes (5 to 7 ml) of VTM to transport bulk (e.g., tissue) samples; these volumes should not be used for swabs because of the greater dilution effect.

2. Agar-containing transport systems (Stuart, Amies)

Stuart and Amies media are sometimes used to reduce the number of transport systems in an institution. Upon receipt in the laboratory, swabs are transferred to one of the liquid transport media described above. Stuart transport medium may be less satisfactory than liquid medium (9).

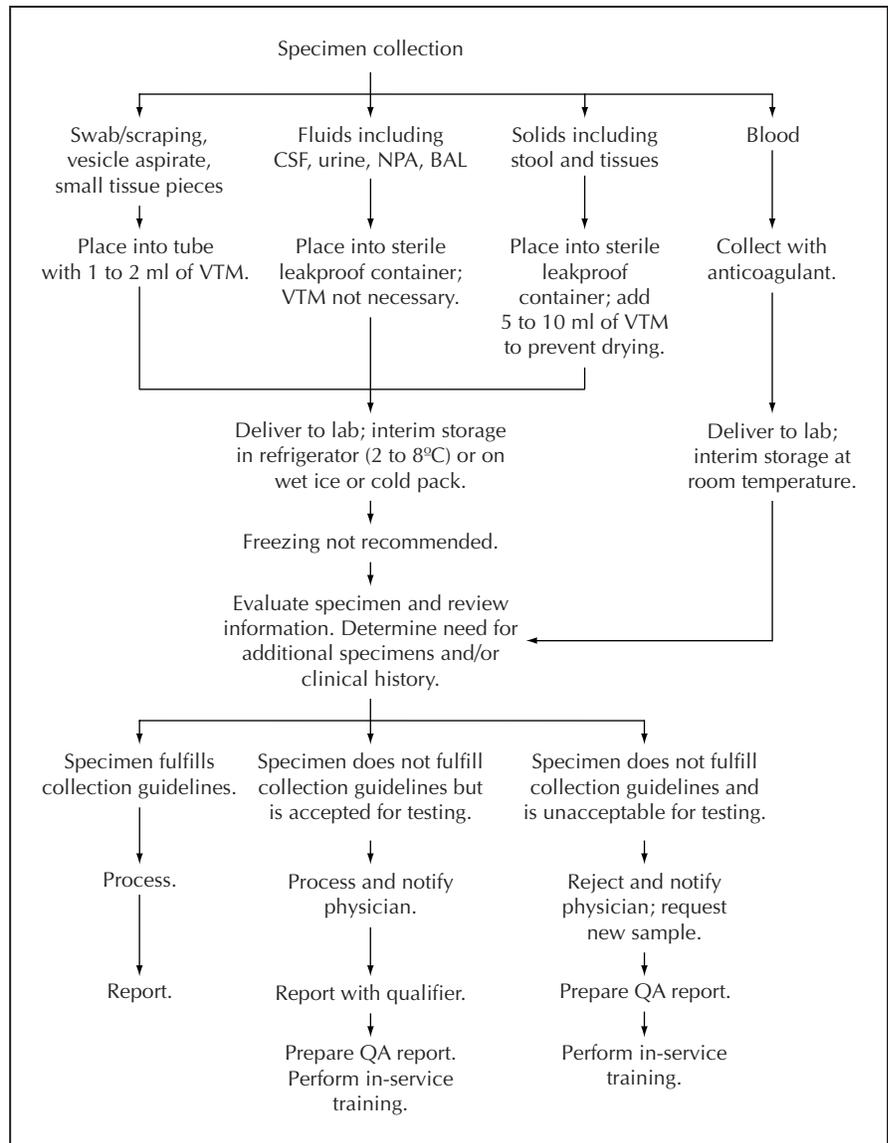

Figure 10.4–1 Summary of collection, transport, and evaluation of specimens for viral culture. NPA, nasopharyngeal aspirate; BAL, bronchoalveolar lavage fluid.

III. TEST ORDERING AND PATIENT INFORMATION

Information must be provided that uniquely identifies the patient and the ordering physician and states the viral agent(s) for which the specimen is to be tested. Laboratory utilization and cost containment issues preclude the practice of ordering “viral studies” on all specimens for which a viral laboratory diagnosis is being sought, and most requests now state the specific virus(es) being considered. However, a general “viral studies” request is usually ordered if the candidate etiologic agent(s) is not clear or symptoms are not typical, or if multiple agents are associated with the same clinical presentation. In these situations it is important to obtain information (clinical history, date of onset, history of recent exposure or vaccination, pertinent travel history, and animal or arthropod bite or exposure) that will enable the laboratory scientist to select an appropriate testing algorithm and determine the need for additional assays or specimens.

IV. TRANSPORT AND STORAGE

Place the tightly capped specimen container and the laboratory requisition form into separate compartments of a plastic specimen transport bag. Deliver all specimens to the laboratory as soon after collection as possible; a loss of infectivity occurs over time, resulting in the diminished likelihood of a positive result. Loss of viability is slower at refrigeration temperatures than at ambient temperature; samples containing labile viruses (e.g., respiratory syncytial virus [RSV] or cytomegalovirus [CMV]) at low titers are those most likely to show loss of infectivity with delayed transport. If immediate delivery to the laboratory is not possible, store specimens in a refrigerator (2 to 8°C) or place them on wet ice or a cold pack. Store and transport anticoagulated blood samples at ambient temperature because chilling may interfere with cell separation techniques.

Store specimens for which culture will be delayed beyond 48 h after collection at -70°C or lower; avoid freezing at higher temperatures and freeze-thaw cycles. If possible, snap-freeze specimens in a slurry of dry ice and acetone prior to storage. With few exceptions (e.g., arboviral studies), frozen blood specimens are unsuitable for testing. Transport frozen specimens on sufficient dry ice to ensure that specimens remain frozen until receipt by the laboratory. Pack, label, and ship specimens in compliance with regulatory guidelines.

V. SPECIMEN ACCESSIONING AND EVALUATION

It is essential to utilize a manual or computerized accessioning system that uniquely identifies each specimen and stores information required for laboratory records, including patient and physician identification, specimen type, date and time of collection, specimen condition, and test(s) requested. A system must also be in place for bringing unusual requests to the immediate attention of the laboratory director or supervisor.

No laboratory procedure can compensate for improper or inappropriate specimen collection and handling. Conditions that warrant specimen rejection include drying or warm-temperature storage. In some cases, when it is not reasonable or possible to obtain a replacement sample, it is recommended that a qualifier be included in the report when reporting a negative result. Maintain a record of rejected specimens, and review the information at least monthly to identify areas where in-service training or other intervention is necessary. Periodically review collection and transport guidelines with laboratory staff, and develop a system for identifying and correcting problems with specimen collection and transport. Prepare QA reports consistent with institutional policy, and include the corrective action taken. Establish a system to follow up with corrective action and monitor compliance with recommendations.

VI. SAFETY CONSIDERATIONS

While viruses encountered in the diagnostic laboratory usually encompass BSL 2 agents, a laboratory may be called on to assist in collection and referral of specimens requiring BSL 3 or BSL 4 practices (11). Fortunately, infections involving the latter category (e.g., arboviruses, arenaviruses, filoviruses, poxviruses, and rabies) are usually associated with specific clinical presentations, travel history, and/or animal or insect vector exposures.

VII. SPECIMEN PROCESSING**A. Fluids and aspirates**

☑ **NOTE:** Process vesicle aspirates collected in VTM as described for swab and scraping specimens.

Fluid specimens contain various amounts and types of cells, with virus both extra- and intracellular. Laboratories vary with respect to preinoculation specimen preparation procedures. For example, the addition of antimicrobial agents and thorough suspension of the sample is a simple but satisfactory preparatory

VII. SPECIMEN PROCESSING
(continued)

method for most fluid specimens. Alternatively, fluid specimens may be processed by suspending the cells in a small amount of VTM, diluent, or supernatant, after pelleting them by low-speed centrifugation. Yet another approach is to use clarified supernatant after cell disruption by sonication or vigorous vortexing with glass beads. Although one might suspect that the greatest culture positivity, particularly with a cell-associated virus such as CMV, would be achieved by using the cellular component, it has been demonstrated that clarified supernatant or a well-suspended, unprocessed bronchoalveolar lavage fluid sample can yield higher isolation rates than do pelleted cells suspended in VTM (1).

1. Materials
 - a. Pipettes (assorted) and pipetting device
 - b. Antimicrobial agent concentrate (see Appendix 10.4-1)
 - c. Vortex mixer
2. For the procedure, see Fig. 10.4-2.

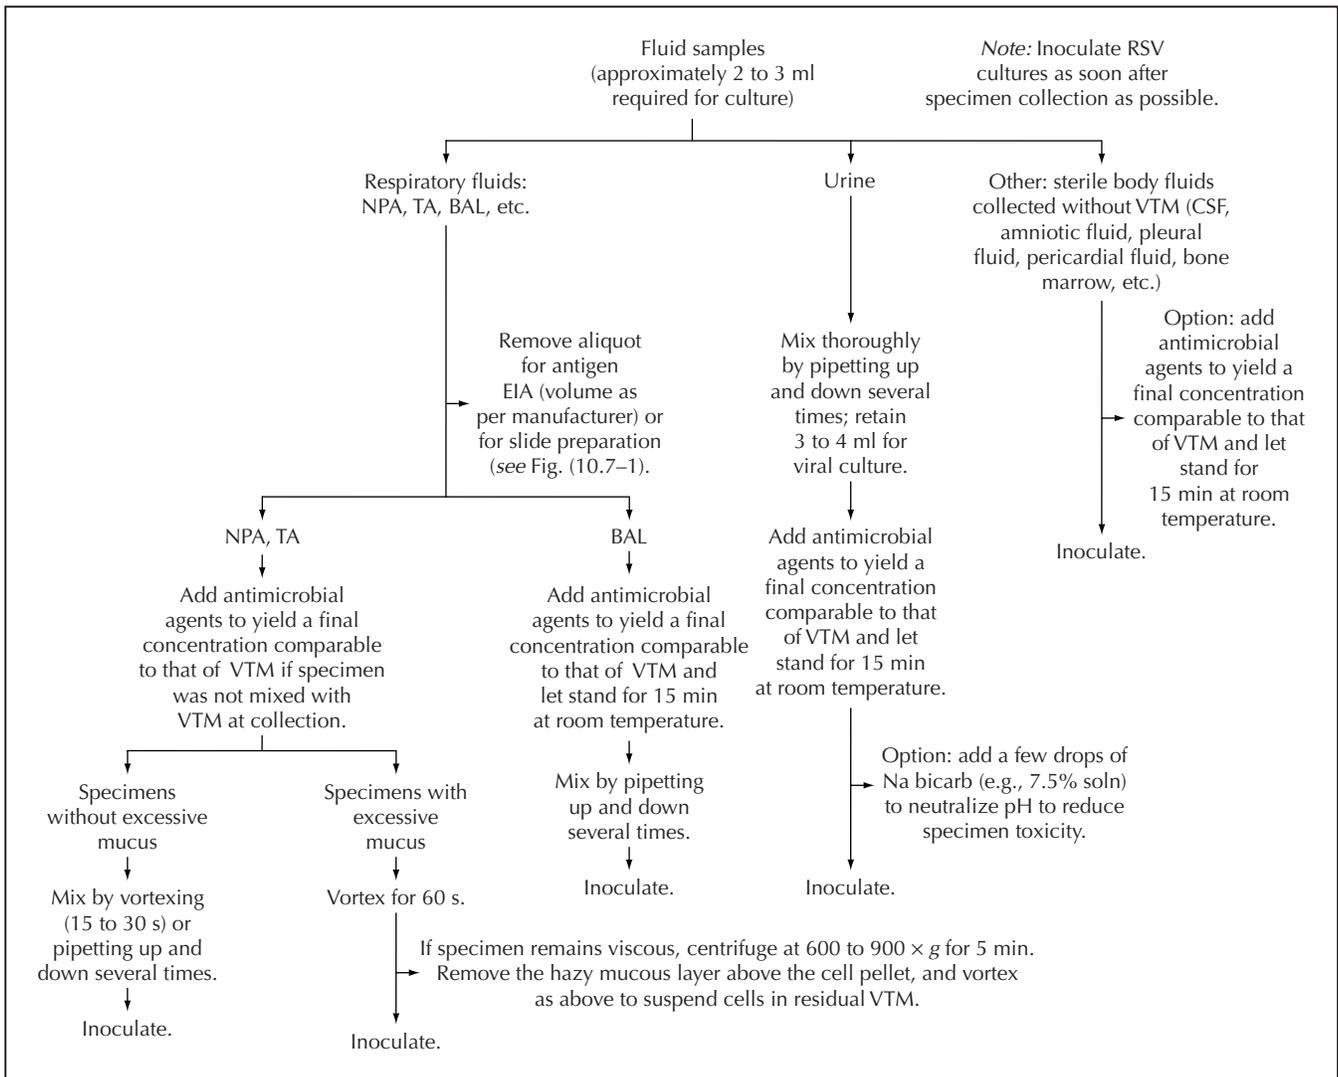

Figure 10.4-2 Preparation of fluid specimens. soln, solution; NPA, nasopharyngeal aspirate; TA, tracheal aspirate; BAL, bronchoalveolar lavage fluid.

VII. SPECIMEN PROCESSING (continued)

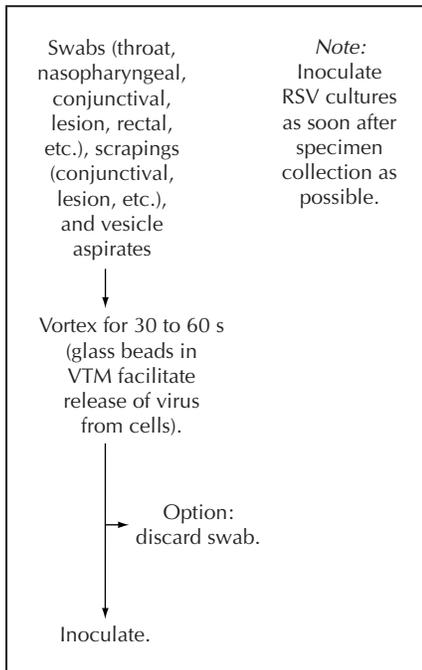

Figure 10.4-3 Preparation of swabs, scrapings, and vesicle aspirates collected in VTM.

B. Swabs, scrapings, and aspirates collected in VTM

1. Materials
 - a. Forceps
 - b. Vortex mixer
2. For the procedure, see Fig. 10.4-3.

C. Solid specimens

1. Materials
 - a. Pipettes (assorted) and pipetting device
 - b. 15-ml sterile screw-cap centrifuge tubes
 - c. Tongue blades
 - d. Sterile petri plates
 - e. Scalpels (for tissue samples)
 - f. Sterile disposable tissue grinders
 - g. Diluent: VTM or Hanks' balanced salt solution (HBSS) with antimicrobial agents
 - h. Vortex mixer
 - i. Centrifuge, refrigerated, with swinging bucket rotor
2. Procedure
 - a. For details on tissue samples, see Fig. 10.4-4.
 - b. For details on stool samples, see Fig. 10.4-5.

D. Anticoagulated blood

Viruses may be associated with various components of the blood, including PMNs (CMV), plasma (enteroviruses, arboviruses), or mononuclear cells (human immunodeficiency virus [HIV], enteroviruses, measles virus, Epstein-Barr virus). Mixed leukocyte populations (PMNs, lymphocytes, monocytes) can be recovered from anticoagulated blood by allowing RBCs to settle by gravity and harvesting the leukocyte-rich plasma. Dextran, an erythrocyte-aggregating agent, accelerates RBC sedimentation, and this method is preferred to sedimentation of untreated anticoagulated blood. Leukocytes separated by gradient centrifugation methods (3, 4) have been shown to yield higher rates of viral recovery than buffy coat preparations derived by gravity separation alone (5, 8). More recently, a modification of a rapid NH_4Cl treatment method (4) has been shown to recover WBC types in proportions similar to those found in whole blood and was useful for preparation of leukocytes for CMV culture (10).

Several cell separation products are available and should be used by following the manufacturers' instructions.

Ammonium chloride lysis method

1. Materials
 - a. Sterile pipettes (assorted) and pipetting device
 - b. Sterile 15-ml screw-cap centrifuge tubes
 - c. NH_4Cl lysis: 0.155 M NH_4Cl , pH 7.2 (Appendix 10.4-2)
 - d. Centrifuge, swinging bucket rotor
2. Procedure

NH_4Cl lysis: Fig. 10.4-6

E. Semen

Semen is not generally collected for diagnostic viral cultures, but it is sometimes used in the fertility practice and research settings (e.g., CMV, HIV type 1). Toxicity is extensive with this sample and has been shown to be associated with the enzyme-rich fluid fraction rather than the pelleted cellular elements when the sample is fractionated by centrifugation (7).

APPENDIX 10.4–1

VTM

A. HBSS with bovine serum albumin

1. Aseptically combine the following sterile reagents.

bovine serum albumin, 7.5% sterile solution	33.00 ml
HEPES, 1 M solution	10.00 ml
antimicrobial agents	variable, depending on concentrations used
HBSS, q.s. to	500.0 ml

2. The final pH should be 7.2 to 7.4 (reddish-orange color). Adjust the pH with 7.5% sodium bicarbonate solution before adding the HEPES.
3. Dispense 2.0- to 3.0-ml volumes into sterile 4-ml screw-cap tubes; dispense 5.0- to 7.0-ml volumes into 15-ml centrifuge tubes. Store frozen at -20°C for up to 6 months. Thaw just before use.
 - **NOTE:** Nystatin is insoluble in water; keep material in suspension during preparation and dispensing.
 - **NOTE:** Include three to five small (e.g., 5-mm) sterile glass beads in each vial and tube to facilitate specimen processing. Tubes should be able to withstand freezing at -70°C or lower for specimen storage (e.g., Nunc cryotubes; polypropylene centrifuge tubes).

APPENDIX 10.4–1 (continued)**B.** 2-SP (0.2 M sucrose–0.02 M phosphate) medium

1. Dissolve the following ingredients separately in approximately 300 ml of deionized water.

KH ₂ PO ₄	2.01 g
Na ₂ HPO ₄	1.13 g
sucrose	68.46 g

2. Combine the solutions and add deionized water to 1,000 ml.
3. Adjust the pH to 7.2 to 7.4.
4. Add HEPES to a final concentration of 20 mM (20.0 ml of 1 M solution per 1,000 ml).
5. Sterilize by using a 0.2- μ m-pore-size filter.
6. Aseptically add sterile antimicrobial agent concentrates.
7. Dispense 2- to 3-ml volumes into sterile 4-ml screw-cap tubes; dispense 5- to 7-ml volumes into 15-ml centrifuge tubes.
8. Store frozen at -20°C for up to 6 months. Thaw just before use. See notes above regarding nystatin and glass beads.

C. Concentration of antimicrobials in VTM

Three commonly used antimicrobial combinations are gentamicin-vancomycin-amphotericin B (or nystatin [Mycostatin]), penicillin-streptomycin-gentamicin-amphotericin B, and penicillin-streptomycin-amphotericin B (or nystatin). The following ranges (i.e., final concentrations per milliliter of transport medium or processed specimen) have been used: amphotericin, 2 to 40 $\mu\text{g}/\text{ml}$; vancomycin, 25 to 1,000 $\mu\text{g}/\text{ml}$; gentamicin, 25 to 150 $\mu\text{g}/\text{ml}$; penicillin, 50 to 55 U/ml; streptomycin, 50 to 500 $\mu\text{g}/\text{ml}$; and nystatin, 50 to 200 U/ml. The higher concentrations may be useful for specimens likely to contain high rates of microbial contamination (e.g., stool); however, high antimicrobial agent concentrations may be toxic to cell culture monolayers. Monitor toxicity by observing cell cultures that have been mock inoculated with VTM or diluent containing the antimicrobial agents.

APPENDIX 10.4–2**NH₄Cl Lysis**

Ammonium chloride lysing solution (0.155 M), with 10 mM NaHCO₃, pH 7.2

- A. Place 4.15 g of NH₄Cl and 0.42 g of NaHCO₃ in a 500-ml volumetric flask, add approximately 300 ml of double deionized water, swirl to dissolve, and then q.s. to 500 ml.
- B. Sterilize by filtration using a 0.22- μ m-pore-size filter.
- C. Store at 2 to 8 $^{\circ}\text{C}$ (up to 6 months).

10.5

Viral Culture: Isolation of Viruses in Cell Cultures

I. PRINCIPLE

Viral culture laboratories generally use a combination of tube and shell vial cultures. A number of variables can influence the sensitivity of viral cultures, including cell culture type, age and confluence of the monolayer, the number of tubes or vials inoculated, the inoculation and incubation conditions, and the method and reagent used for isolate detection or identification.

A. Tube cultures

Adherent cell culture monolayers are inoculated and observed for evidence of viral replication, most commonly observed as cytopathic effect (CPE) or hemadsorption (HAd). Once viral CPE or HAd is observed, isolate identifi-

cation is confirmed, usually by immunofluorescence (IF).

B. Shell vial cultures

The shell vial culture method uses centrifugation-enhanced inoculation of cells monolayered on a coverslip contained in a flat-bottomed shell vial. After incubation for 1 to 5 days, the monolayers are fixed and examined, most frequently by IF, for evidence of viral infection. The overnight pre-CPE detection of cytomegalovirus (CMV) in shell vial cultures, by using a monoclonal antibody directed against a viral protein expressed in the cell nucleus within several hours after infection, in-

troduced the concept of rapid viral cultures (10, 18). Unlike for most CMV shell vial cultures, CPE may be apparent for other viral cultures by the time staining is performed, depending on the length of incubation.

Despite the great utility of shell vial cultures, this methodology does not eliminate the utility of tube cultures. Furthermore, the use of shell vial cultures does not eliminate the need to develop cell culture expertise, including the ability to identify viral CPE and differentiate it from problems that may arise in inoculated cell cultures, even during brief incubation.

PREANALYTICAL CONSIDERATIONS

II. SPECIMENS

- A. Prepare specimens as described in procedure 10.4.
- B. Thaw frozen specimens rapidly and completely by swirling in a 37°C water bath until they are *almost* thawed; do not allow thawed specimens to remain at 37°C.

III. MATERIALS

A. Supplies

1. Racks designed to hold culture tubes in a slightly slanted horizontal position with the necks slightly raised
2. Sterile individually wrapped pipettes (1-, 2-, 5-, and 10-ml sizes) and safety pipetting devices
3. Cold blocks or ice
4. Personal protective gear
5. Waste containers
Discard specimens, cell cultures, and other infectious waste based on local regulations.
6. Microscope slides (1 by 3 in.) for mounting shell vial coverslips

7. Teflon-coated microscope slides with 5- to 8-mm wells and no. 1 coverslips for IF
8. 0.22- μ m-pore-size filters for culture decontamination
9. Sterile screw-cap vials (2 and 4 ml) suitable for freezing isolates at -70°C
10. Sterile 15-ml polypropylene conical centrifuge tubes
11. Labels for tubes and marking pens
12. Dry ice

B. Cell cultures

Select cell culture types based on the guidelines presented in procedure 10.2.

III. MATERIALS (continued)

Include QC information on reagent container and in QC records.

C. Reagents

1. Cell culture medium (*see* procedure 10.2)
2. Immunologic reagents
Reagents are available from several sources. Most antibody reagents used for viral identification are monoclonal antibodies (MAbs); because of their high specificity and lower binding efficiencies, a mixture of MAbs directed against different viral epitopes is generally more useful than individual MAB preparations. Mixtures of MAbs (blends, pools) directed against two or more viruses are also available for detecting multiple viruses with a single reagent (13, 15, 19). Recently, mixed antibody preparations labeled with different fluorescing reagents have been introduced for the simultaneous identification of common virus pairs (e.g., influenza virus types A and B [1, 3], herpes simplex virus [HSV], and CMV).
3. Sterile phosphate-buffered saline (PBS), pH 7.2 to 7.6
4. Hanks' balanced salt solution (HBSS)
5. Buffered glycerol mounting medium, pH 8.0, for IF
6. Acetone or other fixative recommended by the antibody manufacturer
7. Guinea pig blood in Alsever's solution for HAd
8. Disinfectants
Hypochlorite solution (0.5%), Wescodyne, 70% ethanol

D. Equipment

1. Microscope ($\times 100$)
Shell vials can be examined by using an inverted microscope with a glass microscope slide over the objective to support the vial. Tube cultures can be examined by using

a standard or inverted microscope; tubes can be held in place with a holder consisting of two parallel tracks glued to the stage.

■ **NOTE:** One end of the holder should be slightly higher so that the culture medium does not flow into the caps during observation.

2. Class II biological safety cabinet (certified semiannually)
Wipe down all interior cabinet surfaces with 70% ethanol or another appropriate reagent before and after each use.
■ **NOTE:** 10% Clorox is used by many laboratories to wipe down bench surfaces; this material will cause pitting and deterioration of the stainless steel surfaces of the biological safety cabinet.
3. Centrifuge
Swinging bucket rotor with carriers to accommodate 15-ml centrifuge tubes and shell vials (15 by 45 mm); size 00 rubber stoppers may be used as cushions to adapt carriers to hold shell vials.
4. Incubator (34 to 37°C)
A CO₂ environment is not necessary for tube or shell vial cultures since these vessels are generally tightly capped during incubation. However, cell culture methods with plastic dishes, microtiter plates, or vented flasks require an atmosphere containing 5 to 8% CO₂.
5. Roller drum (optional) to hold tubes horizontally in incubator at 12 to 15 rph
6. Rotator (15 to 20 rpm) or rocker (for IF)
7. Fluorescence microscope equipped with filters suitable for fluorescein isothiocyanate (FITC) or fluorochrome of choice
8. Refrigerator at 2 to 8°C
9. Ultralow freezer, -70°C or lower

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL****A. Incubators**

1. Temperature stability is important. If a universal incubation temperature of 35°C is selected, the acceptable range should be 34 to 37°C. Check incubators for hot spots and utilize a continuous temperature-monitoring system.
2. Temperatures above 36°C may adversely affect respiratory virus recovery, particularly that of rhinoviruses, which prefer 33°C.

IV. QUALITY CONTROL (continued)

B. Cell cultures

1. Record the lot number of cell cultures used for each specimen.
2. Uninoculated (negative) controls
 - a. Select several uninoculated controls from each lot. Inoculate, observe, and process in parallel with inoculated specimens.
 - b. Utilize uninoculated lot-matched cultures as negative controls for assays (e.g., HAd and IF).
3. Inoculated (positive) controls
 - a. Use viral QC stocks to assess cell culture sensitivity. Positive cell culture controls can be particularly useful when a sensitivity problem is suspected or when new culture types or sources are being evaluated. Cell culture susceptibility can be affected by several variables (e.g., monolayer density and age, mycoplasmal contamination, endogenous virus contamination), and quality can vary from lot to lot. A typical QC panel for a general viral culture laboratory consists of those viruses most likely to be encountered in the patient population served by the laboratory. Cell culture sensitivity is best determined by low virus doses or, ideally, by titrating characterized stocks (Appendix 10.5–1). However, the time and cost of performing titrations on each lot of cells are prohibitive, and laboratories generally limit use of titrations to special circumstances (e.g., reduction in isolation rate, evaluation of new cell lines or vendors, or development of a new isolation procedure). Communication among laboratories regarding suspected cell culture problems is invaluable for identifying problems with cell culture performance.
 - b. Use virus-inoculated cell cultures as controls for assays (e.g., HAd or IF).
 NOTE: Characterized viral QC material can be obtained from several sources, including proficiency testing samples, reference laboratories, or the ATCC (Manassas, Va., [800] 638-6597). Prepare stock material by inoculating several tubes and harvesting positive cultures as described for viral isolation; dispense in single-use aliquots and store at -70°C or lower.

C. Fetal bovine serum (FBS) and other cell culture reagents

1. Cell culture reagents must be sterile and nontoxic to cell culture monolayers.
2. Cell culture medium must maintain cells in a metabolically active condition and must not be inhibitory to viral replication.

V. PROCEDURES

A. Inoculation (Fig. 10.5–1)

1. The recommended method consists of adsorption of the prepared specimen onto a drained monolayer as described in Fig. 10.5–1. Alternatively, the specimen can be inoculated directly into the tube containing 1 to 2 ml of cell culture medium; refeed tubes with fresh medium before inoculation. The latter method may be particularly useful for specimens known to be very toxic to cell monolayers (stool suspensions, blood, bone marrow, and urine).
2. A variety of centrifugation forces and times have been used for shell vial cultures (reviewed in reference 11). Centrifugation forces of 700 to $900 \times g$ for 30 to 45 min are most commonly used, although a shorter centrifugation at $3,500 \times g$ has provided good results without adversely affecting monolayer integrity (5).

B. Incubation

1. Many laboratories use an incubation temperature of 35°C (34 to 37°C) for all viral cultures, while others incubate respiratory virus cultures at 33 to 34°C .

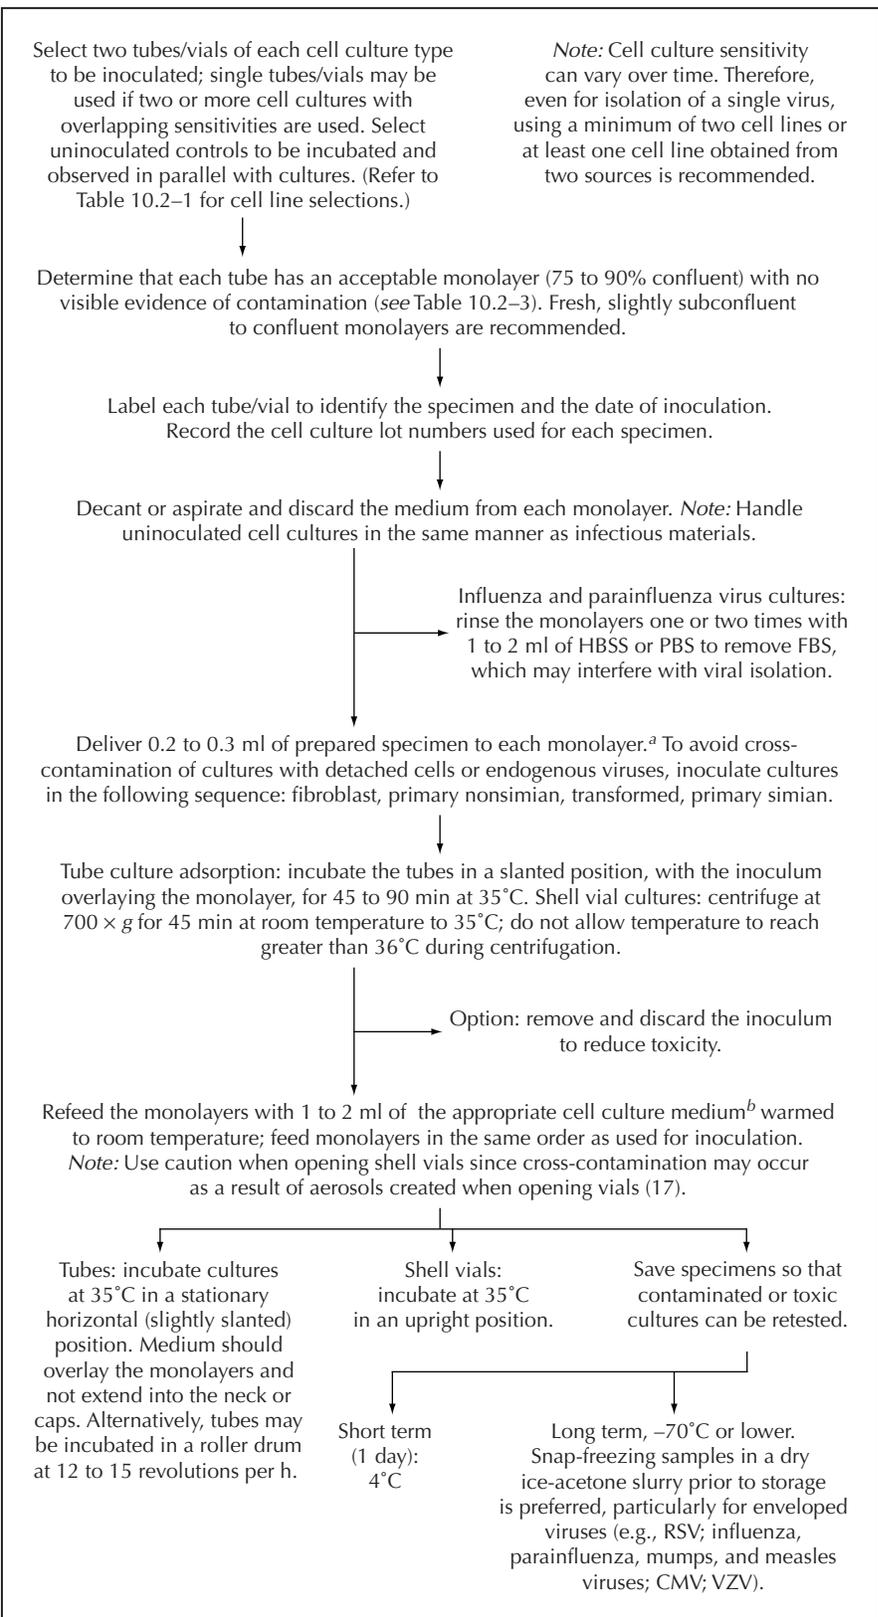

Figure 10.5-1 Inoculation of tube and shell vial cell cultures for the detection of cytopathic and hemadsorbing viruses (see Table 10.5-1). RSV, respiratory syncytial virus.

^a CMV antigenemia or molecular assays (e.g., PCR) have largely supplanted cell culture for detecting CMV in blood samples. When using shell vial cultures for recovery of CMV from blood, inoculate three vials with approximately 1.5×10^6 leukocytes per vial. It has been reported that a total of at least 4×10^6 leukocytes is recommended for the sensitive detection of CMV viremia using human lung fibroblasts (2); concentrations of $>2 \times 10^6$ cells per vial are not generally recommended because of toxicity.

^b Eagle minimal essential medium (EMEM) supplemented with 2% heat-inactivated FBS is a medium suitable for all or most viral cultures performed in the diagnostic setting with monolayered cell cultures; serum-free EMEM or other serum-free cell culture medium is used by many laboratories for the isolation of influenza and parainfluenza viruses. Medium containing trypsin is recommended for influenza virus cultures when using MDCK cells (see Table 10.2-1).

V. PROCEDURES (*continued*)

2. Incubate shell vials in an upright position. Tubes may be incubated in a stationary horizontal position or in a roller drum. Low-speed rolling (12 to 15 rph) has been shown to enhance recovery of several viruses (reviewed in reference 11).

☑ **NOTE:** Tissue degeneration may accelerate for some cell lines during roller incubation.

3. Observe inoculated tube cultures for 10 to 14 days after inoculation. Longer incubation times, up to 4 to 6 weeks, have traditionally been used for CMV tube cultures, particularly for isolation from blood and tissue specimens containing low concentrations of virus. However, extended culture times may have little clinical value. Time points for terminating shell vial cultures also vary. For example, some laboratories perform staining for CMV at 24 h, while others stain at 48 h, and yet others stain at both time points. Incubation times for shell vial cultures for other viruses range from 24 h to 4 to 5 days, depending on the virus and the laboratory's experience with sensitivity at different time points compared with that of tube cultures.

C. Observation of inoculated monolayers

1. Observe monolayers for the development of viral CPE and/or HAd (Fig. 10.5–2) and problems and conditions sometimes encountered with cell cultures (Fig. 10.5–3); record all observations and manipulations.
2. Most of the human viruses encountered in the diagnostic virology laboratory produce a characteristic CPE (Table 10.5–1). CPE represents a composite of morphological changes that may include swelling, rounding, clumping, and increased refractility of cells; cytoplasmic vacuolation, granulation, and nuclear condensation; and the development of multinucleated giant cells (syncytia). It is usually progressive and may lead to complete monolayer destruction. The appearance, the time required for the development of CPE, and the rate of progression are determined not only by the type and dose of virus in the inoculum but also by the monolayer type, age, and density. These characteristics also provide a basis for tentative identification of the viral isolate. Commonly encountered CPEs are illustrated in Fig. 10.5–4, parts 1 to 7.
3. Endogenous viruses can also produce CPE, including many simian viruses. Simian virus 40 (SV40) (vacuolating virus) produces cytoplasmic vacuoles, and simian foamy virus produces large vacuoles resembling soap foam. Simian adenoviruses, herpes B virus, enteroviruses, reovirus, and measles virus can produce CPE mimicking the CPE produced by their human counterparts and can cause human infections associated with high mortality (herpes B virus, Marburg virus).

D. HAd procedure

1. HAd with guinea pig RBCs (*see* Fig. 10.5–5) is a simple and inexpensive way to screen inoculated cell cultures to detect influenza, parainfluenza, mumps, and Newcastle disease viruses. Perform this procedure as shown in Fig. 10.5–6.
2. SV5, a simian parainfluenza virus, hemadsorbs guinea pig RBCs and is an important endogenous contaminant of primary monkey kidney cells.
3. HAd, the attachment of RBCs to infected cells, is mediated by hemagglutinins, viral envelope proteins that are inserted into the plasma membranes of infected cells during viral replication.
4. Not all hemadsorbing viruses produce CPE (Table 10.5–1).

E. Isolate detection and identification

1. Direct or indirect IF with MAbs is the method most frequently used by diagnostic laboratories to identify viral isolates in tube and shell vial cultures. FITC is the most commonly used fluorochrome, with specific staining appearing as bright to brilliant apple-green fluorescence.

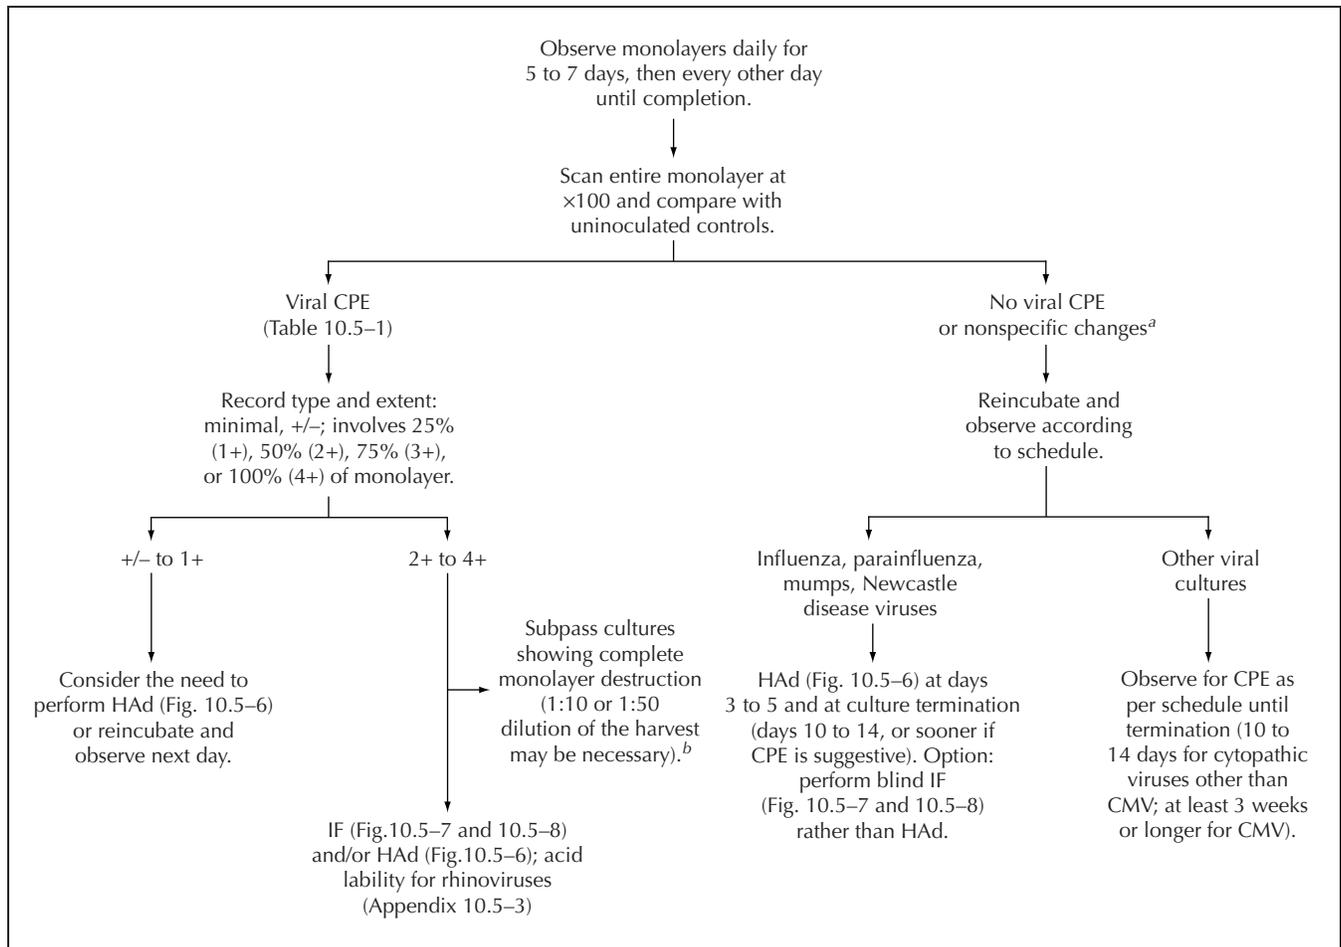

Figure 10.5-2 Observation of inoculated monolayers: CPE and HAd. *Note:* Rarely, cells exhibiting minimal CPE revert to a normal appearance. Subpassage or reinoculation may be helpful in this instance. RSV, respiratory syncytial virus.

^a See Fig. 10.5-3.

^b Viral viability may decline rapidly with incubation in the absence of cells, particularly with labile viruses (e.g., RSV, CMV).

V. PROCEDURES *(continued)*

2. Prepare slides from tube cultures for isolate identification by IF or immunoperoxidase staining as described in Fig. 10.5-7. This procedure yields cell spots suitable for culture confirmation of isolates obtained in tube cultures.
3. Perform IF for tube culture confirmation as described in Fig. 10.5-8. IF staining patterns vary with the virus and the antibody preparation used (Fig. 10.5-9).
4. For shell vial cultures, establish the time points for fixing and staining monolayers and follow the procedure described in Fig. 10.5-10.
5. Perform IF on shell vial coverslips as described in Fig. 10.5-11. IF staining patterns vary with the virus and the antibody preparation used (Fig. 10.5-9).
6. Commercial reagents are supplied either at the appropriate working dilution or with instructions for preparing the optimal working dilution; products generally contain a counterstain such as trypan blue which stains cells to aid in visualization of cells and provide a contrasting background color for the IF staining.

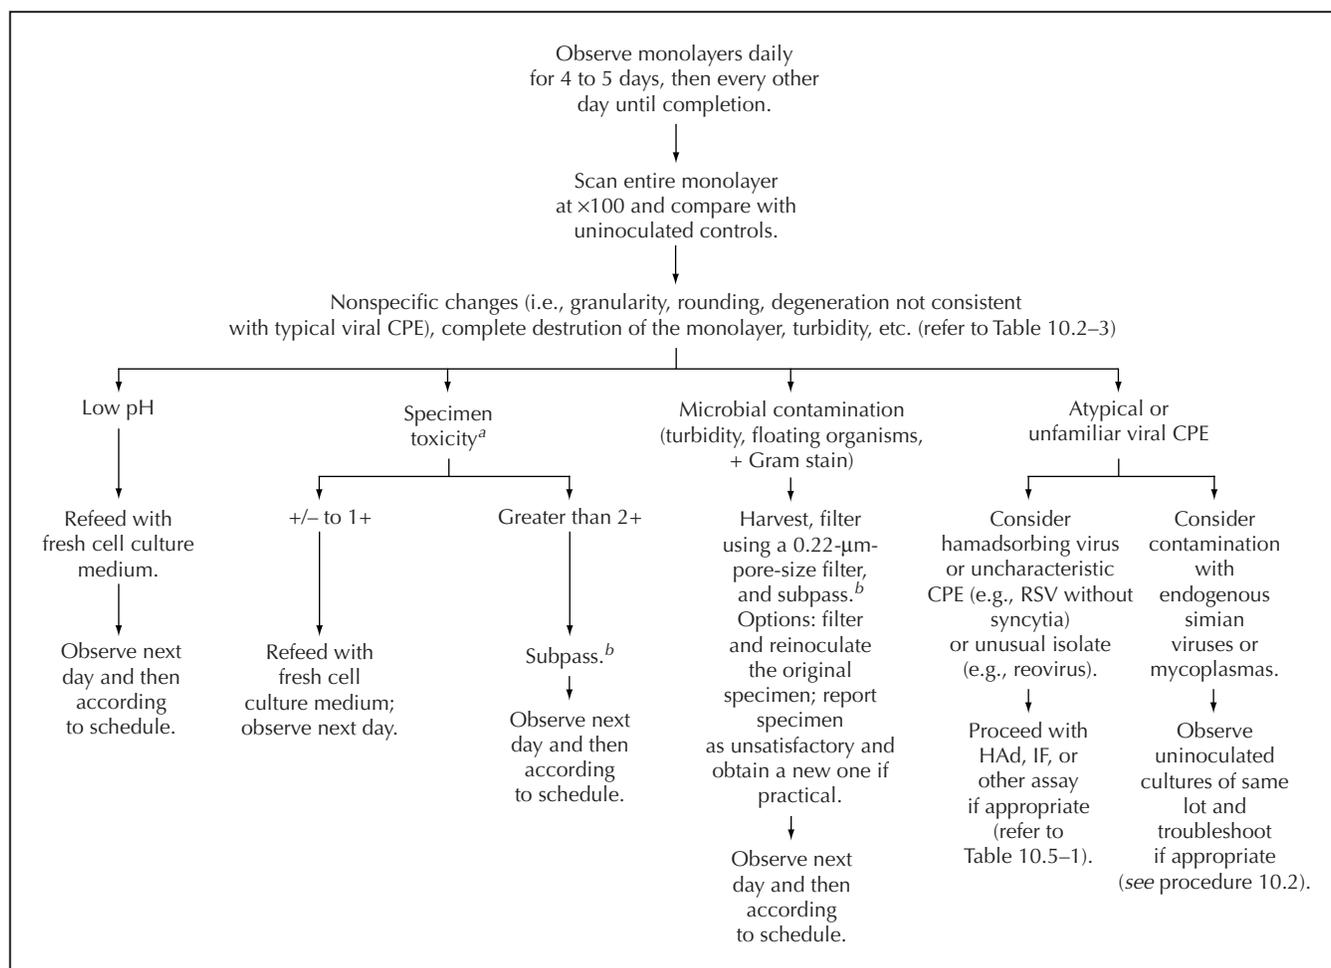

Figure 10.5-3 Observation of inoculated cell cultures: toxicity, microbial contamination, and atypical changes. RSV, respiratory syncytial virus.

^a In rare cases, specimen toxicity may be so great that two or three subpassages are required. Unlike viral CPE, toxicity may sometimes be observed at 3 to 4 h after inoculation.

^b Viral viability may decline rapidly with incubation in the absence of cells, particularly with labile viruses (e.g., respiratory syncytial virus, CMV).

V. PROCEDURES (continued)

7. In addition to IF, immunoperoxidase staining, solid-phase EIA, or nucleic acid hybridization (8, 12) can also be used to identify isolates.
8. Other immunologic methods are occasionally used by the diagnostic laboratory (e.g., neutralization for typing enteroviruses, adenoviruses [Appendix 10.5-2]; HAd inhibition, hemagglutination inhibition [HI] for subtyping influenza virus isolates). Alternatively, laboratories may arrange to send isolates to reference or public health laboratories when typing or subtyping is important (e.g., influenza surveillance).
9. Immunologic reagents are not available for identification of rhinoviruses; these viruses are distinguished from enteroviruses with the acid lability assay (Appendix 10.5-3).

F. Rubella interference assay (see Appendix 10.5-4)

Table 10.5-1 Viral culture characteristics^a

Virus	Characteristic CPE ^c				Shell vial applications	
	Appearance	Development ^b (days)	Progression	Comment(s)		
Adenoviruses	Enlarged, rounded cells in tightly associated grape-like clusters. Some isolates may produce a lattice-type arrangement of rounded cells.	4-7	Moderate	CPE is less characteristic in diploid fibroblasts.	IF (group-specific antibody), neutralization ^c useful for typing (Appendix 10.5-2)	Sensitivity may be low compared with that of tube cultures (15, 16).
CMV	Plump, rounded cells in elongated foci parallel to the long axis of the cell	7-10	Slow	CPE may take 2-3 weeks or longer to develop with low viral concentrations; CPE may develop rapidly with specimens containing high viral concentrations. Some isolates may not progress beyond a few patches of CPE.	IF; identification of isolates with minimal CPE may be facilitated by subpassing harvested cells and fluid into centrifugation-enhanced shell vial cultures.	The shell vial technique has largely supplanted tube culture for this agent.
Enteroviruses	Rounded, highly refractile cells in loose clusters or dispersed throughout monolayer; varies with enterovirus group.	2-5	Moderate to rapid, depending on the virus		IF (panenterovirus MAb, polio blends, type-specific MAbs); isolates not confirmable by IF may be identified by neutralization ^c (Appendix 10.5-2). A panenterovirus MAb has been shown to be useful for culture confirmation of many isolates.	Ruling out poliovirus is important and can be accomplished by using a blend of MAbs to the three poliovirus types.

(continued)

Table 10.5-1 Viral culture characteristics^a (continued)

Virus	Characteristic CPE ^b				Isolate identification	Shell vial applications
	Appearance	Development ^b (days)	Progression	Comment(s)		
HSV	Clusters of rounded, ballooned cells with or without syncytia. Early CPE is focal but then progresses throughout the monolayer.	1-3	Moderate to rapid	CPE may develop more slowly and be less characteristic in human fibroblasts. Simian B virus produces a similar CPE in simian cells.	IF (type-specific MAbs, type 1-type 2 blends)	Shell vials may yield a less dramatic improvement over tube cultures since most isolates can be detected from genital specimens collected from symptomatic individuals within 24-72 h after inoculation of tube cultures. However, shell vial cultures may improve the recovery of HSV in less sensitive cell lines and with specimens containing low viral concentrations (22).
Influenza virus	Variable. No CPE may be produced or may include granular and vacuolated appearance or nonspecific degeneration. Rounded refractile cells may be associated with type B.	3-5	Moderate	HAd with guinea pig RBCs; degree of HAd is independent of the presence or degree of CPE. Blind IF (e.g., at days 3-5 and/or at culture termination) rather than HAd may enhance isolation. Incorporate trypsin in medium when using MDCK cells (6, 20).	IF (type-specific MAbs, dual-labeled mixtures [1, 3], pools containing antibodies against several respiratory viruses). Subtyping by IF, HI	Shell vials have been shown to be useful for respiratory viruses (6, 12), including the use of MAb pools (13, 15, 16, 18). Staining performed at 1-4 days
Measles virus	Syncytia develop by fusion of cells. Nuclei may encircle granular mass of giant cell. Extensive vacuolization may also be present.	5-10	Slow to moderate		IF	A-549 useful (urine specimens required longer [up to 5 days] than NP swabs [18-36 h] [14])

Mumps virus	Cell rounding and syncytium formation. May appear as nonspecific-looking granularity with progressive degeneration.	3–7	Moderate	HAd with guinea pig RBCs	IF	Shell vials have been shown to be useful for respiratory viruses (12, 13, 15, 16, 19). Staining performed at 1–4 days.
Parainfluenza viruses	Variable, with increased rounding, granularity, and progressive degeneration; syncytium formation associated with types 2 and 3.	3–7; type 4 may require incubation beyond the usual 10–14 days	Moderate	HAd with guinea pig RBCs; type 4 hemadsorbs better at room temp or 37°C than at the usual incubation temp of 4°C (4) Blind IF (e.g., at days 3–5 and/or at culture termination) may enhance isolation. Incorporate trypsin in medium when using LLC-MK ₂ cells (7).	IF (type-specific MAbs, pools containing antibodies against several respiratory viruses, including parainfluenza virus types 1, 2, and 3)	Shell vials have been shown to be useful for respiratory viruses (12, 13, 15, 16, 19). Staining performed at 1–4 days.
Reoviruses	Nonspecific-looking granular appearance with progressive degeneration and detaching of the monolayer	7–10	Slow to moderate	CPE may be difficult to distinguish from nonspecific monolayer degeneration.	Neutralization ^c (Appendix 10.5–2)	
RSV ^d	Syncytia develop in some cell lines, particularly confluent HEp-2 cells. May also appear as granular progressive degeneration.	3–5	Moderate	Blind IF (e.g., at days 3–5 and/or at culture termination) may enhance isolation.	IF (type-specific MAbs, pools containing antibodies against several respiratory viruses)	Shell vials have been shown to be useful for respiratory viruses (12, 13, 15, 16, 19). Staining performed at 1–4 days; longer incubation shown to detect more isolates (15).
Rhinoviruses	Enterovirus-like	5–7	Moderate	Incubation at 33°C preferred.	Acid lability assay (Appendix 10.5–3)	
Rubella virus	CPE not produced on primary isolation				Interference assay (Appendix 10.5–4), IF	Shell vial technique appears useful (21).

(continued)

Table 10.5-1 Viral culture characteristics^a (continued)

Virus	Characteristic CPE ^c				Shell vial applications
	Appearance	Development ^b (days)	Progression	Comment(s)	
Vaccinia virus	Syncytia and clusters of rounded, enlarged, refractile cells with cytoplasmic strands frequently bridging foci of CPE	1-3	Moderate to rapid	HAd with chicken RBCs	IF, neutralization ^c (Appendix 10.5-2)
VZV	Foci of enlarged, rounded, refractile cells with or without syncytia Cytoplasmic strands and granularity may be prominent as CPE progresses.	4-7	Slow to moderate		IF; identification of isolates with minimal CPE may be facilitated by subpassing harvested cells and fluid into centrifugation-enhanced shell vial cultures.

^a Certain viruses require specialized culture techniques or are noncultivable. Refer to Table 10.5-2.

^b Time generally required for majority of isolates to produce CPE or HAd.

^c Neutralization assay involves mixing the isolate with antiserum containing neutralizing antibodies and, after a brief incubation, inoculating the cell cultures with the virus-antibody mixture(s). Neutralization by an antibody is determined by the failure to develop CPE, thereby establishing viral identity (Appendix 10.5-2).

^d RSV, respiratory syncytial virus.

^e See Fig. 10.5-4, parts 1 to 6.

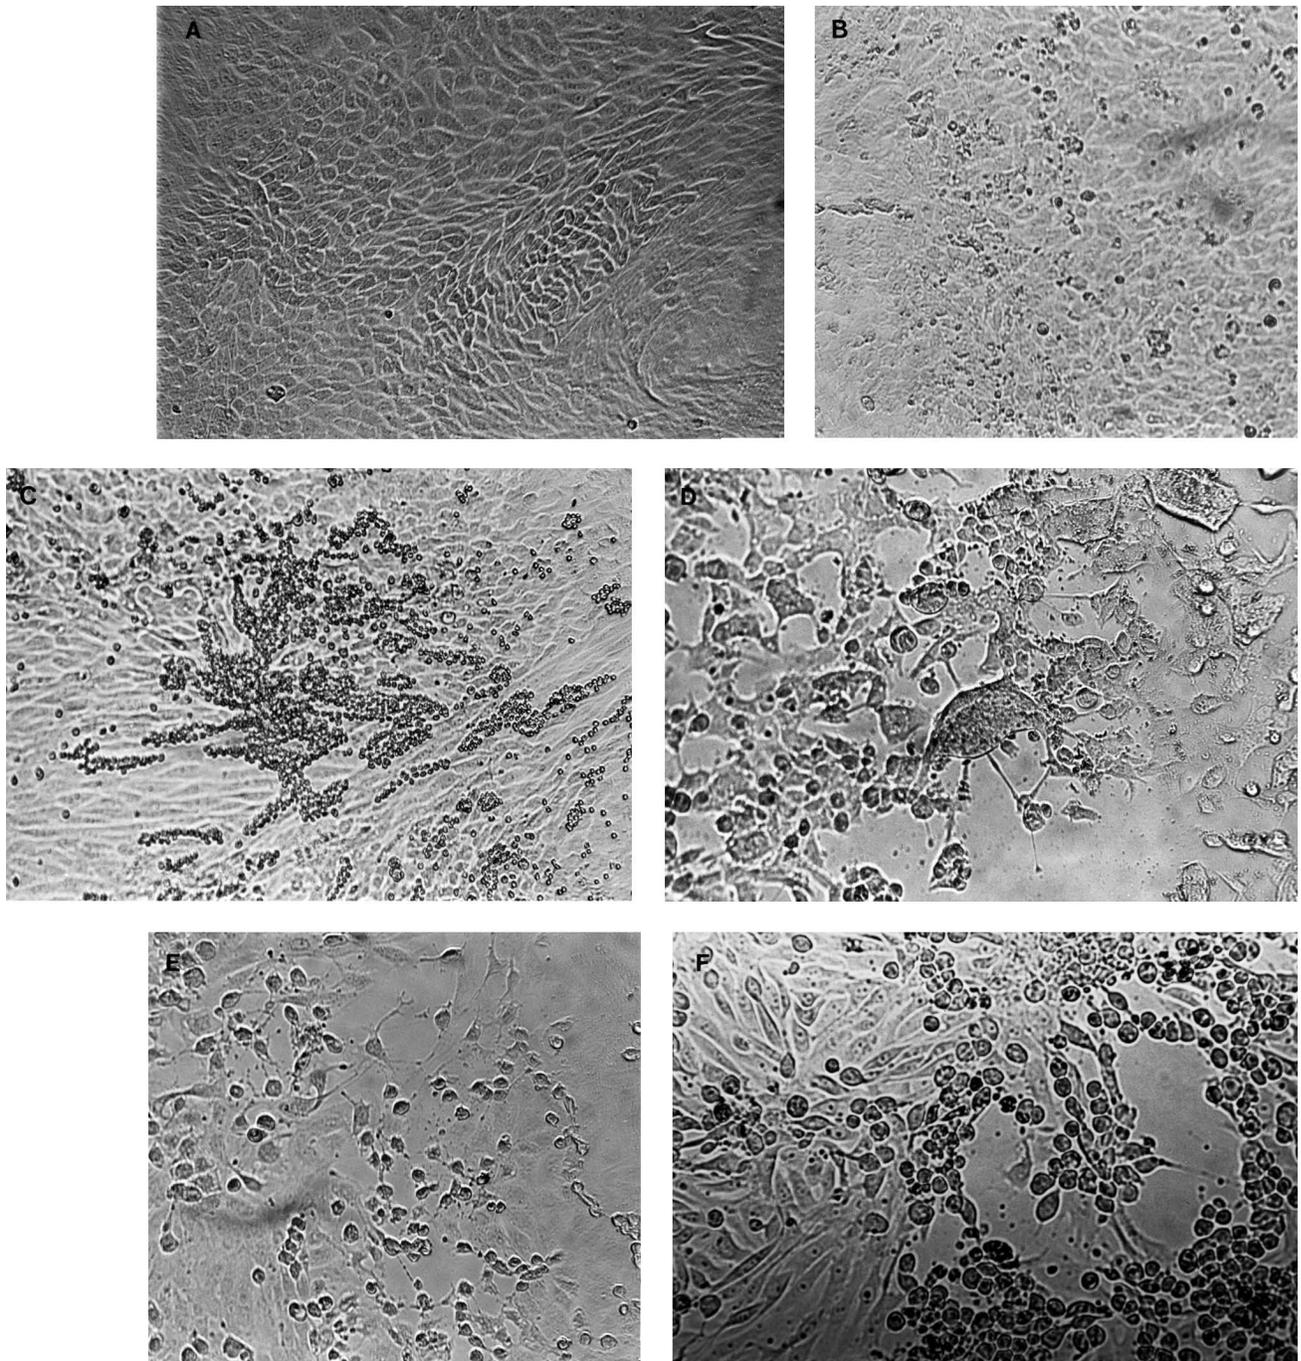

Figure 10.5-4 (part 1) Primary rhesus monkey kidney cell cultures. Original magnification, $\times 200$. (A) Uninoculated confluent monolayer; (B) influenza virus type B-infected culture showing granular cytopathic changes produced by some influenza virus strains; (C) culture infected with influenza virus type A, showing HA of guinea pig RBCs; (D) cellular rounding and syncytium formation produced by measles virus; (E) culture infected with coxsackievirus type B3 showing scattered rounded refractile cells frequently referred to as enterovirus-like CPE; (F) CPE produced by echovirus type 11 (courtesy of CDC).

(L) Same field as panel K viewed with a tetramethyl rhodamine isocyanate/rhodamine filter. Influenza B-infected cells appear hot pink to red ($\times 200$); arrows indicate the location of influenza A-infected cells observed in panel K but which are not visible with this filter system. Provided by Chemicon International.

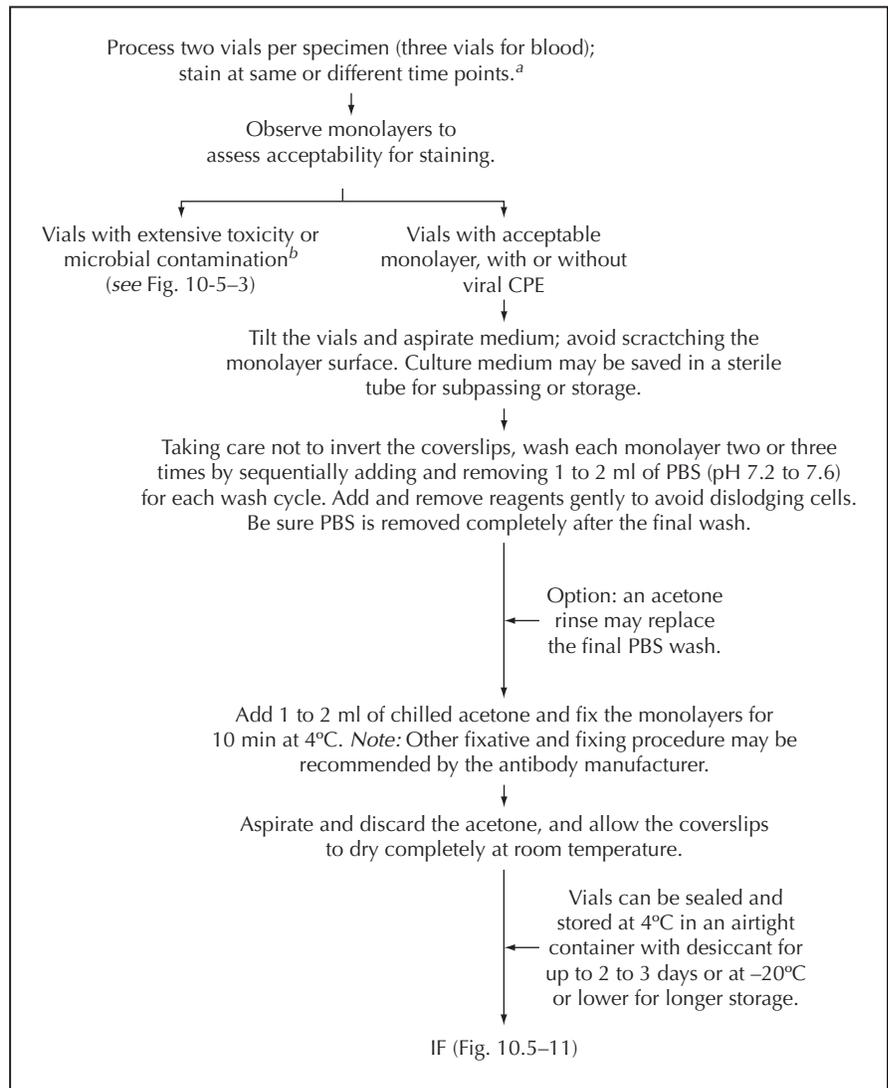

Figure 10.5-10 Shell vial processing.

^a The sensitivity of shell vial cultures is influenced by the length of incubation, and each laboratory must determine appropriate staining timepoints. Typically, shell vial incubation times range from 18 to 36 h (e.g., CMV, HSV) to up to 5 days (e.g., VZV).

^b Complete monolayer destruction may also be caused by a rapid CPE.

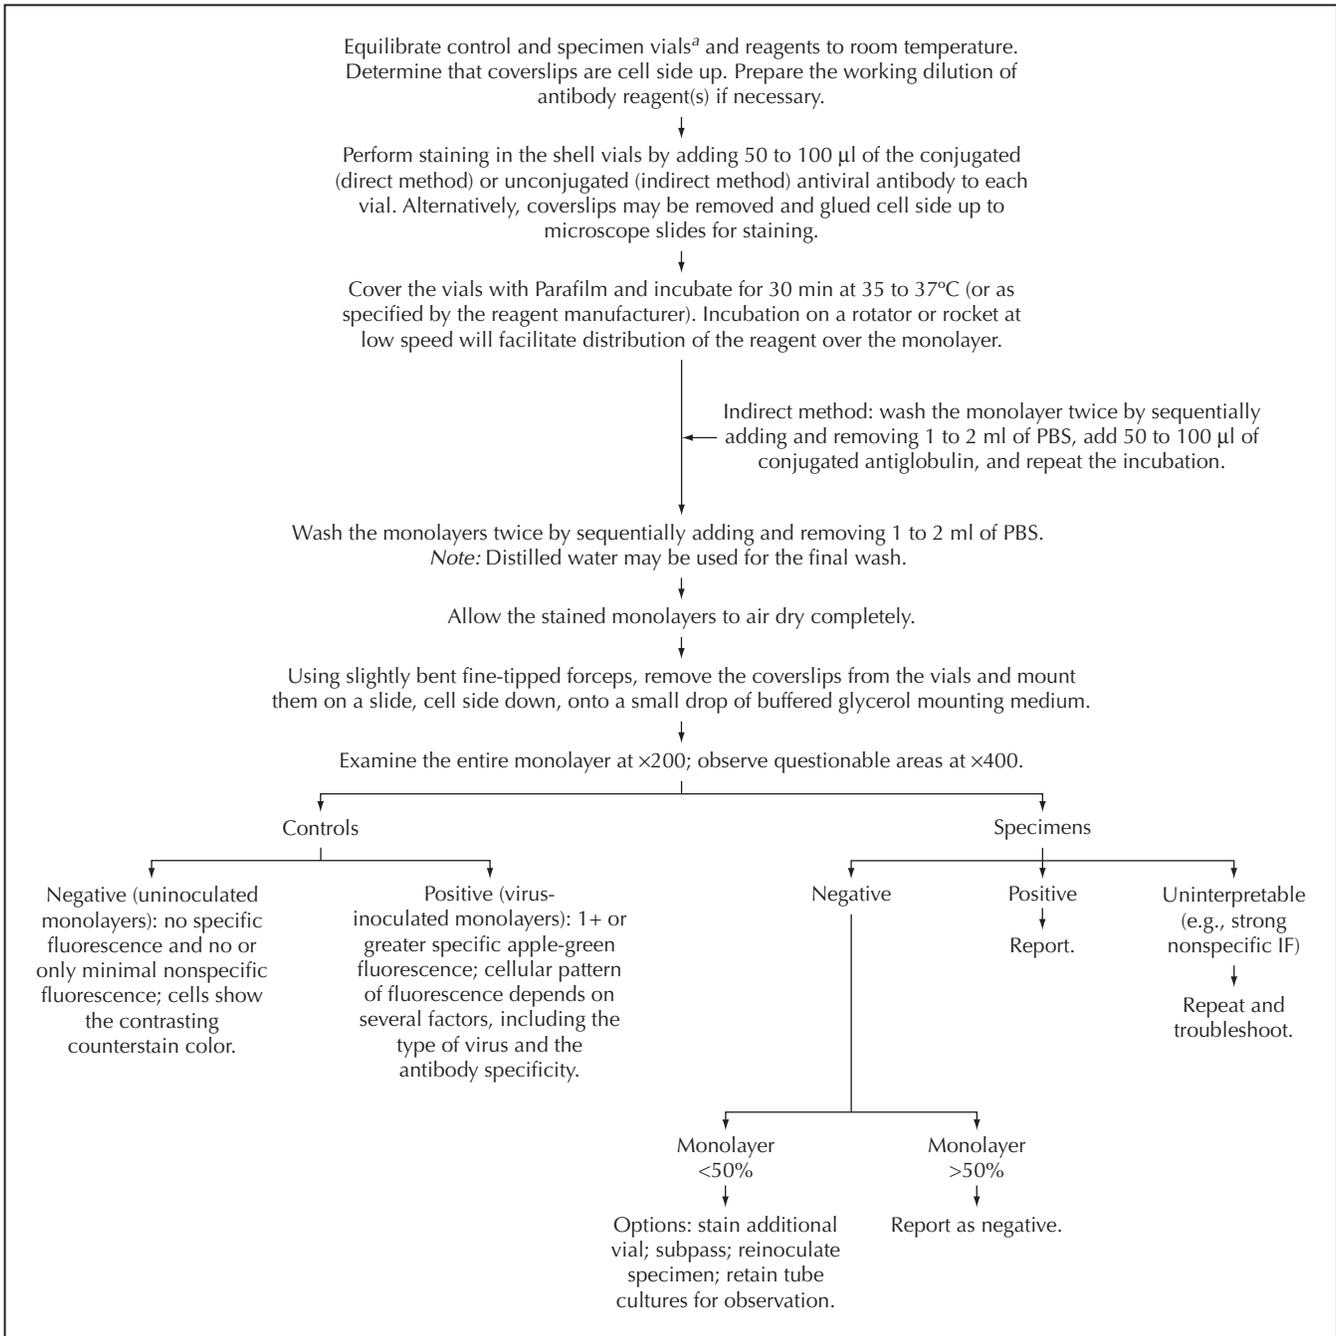

Figure 10.5–11 Shell vial cultures, IF.

^a When removing vials from storage, allow them to equilibrate to room temperature before opening the storage container.

V. PROCEDURES (*continued*)**G. Refeeding inoculated cultures**

1. Pipette or aspirate the medium from the culture tubes or vials.
 NOTE: Be careful not to scrape the monolayers.
2. Using a separate pipette for each specimen, add 1 to 2 ml of cell culture maintenance medium to each tube.
 NOTE: To reduce cross-contamination with detached cells or endogenous viruses, aspirate and refeed in the following sequence: fibroblast, primary nonsimian, transformed, and primary simian.

H. Harvesting and subpassing inoculated cultures

1. Isolates are frequently harvested and stored for many reasons, such as to provide teaching and QC material and to provide material for additional identification procedures (e.g., neutralization, acid lability, or HI). The extent to which viruses are shed or released into culture medium depends on the particular virus. For example, while most enteroviruses are readily released into the culture fluid, CMV and varicella-zoster virus (VZV) are cell associated, and successful harvesting and subpassing require infected cells; subpassage of CMV or VZV cultures with a CPE less than 2+ may not be efficient.
2. To harvest isolates, use a plastic 1-ml pipette or sterile rubber policeman to dislodge cells from the tube surface, and mix cells and fluid by pipetting up and down several times.
 NOTE: Successful subpassage of isolates may generally be accomplished by using the fluid only for isolates other than CMV, VZV, or adenoviruses.
3. To subpass cultures, deliver 0.2 to 0.3 ml of the harvested material to each new tube to be inoculated.
 NOTE: Isolates exhibiting very strong and rapid CPE may first be diluted (e.g., 1:10, 1:100, or greater) with HBSS.
4. To store isolates, transfer harvested material to a tube suitable for low-temperature storage (e.g., Nunc cryotube) and store at -70°C or lower.
 NOTE: Rapid freezing in a dry ice-acetone slurry is recommended; adding a cryopreservative is recommended for CMV and VZV harvests (add dimethyl sulfoxide [DMSO] to a final concentration of 10%).

I. Culture decontamination

1. Harvest cells and fluids as described above.
2. Draw the harvested material into a 3- to 5-ml disposable plastic syringe, attach a disposable 0.2- μm -pore-size filter (e.g., Millipore), and expel the material into a sterile tube.
 NOTE: Filtration of CMV and VZV cultures may markedly reduce the viral titer of recovered material, particularly with cultures exhibiting less than a 3+ CPE. Cell disruption by addition of glass beads and vortexing the material for 60 s before filtration will facilitate viral release. Viruses not adversely affected by freezing and thawing (e.g., unenveloped viruses such as adenoviruses and enteroviruses) may be subjected to three rapid freeze-thaw cycles to facilitate viral release.

POSTANALYTICAL CONSIDERATIONS

VI. PROCEDURE NOTES

Observe standard precautions.

- A. Observe standard precautions.
- B. Cell culture fluids may contain large concentrations of virus capable of aerosolization. Place a pipette discard jar or bucket containing 2 to 3 in. (ca. 5 to 7.5 cm) of liquid disinfectant (e.g., Wescodyne) inside the biological safety cabinet; to discard contaminated pipettes, immerse the tip in the disinfectant and then disengage it from the pipetting device. If the discard container is to be reused, seal it or place it into a sealable container and autoclave. If a suction apparatus is used, include an aerosol trap containing disinfectant between the collection flask and the vacuum source.
- C. Use aseptic techniques for all cell culture manipulations (*see* Appendix 10.2–2).
- D. Use appropriate measures to minimize the potential risk of cross-contamination of cultures and infection of personnel from manipulations that generate aerosols or may contaminate gloved hands (e.g., disengaging pipettes from pipetting devices, removing shell vial caps or stoppers, pouring).
- E. The sensitivity of viral culture is affected by a number of variables, including the viral concentration; specimen type and quality; cell culture type, age, density, and quality; number of tubes or vials inoculated; incubation conditions; and choice of detection or identification reagent.
- F. Blind subpassage of negative tube cultures midway through the incubation-observation period may slightly increase the number of positive cultures. However, this practice has been largely discontinued because of the expense and time involved. Subpassage is now generally limited to specimens showing toxicity or contamination or to prepare larger volumes of isolates for additional studies (e.g., antiviral susceptibility testing).
- G. Vaccinia virus, simian B virus, arboviruses, arenaviruses, and filoviruses replicate in some heteroploid cell lines that may be in use in the routine diagnostic setting. While not frequently encountered, the symptoms and travel or exposure history should alert the laboratorian to the special safety considerations required for processing these specimens and the need to contact the appropriate public health department laboratory, CDC, or specialized reference laboratory.
- H. Monolayers exhibiting CPE or HAd but not needed for identification or harvesting may be preserved indefinitely for teaching purposes (Appendix 10.5–7).

VII. CULTURE RESULTS

- A. A positive viral culture is one exhibiting evidence of viral replication by the development of CPE, positive HAd, and/or the presence of a viral antigen or nucleic acid.
 - **NOTE:** Identification on the basis of CPE or HAd is tentative, and reports should not be based on these findings.
- B. A negative viral culture is one that fails to develop CPE and/or HAd or one in which no viral antigen or nucleic acid is detected after incubation of an acceptable monolayer for the prescribed period of time.
- C. An incomplete or unsatisfactory culture is one that cannot be completed or processed in the appropriate manner for reasons that include extensive microbial contamination.

VIII. LIMITATION OF THE PROCEDURE

A negative viral culture does not rule out the possibility of a viral etiology. Reasons include a low viral titer, nonviable virus, insensitive cell cultures, or the agent may be noncultivable or require specialized techniques.

APPENDIX 10.5-1

Viral Titration and Determination of TCID₅₀

Reprinted from S. M. Lipson. 1992. Neutralization test for the identification and typing of viral isolates, p. 8.14.1–8.14.8. In H. D. Isenberg (ed.), *Clinical Microbiology Procedures Handbook*, vol. 2. American Society for Microbiology, Washington, D.C.

A. Viral quantitation

The viral isolate to be identified in the neutralization assay must be quantitated to ensure optimal performance of the assay. Viral quantitation is achieved by preparing a series of dilutions of the material and assaying this material by using either quantitative or quantal assay systems. In the quantitative assay, the number of infectious viral particles is established by using a plaque or infectious-focus assay (2). Although this type of assay is more precise, it is, like the plaque reduction neutralization assay, extremely cumbersome, costly, and labor-intensive. Thus, these quantitative procedures are reserved for the research setting or are limited to special procedures.

The viral quantitation method used in the diagnostic laboratory is the endpoint dilution method. This is a quantal assay, since it measures an “all-or-none” effect and does not determine the number of infectious particles (1). Thus, the quantal assay determines only that the material contains a sufficient dose of infectious virus to produce infection in a susceptible host system. With the endpoint dilution method, the viral titer is expressed as the 50% tissue culture infective dose (TCID₅₀) or, in animals, as the 50% lethal dose.

B. Preparation of the viral titration (Fig. 10.5-A1)

1. Harvest the viral isolate to be titrated (*see* item V.H.1 to 4 above) or thaw a frozen aliquot.
2. Determine the number of serial 10-fold dilutions to be inoculated.
 - a. With slower-growing low-titered viruses (e.g., adenoviruses), prepare dilutions ranging from 10⁻¹ through 10⁻⁵, and inoculate tubes starting with the undiluted material.
 - b. With high-titered material (e.g., many enteroviruses), prepare dilutions ranging from 10⁻¹ through 10⁻⁷, and inoculate tubes starting with 10⁻¹ or 10⁻².
3. Label sterile dilution tubes for each virus to be titrated.
4. Add 1.8 ml of HBSS to each dilution tube.
5. Add 0.2 ml of each virus to be titrated to the corresponding tube labeled 10⁻¹, and mix by pipetting up and down several times.
6. With a new pipette, remove 0.2 ml from the 10⁻¹ dilution, transfer it to the tube labeled 10⁻², and mix.
7. Continue preparing dilutions through the highest dilution, using a new pipette for each dilution.
8. Label four to six cell culture tubes for each dilution to be inoculated; select two tubes as negative (uninoculated controls).
9. Refeed each tube with 1.0 ml of maintenance medium.
10. Inoculate 0.1 ml of each virus dilution into the corresponding culture tubes.
11. Incubate the culture tubes at 35 to 37°C for 7 to 10 days. Observe the cell culture

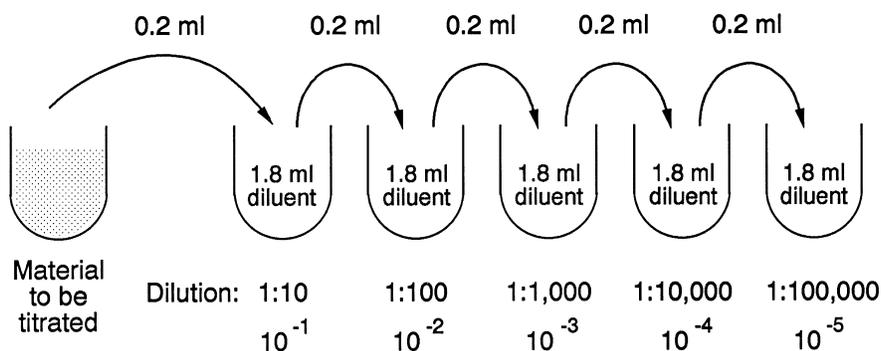

Figure 10.5-A1 Viral titration with serial 10-fold dilutions.

APPENDIX 10.5–1 (continued)

Table 10.5–A1 Calculation of TCID₅₀ by the Reed-Muench method (1)

Dilution	Observed value ^a		Cumulative value			
	(1) Pos	(2) Neg	(3) Pos ^b	(4) Neg ^c	(5) Ratio ^d	(6) % Pos ^e
10 ⁻⁵	5	0	10	0	10/10	100.0
10 ⁻⁶	4	1	5	1	5/6	83.3
10 ⁻⁷	1	4	1	5	1/6	16.7
10 ⁻⁸	0	5	0	10	0/10	0.0

^a Pos, tube showing CPE; Neg, tube not showing CPE.

^b Obtained by adding numbers in column 1, starting at the bottom.

^c Obtained by adding numbers in column 2, starting at the top.

^d Value in column 3/(value in column 3 + value in column 4).

^e $\frac{\% \text{ CPE next above } 50\% - 50}{\% \text{ CPE next above } 50\% - \% \text{ CPE next below } 50\%}$ = proportional distance between the two dilutions at which 50% CPE occurs

From the above example: $\frac{83.3 - 50}{83.3 - 16.7} = 0.5$

One TCID₅₀ in this case is 10^{-6.5}, and therefore 100 TCID₅₀s equal 10^{-4.5}.

monolayers daily for the development of CPE, and record the presence or absence of CPE (see Fig. 10.5–2).

12. *Note:* some viruses grow more slowly than others. For example, culture readings should be terminated after 10 to 12 days with the slower-growing adenoviruses, while a 7-day incubation period would be appropriate for the faster-growing enteroviruses.

C. Calculation of TCID₅₀ by the Reed-Muench method (1)

The TCID₅₀ is that dilution that produces CPE in one-half of the cumulative number of cell cultures (Table 10.5–A1).

1. Record the number of positive (column 1) and negative (column 2) values.
2. Calculate the cumulative numbers of positive (column 3) and negative (column 4) tubes.
3. Calculate the percentage of positive tubes (column 5) by using the cumulative values.
4. Calculate the proportionate distance between the dilution showing >50% CPE and the dilution showing <50% CPE.
5. Calculate the TCID₅₀ by adding the proportionate distance factor (as a negative value) to the dilution (negative logarithm) showing >50% CPE.
6. Since each tube was inoculated with 0.1 ml of each virus dilution, the TCID₅₀ is expressed as TCID₅₀/0.1 ml.
7. *Note:* the proportionate distance must be multiplied by a correction factor, which is the logarithm of the dilution factor. In this procedure, with 10-fold dilutions, that factor is equal to 1, and the step can be disregarded. However, if other dilution series are used, the factor must be considered. For example, the correction factor for a twofold dilution series would be 0.3, and that for a fivefold dilution series would be 0.7.

APPENDIX 10.5-2

Viral Neutralization Assay

Reprinted from **S. M. Lipson**. 1992. Neutralization test for the identification and typing of viral isolates, p. 8.14.1–8.14.8. In H. D. Isenberg (ed.), *Clinical Microbiology Procedures Handbook*, vol. 2. American Society for Microbiology, Washington, D.C.

I. PRINCIPLE

The neutralization test is a highly sensitive assay applicable to the identification of all viral isolates. However, it is costly and labor-intensive to perform and has been largely supplanted by more rapid and convenient methods. Currently, the major applications of the neutralization test in the diagnostic virology laboratory are for the identification of enteroviruses and the typing of adenoviruses (1, 3, 4).

The neutralization test is a biphasic system consisting of (i) an antigen-antibody reaction step, in which the virus to be identified is mixed and incubated with the appropriate antibody reagent(s), and (ii) an inoculation step, in which the mixture is inoculated into the appropriate host system (e.g., cell cultures, animals). The absence of infectivity, for example, the failure of CPE or HA_D to develop in cell cultures, constitutes a positive neutralization reaction and indicates the identity of the virus.

II. SPECIMEN

Cell culture harvest of isolate to be identified (*see* item V.H.1 to 4 above).

- A. Titrate the viral isolate and determine the 50% tissue culture infective dose (TCID₅₀) as described in Appendix 10.5-1.
- B. Alternatively, select the test dilution empirically. For example, use a 1:10 or 1:50 dilution for isolates with a slowly progressing CPE (e.g., adenovirus) and a 1:500 or 1:1,000 dilution for viruses with a rapidly progressing CPE (e.g., enteroviruses).

III. MATERIALS

A. Cell cultures and reagents

1. Cell culture monolayers

- a. Perform the neutralization test with the same type of cell culture as used for determination of the test dose (TCID₅₀).
- b. Refeed the cell cultures with maintenance medium prior to performing the assay.

2. Cell culture maintenance medium. For example, use Eagle minimum essential medium supplemented with 50 µg of gentamicin per ml, 1.25 µg of amphotericin B per ml, and 2% heat-inactivated fetal bovine serum.

3. Antiviral neutralizing antisera

a. Availability

Antisera suitable for neutralization tests for many viruses are available from numerous commercial sources and reference laboratories. Pools for the identification of enterovirus isolates are available on a more limited basis. There are differences in the quality of products obtained from different sources or different lots. It is therefore the responsibility of the individual laboratory to monitor reagent quality by using homologous and heterologous viruses.

b. Preparation and storage

- (1) Reconstitute lyophilized antiserum according to the recommendation of the manufacturer. Product data sheets should include information on reagent potency as well as storage and shelf life guidelines. Label containers with expiration dates.
- (2) Heat inactivate the serum in a 56°C water bath for 30 min to inactivate nonspecific heat-labile inhibitors of infectivity. Alternatively, heat inactivate the serum just prior to use.
- (3) Dispense antiserum into aliquot volumes consistent with the needs of the laboratory. Freeze and store the aliquots at –70°C. Avoid repeated freeze-thaw cycles. Label containers with expiration dates.

Include QC information on reagent container and in QC records.

APPENDIX 10.5–2 (continued)

- (4) Record all pertinent information, including source, viral specificity and cross-reactivity, donor species, lot number, potency (neutralizing units), aliquot volume and quantity, recommended test dilution and suggested diluent, lot number of matching normal (nonimmune) serum (if applicable), and dates of receipt, opening, use, heat inactivation, and expiration.
- (5) Detailed step-by-step instructions for the reconstitution, storage, and use of the Lim Benyesh-Melnick (LBM) intersecting serum pools for the identification of enteroviruses are provided with the reagents.
- (6) Handle all sera aseptically to maintain sterility.
- (7) Monitor antisera for deterioration by performing neutralization assays with the matching (homologous) viruses. Perform these assays periodically (e.g., annually) on frozen stock, whenever the material has been subjected to improper storage conditions, or if deterioration is suspected based on performance.

4. HBSS, pH 7.2 to 7.6

B. Supplies

1. Sterile capped tubes (12 by 75 mm)
2. Assorted sterile pipettes and pipetting device
3. Autoclavable containers for discarding cultures

C. Equipment

1. Class II biological safety cabinet
2. Water bath, 56°C
3. Incubator, 35 to 37°C
4. Inverted microscope or standard microscope fitted with tracks for the observation of culture tubes; 10× to 20× objectives
5. Freezer, –70°C

IV. QUALITY CONTROL

- A. Test each lot of antiserum at the working dilution prior to use to determine whether the reagent has a toxic effect on the cell cultures used for neutralization tests.
 1. Inoculate 0.1 ml of each working dilution of serum into two tubes of the appropriate cell culture type.
 2. Observe the cultures for 7 to 10 days for evidence of toxicity (cell rounding and degeneration of the monolayer).
- B. Include a normal serum control, a positive serum control, a virus check titration, and a negative cell control with each assay.
 1. Normal serum control

Include a normal (nonimmune, negative) serum to determine whether the virus is nonspecifically inactivated by antiserum components.

 - a. Include a nonimmune serum obtained from the same animal species as used to produce the antiserum. Ideally, normal serum should be obtained as a preimmune serum from the animal prior to inoculation.
 - b. Use the normal serum at the same dilution as the matching viral antiserum.
 - c. If more than one antiserum from the same animal species is used in a neutralization test (i.e., an antiserum with a different [heterologous] viral specificity), the heterologous serum may substitute for the normal serum.
 2. Positive serum control

Include a reference virus incubated (neutralized) with its matching (homologous) serum as a positive control. Since this is not practical for each antiserum when multiple antisera are used in a neutralization test, select the antiserum to the prevalent or suspected virus.
 3. Virus check titration

Include a confirmatory (check) titration of the virus consisting of 3 or 4 serial log₁₀ dilutions, starting with the test dilution of virus.
 4. Negative cell control

Select two uninoculated lot-matched cell cultures to be incubated and observed in parallel with the neutralization test.

APPENDIX 10.5–2 (continued)

V. PROCEDURE

A. Preparation of antiserum working dilution

1. Dilute each type-specific and normal antiserum 1:10 (or other predetermined dilution) with HBSS. The final working dilution of the type-specific antiserum should contain 20 (or more) neutralization units per 0.1 ml of antiserum. Determine the appropriate dose on the basis of the manufacturer's specifications and in-house QC results.
2. If the serum has not been heat inactivated, place the diluted serum in a 56°C water bath for 30 min.
3. The working dilutions of antisera may be stored at 4°C for up to 5 days. Diluted antiserum may be stored at –70°C for extended periods (i.e., months to years).
4. Do not repeatedly freeze-thaw undiluted or working dilution sera. Aliquot in single-use volumes, and freeze at –70°C.

B. Preparation of virus test dilution and check titration

1. Determine the dilution of each unknown and control virus to be used.
 - a. Prepare a dilution of virus in HBSS that contains 100 TCID₅₀s/0.1-ml volume (Appendix 10.5–1). For example, if the TCID₅₀ of a viral harvest is 10^{–3}/0.1 ml (1:1,000 dilution), use the material at 10^{–1} (1:10 dilution) in the neutralization test by combining 1 part undiluted material with 9 parts diluent.
 - b. Alternatively, prepare a dilution of virus based on culture characteristics (item II.B).
2. Check titration

Starting with the virus test dilution, prepare three additional serial log₁₀ dilutions with HBSS as diluent. For example, if the test dilution is 10^{–1}, prepare dilutions through 10^{–4} (Appendix 10.5–1).

C. Performance of the neutralization test

1. For each virus to be neutralized, add 0.3 ml of the diluted normal serum to a labeled tube.
2. For each virus to be neutralized, add 0.3 ml of the appropriate diluted immune antiserum to a labeled tube.
3. Add 0.3 ml of the viral dilution containing 100 TCID₅₀s/0.1 ml to the corresponding serum tubes.
4. Gently agitate the virus-serum mixtures, and incubate them and the virus check titration at room temperature for 1 h or as specified by the antiserum manufacturer.
5. Inoculate 0.2 ml of each virus-serum mixture into two cell culture tubes, each containing 1 to 2 ml of maintenance medium.
6. Inoculate 0.1 ml of the test dose and each dilution of the check titration into two or three cell culture tubes, each containing 1 to 2 ml of maintenance medium.
7. Incubate the cell culture tubes at 35 to 37°C. Observe the monolayers daily for the appearance of CPE. Record the presence or absence of CPE for each tube (*see* Fig. 10.5–2).

VI. RESULTS

A. The neutralization test is completed when the anticipated endpoint of the check titration is achieved. The endpoint should be attained after an incubation period of 7 to 10 days, depending on the virus.

B. Controls

1. The degree of CPE in the normal serum control should be similar to that observed in the virus test dilution of the check titration.
2. The positive control should show no or only minimal (breakthrough) CPE compared with CPE in the virus control.
3. The virus test dose of 100 TCID₅₀s is confirmed by the development of CPE in the virus test dilution and in the two subsequent serial dilutions of the check titration. In most cases, a test dose of 3 to 300 TCID₅₀s is acceptable.
4. The negative cell control should not show any CPE, and the monolayer quality should be acceptable.

Table 10.5–A2 Problems associated with interpretation of the neutralization test

Problem	Definition	Possible cause(s)	Solution
No neutralization	CPE develops at same rate with all or most antisera.	Test dose of virus too strong Serum deteriorated	Redetermine endpoint titers. Obtain new antisera. Check storage conditions.
Breakthrough	Neutralized virus produces delayed and reduced CPE.	Test dose of virus too strong Cross-reactivity Antiserum deteriorated or failed to attain expected efficacy Clumps or aggregates in virus suspension	Redetermine endpoint titers. Check product specifications for cross-reactive properties; obtain non-cross-reactive serum if possible. Check against reference virus; use lower dilution. Other methods, such as kinetic neutralization assay (2), required. Remove by ultrafiltration.
Neutralization by more than one antiserum	CPE is inhibited by two or more antisera.	Cross-reactivity Test dose of virus too weak Antiserum dose too strong	Check product specifications for cross-reactive properties. Redetermine endpoint titers. Check suggested working dilution. Heat inactivate serum (56°C, 30 min). Obtain new antiserum.
Nonspecific virus inactivation	Virus is neutralized (no CPE) by normal serum.	Serum not heat inactivated or contains nonspecific viral inhibitors Virus inactivated during incubation step	Check recommended temp. Check incubator-water bath temp.
Monolayer toxicity	Nonspecific degeneration of culture monolayer	Serum not heat inactivated or is toxic to cells	Heat inactivate serum (56°C, 30 min). Obtain new antiserum.

APPENDIX 10.5–2 (continued)

C. Specimens

Compare the development and degree of CPE observed in the neutralized tubes with those observed in the normal serum controls and in the test dilution of the check titration.

1. The absence of CPE in tubes inoculated with a particular virus-antiserum mixture indicates a positive neutralization reaction and thus identifies the viral isolate.
2. The simultaneous development of CPE in the unknown virus-antiserum mixture, the normal serum control, and the test dilution indicates that there is no relationship between the unknown virus and the antiserum.
3. Occasionally, the neutralization test may be difficult to interpret. In such cases, consider the factors presented in Table 10.5–A2 or the possibility of a mixed infection.

APPENDIX 10.5-3

Acid Lability Assay

Reprinted from S. Aarnaes. 1992. Differentiation of rhinoviruses from enteroviruses: acid lability test, 8.13.1-8.13.3. In H. D. Isenberg (ed.), *Clinical Microbiology Procedures Handbook*, vol. 2. American Society for Microbiology, Washington, D.C.

I. PRINCIPLE

The differentiation of rhinoviruses from enteroviruses cannot be made on the basis of routine cultural characteristics, since both groups may be isolated from respiratory samples and produce similar CPEs. Furthermore, routine confirmation of a suspected rhinovirus isolate is not feasible because of the very numerous rhinovirus types. While extreme lability, short-term shedding, and preference for cultivation at 33°C limit the number of rhinovirus isolates, the possibility that a rhinovirus may be isolated must be considered. The suspected rhinovirus isolate can be conveniently differentiated from an enterovirus on the basis of acid lability (1, 2). Enteroviruses have been shown to be stable at pHs 3.0 to 5.0. Rhinoviruses, by contrast, are inactivated at a low pH.

II. SPECIMEN

Cell culture supernatants from cultures showing a 3 to 4+ CPE are suitable specimens (see Fig. 10.5-2).

III. MATERIALS

A. Reagents and supplies

1. Human diploid fibroblast cultures

2. Citrate buffer, 0.1 M, pH 4.0

a. Stock solutions

(1) Citric acid solution, 0.1 M

citric acid21.01 g

deionized waterto 1,000.00 ml

(2) Sodium citrate solution, 0.1 M

sodium citrate29.41 g

deionized waterto 1,000.00 ml

(3) Sterilize by filtration through a 0.2- μ m-pore-size filter. Store at 2 to 8°C.

Shelf life is 6 months or longer.

b. Citrate buffer, pH 4.0

(1) Ingredients

citric acid, 0.1 M 33.0 ml

sodium citrate, 0.1 M 17.0 ml

(2) Aseptically combine sterile stock solutions. Prepare fresh on day of use.

3. Phosphate buffer, 0.1 M, pH 7.0

a. Ingredients

Na₂HPO₄8.7 g

KH₂PO₄5.3 g

deionized water to 1,000.0 ml

b. Sterilize by filtration through a 0.2- μ m-pore-size filter. Store at 2 to 8°C. Shelf life is 1 year.

4. Phosphate buffer, 0.5 M, pH 7.2

a. Ingredients

Na₂HPO₄ 51.1 g

KH₂PO₄ 19.0 g

deionized water to 1,000.0 ml

b. Sterilize by filtration through a 0.2- μ m-pore-size filter. Store at 2 to 8°C. Shelf life is 1 year.

5. Cell culture maintenance medium: Eagle's minimal essential medium supplemented with 2% heat-inactivated fetal bovine serum

Include QC information on reagent container and in QC records.

APPENDIX 10.5–3 (continued)

6. Sterile disposable capped tubes, 12 by 75 mm and 13 by 100 mm
 7. Sterile pipettes (assorted) and pipetting device
 8. Cell culture racks
- B. Equipment
1. Incubator, 33°C
 2. Inverted microscope or standard microscope fitted with stage tracks to accommodate cell culture tube
- IV. QUALITY CONTROL
- A. Positive control
1. Determine the 50% tissue culture infective dose (TCID₅₀) of a reference rhinovirus (see Appendix 10.5–1).
 2. Treat the reference virus with the buffer solutions in the same manner as the unknown virus. Use the reference virus at approximately 1,000 TCID₅₀/ml.
- B. Negative control
- Treat supernatant fluid from negative (uninoculated) cell culture controls with buffer solutions in the same manner as the unknown virus.
- V. PROCEDURE
- A. Add 0.5 ml of each unknown virus, the reference rhinovirus, and the negative control supernatant to a labeled tube (13 by 100 mm) containing 0.5 ml of citrate buffer (pH 4.0).
- B. Add 0.5 ml of each unknown virus, the reference rhinovirus, and the negative control supernatant to a labeled tube (13 by 100 mm) containing 0.5 ml of phosphate buffer (pH 7.0).
- C. Incubate the tubes containing the virus and control mixtures at 37°C for 1 h.
- D. Following the incubation, add 4.0 ml of 0.5 M phosphate buffer (pH 7.2) to each mixture of virus and control. This represents a 1:10 (10⁻¹) dilution of the original material.
- E. Prepare serial 10-fold dilutions (10⁻² to 10⁻⁵) of each unknown and reference virus mixture. Use cell culture maintenance medium as diluent. Serial titration of the negative control is not necessary.
1. Add 0.9 ml of diluent to four labeled tubes (12 by 75 mm) for each mixture to be titrated.
 2. Transfer 0.1 ml of the 1:10 dilution of each material to the appropriate 10⁻² dilution tube, and mix by pipetting up and down. This represents a 1:100 (10⁻²) dilution of the original material.
 3. Prepare the remaining dilutions in the same manner. Use a separate pipette for each dilution.
- F. Inoculate two or three diploid fibroblast cultures containing 1.0 ml of maintenance medium with 0.2 ml of each of the unknown and reference virus dilutions.
- G. Inoculate two diploid fibroblast cultures containing 1.0 ml of maintenance medium with 0.2 ml of the negative control.
- H. Incubate the cell cultures at 33°C in a stationary rack, and examine them daily for CPE. Record the titers.
- VI. RESULTS
- A. Rhinoviruses are acid labile and will show either a total inactivation or a reduction in titer in the material treated with acid (pH 4.0) compared with the activity and titer of viruses treated with the pH 7.0 buffer. High-titered isolates may not be completely inactivated, and in such cases, a ≥100-fold reduction in titer would be interpreted as acid lability. Although definitive confirmation requires a neutralization test, the combination of enterovirus-type CPE and acid lability is considered sufficient to designate an isolate a rhinovirus.
- B. An enterovirus will show no reduction in titer after treatment at pH 4.0 compared with the titer after treatment at pH 7.0.
- C. The rhinovirus control should show either total or a ≥100-fold reduction in titer after treatment at pH 4.0.
- D. Negative controls should show no toxicity or CPE.

APPENDIX 10.5–4

Rubella Interference Assay

Reprinted from **S. Aarnaes and B. J. Daidone.** 1992. Observation and maintenance of inoculated cell cultures, p. 8.7.1–8.7.16. In H. D. Isenberg (ed.), *Clinical Microbiology Procedures Handbook*, vol. 2. American Society for Microbiology, Washington, D.C.

A. Cells

Primary African green monkey kidney (AGMK) cells are the cells of choice for isolation of rubella virus from clinical specimens. A CPE is not produced, and a positive rubella culture is detected by interference with the growth of a superinfected challenge virus.

B. Materials (in addition to materials used for routine viral culture)

1. Five specimen-inoculated tubes and four each of lot-matched negative and positive (rubella-inoculated) controls
2. Challenge virus (echovirus type 11 or coxsackievirus A9) diluted with maintenance medium or HBSS to contain 100 50% tissue culture infective doses (TCID₅₀s) per 0.1 ml. Determine endpoint titer and appropriate dilution as described in Appendix 10.5–1. Do not inoculate specimens until a titered challenge virus is available.
3. Incubator, 35 to 37°C

C. Interference assay

1. Procedure

- a. Remove the culture medium from the tubes to be challenged, and save it. Store the harvested fluid at –70°C; discard negative harvests upon completion of the interference assay.
- b. Refeed tubes to be challenged with 1 ml of maintenance medium.
- c. Deliver 0.1 ml of the challenge virus dilution containing 100 TCID₅₀s to each specimen and control tube to be challenged.
- d. Refeed unchallenged tubes weekly with 1 ml of culture maintenance medium.
- e. Incubate challenged and unchallenged cultures at 35°C. Observe challenged cultures daily for 7 days for the development of enterovirus CPE.

2. Schedule summary

a. At 1 week

- (1) Challenge one specimen tube, one lot-matched positive control, and one lot-matched negative control.
- (2) Refeed unchallenged tubes with maintenance medium.

b. At 2 weeks

- (1) Challenge one specimen tube, one lot-matched positive control, and one lot-matched negative control.
- (2) Subpassage harvested cells and fluid from one specimen tube into two AGMK cell tubes. Prepare two lot-matched positive and negative controls.
- (3) Refeed unchallenged tubes with maintenance medium.

c. At 3 weeks

- (1) Challenge two specimen tubes (one from primary inoculation and one subpassage) and the lot-matched positive and negative controls.
- (2) Refeed unchallenged tubes with maintenance medium.

APPENDIX 10.5–4 (continued)

- d. At 4 weeks
 - Challenge two specimen tubes (one from primary inoculation and one subpassage) and the lot-matched positive and negative controls.
- D. Interpretation of interference assay
 - 1. Controls
 - a. The challenged positive control should show no enterovirus CPE.
 - b. The challenged negative control should show enterovirus CPE.
 - c. The unchallenged negative control should show no CPE.
 - 2. Specimens
 - a. Cultures that exhibit enterovirus CPE are negative for rubella virus.
 - b. Cultures that do not exhibit enterovirus CPE are considered positive for rubella virus and may be confirmed by neutralization (*see* Appendix 10.5–2) or other immunoassay.
 - c. Subpassage cultures exhibiting partial interference.
 - **NOTE:** Infection of AGMK cells by simian viruses may be associated with reduced sensitivity for the recovery of rubella virus (1). Therefore, in addition to the positive and negative controls included in the interference assay, select 8 to 10 uninoculated AGMK cell tubes from each lot, and observe these in parallel with specimen-inoculated tubes. Observe for the development of spontaneous CPE, and use guinea pig RBCs to test for HAd in two tubes each week (*see* Fig. 10.5–6).

Reference

1. **Herrmann, K. L.** 1979. Rubella virus, p. 725–766. In E. H. Lennette and N. J. Schmidt (ed.), *Diagnostic Procedures for Viral, Rickettsial, and Chlamydial Infections*, 5th ed. American Public Health Association, Washington, D.C.

APPENDIX 10.5–5

Preparation of 10% RBC Suspension

■ **NOTE:** Use aseptic technique.

1. Obtain guinea pig RBCs collected aseptically in Alsever's solution. Store at 4°C and use within 7 days of receipt.
2. Transfer 5 to 7 ml of suspended blood to a sterile, graduated, 15-ml conical centrifuge tube.
3. Add an equal volume of phosphate-buffered saline (PBS) and centrifuge at 700 to 900 × *g* for 5 min at room temperature.
4. Discard the supernatant, suspend the RBC pellet in 10 ml of PBS by gently pipetting up and down several times, and centrifuge the suspension at 700 to 900 × *g* for 5 min at room temperature.
5. Repeat step 4 twice.
6. Discard the supernatant, and measure the packed cell volume.
7. Add a volume of PBS equal to nine times the packed cell volume.
8. Store at 4°C and use within 7 days. Discard if evidence of hemolysis or contamination occurs.

APPENDIX 10.5–6

Hemagglutination Procedure

Several viruses, including those identified in Table 10.5–A3, agglutinate RBCs of various avian and mammalian species.

■ **NOTE:** The procedure can be performed using microtiter trays, adjusting volumes accordingly.

Procedure

1. Prepare a 10% suspension of RBCs by using as described in Appendix 10.5–5. Store at 4°C and use within 1 week of preparation.
2. On the same day as performing the hemagglutination procedure, dilute an aliquot of the 10% stock suspension with phosphate-buffered saline (PBS) (pH 7.2 to 7.4) or physiologic saline to yield a 0.5% RBC suspension.

APPENDIX 10.5–6 (continued)

Table 10.5–A3 Hemagglutination characteristics of representative viruses

Virus	RBC type	Incubation temp (°C) ^a
Adenovirus	Monkey or rat ^b	37
Enteroviruses (some)	Human O	4, 37, RT
Influenza, mumps, parainfluenza, Newcastle disease viruses	Chicken or guinea pig	RT, 4
Measles virus	Monkey	37
Reoviruses	Human O	RT

^a RT, room temperature.^b Depends on virus type.

3. Label 12- by 75-mm tubes starting with 1:10 through 1:160.
4. Label one tube as an RBC control and one tube as a monolayer supernatant control.
5. Add 0.9 ml of PBS or saline to the 1:10 tube and 0.5 ml to the other tubes, including the control tubes.
6. Add 0.1 ml of viral culture supernatant to the 1:10 tube and mix well by pipetting up and down several times.
7. Transfer 0.5 ml from the 1:10 viral supernatant dilution to the 1:20 dilution tube and mix as before. Continue preparing serial dilutions in the same manner, discarding 0.5 ml from the final dilution (1:160).
8. Add 0.5 ml of cell culture supernatant from a lot-matched uninoculated control monolayer to the tube serving as the monolayer supernatant control. Mix by pipetting up and down several times and discard 0.5 ml of material from the tube.
9. Add 0.5 ml of RBC suspension to each tube, including the controls.
10. Shake to mix and incubate at the appropriate temperature (refer to Table 10.5–A3) for 30 to 45 min.
11. Read the agglutination patterns in each tube. The RBC and uninoculated supernatant controls should exhibit a button of settled RBCs at the tube bottom. Positive agglutination is recorded for tubes exhibiting a diffuse carpet of RBCs, while intermediate patterns are recorded as +/- . The hemagglutination endpoint is the highest dilution to show a + (complete) agglutination pattern.

■ **NOTE:** Incubation of a viral supernatant with homologous antibody prior to the addition of the RBCs will result in inhibition of the agglutination reaction. This forms the basis for the HI assay which has been used primarily to identify influenza virus subtypes but is not typically performed in the routine viral diagnostic setting. Prior to using an antiserum in the HI test, nonspecific inhibitors of agglutination must be removed. Methods vary with the species of antiserum used, and the procedure should be performed as indicated by the reagent source.

APPENDIX 10.5–7

Preservation of Cell Culture Monolayers (1)

1. Prepare buffered formaldehyde preservative medium by combining the following ingredients. Store at room temperature.

formaldehyde solution (37 to 40%) 100 ml
 distilled water 900 ml
 sodium phosphate, monobasic
 (NaH₂PO₄·H₂O) 4 g
 sodium phosphate, dibasic (Na₂HPO₄) 6.5 g

2. Aspirate the medium from the cell culture tubes to be preserved.
3. Add 2 to 4 ml of preservative to each tube.
4. Store tubes indefinitely at room temperature.

1. Gurtler, J. H., C. Ballew, C. M. Preissner, and T. F. Smith. 1982. Cell culture medium for preserving cytopathic effects in cell cultures. *Lab. Med.* **13**:244–245.

10.6

Isolation of *Chlamydia* spp. in Cell Culture

Chlamydiae are obligate intracellular bacteria that contain RNA and DNA, have a cell wall resembling those of gram-negative bacteria, and multiply by binary fission in a manner distinct from those of other bacteria. The 300- to 400-nm spherical elementary body (EB) is the infectious form of the organism. Following cellular

infection, the EB reorganizes into a larger, metabolically active reticulate body (RB), which divides repeatedly by binary fission for 24 to 48 h and eventually develops into the characteristic intracytoplasmic inclusion. Human infections associated with the genus *Chlamydia* are summarized in Table 10.6–1. Despite the introduction of nu-

merous nonculture assays, including amplified assays, culture remains an important assay for the detection of *Chlamydia trachomatis* infections and, because of its specificity, is recommended for laboratory testing in cases of sexual abuse and medicolegal situations.

I. PRINCIPLE

Chlamydiae are obligate intracellular bacteria, and the propagation of these organisms requires the use of cell culture techniques as used in culturing viruses. Although the growth cycles of the species *C. trachomatis*, *Chlamydia psittaci*, and *Chlamydia pneumoniae* vary to some extent, in general, a complete cycle takes from 36 to 72 h. The infectious EB enters the host cell and then, inside a cytoplasmic inclusion during the initial 8 to 12 h, reorganizes into the noninfectious RB (Fig.

10.6–1). After this latent phase, there is rapid growth of the inclusion, during which time the RB divides by binary fission. The RB then begins to reorganize into EBs within 24 to 72 h and forms an inclusion that often displaces the nucleus to one side of the host cell. The cell may rupture, releasing the infectious EBs, which, for some strains, are capable of initiating another round of replication in vitro. (For further discussion, see Appendixes 10.6–3 and 10.6–4).

II. SPECIMEN

A. Collection

Chlamydiae replicate primarily in columnar epithelium, and specimens should be collected in a manner that optimizes obtaining these cells.

1. Obtain samples as described in Table 10.6–2.

Table 10.6–1 Human chlamydial infections

Organism	Disease(s)
<i>C. trachomatis</i>	
Serotypes A, B, Ba, and C	Trachoma
Serotypes D through K	Cervicitis, epididymitis, inclusion conjunctivitis, nongonococcal disease, pelvic inflammatory disease, neonatal pneumonitis, proctitis
Serotypes L-1, L-2, and L-3	Lymphogranuloma venereum
<i>C. psittaci</i>	Psittacosis, ornithosis following contact with infected birds
<i>C. pneumoniae</i>	Upper and lower respiratory tract disease

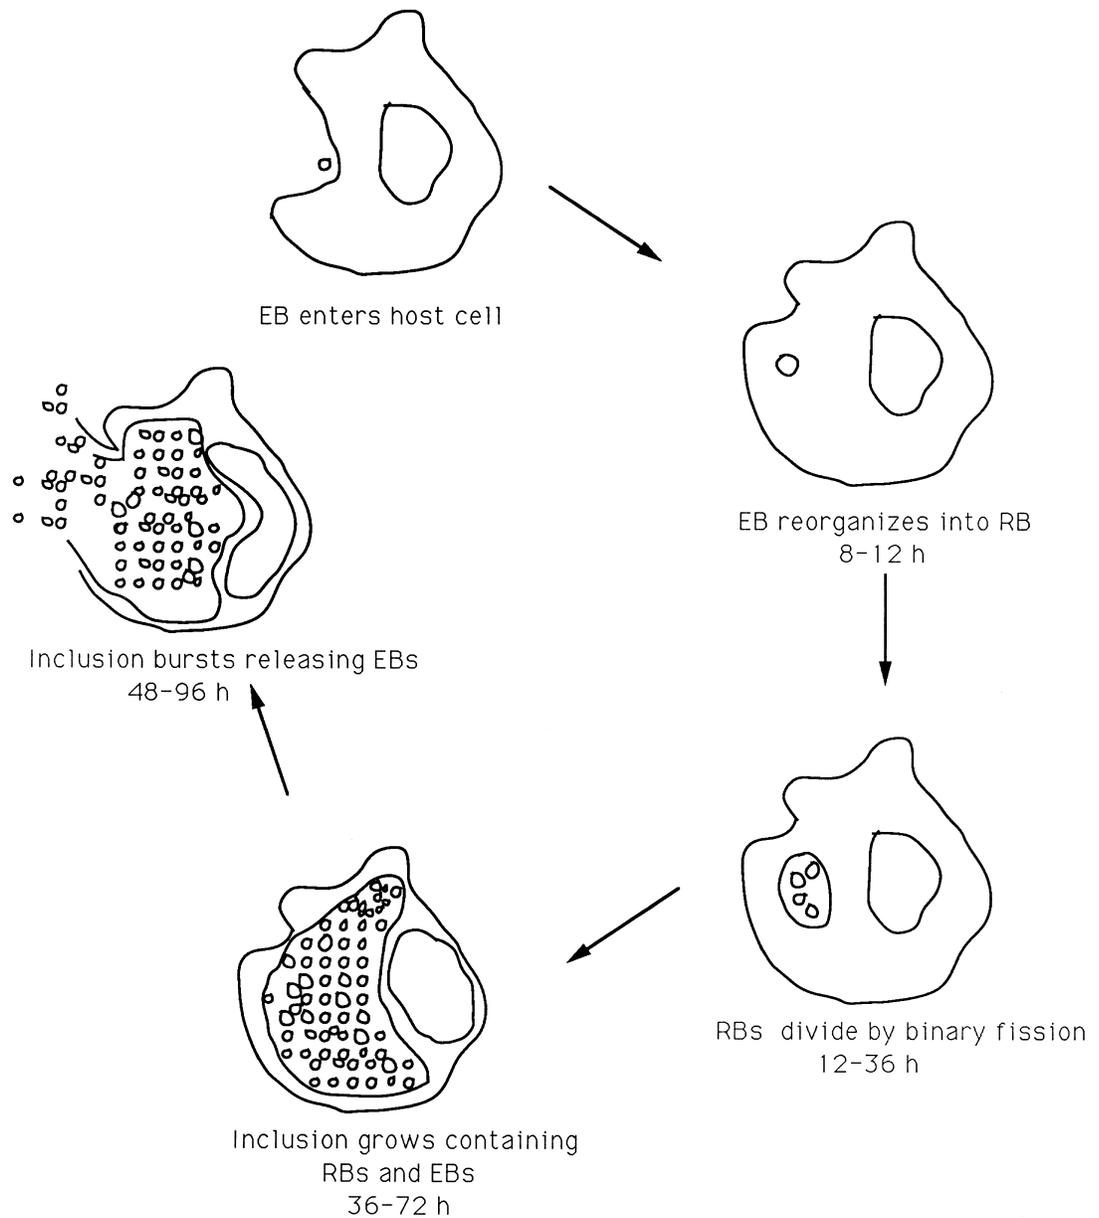

Figure 10.6-1 Developmental cycle of *Chlamydia* spp.

II. SPECIMEN (continued)

- Specimens that consist solely of a purulent discharge are not appropriate. Using a sterile swab, clean the discharge from the area to be sampled (e.g., cervix, urethra, conjunctiva), and use a new swab to obtain a sample of the epithelial cells.
- Immediately place swabs, scrapings, tissue biopsy samples, and small-volume aspirates into sterile leakproof screw-cap vials containing 1 to 2 ml of a chlamydial transport medium (CTM) such as 2-SP.
- Collect nasopharyngeal aspirates and sputum specimens into sterile screw-cap containers, and mix with an equal volume of CTM.

B. Transport and storage

- Place the specimen at 4°C, and transport it to the laboratory as soon as possible. Transport on wet ice or with a cold pack (2 to 8°C) if transport

Table 10.6–2 Collection of specimens

Type of specimen	Method of collection	Comment(s)
Swabs		
Cervical	Remove exocervical mucus with swab, and discard. Insert fresh swab at least 1 cm into endocervical canal, and rotate swab for 10 s.	Additional collection of urethral swab may increase number of positive individuals.
Conjunctival	Remove purulent exudate if present. Then, using flexible fine-shafted swab, rotate swab tip (premoistened with saline) over conjunctival surface.	
Nasopharyngeal	Insert dry, fine-shafted swab through nostril into nasopharynx, and rotate swab.	Preferred to throat swab
Rectal	Insert premoistened swab into rectum, and roll swab against mucosal surface.	Collected primarily in cases of proctitis
Urethral	Express and discard any exudate. Insert fine, flexible-shafted swab 2–4 cm into urethra, rotate swab gently two or three times, and withdraw swab. Patient should not urinate for at least 1 h before specimen collection.	
Vaginal	Rotate swab against mucosal surface for 10 s.	<i>C. trachomatis</i> is not associated with vaginitis but can infect anestro-genic vagina.
Fluids and aspirates		
Epididymal aspirate	Mix with equal volume of CTM.	
Fallopian tube aspirate	Same as above	
Nasopharyngeal aspirates and other respiratory tract fluids or washes	Place into sterile screw-cap container. May be mixed with equal volume of CTM if transport to laboratory is not immediate.	
Semen, seminal fluid	Mix with equal volume of CTM.	These specimens are usually toxic to cell cultures.
Tissues		
Endometrial or tubal biopsy samples; lung, surgical, and autopsy tissues	Place into sterile screw-cap container. Add CTM to prevent drying.	

II. SPECIMEN (*continued*)

time is more than a few minutes. Ideally, specimens should be transported to the laboratory within 4 h of collection.

2. Upon receipt in the laboratory, place the specimen at 4°C. If specimens cannot be cultured within 48 h, freeze them at –70°C. The loss in inclusion-forming units (IFU) is greater if the specimen is frozen rather than refrigerated during the initial 24 h and is comparable to the loss when specimens are held for 48 h at 4°C (1). After 48 h, the viability of *C. trachomatis* at 4°C drops below that which would be obtained if the specimen were frozen at –70°C.

III. MATERIALS

A. Reagents

☑ Indicate the expiration date on the label and in the work record or on the manufacturer's label.

1. CTM: 2-SP (0.2 M sucrose, 0.02 M phosphate)

- a. Dissolve the following ingredients separately in approximately 300 ml of deionized water.

K_2HPO_4 2.01 g

KH_2PO_4 1.01 g

sucrose 68.46 g

- b. Combine the solutions, and add deionized water to 1,000.0 ml.

- c. Adjust the pH to 7.2 to 7.4.

- d. Sterilize by Millipore filtration through a 0.2- μ m-pore-size filter.

- e. Aseptically add sterile antimicrobial solutions. The choice and concentration of antimicrobial agents may vary depending on individual laboratory experience with contamination. Antimicrobial agents (and final concentrations) frequently used include gentamicin (50 μ g/ml), vancomycin (100 μ g/ml), and amphotericin B (25 μ g/ml). Nystatin (25 U/ml) may be used in place of amphotericin B; nystatin is not soluble in aqueous form, and care must be taken to keep this material in suspension while dispensing. Do not include penicillin in CTM.

- f. Dispense 1- to 2-ml volumes into sterile screw-cap vials. Three or four sterile 5-mm-diameter glass beads added to each vial will facilitate disruption of cells prior to inoculation. Glass beads may be sterilized by autoclaving or by dry heat (160°C, 60 min).

- g. Store at -20°C for up to 6 months or at 4°C for 1 week.

- h. *Note:* Some laboratories include 3 to 10% heat-inactivated fetal bovine serum in CTM. This may help retain viability of cells during freezing. However, each lot of serum must be shown to be free of chlamydial inhibitors and antibodies.

2. Chlamydial isolation medium

- a. Aseptically combine the following sterile stock solutions.

Eagle's minimal essential medium (EMEM), 10 \times ,
in Earle's salts without
glutamine 50.0 ml
glutamine (200 mM) 5.0 ml
fetal bovine serum
(heat inactivated

[56°C, 30 min]) 50.0 ml

cycloheximide (100 \times stock) .. 5.0 ml

gentamicin, sufficient volume

to yield 50 μ g/ml

HEPES may be included as an additional buffer to yield a final concentration of 20 mM.

- b. Add sterile deionized water to a final volume of 500.0 ml. The medium should be reddish orange to cherry red, indicating a pH of 7.2 to 7.4.

- c. Dispense 100- to 500-ml volumes into sterile screw-cap bottles.

- d. Store at 4°C for up to 2 weeks once glutamine and cycloheximide have been added. Without these components, medium may be stored for up to 3 months at 4°C, with glutamine and cycloheximide added when the medium is used.

- e. If 1 \times EMEM is used, eliminate the deionized water and bring the final volume to 500 ml with the 1 \times EMEM.

3. Cycloheximide (100 \times stock)

- a. Ingredients

cycloheximide 10.0 mg

deionized water 100.0 ml

- b. Dissolve cycloheximide in water, and sterilize by filtration through a 0.2- μ m-pore-size filter.

- c. Aliquot in small volumes, and store frozen in the dark. The material may be stored at -20°C or lower for up to 1 year.

- d. The final concentration of cycloheximide in the chlamydial isolation medium is usually 1 μ g/ml; however, this may vary with each new lot or batch of cycloheximide. Using the chlamydial control stock (Appendix 10.6-1), assay each new

III. MATERIALS (continued)

batch at several concentrations ranging from 0.5 to 2.5 $\mu\text{g/ml}$. The optimal concentration is that which yields an inclusion number equal to or greater than the count obtained with the cycloheximide currently in use.

- e. Cycloheximide is toxic. Avoid inhalation and exposure to skin.
4. Streptomycin-vancomycin stock (20 \times)
A stock solution of 2 mg/ml can be prepared, aliquoted, and frozen at -20°C or lower. To use, add 0.1 ml to each 2.0 ml of specimen to be decontaminated.
5. 0.01 M phosphate-buffered saline (PBS), pH 7.2
 - a. Ingredients

NaCl	8.00 g
KCl	0.20 g
Na_2HPO_4	1.15 g
KH_2PO_4	0.20 g
deionized water	to 1,000.0 ml

 - b. Dissolve the components completely in distilled water.
 - c. Sterilize by filtration through a 0.2- μm -pore-size filter, and dispense into sterile screw-cap bottles.
 - d. Store at 4°C . Do not use if cloudiness or a precipitate develops.
6. Hanks' balanced salt solution (HBSS), pH 7.2 to 7.6
7. Cell culture medium
Isolation medium is EMEM with Earle's salts and 10% heat-inactivated fetal bovine serum, 2 mM glutamine, gentamicin (50 $\mu\text{g/ml}$), and cycloheximide (1 $\mu\text{g/ml}$). The optimal cycloheximide concentration may range from 0.5 to 2.0 $\mu\text{g/ml}$; determine the appropriate concentration for each batch of cycloheximide. While a high-glucose medium (e.g., 30 μM) is frequently used, its efficacy in detecting inclusions when immunostaining rather than iodine staining is used has not been determined. Cycloheximide is not included in culture medium used to maintain cell cultures prior to inoculation.
8. Acetone or methanol to fix monolayers: choice depends on fixative specified by the immunostaining reagent supplier.

9. Immunostaining reagents (monoclonal or polyclonal antibodies)
Fluorescein- or enzyme-conjugated antibodies suitable for culture confirmation by immunostaining procedures are commercially available. Direct immunofluorescence is the assay most frequently used for culture confirmation. Immunoreagents may be obtained at the working dilution and containing a counterstain. In all cases, the manufacturer's instructions must be followed when these products are used.
10. Buffered-glycerol mounting medium, pH ≥ 8.0

B. Supplies

1. Screw-cap vials containing 1 to 2 ml of CTM
2. Collection swabs
Test each lot of swabs for inactivation of chlamydial replication and toxicity (Appendix 10.6–2). Use cotton, Dacron, or rayon swabs with metal or plastic shafts; do not use calcium alginate or wooden-shafted swabs. Cytobrushes may also be used to obtain cervical specimens. Both collection devices yield comparable results (7).
3. Cell culture vials or plates (Appendix 10.6–3)
Shell vial cultures can be obtained from several sources. Alternatively, 1-dram shell vials (12 by 45 mm) can be purchased for seeding in the laboratory. McCoy cells, a continuous mouse fibroblast line, are the cells most commonly used to culture *C. trachomatis* from clinical material (12), while HL (5) and HEp-2 (10) cells are preferred for propagating *C. pneumoniae* (5, 9).
 - a. Use cell culture monolayers within 1 week of receipt.
 - b. See procedure 10.2 for assessment and storage of cell culture monolayers.
 - c. Incubate cultures at 35 to 37°C prior to inoculation. Confluent monolayers may be incubated at room temperature to retard monolayer overgrowth.
4. Sterile pipettes and safety pipetting device
5. Protective clothing and gloves

III. MATERIALS (*continued*)

6. Sterile disposable tissue grinder, scalpels, small sterile petri plates, and CTM for processing tissue samples
 7. Stock strains to be used as positive controls (Appendix 10.6–1)
 8. Glass slides, 1 by 3 in.
- C. Equipment**
1. Vortex mixer
 2. Incubator, $36 \pm 1^\circ\text{C}$ with 5 to 8% CO_2
 CO_2 is not needed for confluent monolayers in tightly capped vials.
 3. Class II biological safety cabinet
 4. Centrifuge and carriers to accommodate shell vials
 5. Refrigerator
 6. Freezer, -70°C for storage of specimens and isolates; -20°C or lower for storage of CTM and reagents requiring frozen storage
 7. Inverted light microscope, $\times 100$ to $\times 200$
 8. Microscope ($\times 200$ to $\times 400$), fluorescence or light, depending on whether fluorescein- or enzyme-conjugated immunostaining reagents are used

IV. QUALITY CONTROL

- A. Include a positive control with each batch of chlamydial cultures. Ideally, the control used when genital specimens are cultured should be a *C. trachomatis* serovar that is commonly isolated from the genital tract (e.g., serovar E or D). Prepare control stock as described in Appendix 10.6–1.
- B. Include a negative control with each run.
- C. Studies have shown variation in the abilities of different types and lots of swabs to affect chlamydial recovery (2, 8). Test each lot of swabs for chlamydial inactivation (Appendix 10.6–2).

V. PROCEDURE**A. Specimen preparation**

The principles of specimen preparation for chlamydial cultures are similar to those applied to preparation of specimens for viral culture (*see* procedure 10.4). Do not include penicillin in reagents used for specimen preparation.

1. Swabs or scrapings
Vortex the sample for 2 min, and discard the swabs.
2. Fluids
 - a. Mix with an equal volume of CTM.
 - b. Vortex for 2 min.
3. Tissues
Vortex 1- to 2-mm fragments in 1 to 2 ml of CTM with three or four sterile glass beads. For larger pieces, process in a sterile tissue grinder using 2 to 6 ml of CTM.

B. Inoculation and incubation of cell cultures

1. Inoculate each specimen into two shell vials. Examine each monolayer prior to inoculation to ensure that the monolayer is healthy and confluent (*see* procedure 10.5).
2. Revortex specimens prior to inoculation.
3. Remove the culture medium from the vials to be inoculated, and discard it.
4. Add 0.2 ml of vortexed specimen to each of two labeled vials. Inoculate positive control vials with stock material diluted to contain 50 to 100 IFU/0.2 ml (Appendix 10.6–1). Mock-inoculate negative control vials with 0.2 ml of CTM.
5. Centrifuge the inoculated vials in a swinging bucket rotor at $1,500 \times g$ for 45 to 60 min at 22 to 37°C .
6. After centrifugation, remove vials from the centrifuge, and feed the cultures with chlamydial isolation medium containing cycloheximide. Alternatively, remove the vials from the centrifuge and incubate them in a stationary position at 37°C for an additional 60 min prior to adding the medium. With

V. PROCEDURE (*continued*)

potentially toxic specimens (e.g., tissue homogenates), remove the inoculum and rinse the monolayer once with HBSS prior to adding the isolation medium.

7. Incubate the cultures at 37°C for 48 to 72 h. A CO₂ incubator (5 to 8%) is not necessary when tightly stoppered vials are used.

C. Fixation of monolayers

1. After incubation is completed, examine cultures with an inverted microscope to identify those that are unsatisfactory because of contamination or excessive toxicity. Reinoculate these samples, or obtain new specimens.
2. If blind subpassage is to be performed, select one vial for fixation and immunostaining, and put aside the second vial for harvesting and subpassage as described below.
3. Remove medium from the cultures to be stained.
4. Rinse each monolayer by adding and removing 1 ml of PBS.
5. Add 1 ml of fixative (as specified for the staining reagent), and fix the monolayer for 10 min.
6. Decant the fixative, and rinse the monolayer with 1 ml of PBS as described above.
7. The monolayer is now ready to be stained.

D. Immunostaining of monolayers (direct immunofluorescence)

1. Include positive and negative controls.
2. Add approximately 0.05 ml of immunoreagent to each vial so that the monolayer is covered. Do not add immunoreagent to dry monolayers. If necessary, premoisten the monolayers by rinsing them with distilled water.
3. Cover the vials, and incubate them for 30 min at room temperature or as specified by the reagent manufacturer. Incubation may be performed on a rotator (approximately 20 rpm) to facilitate distribution of the reagent.
4. Remove the reagent from each vial, and rinse the monolayer once with distilled water.
5. Allow the monolayers to air dry completely. Using slightly curved fine-tipped forceps, remove each coverslip and place it cell side down on a drop of buffered-glycerol mounting medium.
6. Using a fluorescence microscope, examine the entire monolayer at $\times 200$, and confirm questionable inclusions at $\times 400$.
7. If coverslips cannot be examined right after staining, store in the dark at 4°C for up to 24 h.

E. Blind subpassage

1. Remove the medium from the vial to be subpassaged, and add 1 ml of CTM and three or four sterile glass beads. Alternatively, if the monolayer appears fragile or is lifting off the coverslip, add the glass beads directly to the vial and proceed to step V.E.2.
2. Recap the vial, and vortex it for 2 min.
3. Inoculate one or two monolayers with 0.1 ml of the harvested material by proceeding with inoculation as described above.

■ **NOTE:** As an alternative to mechanically disrupting cells to perform a blind pass, cultures of *C. pneumoniae* have been recentrifuged on days 3, 4, and 5 and stained on day 7 of the culture protocol. Recentrifugation of the original culture has been reported to increase the number of IFU up to 5,000-fold (9).

4. The remaining material may be transferred to a cryotube and stored at -70°C or lower.

VI. RESULTS**A. Control cultures**

1. The positive control must show strongly fluorescent (brilliant apple-green) characteristic intracytoplasmic inclusions (Fig. 10.6–2). Inclusions often occupy >50% of the cellular cytoplasm; smaller ones may be observed in younger cultures or if secondary infection is taking place.
2. The negative control should have a satisfactory monolayer and show minimal to no nonspecific fluorescence.

B. Specimen cultures

1. A positive culture is one showing one or more characteristic fluorescent intracytoplasmic inclusions.
2. A negative culture is one that has minimal or no nonspecific staining and no chlamydial inclusions.
3. An unsatisfactory culture is one showing strong nonspecific fluorescence that interferes with reading or one that does not contain an adequate monolayer ($\geq 75\%$ of that observed in the negative control) as a result of contamination or toxicity. Subpassage, or obtain a replacement sample. Although an attempt may be made to treat a contaminated specimen with an antimicrobial concentrate and then reinoculate it, it is better to obtain a new sample.

VII. PROCEDURE NOTES

- A. Tissue and semen samples may be toxic to the cell culture monolayers. Inoculate these samples undiluted and after dilution (1:10 and 1:100) in HBSS. With semen samples, high-speed centrifugation may be used to reduce toxicity (*see* procedure 10.4).
- B. Avoid chilling during centrifugation, since EBs attach to but do not efficiently enter the host cell at cool temperatures. Temperatures above 37°C may result in loss of chlamydial viability.
- C. Some workers have reported an isolation rate of $\geq 10\%$ when primary cultures are subpassaged (12). However, the percent increase detected by a blind subpassage should be determined by each laboratory, and the extra cost and time required to complete a blind subpassage should be taken into account.

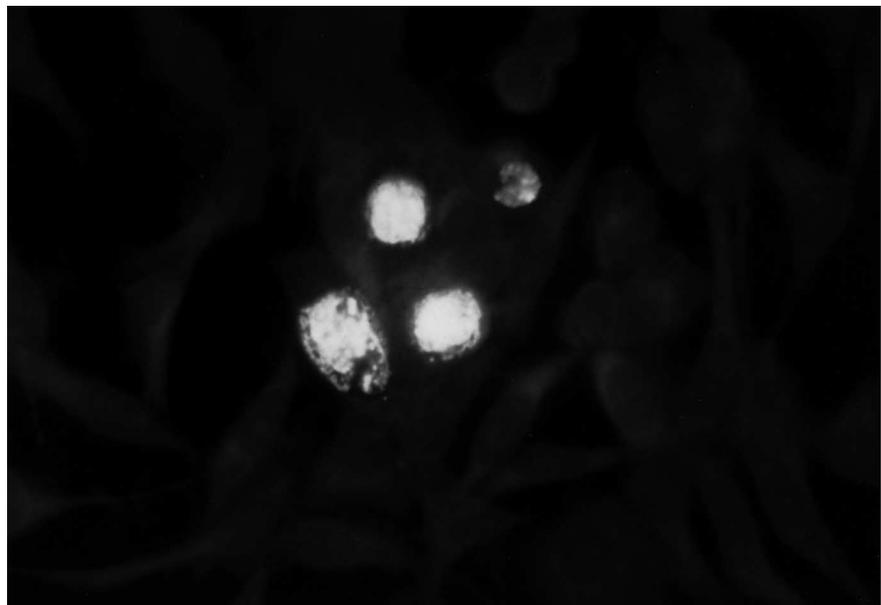

Figure 10.6–2 Typical chlamydial inclusions in a culture stained at 48 h with a monoclonal antibody to *C. trachomatis*.

VII. PROCEDURE NOTES

(continued)

- D.** Although there are reports of 96-well microtiter plates used for chlamydial cultures, this method has been shown to be less sensitive than culture systems using shell vials (11). A high-volume laboratory, however, might prefer to use microtiter plates for convenience. Seeding of microtiter plates must be done in-house, and centrifuge carriers designed for microtiter plates must be used for the inoculation step. When using microtiter plates, it is essential to incubate the plates in 5% CO₂.
- E.** While a monoclonal antibody recognizing the major outer membrane protein would be adequate for genital cultures, respiratory cultures should be stained with a lipopolysaccharide monoclonal antibody, since *C. psittaci* and *C. pneumoniae* can be recovered from these sites (Appendix 10.6–4).
- F.** Alternative staining methods for the detection of chlamydial inclusions are available (2, 3, 11). However, these methods are less sensitive than immunostaining with fluorescein-or enzyme-conjugated antibodies (Appendix 10.6–4).
- 1. Iodine**
Methanol-fixed monolayers are stained for 5 to 10 min with 0.5 to 1 ml of either Lugol's iodine or 5% iodine in 10% potassium iodide. The monolayers are rinsed with PBS and examined by light microscopy for reddish-brown glycogen-containing cytoplasmic inclusions. *C. psittaci* and *C. pneumoniae* inclusions do not stain with iodine.
- 2. Giemsa**
Various versions of the Giemsa stain have been used to visualize chlamydial inclusions, but this method is not routinely used for culture confirmation.
- G.** A standard chlamydial culture is one in which culture confirmation involves the visual identification of characteristic inclusions; methods that utilize solubilized cell culture monolayers (e.g., solid-phase EIA) may result in false-positive results as a result of cross-reactivity with organisms present in clinical samples (4).
- H.** Although DEAE-dextran is not routinely included in the isolation medium in the diagnostic laboratory, some workers have reported increased isolation rates when monolayers were treated with DEAE-dextran prior to inoculation (6). Decant medium from the monolayers, add 1 ml of DEAE-dextran in HBSS (30 µg/ml), and incubate the monolayers at room temperature for 30 min. Remove the DEAE-dextran solution prior to inoculation, or, alternatively, remove the solution along with the inoculum after centrifugation. The use of DEAE does not eliminate the need for cycloheximide in the isolation medium.
- I.** The procedure described for the isolation of *C. trachomatis* can be applied to the isolation of *C. psittaci* and *C. pneumoniae*. The human cell line HeLa 229 has been used for the culture of these two species. In addition, the HL and HEP2 cell lines have been reported to be more sensitive than HeLa 229 and McCoy cells for the primary isolation of *C. pneumoniae* (5, 10).
- J.** All specimen and culture manipulations should be carried out in a class II biological safety cabinet with appropriate safety precautions. Laboratory infections with *C. psittaci* have been reported, and isolation attempts should be done only by laboratories meeting the biohazard safety requirements.

APPENDIX 10.6–1

Preparation of Chlamydial Control Stock

- A. Control material may be obtained from a reference laboratory (e.g., ATCC, Manassas, Va.) or prepared with a clinical isolate.
- B. Inoculate vials following the procedure described in item V.B above. Follow instructions provided by the supplier for inoculum dilutions and volumes to use. For example, duplicate vials may be inoculated with 5, 50, and 100 μ l of the material.
- C. Determine the volume that produces inclusions in 80 to 100% of the cells in 48 h, and subpassage 20 μ l of this material into each of 10 vials following the procedure described in item V.E above.
- D. After 48 h (72 h for *C. pneumoniae*), stain one or two vials to confirm 80 to 100% infection of the monolayer, and harvest the remaining vials as described for subpassage (see item V.E above).
- E. Pool the contents of the vials, and aliquot the pool in small volumes (e.g., 0.02 ml).
- F. Freeze aliquots at -70°C .
- G. Thaw a frozen aliquot, and prepare four or five serial 10-fold dilutions in CTM or HBSS.
- H. Inoculate two or three McCoy cell vials (HL or HEp-2 for *C. pneumoniae*) with each dilution (see item V.B above).
- I. Fix and stain the vials after incubation for 48 h (72 h for *C. pneumoniae*) (see items V.C and D above).
- J. Count the inclusions at each dilution, and determine the dilution necessary to obtain 50 to 100 inclusions per coverslip monolayer. This dilution contains 50 to 100 IFU/0.2 ml.

APPENDIX 10.6–2**Procedure for Pretesting Swabs**

- A. For each lot of swabs to be tested, prepare four tubes, each containing 1 to 2 ml of CTM containing chlamydial control stock at 250 to 500 IFU/ml of CTM.
- B. Place one swab into each of two tubes. Use the other two tubes as no-swab controls.
- C. Incubate the tubes to reflect the conditions of specimen transport as defined by the laboratory. For example, incubate the tubes for 2 h at room temperature and then place them at 4°C for 24 h.
- D. Inoculate two cell culture monolayers with each of the test and control samples at each time point (e.g., 2 and 24 h for the example given above) by using the procedure described in item V.B above.
- E. Harvest (*see* item V.C above) and stain (*see* item V.D above) cultures in the usual manner.
- F. Count the inclusions in each monolayer. Do not use lots producing extensive monolayer toxicity and/or a $\geq 20\%$ reduction in inclusion counts (compared with the no-swab controls).

APPENDIX 10.6–3**Cell Lines**

A variety of cell lines have been reported to support the growth of chlamydiae. However, the most widely used cell lines for culturing *C. trachomatis* are McCoy and HeLa 229. The HL and HEP-2 cell lines are preferred for the primary isolation of *C. pneumoniae* (1). Cell monolayers are prepared on coverslips in shell vials or microtiter plates. Centrifugation of the specimen onto the monolayer (3, 4) and incorporation of inhibitors of eukaryotic cell protein synthesis into the cell culture medium give higher chlamydial yields. Although many metabolic inhibitors, including 5-iododeoxyuridine, cytochalasin ementine, and irradiation, have been used, cycloheximide is the cell inhibitor most commonly used for chlamydial cultures. Pretreatment of the monolayers with DEAE-dextran has also been reported to enhance recovery when a strain is grown from the trachoma biovar. However, this pretreatment is not commonly used for primary isolation (2).

■ **NOTE:** Refer to procedure 10.2 for commercial cell culture sources and maintenance.

APPENDIX 10.6-4

Detection of Inclusions

Chlamydial inclusions, which contain 100 to 1,000 EBs (1), can be detected by a variety of staining methods. Before the advent of monoclonal antibodies, both Giemsa and iodine stains were used to detect the typical intracytoplasmic inclusions in infected cultures. Giemsa stain was used primarily on direct smears, and iodine was used to identify the glycogen-containing inclusions that are produced by *C. trachomatis* but not *C. pneumoniae* or *C. psittaci* (4). However, monoclonal antibodies directed at either the major outer membrane protein of *C. trachomatis* or the lipopolysaccharide of chlamydiae have proven to be more sensitive than either of these staining methods (2, 3). It is important to remember that in general, the monoclonal antibodies to major outer membrane protein react only with *C. trachomatis*, while the monoclonal antibodies to lipopolysaccharide detect all species within this genus.

10.7

Direct Detection of Viruses and *Chlamydia* in Clinical Samples

I. MOLECULAR DETECTION ASSAYS

Commercially available assays for diagnostic testing are available for several viral agents and for *Chlamydia trachomatis* (Table 10.7–1) and are discussed in section 12.

Table 10.7–1 Direct specimen testing: viral and chlamydial infections^a

Method ^b	Specimen type or source ^c	Representative agent(s)
Antigen detection kits and reagents (e.g. IF, EIA, OIA, latex agglutination)	Blood leukocytes	CMV
	Genitourinary tract	<i>C. trachomatis</i>
	Lesion	HSVs, varicella-zoster virus
	Ocular	HSV (negative results may require confirmation by culture), <i>C. trachomatis</i>
	Respiratory tract	Adenoviruses, influenza virus types A and B, measles virus, parainfluenza virus types 1–4, respiratory syncytial virus, <i>C. trachomatis</i> . <i>Note:</i> Pools containing antibodies to several respiratory viruses are available commercially.
	Serum, plasma	HBV, HIV-1
	Stool	Adenoviruses (group), enteric adenoviruses (types 40 and 41), rotaviruses
Nucleic acid assays		
	Nonamplified	Genitourinary tract
Amplified	Blood leukocytes	CMV DNA, HIV-1 DNA
	Genitourinary tract	<i>C. trachomatis</i>
	Serum, plasma	HBV DNA, HCV RNA, HIV-1 RNA, CMV mRNA

^a Abbreviations: OIA, optic immunoassay; HBV, hepatitis B virus; HIV-1, human immunodeficiency virus type 1; HPV, human papillomavirus.

^b Refer to kit manufacturer regarding specimens for which the reagent can be used and specific instructions regarding collection, transport, and storage of specimens.

^c Anti-chlamydial LPS MAbs may cross-react with bacteria present in vaginal, rectal, and oral specimens, and false-positive results have been reported with EIA testing of vaginal specimens from children (2, 5, 6, 11) and of rectal specimens from adults (12) and children (11) and with direct IF staining of rectal smears from adults and children (6, 11).

**II. ANTIGEN DETECTION ASSAYS:
IMMUNOFLUORESCENCE (IF)
PROCEDURE**

■ **NOTE:** Other antigen detection procedures are discussed elsewhere in this publication.

IF is very widely applied in the diagnostic virology setting and has been shown to be very useful for the detection of viruses in leukocytes (e.g., cytomegalovirus [CMV]) and other cells derived from respiratory, genital, ocular, and cutaneous samples. Although the method requires expertise using a fluorescence microscope and interpretation of staining patterns, it has been shown to be a rapid and convenient method and allows for assessment of each sample for adequacy.

The procedure presented below is useful for developing assays using analyte-specific reagents and also provides generic technical information that is useful when following manufacturers' instructions for diagnostic kits. Kits and reagents are available for detection of numerous agents using either the direct IF (labeled primary antibody) or indirect IF (unlabeled primary antibody followed by labeled secondary antibody) method. Limitations imposed by the very high specificity of monoclonal antibodies (MAbs) and lower binding efficiencies are overcome by using mixtures of MAbs directed against different viral epitopes (10). Mixtures of MAbs (blends, pools) directed against two or more viruses (8, 13) are also available, as are preparations containing antibodies to two different viruses, each labeled with a different fluorochrome.

A. Supplies, reagents, and equipment

1. Sterile individually wrapped pipettes (1, 2, 5, and 10 ml) and safety pipetting device
2. Waste containers
Discard specimens, cell cultures, and other infectious waste based on local regulations.
3. Acetone-cleaned, Teflon-coated microscope slides with 5- to 8-mm wells and no. 1 coverslips
4. Coplin jars or staining dishes and racks
5. Slide storage boxes and desiccant
6. Scalpels, tongue depressors, or spatulas (for tissue impression smears)
7. PPE
8. Most antibody reagents used for IF assays are MAbs; because of their high specificity and lower binding efficiencies, a mixture of MAbs directed against different viral epitopes is generally more useful than individual MAb preparations. Mixtures of MAbs (blends or pools) directed against two or more viruses are also available for detecting multiple viruses by using a single reagent. Recently, mixed-antibody preparations labeled with different fluorescing reagents have been introduced for the simultaneous identification of common virus pairs (e.g., influenza virus types A and B, herpes simplex virus [HSV], and CMV).
9. Phosphate-buffered saline (PBS) (pH 7.1 to 7.6)
10. Acetone (reagent grade) or fixative recommended by reagent manufacturer (e.g., methanol, ethanol, paraformaldehyde)
11. Buffered-glycerol mounting medium, pH 8.0 for IF
12. Cytofuge and funnels, optional, for cytospin preparations
13. Centrifuge, low speed, with carriers to hold 15-ml centrifuge tubes
14. Rotator (15 to 20 rpm) or rocker
15. Fluorescence microscope equipped with filters suitable for fluorescein isothiocyanate (FITC) or fluorochrome of choice
16. Refrigerator
17. Incubator, 37°C

II. ANTIGEN DETECTION

ASSAYS:

IMMUNOFLUORESCENCE (IF) PROCEDURE (continued)

B. QC

1. Include positive and negative cell spots in each run.
2. Unless predetermined and stated by the manufacturer, determine the optimal working dilution to use for antibodies, and conjugate and assess cross-reactivity with other viruses.

C. Cell spot preparation

1. Aspirates and fluids containing cells (other than blood)
Follow the procedure described in Fig. 10.7-1. Alternatively, cytospin samples may be prepared by following the cytofuge manufacturer's instructions.
2. Swab specimens or scrapings
Follow the procedure described in Fig. 10.7-2.
NOTE: Swab specimens or scrapings may be placed into 1 to 2 ml of viral transport medium or PBS. After vortexing to release cells from the swab, the specimen may be processed in the same manner as aspirates and fluids; cell yield may be low for specimens processed in this manner.
3. Blood
Kits are commercially available for detection of CMV antigen in the nuclei of peripheral blood PMNs (Fig. 10.7-3).
 - a. Collect blood with anticoagulant (e.g., EDTA, heparin) as recommended by the manufacturer. Store blood at room temperature before cell separation; for optimal results, prepare slides within several hours of specimen collection.
 - b. The test can be applied quantitatively by applying a known number of leukocytes to the slides; however, it is important to determine whether an adequate number of cells are actually present at the time of reading. The number of cells can be estimated visually with experience; the number can also be estimated by inserting a micrometer disk in the ocular lens of the microscope and counting the cells in several representative fields. The average number of cells per field multiplied by the number of fields per well will give an estimate of the number of cells.
4. Tissues
 - a. Prepare impression smears as described in Fig. 10.7-2.
 - b. Prepare cell spots from tissue homogenates as described for aspirates in Fig. 10.7-1. Homogenates may be prepared by using a tissue grinder (Fig. 10.4-4) or a Tekmar Stomacher tissue grinder.
 - c. Acetone- or formalin-fixed frozen sections 4 to 6 μm thick are suitable for staining.
 - d. Paraffin-embedded tissues may be used after deparaffinization.

D. IF staining

Follow the procedure described in Fig. 10.5-8.

E. Observation of viral antigens

Use a $10\times$ objective to focus the slide. Then examine the entire cell spot at $20\times$. Cell morphology should be clear, with nuclear and cytoplasmic details defined. Use a higher magnification ($\times 40$ or $\times 63$) for closer examination of cellular detail and for examining questionable areas.

1. Assess control slides before examining test slides; repeat the assay if the controls do not yield the expected results. Refer to Table 10.7-2 for troubleshooting guidelines.
2. The positive control slide (virus-infected cells with homologous antibody) should have numerous cells with characteristic and intense (3+ to 4+) apple-green (for FITC) fluorescence. The number or percentage of fluorescing cells can also be determined, if desired.
3. The negative control should exhibit no (0) or minimal dim ($<1+$) fluorescence.

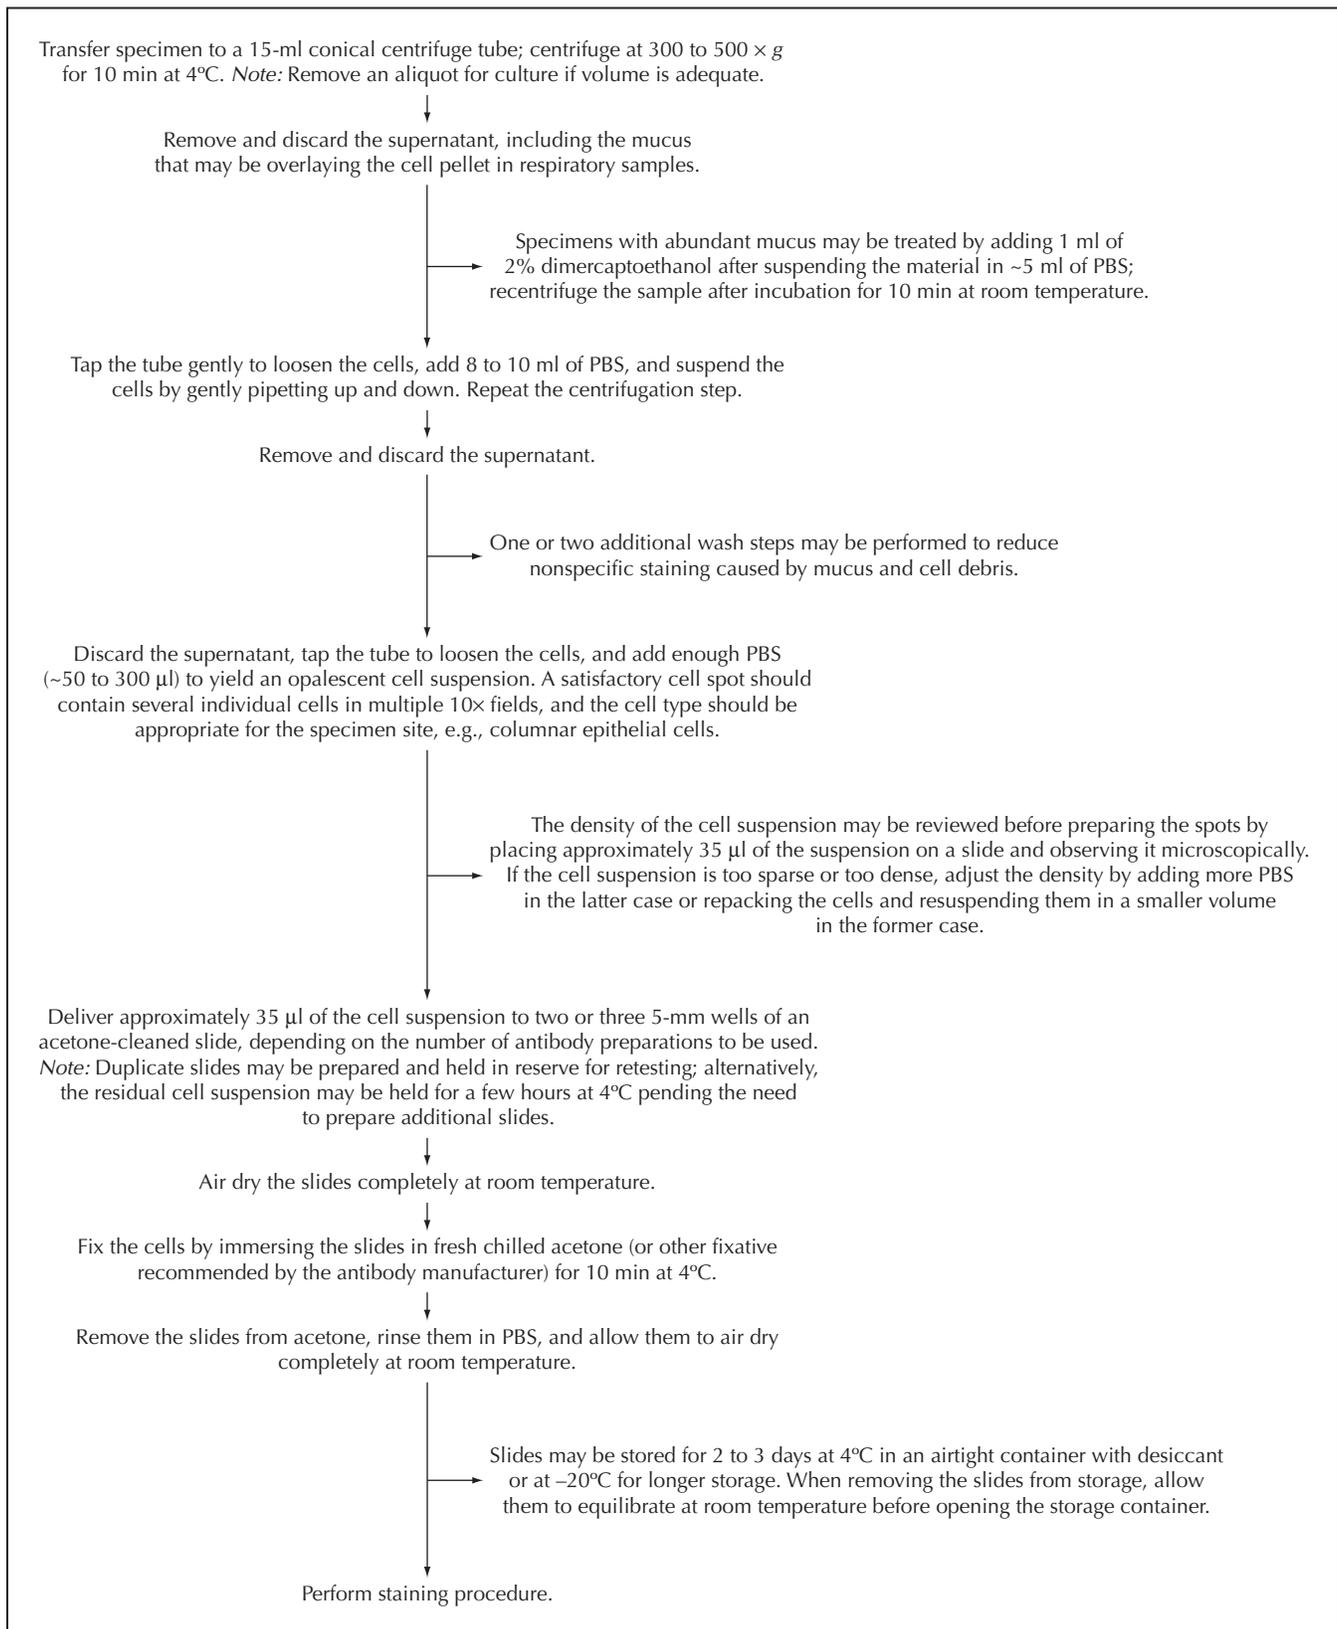

Figure 10.7–1 Preparation of aspirates and fluids for IF.

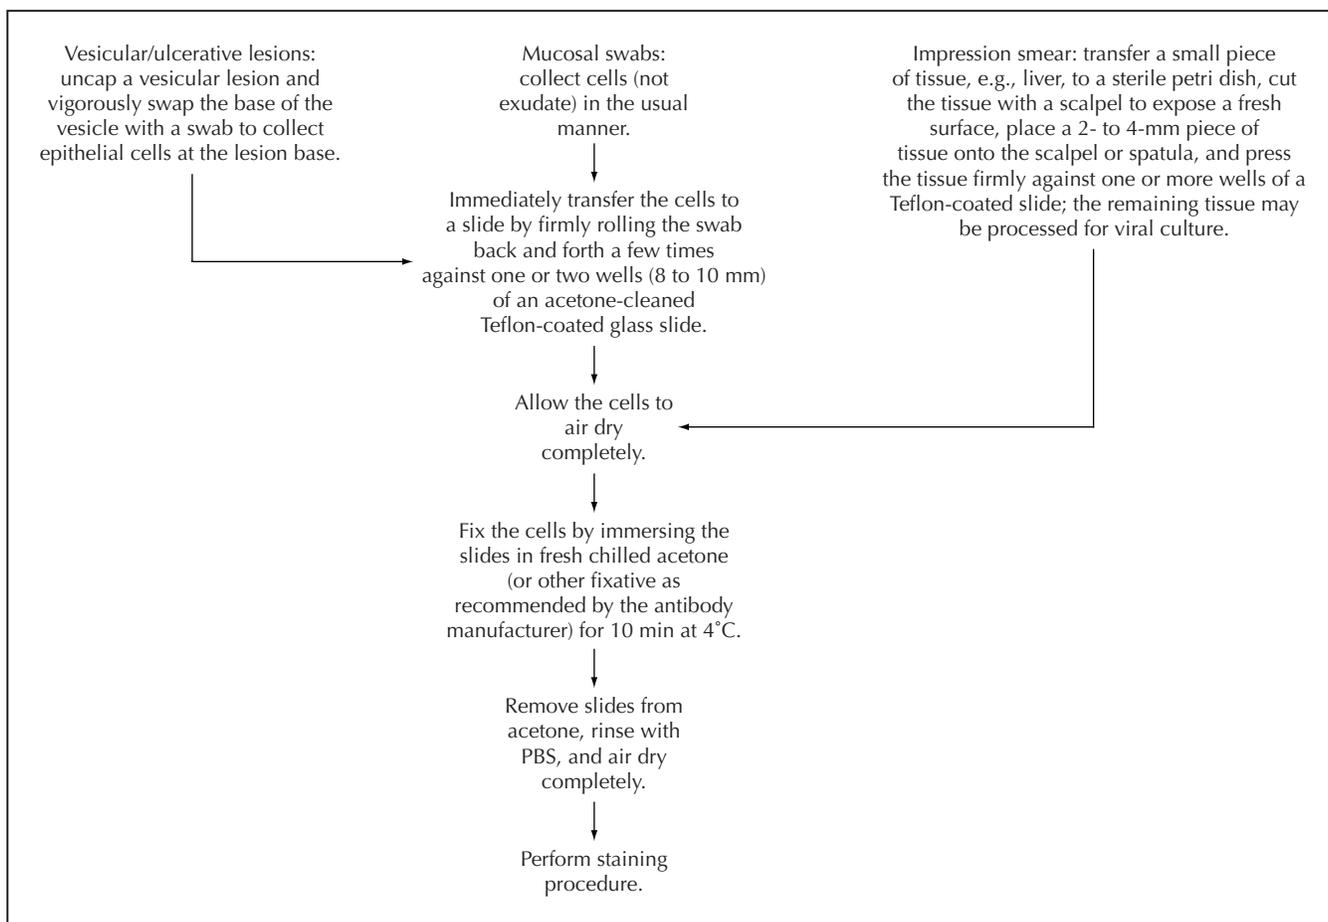

Figure 10.7–2 Preparation of swabs, scrapings, and impression smears for IF.

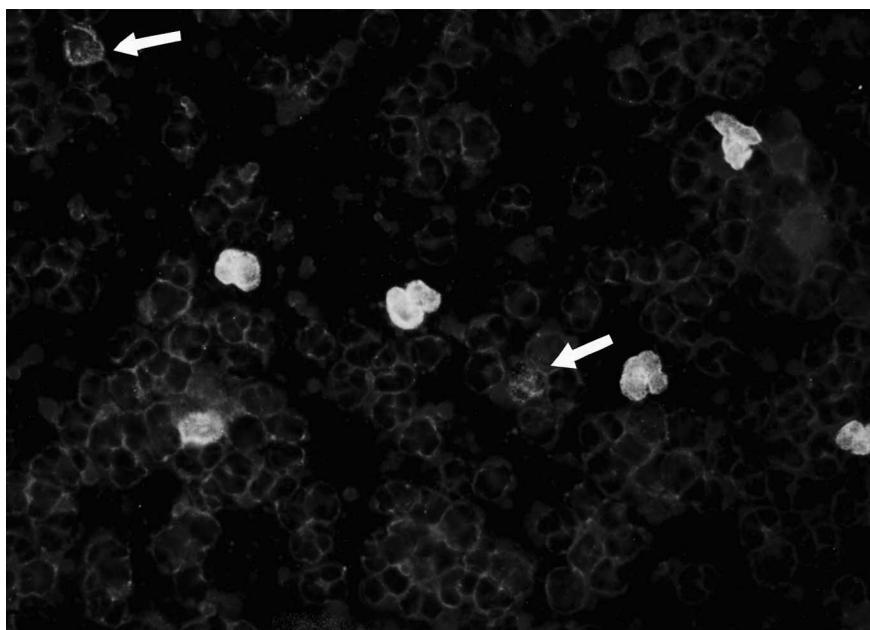

Figure 10.7–3 Leukocyte preparation with several cells showing intense CMV pp65 staining and a few cells (arrows) showing weak speckled nuclear staining ($\times 400$). Provided by Chemicon International.

Table 10.7–2 Troubleshooting IF problems

Problem	Causes	Solution
Weak or no specific fluorescence, including positive controls	Wrong (too weak) concn of immunoreagent used	Retitrate reagent.
	Deterioration of reagent	Retitrate and/or replace. Store properly, and aliquot if necessary.
	Counterstain too strong	Review concn and counterstaining time.
	Rapid fading of fluorescence	pH of mounting medium must be greater than that of wash buffer; use mounting medium that contains photobleaching inhibitor.
	Wrong filters or inadequate light source	Review use and maintenance of equipment; replace light bulb.
	Cannot achieve sharp focus because of dirty or improperly focused optics	Review procedures for maintenance and use of optics.
	Nonspecific glare or haze masking specific fluorescence	Allow cell spots to air dry completely before mounting; use fresh acetone.
Weak or no fluorescence with test slides but positive controls acceptable	Antigens destroyed by fixative	Use alternative fixative.
	Controls do not adequately reflect actual test conditions	Review procedure. Determine whether same or different reagents or methods were used for test and control slides.
Nonspecific fluorescence and/or false positives with test slides and negative controls	Improper slide cleaning, preparation, or fixation	Review procedures.
	Wrong concn (too strong) of immunoreagent used	Retitrate reagent.
	Cross-reactive immunoreagent	Identify non-cross-reactive concn of reagent, or obtain a better product.
	Binding of antibody via Fc receptors	Use conjugated F(ab') ₂ fragments.
	Trapping of immunoreagent on heavy or raised cell preparations	Avoid heavy cell preparations, which obscure cellular morphology and complicate reading. Increase number of washes during staining.
	Inappropriate immersion oil	Use immersion oil designated for fluorescence microscopy.
	Inadequate removal of fixative	Air dry cell spots completely after fixing. Rinse slides with PBS and/or water just prior to staining.
	Water in acetone	Replace acetone.
	Slides dried during staining	Use properly sealed moist chamber during incubation. Apply adequate reagent volumes to cell spots.
	Mounting medium not appropriate for IF, or pH too low	Obtain proper reagents. pH of mounting medium must be greater than that of wash buffer.
Mounting medium applied to wet cells	Mounting medium applied to wet cells	Allow cell spots to air dry completely before mounting.
	Wrong filters or equipment	Review use and maintenance of equipment.

Table 10.7–2 (continued)

Problem	Causes	Solution
	Reading error	Must be able to differentiate specific patterns of fluorescence from nonspecific staining.
	Precipitated material in immunoreagent	Microcentrifuge reagent for 1 min, or filter through a 0.45- μ m-pore-size filter.
Nonspecific fluorescence and/or false positives with test slides but negative controls acceptable	Controls do not adequately reflect test conditions	Review procedure. Determine whether same or different reagents or methods were used for test and control slides.
	Reading error	More reading experience needed, since controls may be easier to read and interpret than test slides.
	Reagent cross-contamination	Take care to confine reagents to wells.
	Inoculum debris or microorganisms on test slide	Increase number of washes.

II. ANTIGEN DETECTION ASSAYS: IMMUNOFLUORESCENCE (IF) PROCEDURE (continued)

4. A positive specimen is one in which one or more intact cells exhibit a characteristic staining pattern with a 2+ or greater staining intensity.
 - **NOTE:** Slides with weak staining and/or a single positive cell might be considered equivocal.
5. A negative specimen is one that contains an adequate number of cells typical of the sampling site and in which all cells exhibit minimal (<1) or no (0) fluorescence.
6. An unsatisfactory specimen is one in which strong nonspecific staining interferes with reading, or the slide contains too few intact cells typical of the site. Clinical samples should contain several cells in several 10 \times fields. Prepare new cell spots from the residual sample, and repeat the assay or request a new sample.
 - **NOTE:** The specific pattern of fluorescence depends on several variables, including the viral protein(s) being targeted and the type of antibody preparation (e.g., single MAb, mixed MAbs, or polyclonal antiserum). The expected pattern with a particular antibody preparation should be provided by the manufacturer. Positive controls, provided that the cells represent those in the test slides, are the best tool for determining characteristic staining. Refer to Fig. 10.5–9 in procedure 10.5 for examples of IF staining.

F. Observation for *C. trachomatis* elementary bodies (EBs) (staining for other chlamydial species may be performed in the same manner)

- **NOTE:** Fix slides for *Chlamydia pneumoniae* by using acetone, not methanol.

Extracellular EBs are approximately 300 nm in diameter and appear as bright apple-green punctate structures; EBs show a smooth edge when stained with anti-major outer membrane protein (anti-MOMP) antibodies. Chlamydial reticulate bodies or intermediate forms of the organism may stain with a peripheral halo and are larger than EBs; do not include these structures in the EB counts.

1. Examine control slides and determine whether they are acceptable before observing specimen slides. Examine slides at 40 \times ; use 63 \times or 100 \times to facilitate confirmation of suspected EBs (glycerol or oil objectives will facilitate reading).

II. ANTIGEN DETECTION ASSAYS: IMMUNOFLUORESCENCE (IF) PROCEDURE (continued)

2. A positive specimen is one that contains a quantity of EBs equal to or greater than the established cutoff number (e.g., 1, 2, or 5).
3. A negative specimen is one that contains an adequate number of columnar epithelial cells and no EBs.
 - ☑ **NOTE:** Report as positive for *C. trachomatis* if an anti-MOMP MAb is used; report as positive for *Chlamydia* spp. if an antilipoplysaccharide (anti-LPS) antibody is used.
4. An equivocal sample is one that contains fewer EBs than the established positive cutoff number.
5. An unsatisfactory sample is one in which EBs were not observed but which exhibits strong nonspecific staining that interferes with reading or that contains an insufficient number of cells. Specimen slides should contain two to three columnar epithelial cells per high dry field.

III. ELECTRON MICROSCOPY (EM)

EM (1, 3, 4, 9) can be used to visualize viral particles in specimens and can be very useful for studying virus-cell relationships and for attempting to assign a viral origin to a disease of unknown etiology. However, EM is generally less sensitive than other methods and is of limited availability. Negative staining, usually with phosphotungstic acid, can be used to visualize viral particles in specimen fluids and extracts containing at least 10^5 to 10^6 particles per ml; thin sectioning is useful for detecting viruses in tissues. Enhancement methods such as immunoelectron microscopy and/or concentration by ultracentrifugation increase the sensitivity of this method.

EM is useful in investigating suspected outbreaks of viral gastroenteritis caused by viruses for which other methods are not readily available (e.g., Norwalk agent, astroviruses, and caliciviruses). Collect stool within 2 to 3 days of onset of symptoms. Store and ship at 4°C; do not freeze. Contact the local or state public health laboratory or the Enteric Diseases Branch, CDC, Atlanta, GA 30333.

IV. CYTOHISTOPATHOLOGY

Examination of exfoliated cells, biopsy samples, and autopsy tissues may reveal nonspecific changes suggestive of viral infections, and several viruses are associated with the development of characteristic inclusion bodies (7) (Table 10.7–3). Cytohistopathology is generally less sensitive than other viral and chlamydial detection methods. However, this method is useful for detecting agents for which other diagnostic assays are not available (e.g., molluscum contagiosum) and to demonstrate organ or tissue involvement. For example, CMV inclusions in alveolar epithelial cells may be a better indicator of pulmonary CMV disease than positive culture or PCR results on bronchoalveolar lavage samples.

Table 10.7–3 Inclusion morphology

Agent ^a	Inclusion
CMV (Fig. 10.7–4A)	Enlarged (cytomegalic) cells with a large single basophilic intranuclear inclusion that nearly fills the nucleus and is surrounded by a clear halo (owl's eye appearance); associated with small Papanicolaou-positive cytoplasmic inclusions
<i>C. trachomatis</i> (Fig. 10.7–4B)	Giemsa- or Papanicolaou-stained smears may reveal typical intracytoplasmic inclusions. Sensitive method for examination of ocular specimens, for which the sensitivity has been estimated to approach 95% compared with culture, but insensitive for urogenital samples
HSV, VZV	Large eosinophilic Cowdry type A intranuclear inclusion with a halo of nuclear chromatin (mature form); associated with multinuclearity with indented (molded) nuclei. The Tzanck smear (Fig. 10.7–4C) is a classic method involving Giemsa staining of epithelial cells scraped from the lesion base.
HPV	Squamous cells appear swollen and contain an enlarged nucleus and perinuclear halo with poor cytoplasmic keratinization resulting in irregular staining (koilocytic change).
Measles virus	Large multinucleated giant cells with eosinophilic nuclear and cytoplasmic inclusions; high sensitivity for giant-cell pneumonia in immunocompromised patients (Warthin-Finkelday inclusions)
Molluscum contagiosum (Fig. 10.7–4D)	Large dense intracytoplasmic eosinophilic inclusions (molluscum bodies) occupying the entire squamous cell and resulting in peripheral displacement of a flattened nucleus
Rabies virus	Seller's stain reveals large eosinophilic cytoplasmic inclusions (Negri body), often with blue-staining granules or inner bodies arranged in concentric layers; several inclusion bodies, usually of variable size, may be present in one neuron.

^a Abbreviations: VZV, varicella-zoster virus; HPV, human papillomavirus.

11.1.1

Introduction

Since the previous edition of CMPH, there have been remarkable advances in the clinical immunology laboratory. Laboratory directors in clinical microbiology and clinical immunology interact with all fields of medicine. The intent of section 11 is to highlight procedures for major assays which are called upon in the clinical microbiology and clinical immunology laboratories. This field has expanded into many domains of diagnostic testing. Although the section cannot cover the full spectrum of laboratory immunology testing, a table from EPCM (1) provides generic descriptions of assays used in serologic diagnosis, including latex agglutination for antigen and antibody detection, staphylococcal coagglutination, EIAs for antibody and antigen detection, direct fluorescent-antibody testing for antigen

detection, indirect fluorescent-antibody testing for antigen and antibody detection, immunoblot procedures, complement fixation, hemagglutination inhibition, and immunodiffusion testing. In addition, a procedure has been added listing emerging immunological assays (11.1.3). This addition provides unique outlines for flow cytometry-based assays for apoptosis, chemokine detection, dendritic-cell detection, and tetramer assays. Diagnostic procedures added include basic serologic assays (procedures 11.2 to 11.9). New tests have been added for cellular immunology (procedures 11.10 through 11.18). Several flow cytometric assay procedures are provided (procedures 11.15 through 11.18). Methods are also provided for the assay of human cellular cytokines and studies of lymphocyte proliferation and natural killer

cells. For other details on laboratory immunology procedures, please refer to the *Manual of Clinical Laboratory Immunology*, 6th ed. (2), as well as to *Clinical and Diagnostic Laboratory Immunology*. Section 11 provides specific details for utilization of immunologic tests in the microbiologic setting as well as for cellular assays to determine the immunocompetence of the host. The tables provided by W. M. Janda (procedure 11.1.2) and A. Garcia (procedure 11.1.3) cover both basic concepts and concepts for emerging immunologic assays. Our thrust has been to add the important immunological approaches that define the host response against microbial agents to the armamentarium of clinical microbiologists, thereby to broaden the assessment of clinically overt infectious disease.

11.1.2

Immunologic Assays Used in the Serologic Diagnosis of Infectious Diseases

The following table is a summary of various tests that can be used in clinical microbiology laboratories for the serologic diagnosis of infectious diseases.

Table 11.1.2-1 Generic description of immunologic assays used in the serologic diagnosis of infectious diseases^{a,b}

Test	Basic principle	Specimen type evaluated	Basic materials	Basic QC
Latex agglutination for antigen detection	Latex spheres coated with specific immunoglobulins agglutinate in the presence of antigen.	CSF, urine, or serum	<ol style="list-style-type: none"> 1. Latex beads coated with specific antibodies 2. Positive and negative antigen controls 3. Mixing sticks 4. Reaction slides 5. Heat block or boiling water bath 6. Centrifuge 	Positive and negative controls should be performed with each batch of patient specimens.
Latex agglutination for antibody detection	Latex spheres coated with specific antigens agglutinate in the presence of serum containing the corresponding specific antibody.	Serum or plasma	<ol style="list-style-type: none"> 1. Latex beads coated with specific antibodies 2. Mixing sticks 3. Glass agglutination slides 4. Appropriate positive and negative controls 	Inclusion of positive and negative controls each time test is performed
Staphylococcal coagglutination	Staphylococcal cells are sensitized with antibody against specific antigens by the ability of staphylococcal protein A to bind immunoglobulin to the bacterial cell surface by the Fc regions of the antibody molecules.	Suspension of the organism to be identified prepared in PBS, buffered saline, etc., depending on the kit (usually used for bacterial identification)	<ol style="list-style-type: none"> 1. Staphylococcal cells sensitized with specific antibody 2. Nonsensitized staphylococcal cells (negative control reagent) 3. Reaction slides or cards 4. Mixing sticks 	Inclusion of positive and negative controls each time the test is performed

Basic procedure	Expected results	Basic limitations	Generic examples
<p>Mix specimen with reagent on a glass slide and inspect for specific agglutination.</p>	<ol style="list-style-type: none"> 1. Positive control must yield a strong agglutination reaction within 10 min. 2. Negative control must show no agglutination. 3. Specimens showing agglutination are positive. 4. Specimens showing no agglutination are negative. 	<ol style="list-style-type: none"> 1. Tests should not be used to replace culture (CSF antigen detection). 2. Urine and serum specimens require additional processing to prevent uninterpretable results. 3. Low antigen levels may result in false-negative tests. 	<p>Several commercial kits for detection of bacterial antigens (group B streptococcus, <i>Haemophilus influenzae</i> type b, <i>Streptococcus pneumoniae</i>, and <i>Neisseria meningitidis</i> serogroups A, C, Y, and W135) in CSF; also kits for detection of <i>Cryptococcus neoformans</i> capsular polysaccharide in CSF</p>
<ol style="list-style-type: none"> 1. Mix serum specimen on a glass slide. 2. Rock or rotate slide for specified period. 3. Inspect for agglutination. 	<ol style="list-style-type: none"> 1. Positive control must produce appropriate specific agglutination reaction. 2. Negative control must not show agglutination. 3. Patient specimens showing agglutination contain specific antibody. 4. Negative specimens show no agglutination. 	<ol style="list-style-type: none"> 1. Low levels of antibody may not be reliably detected. 2. Some kits may not be able to produce results that correlate with traditional antibody titers. 	<p>Latex agglutination tests for detection of rubella virus and CMV antibodies</p>
<ol style="list-style-type: none"> 1. Standardized, properly processed bacterial cell suspension (1 drop) is reacted with antibody-sensitized staphylococcal cells (1 drop) and cells that are not sensitized in circles or walls of a reaction slide. 2. Mix and rock or rotate the reaction slide for specified period. 3. Inspect for specific agglutination. 	<ol style="list-style-type: none"> 1. Positive control suspension must produce at least 2+ agglutination with the sensitized cells and no agglutination with the control cells. 2. Negative control suspension must show no agglutination with either the sensitized or the control staphylococcal cells. 3. Agglutination reactions of 2+ or greater with the sensitized cells and no agglutination with the nonsensitized cells on patient isolates are positive. 	<ol style="list-style-type: none"> 1. Isolates that show no agglutination must be identified by other methods. 2. Not all strains of an organism may be identified by a particular test. For example, not all strains of <i>Neisseria gonorrhoeae</i> are identified by commercially available coagglutination tests due to lack of appropriate monoclonal antibodies on the surfaces of the sensitized staphylococcal cells. 	<p>Coagglutination tests for the identification of <i>N. gonorrhoeae</i> (e.g., Phadebact OMNI, Gonogen, Meritec)</p>

Table 11.1.2–1 Generic description of immunologic assays used in the serologic diagnosis of infectious diseases^{a,b} (continued)

Test	Basic principle	Specimen type evaluated	Basic materials	Basic QC
EIA for antibody detection	Antigen is bound to a solid phase (bead or microtiter well). Antibody present in the specimen binds to the antigen on the solid phase. This complex is then reacted with a second antibody that is enzyme labeled and also directed against the antigen (the conjugate is often an anti-human immunoglobulin raised in goats). Subsequent exposure of this complex to the enzyme substrate results in the generation of a colored end product that is detected spectrophotometrically.	Serum or plasma	<ol style="list-style-type: none"> 1. Microtiter walls/beads coated with antigen 2. PBS with Tween 80 for serum dilution 3. Detection antibody-enzyme conjugate 4. Chromogenic enzyme substrate 5. Spectrophotometer 6. Incubator 7. Pipettes 	Inclusion of sera known to be positive and negative for antibody being detected; diluent buffer control
EIA for antigen detection	In this case, antibody (e.g., capture antibody) instead of antigen is bound to a solid phase. Antigen present in a specimen binds to the capture antibody on the solid phase. Following wash steps, this complex is reacted with a second enzyme-labeled antibody that is directed against another epitope of the captured antigen. After washing, enzyme substrate is added, resulting in the generation of a colored end product that is detected visually or spectrophotometrically.	Serum, plasma, other body fluids (e.g., stool for detection of <i>Giardia lamblia</i> antigen, respiratory tract secretions for detection of RSV, etc.)	<ol style="list-style-type: none"> 1. Antibody-sensitized microtiter wells, beads, or membrane filters 2. Second enzyme-conjugated antibody directed against other epitopes of the antigen 3. Positive and negative controls that contain antigen or lack the antigen, respectively 4. Some antigen detection EIAs contain calibrators and standards to allow semiquantitation of antigen levels present in certain specimens. 5. Spectrophotometric detection of positive results is used with some kits, although many rely on visual reading for detection of positive and negative tests. 	Known positive and negative control samples

Basic procedure	Expected results	Basic limitations	Generic examples
<ol style="list-style-type: none"> 1. Diluted serum specimen is incubated in antigen-sensitized wall or with antigen-sensitized bead. 2. Incubation and wash stage 3. Addition of enzyme-labeled conjugate directed against antibody (e.g., anti-human IgG raised in goats and linked to HRP) 4. Incubation and wash steps 5. Addition of enzyme substrate and generation of signal 6. Addition of stop solution 7. Generated color assessed spectrophotometrically 	<p>Positive results are determined by comparison with negative control; generally absorbance values 2- to 3-fold greater than the mean absorbance of a group of negative controls are considered positive. Some kits may include low- and high-titer positive controls, calibrations, etc.</p>	<ol style="list-style-type: none"> 1. Sera obtained during the acute phase of infection may contain only antibodies of the IgM class and will not be identified in IgG-specific assays; the converse is also true. 2. Contaminated, icteric, lipemic, heat-inactivated, or hemolyzed sera may produce erroneous results. 3. Departure from specific procedure may affect test results. 	<p>EIA kits for detection of antibodies are available for a wide variety of agents, particularly certain bacteria (e.g., <i>Borrelia burgdorferi</i>) and viruses (HIV-1, CMV, rubella, HSV, measles, mumps, HIV-1/2)</p>
<ol style="list-style-type: none"> 1. The specimen is incubated in a microtiter well or tube containing the capture antibody. 2. Incubate for specified period. 3. Wash steps 4. A second enzyme-labeled antibody that is also directed against epitopes of the antigen is added. 5. Incubate for specified period. 6. Wash steps 7. Enzyme substrate is added and allowed to incubate for a specified period. 8. Addition of stop solution 9. Color reaction is read visually or with a spectrophotometer. 10. In semiquantitative assay, standard curves are prepared from calibrators run in the same assay. 	<ol style="list-style-type: none"> 1. Positive results are determined visually by the presence of a colored endpoint. This may also be done with a spectrophotometer. 2. Semiquantitative results may be determined by standard curves with cutoffs determined by negative controls and regression analysis of standards. 	<ol style="list-style-type: none"> 1. Tests must be used exactly as described in package inserts. 2. Low levels of antigen may not be detected. 3. Antigens already present in serum specimens as antigen-antibody complexes will not be detected unless immune complexes are first dissociated. 	<p>Immunoassays for detection of group A streptococci directly in throat swabs; immunoassays for detection of RSV and influenza A virus in respiratory tract specimens; assays for detection of antigen in stool of patients with <i>G. lamblia</i> and <i>Cryptosporidium parvum</i>; assays for detection of HIV p24 antigen in serum</p>

Table 11.1.2–1 Generic description of immunologic assays used in the serologic diagnosis of infectious diseases^{a,b} (continued)

Test	Basic principle	Specimen type evaluated	Basic materials	Basic QC
Direct fluorescent-antibody test for antigen detection	Specific antibody conjugated to a fluorescent tag (e.g., FITC) is reacted directly with a specimen on a glass slide or with a smear of an organism prepared from a culture plate. After incubation and washing, the slide is examined under a fluorescence microscope and examined for specific immunofluorescence.	Specimens may include smears made directly from clinical specimens (e.g., endocervical smears for detection of <i>Chlamydia trachomatis</i>) or from cultures, where this procedure may be used for identification (e.g., identification of <i>Legionella</i> spp. from cultures grown on BCYE medium, identification of respiratory viruses growing in shell vials, etc.)	<ol style="list-style-type: none"> 1. Appropriate clinical specimens 2. Teflon-coated slides used for immunofluorescence (i.e., with specimen wells) 3. Specific antibodies conjugated directly to a fluorophore (e.g., FITC) 4. Humidor for slide incubation 5. Pipettes 	Positive and negative controls performed along with clinical specimens
IFA test for antigen detection	A specimen fixed on a slide is overlaid with an excess of unlabeled immune serum directed against the antigen and incubated. After a wash step, the specimen-antibody complex is reacted with a fluorochrome-labeled antibody directed against the species of the first unlabeled antibody (e.g., goat anti-human immunoglobulin conjugated to FITC). After a wash step, the specimen is examined under a fluorescence microscope fitted with the appropriate barrier filters for detection of specific immunofluorescence.	IFA tests can be used for detection of antigens in various clinical specimens (e.g., IFA test for <i>Pneumocystis carinii</i> in bronchoalveolar lavage specimens).	<ol style="list-style-type: none"> 1. Appropriate clinical specimens 2. Unlabeled specific antibodies directed against the antigen of interest 3. Fluorochrome-conjugated antibodies directed against the unlabeled antibodies (e.g., FITC-labeled anti-goat antibodies raised in mice) 4. Teflon-coated immunofluorescence slides with multiple wells 5. Humidor for incubation 6. Pipettes 	Positive and negative control slides prepared from previously tested patient specimens are processed through the procedure along with unknown patient specimens.

Basic procedure	Expected results	Basic limitations	Generic examples
<ol style="list-style-type: none"> 1. Specimen is applied to a well on a Teflon-coated immunofluorescence slide and fixed. 2. Specimen is overlaid with labeled conjugate and incubated in humidior for 15- to 30-min period. 3. Slide is washed to remove unbound conjugate. 4. Air dry specimen and apply mounting fluid and coverslip. 5. Examine under a microscope outfitted with a UV light source and appropriate barrier filters for assay under consideration. 	<p>Positive control and positive patient specimens show specific apple-green immunofluorescence (FITC); negative control and negative patient samples show no fluorescence.</p>	<p>Usually used only for antigen detection; while more rapid and less nonspecific, direct fluorescence procedures may be less sensitive and produce duller fluorescence than indirect immunofluorescence antigen detection methods.</p>	<p>Direct fluorescent-antibody test for <i>C. trachomatis</i></p>
<ol style="list-style-type: none"> 1. Appropriate clinical specimen and positive and negative control material are placed in wells of Teflon-coated immunofluorescence slide. 2. Slides are dried and fixed. 3. The wells are overlaid with unlabeled antibodies directed against the antigen of interest. 4. Incubate slides for 15–30 min in humidior. 5. Wash and blot slide dry. 6. Overlay wells with fluorochrome-conjugated antibody. 7. Incubate in humidior for 15–30 min. 8. Wash and blot slide dry. 9. Add mounting medium and place a coverslip over wells. 10. Read wells for specific immunofluorescence under a fluorescence microscope with appropriate filter system for fluorochrome detection. 	<ol style="list-style-type: none"> 1. Positive control material reveals presence of specific immunofluorescence of the antigen. 2. No immunofluorescence should be observed with negative control material. 3. Positive and negative patient specimens are determined by comparison of unknowns with the immunofluorescence observed in the positive control. 	<ol style="list-style-type: none"> 1. Positive and negative controls of human origin should be tested to verify reagent performance. 2. Care must be taken to minimize nonspecific immunofluorescence caused by “trapping” of the fluorochrome (e.g., treatment of sputa with mucolytic agents when looking for <i>P. carinii</i> by IFA test). 3. Test may not detect antigens present in low concentrations or in inappropriately collected specimens. 	<p><i>P. carinii</i> IFA test.</p>

(continued)

Table 11.1.2–1 Generic description of immunologic assays used in the serologic diagnosis of infectious diseases^{a,b} (*continued*)

Test	Basic principle	Specimen type evaluated	Basic materials	Basic QC
IFA test for antibody detection	This test is performed as described for the indirect assay; however, the first unlabeled antibody used in the test is that of the patient. Patient serum is serially diluted and placed on a series of immunofluorescence slide wells containing the same antigen. After an incubation and wash step, fluorochrome-labeled goat anti-human antibody is applied to each well. After another incubation-wash step, the slide is observed with a fluorescence microscope. The reciprocal of the highest dilution of the patient's serum that shows specific immunofluorescence is called the titer. Titers may be determined for both IgG and IgM. In the latter determination, the fluorochrome-labeled conjugate is directed against human IgM.	An antibody titer can be determined with a single serum. To document recent infection, an acute-phase specimen (collected early in the illness) and a convalescent-phase specimen (collected 2–3 weeks later) are needed to demonstrate an increase in titer of antibody against the antigen being tested.	<ol style="list-style-type: none"> 1. Teflon-coated immunofluorescence slides, each well of which contains the antigen of interest (e.g., cells infected with CMV and expressing CMV-specific antigens) 2. Patient serum (acute and convalescent) 3. Low- and high-titer positive and negative control sera 4. Fluorochrome-labeled anti-human immunoglobulin raised in another animal species (e.g., FITC-labeled anti-human immunoglobulins raised in goats) 5. Humidor for incubations 6. Pipettes 	<ol style="list-style-type: none"> 1. Negative, low-titer positive, and high-titer positive control sera are included with each test run performed on patient specimens. 2. Negative control serum is usually tested at titers of 4 and 16, while the low- and high-titer positive controls are run at 4 dilutions, usually 1 twofold dilution below and 2 twofold dilutions above the expected titer (e.g., if the low positive control has an expected titer of 64, it should be tested at titers of 32, 64, 128, and 256). 3. A conjugate control using PBS is also included.

Basic procedure	Expected results	Basic limitations	Generic examples
<ol style="list-style-type: none"> 1. Prepare twofold serial dilutions of the control sera and patients' sera. Depending on individual lab procedures, patient serum may be screened at 1 dilution (e.g., 1:16) or at 2 dilutions (e.g., 1:16 and 1:64). 2. Place 0.10 ml of the diluted control and patient sera on appropriately labeled wells of the immunofluorescence slide. 3. Incubate slide in humidior for 30 min at 37°C. 4. Rinse off sera and gently blot slide dry. 5. Place a drop of fluorochrome-tagged, appropriately diluted goat anti-human immunoglobulin on each of the slide wells. 6. Incubate in humidior for 30 min at 37°C. 7. Rinse slides, and blot dry. 8. Place small drops of buffered glycerol on each well and place a coverslip on the slide. 9. Read for specific immunofluorescence under the high-dry objective of the fluorescence microscope. 	<ol style="list-style-type: none"> 1. No immunofluorescence should be observed with either dilution of the negative control or with the PBS conjugate control. 2. Low- and high-titer control sera should agree with the predetermined titers, or neither titer should be $> \pm 1$ dilution off the expected titer. 3. If the controls are correct, the antibody titer is defined as the reciprocal of the highest dilution giving characteristic immunofluorescence. 	<p>Rheumatoid factor present in patient sera may cause false-positive results in tests for both IgG and IgM.</p>	<p>IFA tests are available for the detection of antibodies against several viral agents (e.g., CMV, HSV, HIV-1) and toxoplasma.</p>

(continued)

Table 11.1.2–1 Generic description of immunologic assays used in the serologic diagnosis of infectious diseases^{a,b} (*continued*)

Test	Basic principle	Specimen type evaluated	Basic materials	Basic QC
Immunoblot procedure	In this modified EIA, a mixture of different antigens (e.g., a lysate prepared from a virus growing in culture) is separated into its component proteins by molecular weight with electrophoresis. The separated components are then electrophoretically transblotted onto a sheet of nitrocellulose paper. The sheet is cut into strips that are used as the solid phase for reaction with patient sera. Subsequently, the strip is incubated with enzyme-labeled anti-human immunoglobulin. After wash steps, enzyme substrate is added. The presence of antibody in patient serum that is reactive with antigens separated on the nitrocellulose strip is indicated by the appearance of a colored band at the location of that particular antigen on the strip.	Serum or plasma	<ol style="list-style-type: none"> 1. Nitrocellulose strips containing electrophoresed antigen (these may be prepared in-house or purchased from a vendor if available) 2. Plastic container with troughs for holding and incubating nitrocellulose blot strips 3. Pipettes 4. Positive and negative control sera 5. HRP-labeled goat anti-human antibodies (alternatively, biotinylated goat anti-human conjugate and avidin-HRP can be used in place of the HRP-labeled goat anti-human immunoglobulin) 6. HRP substrate 	Negative and low- and high-titer controls should be performed with each test.

Basic procedure	Expected results	Basic limitations	Generic examples
<ol style="list-style-type: none"> 1. The nitrocellulose strip with the electrophoresed antigens is placed in an incubation trough. 2. A dilution of the serum to be tested is placed in the trough along with the antigen strip. 3. After incubation and wash steps, the strip is incubated with goat anti-human IgG labeled with an enzyme. Alternatively, goat anti-human immunoglobulin conjugated to biotin may be used as the conjugate. 4. After incubation and wash steps, the enzyme substrate is added to the trough. The appearance of colored bands at the locations of the various antigens indicates the presence of antibody to that antigen in the original serum specimen. If a biotinylated conjugate is used, then avidin-enzyme is added and, after incubation and wash steps, the enzyme substrate is added for color development. 	<p>The appearance of colored bands on the strip indicates that antibody against that particular antigen was present in the original serum specimen.</p>	<ol style="list-style-type: none"> 1. Test must be performed exactly as described in the package insert. 2. Western blotting is as sensitive as and more specific than standard colorimetric EIA. 	<p>HIV-1 Western immunoblot supplemental test for detection of specific anti-HIV-1 antibodies</p>

Test	Basic principle	Specimen type evaluated	Basic materials	Basic QC
CF	Terminal components of the complement cascade (C7, C8, C9) damage cell membranes in the presence of specific antibody, which fixes complement to the cell surface. In the CF test, erythrocytes are used as the target cells and complement-induced “leakiness” can be detected colorimetrically or visually as an increase in free (rather than cell-bound) hemoglobin. In the presence of specific antibodies to an infectious agent, any complement added to the test system becomes bound, leaving no residual complement for reaction with antibodies to the “indicator” target erythrocytes. Therefore, the presence of specific antibody is indicated by the absence of hemolysis	Serum	<ol style="list-style-type: none"> 1. Sheep erythrocyte suspension 2. Hemolysin (commercially available) 	Known antibody-positive and antibody-negative controls; serum control to detect anticomplementary activity; antigen controls without serum to detect anticomplementary activity; tissue control (the cells or tissue in which the antigen was prepared); buffer control; back titration of commercial complement to ensure use of 5 CH ₅₀ units in each well; cell control to demonstrate absence of hemolysis; reference hemolysis standards

Basic procedure	Expected results	Basic limitations	Generic examples
<p>Sensitization of erythrocytes</p> <ol style="list-style-type: none"> 1. Serial dilutions of hemolysin incubated with 2.8% solution of sheep RBCs in buffer 2. As hemolysin concentration increases, degree of hemolysis increases, to achieve a maximal "plateau." 	<p>Highest dilution of antibody providing 3+ to 4+ fixation of complement (<30% hemolysis) is the endpoint.</p>	<p>All reagents must be free of anticomplementary activity, the correct quantity of complement must be present, and controls must produce expected reactions.</p>	<p>The CF test is considered the reference method for detection of antibodies against a wide variety of viral agents and <i>Mycoplasma pneumoniae</i>. The CF test has been largely supplanted by EIA methodology.</p>
<p>Quantitation of complement</p> <ol style="list-style-type: none"> 1. Various amounts of a 1:400 dilution of cold, reconstituted guinea pig complement are incubated with sensitized RBCs. 2. Volume of complement producing 50% lysis of RBCs (CH_{50} unit) is calculated from graphed results of the hemolysis. 			
<p>CF test</p> <ol style="list-style-type: none"> 1. Block titration of serial dilutions of both antigen and antibody is performed in presence of 5 CH_{50} units of complement at 4°C for 16 h. 2. Patient sera are heated at 56°C for 30 min to inactivate endogenous complement. 3. RBCs that have been sensitized with the optimal dilution of hemolysin are added and the mixture is incubated at 37°C for 30 min. 4. Plates are centrifuged to sediment unlysed erythrocytes. 			

(continued)

Table 11.1.2–1 Generic description of immunologic assays used in the serologic diagnosis of infectious diseases^{a,b} (*continued*)

Test	Basic principle	Specimen type evaluated	Basic materials	Basic QC
Hemagglutination inhibition	Some viruses produce surface proteins that agglutinate erythrocytes from various species. The presence of antibodies to such viruses in patient serum can be determined by specific inhibition of that hemagglutination.	Serum or plasma	<ol style="list-style-type: none"> 1. Erythrocytes from appropriate species (usually chicken) collected in Alsever's solution or heparin 2. Diluent of appropriate pH 3. Solutions to remove nonspecific agglutinins from serum 4. Standardized viral antigen 	Known positive and negative sera; back titration of antigen to ensure that the correct concentration of hemagglutinating units was tested

Basic procedure	Expected results	Basic limitations	Generic examples
<p>Determination of hemagglutinating titer</p> <ol style="list-style-type: none"> 1. Diluted suspension of RBCs is incubated at 4°C or at room temperature with serial dilutions of viral antigen until RBCs in tubes lacking virus settle as a button. 2. Highest antigen dilution that produces partial or complete agglutination equals 1 HAU. <p>Treatment of sera Treat serum by physical means (kaolin), enzymes (neuraminidase), etc., to remove nonspecific agglutinins.</p> <p>Inhibition test Dilutions of antigen containing 4 HAU are mixed with erythrocytes and twofold dilutions of pretreated patient sera and incubated as for the determination of HAU titer.</p>	<p>End point is the last well in which partial or complete inhibition of viral agglutination of RBCs occurs.</p>	<p>Use of test is limited to detection of antibodies against those viruses that possess surface hemagglutinins (e.g., rubella).</p>

Table 11.1.2–1 Generic description of immunologic assays used in the serologic diagnosis of infectious diseases^{a,b} (continued)

Test	Basic principle	Specimen type evaluated	Basic materials	Basic QC
Immunodiffusion test	Double immunodiffusion is used to detect antigen or antibody. Known and unknown reactants are placed in adjoining wells of an agarose matrix and are allowed to passively diffuse towards one another for 12–24 h. A precipitin line forms where optimal levels of antigen and antibody are present. Double diffusion is usually used for the detection of antibodies. CIE is similar to double diffusion, except that the migration of one or both reactants is directed by an electrical field. (Cells to the right describe materials and procedures for fungal immunodiffusion testing.)	Patient serum or plasma for detection of antibody. CIE has been used with other body fluids (e.g., CSF) primarily for the detection of bacterial antigens.	Materials listed are those needed for fungal immunodiffusion. <ol style="list-style-type: none"> <i>Blastomyces dermatitidis</i> immunodiffusion antigen <i>B. dermatitidis</i> immunodiffusion rabbit antisera <i>Coccidioides immitis</i> immunodiffusion antigen <i>C. immitis</i> immunodiffusion rabbit antisera <i>Histoplasma capsulatum</i> immunodiffusion antigen <i>H. capsulatum</i> immunodiffusion rabbit antisera 1% Purified agar Immunodiffusion matrix pattern containing a single central well and 6 peripheral wells located equidistant from the central well and from adjacent wells Reading box containing an incandescent light source with a flat, black background 	For fungal immunodiffusion, control serum containing the antibodies being sought is required to discern lines of identity that may form between the antigen, the known antisera, and the patient's specimen. In addition to homologous testing, each test serum and antigen should also be tested for immunodiffusion reactivity with heterologous sera and antigens.

11.1.3

Emerging Immunological Assays

Table 11.1.3-1 Emerging immunological assays using flow cytometry^a

Test	Basic principle	Specimen type
Sub-G ₀ -G ₁	Apoptosis can be characterized as cells with subdiploid DNA content. These cells can be measured utilizing PI staining and DNA software.	Whole blood, heparinized, is preferred. Isolate PBMCs.
TUNEL	The TUNEL method allows rapid phenotypic identification of individual apoptotic cells using flow cytometry. Cleavage of the genomic DNA during apoptosis is detected by labeling the free 3' OH termini with fluorescein-labeled nucleotides. The reaction is catalyzed by terminal deoxynucleotidyl-transferase in a template-independent fashion. The fluoresceinated DNA is then detected on a single-cell level by flow cytometry. Cell phenotype, activation, or maturation state is established by cell surface labeling with MAb prior to the TUNEL reaction.	Blood should be drawn in ACD. A total of 20 ml is used for this assay.
Annexin V	Apoptosis can be characterized by changes in cell membrane structure. During apoptosis, the cell membrane's phospholipid asymmetry changes: PS is exposed on the outer membrane while membrane integrity is maintained. Annexin V specifically binds PS, while PI or 7-AAD is a DNA binding fluorochrome. When a cell population is exposed to both reagents, apoptotic cells will stain positive for annexin V and negative for PI or 7-AAD, necrotic cells will stain positive for both, and live cells will stain negative for both.	
Caspase 3	Caspase 3 has been implicated as a key protease that is activated during the early stages of apoptosis. The caspases are synthesized as inactive proenzymes that are processed in cells undergoing apoptosis by self-proteolysis and/or cleavage by another protease. The processed forms consist of a large heterodimer of 17–21 kDa and a small one at 12 kDa, subunits which derive from the 32-kDa proenzyme. These subunits form an active enzyme. Active caspase 3 proteolytically cleaves and activates the other caspases, as well as relevant targets in the cytoplasm and nucleus. Caspases trigger a cascade of proteolytic cleavage events within the apoptotic cell, which include numerous cytoplasm and nuclear proteins as well as other caspase family members.	
Chemokines	Chemokines are a new subset of cytokines, which participate in the activation of leukocytes and play a critical role in controlling their movement during inflammation, infectious diseases, tumor growth, and hematopoietic progenitor cell proliferation. Chemokines are 8 to 10 kDa proteins sharing 20–70% homology in amino acids. According to the relative positions of their cysteine residues, chemokines can be subdivided into 4 families, including CXC, CC, C, and CX3C. Chemokines exert their function through a family of 7 G protein-coupled transmembrane receptors.	
DCs	DCs are specialized for antigen uptake, processing and presentation to the T cells. DCs are distinguished from the antigen-presenting cells, such as B cells and monocytes, by their ability to induce a primary immune response, such as activation of immunologically naive T cells. DCs are present in low frequencies in peripheral lymphoid tissue and blood and in nonlymphoid organs. The two distinct peripheral dendritic subsets can be detected using 3- or 4-color flow cytometry, CD123 ⁺ and CD11c ⁺ HLA-DR lineage (CD3, -14, -16, -19, -20, and -56) dim or negative.	Whole blood collected in either EDTA, ACD, or sodium heparin, or PBMCs. Use blood within 24 h of draw.

Table 11.1.3–1 Emerging immunological assays using flow cytometry^a (*continued*)

Test	Basic principle	Specimen type
Tetramer assay	This assay is a peptide epitope-specific assay for antigen-specific T cells. Normally this is done to detect virus-specific (influenza virus, HIV, CMV, EBV, etc.) CD8 ⁺ T cells, but it can be done with any antigen. Sample of blood needs to be prescreened for HLA-A2; it must be HLA-A2 ⁺ in order for the assay to work using the tetramer. HLA-A2 forms a tetramer in solution when bound to a microglobulin and an epitope peptide. Once the class I chain-peptide-microglobulin is ready, it is mixed with fluoresceinated streptavidin, thus forming a tetramer of peptide-loaded MHC class I molecules. The dominant epitope of the antigenic peptide is bound to the appropriate class of HLA. Since this mimics how macrophages, B cells, or DCs present antigens, it can identify antigen-specific cells. The binding affinity of the complex to the T cell is near that of Ab-Ag complexes and is suitable for flow cytometry.	Whole blood, heparinized, is preferred over PBMCs. Whole blood has a lower background, and the tetramer-positive population has a higher MFI in whole blood. PBMC staining is adequate, and fresh and frozen PBMCs give similar results. Staining at room temperature is best.

<ol style="list-style-type: none"> 1. Tetramers labeled with PE (FL2) less background or antigen-presenting cells (FL4) 2. FACS Lysing Solution 3. CD8-, CD3-labeled MAb 4. 1% Fixative 5. Flow cytometer 4-color acquisition/analysis 	Set flow compensation.	<ol style="list-style-type: none"> 1. Use MAb to identify a tetramer-specific population included in the CD3 CD8 population. 2. Gate on CD3⁺ lymphocytes and plot tetramer vs CD8. All tetramer-positive cells will be CD8⁺. 	Due to the infrequency of antigen-specific cells, a minimum of 150,000 lymphocyte events in a flow cytometer must be collected to detect an antigen-specific population of less than 0.1% or higher of T cells. To detect a lower frequency, one will need to stain more cells and collect more events.	Procedure is MHC class I restricted like HLA-A2 ⁺

11.2.1

Introduction

A number of extracellular antigenic products have been identified in cultures of group A streptococci, primarily enzymatic proteins. These include streptolysin O, streptokinase, hyaluronidase, deoxyribonucleases (DNases A, B, C, and D), and adenine dinucleotide glycohydrolase.

Infections by group A streptococci are unique because they can be followed by the serious nonpurulent complications acute rheumatic fever and glomerulonephritis. Rheumatic fever is associated with infection by certain M serotypes (M3 and M18), while glomerulonephritis fol-

lows infection by nephritogenic serotypes (M1, M2, M4, M6, M12, M49, and M60). Rheumatic fever follows untreated tonsillitis-pharyngitis. Glomerulonephritis occurs in as many as 10 to 15% of individuals involved in outbreaks of impetigo. These complications occur after a period of latency following the infection, during which the patient is asymptomatic. The latency period for acute glomerulonephritis is approximately 10 days, and that for acute rheumatic fever is about 20 days.

Serologic tests have been developed to provide evidence for an antecedent group

A streptococcal infection, utilizing assays for serum antibodies against one or more of the antigenic streptococcal extracellular products or cellular components (Table 11.2.1-1). The use of these assays for the diagnosis of acute group A streptococcal infection is rarely indicated. Occasionally, they may be used to confirm that an acute illness is related to group A streptococcal infection, such as in a patient with suspected scarlet fever. For these patients, acute- and convalescent-phase sera obtained 2 to 4 weeks apart can be assayed in tandem so as to demonstrate a rise in titer.

TESTS FOR ANTIBODIES TO EXTRACELLULAR PRODUCTS OF GROUP A STREPTOCOCCI

The anti-streptolysin O (ASO) test was devised by Todd (1) to measure serum neutralizing antibody against streptolysin O. Hemolysin activity is measured by the capacity of the enzyme to lyse erythrocyte membranes, and this activity is neutralized by serum antibody. The ASO test was followed by the development of other neutralizing-antibody tests for enzymes produced by group A streptococci. The ASO test remains the best standardized, most reproducible, and most universal. The use of other tests, such as the antihyaluronidase and antistreptokinase tests, has declined in part because of difficulties in reproducibility and the limited availability of some reagents. In contrast to these tests, the anti-DNase B test has gained usage. DNase B is one of four deoxyribonuclease isozymes (A, B, C, and D) produced by group A streptococci, and because the B isozyme is produced predominantly by group A streptococci, the anti-DNase B test is highly specific for recent group A streptococcal infection. The test is highly reproducible, and reagents are also available commercially.

Although the ASO test is quite reliable, the ASO response is not universal: elevated serum ASO titers are found in only about 85% of individuals with acute

Table 11.2.1-1 Tests of antibodies to extracellular products of group A streptococci

Type of test	Name	Supplier	Comment(s)
ASO	Bacto-Streptolysin O reagent	Difco, Detroit, Mich.	Preferred, most accurate
	ASO latex test	Biotec, Ipswich, Suffolk, United Kingdom	Rapid, qualitative
	Colorcard ASO	Wampole, Cranbury, N.J.	Rapid, semiquantitative
Anti-DNase B	Streptonase-B	Wampole, Cranbury, N.J.	Preferred

11.2.1.1

**TESTS FOR ANTIBODIES TO
EXTRACELLULAR PRODUCTS OF
GROUP A STREPTOCOCCI**
(continued)

rheumatic fever. While the same holds true for other streptococcal antibody tests, a significant proportion of individuals with normal antibody titers for one test have elevated antibody titers for another test. Thus, the number of false negatives can be reduced by performing two or more antibody tests. In addition, skin infection, in contrast to throat infection, is associated with a poor ASO response; thus, the ASO is far less reliable than the anti-DNase B test in cases of postimpetigo nephritis.

The Streptozyme test is an agglutination test that detects antibodies against several streptococcal antigens. Five products (streptolysin O, DNase B, streptokinase, hyaluronidase, and adenine dinucleotide glycohydrolase) are used to coat a sensitized erythrocyte. Antibody against these antigens is tested for by hemagglutination of the coated erythrocytes on a slide. Discrepancies between the streptozyme test and the ASO and anti-DNase B tests on the same serum have been reported in several studies. While the streptozyme test may be used as a screening test, results should be confirmed by the use of more specific tests.

Serum antibody responses to the extracellular products of group A streptococci peak 2 to 3 weeks after the acute infection. Because the nonpurulent complications present 2 to 3 weeks after the acute infection, a single serum sample obtained at presentation of a patient with acute nephritis or acute rheumatic fever should reveal elevated ASO and/or anti-DNase B titers in most patients. An upper limit of normal titer must be established for these tests for proper interpretation.

We recommend that a laboratory establishing procedures for providing evidence of group A streptococcal infection limit itself to two tests for which reagents are readily available and which can be depended on to yield reproducible results. Because interpretation of a single titer depends on the upper limit of normal, it is advisable to survey a healthy population to establish this value for populations of different age groups within a geographic region. In addition, serum controls of known low and high titers should be included in each assay. The ASO and anti-DNase B tests are the most commonly utilized assays. Details of the performance and interpretation of these tests are given in procedures 11.2.2 and 11.2.3.

11.2.2

Anti-Streptolysin O

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Many individuals respond to respiratory infection by group A (and to a lesser degree to group C or G) streptococci with antibody to the hemolysin streptolysin O (anti-streptolysin O [ASO]) that is elabo-

rated by the bacteria. The presence of ASO activity is indicated by the ability of diluted serum to neutralize the hemolytic activity of the streptolysin O reagent.

II. SPECIMEN COLLECTION

Peripheral blood should be collected using aseptic techniques. Blood is stored preferably at 4°C prior to serum separation. Storage for over 72 h may lead to hemolysis, which can result in misinterpretation of the ASO test, as can grossly hemolyzed serum of other causes. The blood sample should be kept refrigerated, on ice, or at room temperature, but it should not be frozen. Shipped specimens should have serum separated prior to shipment.

The serum is clarified by centrifugation of erythrocytes at $500 \times g$ for 5 min, and the serum is transferred to a sterile tube or vial for storage. Sera that will be assayed within a week can be stored at 4°C. If longer storage is necessary, the serum should be stored at -20 or -70°C. Repeated freezing and thawing should be avoided.

Protective gloves are used during the handling of the blood samples and subsequently during the dilution of the sera. Proper precautions for the disposal of blood-contaminated material should be observed.

III. MATERIALS

A. Equipment

1. Disposable 96-well, round-bottom microtiter plates (USA Scientific Plastics, Ocala, Fla.)
2. Micropipette, 100- to 1,000- μ l capacity (P1000 Rainin pipette, Rainin Instruments, Woburn, Mass.)
3. Micropipette, 1- to 100- μ l capacity (P100 Rainin pipette)
4. Multichannel pipette, 12 row, 25- to 100- μ l variable capacity (Finn)
5. Plastic disposable tips for micropipettes
6. Disposable test tubes (13 by 100 mm), sterilized

7. Microtiter plate reading platform with mirror (Dynatech Laboratories Inc., Alexandria, Va.)

8. Centrifuge with rotor and carriers for microtiter plates

9. Conical graduated centrifuge tubes

B. Reagents

1. Streptolysin O reagent, 10-ml vial (Difco Laboratories, Detroit, Mich.; Difco Laboratories, Grand Island, N.Y.; Fisher Scientific, Orangeburg, N.Y.)

2. Citrated fresh type O human erythrocytes (rabbit or sheep RBC, can be substituted)

III. MATERIALS (*continued*)

3. Two internal control sera of known antibody titer, one with high titer and one provided with the streptolysin reagent by the manufacturer
4. ASO buffer concentrate (ns. 2679-79; Fisher Scientific)

ANALYTICAL CONSIDERATIONS**IV. PROCEDURE**

The ASO assay can be performed by a macrodilution or a microdilution assay. The microdilution assay has the advantage of requiring small amounts of serum and reagents. Accurate micropipetting instruments allow for high test reproducibility. The microdilution procedure described by Klein et al. (1) was adapted in our laboratory to use a 0.1-log serum dilution scheme. This scheme has the advantage of determining relatively small increments in antibody titers.

The major precautions for proper test performance include (i) the use of clean instruments and utensils, (ii) the use of fresh streptolysin O reagent with active sulfhydryl-reducing compounds to prevent oxidation and inactivation of the enzyme, (iii) the use of freshly collected (within 1 week) human type O or rabbit or sheep erythrocytes, and (iv) the inclusion of proper controls.

V. ERYTHROCYTE SUSPENSION (2.5%)

Citrate-treated human type O erythrocytes are collected in 3.8% sodium citrate dihydrate in a ratio of 1.0 volume of blood to 1.2 volumes of citrate. Commercially citrate-treated blood bank type O erythrocytes may be used. Pipette 3 to 4 ml of citrate-treated blood into a 12- to 15-ml conical centrifuge tube. Add 2 to 3 volumes of physiologic saline (0.9%) to 1 volume of blood. Mix gently by inverting the tube. Centrifuge at $400 \times g$ for 5 min. Remove the supernatant, and wash the cells twice in physiological saline. After the second wash, suspend the cells in physiological saline and centrifuge for 10 min. The supernatant should be clear. Note the volume of packed erythrocytes, and make a 2.5% suspension by adding 3.9 ml of phosphate-buffered saline (7.4 g of NaCl, 3.17 g of KH_2PO_4 , and 1.8 g of Na_2HPO_4 per liter of distilled water; adjust to pH 6.5 to 6.7 with NaOH) to each 0.1 ml of packed erythrocytes. The cell suspension can be stored at 4°C but should be discarded at the first sign of hemolysis.

VI. STREPTOLYSIN O REAGENT

The streptolysin O reagent is reconstituted by adding 10 ml of sterile distilled water until the lyophilized preparation is dissolved. This should be done immediately prior to use. Store at 2 to 8°C.

VII. SERUM DILUTIONS**A. Stock dilution**

Make a 1:10 serum dilution by adding 50 μl of serum to 450 μl of Bacto streptolysin O buffer or phosphate-buffered saline described above. Cover this dilution and inactivate it at 56°C for 30 min.

B. Serum dilution in the microtiter plate

Each serum is assigned three vertical columns on the microtiter plate; thus, four sera can be assayed in each plate. The top row of wells is used for the initial serum dilutions. We start with initial dilutions of 1:25, 1:30, and 1:40 in the three top wells, but this can be altered to higher or lower starting dilutions. The scheme outlined here is a 0.1-log dilution scheme. Top wells are not used in the assay but only to initiate the dilution process. The bottom row of wells is used for controls that lack serum or lack streptolysin O reagent.

VII. SERUM DILUTIONS

(continued)

Make the initial dilutions as follows. To each of the three top wells, add 30 μl of the stock 1:10 serum dilution. Then add 45 μl of diluent phosphate-buffered saline to the first of the three wells to obtain a 1:25 dilution, 60 μl of diluent to the second well to obtain a 1:30 dilution, and 90 μl of diluent to the third well to obtain a 1:40 dilution. To the remaining wells on the plate, add 50 μl of dilution buffer. Then make twofold serial dilutions with the multichannel pipette by transferring vertically 50 μl from the preceding horizontal row of wells to the following row, mixing gently with the multichannel pipette (three or four strokes) while avoiding the production of air bubbles, and discarding the 50 μl removed from the next to last row of wells. Then add 25 μl of the freshly reconstituted streptolysin O reagent to all wells except those in the top row. Incubate the plate for 30 min at 37°C, followed by addition of 25 μl of the erythrocyte suspension to all the wells. Reincubate plates at 37°C, for 45 min, with careful shaking (by gently tapping the plate) at 15-min intervals. Centrifuge the plates on the carriers at $400 \times g$ for 5 min. Place the plate on the plate reader, using a fluorescent lamp or daylight as a source of light. Cover the top of the plate with clear white paper while reading to avoid light distortion.

POSTANALYTICAL CONSIDERATIONS

VIII. READING AND INTERPRETATION OF TEST

With the plate in the position described above, examine the wells for hemolysis. The ASO titer of a serum is equal to the inverse of the highest serum dilution that inhibits the action of streptolysin, or the serum dilution in the last well that shows no hemolysis. The titer may be expressed in Todd units if the streptolysin reagent used was adjusted against the Todd standard serum, as the Bacto reagent is.

A test is considered uninterpretable if the streptolysin O control well (containing streptolysin O reagent, RBCs, and buffer) does not show total hemolysis or if the erythrocyte control well (without streptolysin O reagent) shows hemolysis. In addition, if the reference serum standards yield titers that differ by more than 1 dilution from the designated titer for that serum, the test should be repeated.

To determine a rise in antibody between acute- and convalescent-phase sera, both sera should be assayed in tandem on the same plate. A difference of at least 0.2 log unit (two wells if the 0.1-log unit serum dilution scheme is used) between the titers of the two sera is considered to be a significant difference. When one serum is assayed, an elevated titer should clearly exceed the upper limit of the normal range as described above. In our laboratory, the upper limit of normal titer is 240 for adults and at least 340 for children. An elevated ASO titer or other streptococcal antibody titer is not diagnostic of acute rheumatic fever but provides evidence for an antecedent group A streptococcal infection in the modified Jones criteria (2). Performance of several streptococcal antibody tests may increase the frequency of finding an elevated antibody titer indicative of a preceding streptococcal infection.

In addition, falsely high titers may be obtained with sera that are contaminated by certain bacterial organisms during shipment or storage or from and in patients with liver disease in whom high serum lipoprotein concentrations may mimic antibody activity by inhibiting the lytic action of the streptolysin on the erythrocyte membrane. Preassay precipitation of these lipoproteins with dextran sulfate will remove this nonspecific inhibitory activity (3).

11.2.3

Anti-DNase B Test

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The anti-DNase test evaluates the ability of diluted serum to neutralize the effect of DNase B to digest a DNA substrate complexed to a colored dye and thus to block the loss of color expressed by the digested substrate. Two microtechniques are avail-

able for the performance of the test; one is described by Nelson et al. (1), and the other is available as a commercial kit from Wampole. The latter method is described here.

II. SPECIMEN COLLECTION

Specimen collection is as described above for the anti-streptolysin O (ASO) test.

III. MATERIALS

A. Reagents

Anti-DNase B test kit (Streptonase-B; Wampole, Cranbury, N.J.)

1. DNase B enzyme reagent (stable for 3 months at 2 to 8°C after opening)
2. Calf thymus DNA with color indicator (DNase substrate). Use within 5 days of preparation.
3. Buffer concentrate (imidazole, calcium chloride, magnesium sulfate, and gelatin, containing 0.5% sodium azide) (stable at 2 to 8°C)
4. Anti-DNase B positive control serum, titer of 1:240 (stable at 2 to 8°C)

B. Supplies

1. Negative control serum (human serum previously found to be negative for anti-DNase B antibodies) (stable at 2 to 8°C)
2. Disposable round-bottom 96-well microtiter plates
3. Serological pipettes, 1.0, 0.05, and 0.025 ml
4. Test tubes (10 by 75 mm) and racks
5. Incubator, 37 ± 2.0°C
6. Distilled water

ANALYTICAL CONSIDERATIONS

IV. PROCEDURE

A. Preparation of reagents

1. Buffer

Bring buffer concentrate to room temperature. If buffer is lyophilized, mix with appropriate amount of distilled water (usually 100 ml). Store at 2 to 8°C.

2. DNase B enzyme reagent

Prepare a stock solution of DNase B by reconstituting with the correct amount of buffer (usually 2 ml) according to the manufacturer's directions. Stock DNase B is stable for 3 months at 4°C. On the day of the test, prepare

IV. PROCEDURE (*continued*)

working DNase B reagent by adding 0.1 ml of the stock to 6.9 ml of buffer. Store at 2 to 8°C.

3. Calf thymus DNA substrate with color indicator

If lyophilized, add appropriate amount of distilled water (usually 12 ml) to the contents of the vial *at least* 3 h before use. Allow substrate to dissolve at room temperature, swirling the vial every 30 min. The dissolved substrate must be used within 5 days. The substrate can be stored at 4°C but must be at room temperature before use.

4. Positive control serum

Use the positive control supplied with the kit or a past positive specimen with a known titer. Make an initial 1:10 dilution by adding 0.5 ml of buffer. The positive control supplied with the kit is already at a 1:10 dilution. Final dilution is 1:240.

B. Serum dilution and assay method

Make a 1:10 dilution of the patient serum by adding 50 µl of serum to 450 µl of buffer. Inactivate serum by placing the Parafilm-covered tube in a 65°C water bath for 30 min. Serum dilutions for titration are performed as described above for the ASO test, except that after the initial dilutions are made, 25 µl of diluent is added to the remaining wells. Using a 25-µl multichannel pipette, make two-fold serum dilutions, leaving a 25-µl volume in each well.

Add 25 µl of the appropriate dilution of DNase B enzyme reagent to each well. Incubate the plates at 37°C for 30 min. Remove the plates from the incubator, and add 50 µl of DNA substrate to each well. Cover the plate carefully with clear sealing tape, using the plate-sealing device. Incubate the plates at 37°C for 15 min, gently mix, and reincubate for 4 h at 37°C. Remove the plates from the incubator, and read the endpoint of each serum titration. As with the ASO test, the two internal control sera are included in the assay. In addition, appropriate enzyme and substrate controls should be included.

V. READING AND INTERPRETATION

DNase activity on the DNA substrate with color indicator is reflected by digestion of the DNA and depolymerization of the colored complex. This results in a pink or pinkish-violet color in the solubilized substrate. Thus, the endpoint of antibody neutralization is reflected in a decrease or loss of the blue or blue-violet color in the well. The antibody titer is the reciprocal of the highest dilution of serum showing a bluish color. As with the ASO test, divergence of the control serum titers by more than 1 dilution requires repetition of the assay. The negative control should read <1:50. The serum control and substrate control wells should show no enzyme activity (blue), and the enzyme control well must show enzyme activity (pink), for valid results.

POSTANALYTICAL CONSIDERATIONS

VI. RESULTS AND CONCLUSIONS

Stability of the reagents provides a decided advantage in reproducibility of the anti-DNase B test over that of the ASO test. The DNase B enzyme can be stored for 3 months at 4°C without any appreciable loss of activity. In practice, we divide the concentrated stock solution into aliquots and store them at -70°C. An aliquot is thawed and diluted in the working buffer to 10 times the working dilution and stored at 4°C for use over a period of about 3 months. Other advantages are that the calf thymus DNA is available commercially and the substrate (the DNA-color conjugate) is stable when stored at 4°C. This obviates a fresh source of erythrocytes and the requirement for processing the cells before each ASO test.

VI. RESULTS AND CONCLUSIONS (*continued*)

To ensure the reproducibility and specificity of the assay, certain precautions need to be considered. Group A streptococci as well as other streptococcal serogroups (B, C, and G) produce DNase isozymes (DNases A, C, and D). Although the isozymes produced by other streptococci are antigenically distinct from the group A streptococcal nucleases, assessment of the purity of the DNase B preparation by the availability of a specific antiserum with known titers for DNase B is important in the standardization and performance of the test. The use of a pure DNase B preparation ensures specificity of the assay for group A streptococcal infections.

In contrast to ASO titers, anti-DNase B titers are elevated following either streptococcal pharyngitis or pyoderma.

11.3

Detection of *Legionella* Antigen by Direct Immunofluorescence

Legionnaires' disease is a type of bacterial pneumonia caused by *Legionella* spp. (2, 13). It is estimated that about 1 to 4% of adults with pneumonia requiring hospitalization have Legionnaires' disease and that about 10,000 adults with community-acquired pneumonia have this disease in the United States each year. About 5 to 20% of patients with Legionnaires' disease die of the disease, with major dependence on promptness of specific antibiotic therapy and underlying health of the patient. Legionnaires' disease occurs worldwide, in both epidemic and sporadic form, with sporadic cases being far more common. The disease is more prevalent in some geographic regions than others, for unclear reasons. The primary host risk factors for the disease include immunosuppression, cigarette smoking, and travel. *Legionella pneumophila* is the cause of more than 90% of cases of community-

acquired Legionnaires' disease, with *L. pneumophila* serogroup 1 being by far the most common causative agent of the disease. Immunosuppressed patients, and those with nosocomial pneumonia, may have infections caused by other *L. pneumophila* serogroups and other *Legionella* spp., in particular *L. micdadei*, *L. longbeachae*, *L. bozemanii*, and *L. dumoffii*. Distribution of the common serogroups and species causing infection may be quite different in various geographic regions. *Legionella* bacteria are commonly found in the aqueous environment, including tap water and sometimes even distilled water. The preponderance of *L. pneumophila* as the cause of Legionnaires' disease has resulted in the development of reagents optimized for detection of this species; detection of other *Legionella* species can be problematic, for reasons of both test sensitivity and specificity. Rarely, organs

other than the lungs and pleural space may be infected by the bacterium, causing such diseases as prosthetic heart valve endocarditis, assorted soft tissue abscesses, and systemic infection.

The *Legionella* direct immunofluorescence antibody (DFA) test can be used for two purposes in the clinical laboratory: (i) detection of the bacteria in clinical specimens and (ii) identification and serotyping of bacterial isolates suspected to be *Legionella* spp. The first use has fallen out of favor in many laboratories because of its requirement for expertise in interpretation and performance, its low sensitivity, and under certain circumstances its low specificity. The DFA test is commonly used by many laboratories for rapid and relatively accurate confirmation of bacterial identity.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

A thin layer of sputum, tissue homogenate, or bacterial suspension is heat fixed to a slide, which is then stained with anti-*Legionella* antibody conjugated with fluorescein isothiocyanate (FITC). The slide is then washed to eliminate unbound antibody and examined microscopically using UV light illumination. The FITC fluoresces under UV light, which causes the *Legionella* bacteria to appear a bright

green color. The presence in clinical specimens of fluorescent bacteria of the proper size and shape is diagnostic of Legionnaires' disease, providing that the test has been performed correctly. A positive test of a bacterial suspension confirms the identity of the bacterium as a *Legionella* sp., again assuming proper performance of the assay and selection of the correct bacteria to test.

II. SPECIMEN TYPES, COLLECTION, AND TRANSPORT

The DFA test has been used to detect the bacterium in a variety of tissues (Table 11.3-1). Lower respiratory tract secretions, including expectorated sputum, are the most frequently tested specimen types. The test can be quite valuable for detecting *Legionella* bacteria in premortem or postmortem lung tissue. The bacteria are very stable in refrigerated or frozen sputum and tissues, and the major determinants of specimen handling are other requirements for the specimen, such as bacterial cul-

Table 11.3–1 Suitable specimen types for *L. pneumophila* DFA testing

Sputum	Vascular grafts
Endotracheal suction	Kidney
Bronchoalveolar lavage fluid	Liver
Transbronchial biopsy specimen	Spleen
Lung biopsy specimen	Soft tissue abscesses, including muscle
Pleural biopsy specimen or pleural fluid	Brain
Bronchoscopic aspirates	Heart valve
Bronchial brushings	Pericardium

II. SPECIMEN TYPES, COLLECTION, AND TRANSPORT (continued)

ture. If the specimen will be tested within 1 to 5 days, then store the specimen in a tightly sealed sterile container at 3 to 5°C. Longer-term storage is best done at –70°C. Since *Legionella* bacteria, and cross-reacting bacteria, are ubiquitous in water, avoid contamination of the specimen with non-filter-sterilized water. Test lots of empty specimen containers before buying them for intrinsic contamination, as on rare occasion, false-positive results may be obtained because of water contamination of the containers before they are sterilized. Preservation of tissues in 10% neutral Formalin obscures the antigen detected by the Bio-Rad monoclonal antibody to *L. pneumophila*, making freezing at –70°C a preferred alternative for long-term storage. However, polyclonal antibodies to the individual *Legionella* serogroups still react with Formalin-fixed materials, making possible examination of Formalin-fixed specimens.

Identification of bacteria by DFA testing requires that the bacteria first be suspended in Formalin. The Formalin concentration used depends on the type of antibody used in the DFA test; polyclonal antibodies work correctly with bacteria that have been suspended in 1 to 10% neutral Formalin, whereas the commercial monoclonal antibody works best with 1% Formalin, as higher Formalin concentrations may cause false-negative reactions with prolonged fixation.

III. MATERIALS

All commercial antibody preparations are available with the antibody conjugated to FITC and with few exceptions are rabbit polyclonal antibodies (Table 11.3–2). The polyclonal antibodies are generally, but not always, serogroup specific and may be available either as polyvalent pools or as monovalent reagents. A monoclonal antibody to all *L. pneumophila* serogroups is also available. Many commercially available antibodies have not been extensively evaluated in terms of their analytical or clinical specificity and sensitivity. The Bio-Rad monoclonal antibody reagent has had the most extensive clinical evaluation (3). Only Food and Drug Administration (FDA)-cleared reagents, and preferably the Bio-Rad monoclonal product, should be used to detect *L. pneumophila* in clinical specimens.

Evaluations of the non-FDA-cleared reagents have not been published. How-

ever, in many cases they are the only reagents available for a broad range of species, and they are exceptionally useful in serogroup and species identification of culture isolates. Since these reagents have not had extensive evaluations, unusual results obtained using them must be confirmed by a reference laboratory.

Microscope slides made specifically for immunofluorescent microscopy give the best results. The slides are ringed or masked by a hydrophobic material, which prevents the antibody from running off the slide or onto an adjacent well. The slides must be cleaned in alcohol and manufactured in such a way that dead *Legionella* bacteria are not present on the slides. One reliable manufacturer is Cel-Line (<http://www.cel-line.com>).

Table 11.3–2 Commercial DFA reagents

Manufacturer	Antibody type	Notes	FDA cleared?
Bio-Rad, http://www.bio-rad.com	Monoclonal	Reacts with all <i>L. pneumophila</i> serogroups. Formerly known as Genetic Systems or Sanofi Pasteur monoclonal antibody	Yes
M-Tech, http://www.4m-tech.com	Polyclonal, monovalent, and polyvalent	Very wide range of antibodies available	No
Trinity Biotech, http://www.trinitybiotech.com	Polyclonal, polyvalent only	Four polyvalent reagents are available: <i>L. pneumophila</i> serogroups 1–6; <i>L. pneumophila</i> serogroups 1–14; and two reagents reacting with non- <i>L. pneumophila</i> spp. Formerly known as MarDx reagents and, before that, BioDx.	Only the <i>L. pneumophila</i> serogroup 1–6 reagent is FDA cleared
SciMedx, http://www.scimedx.com	Polyclonal, polyvalent, and monovalent	<i>L. pneumophila</i> serogroup 1–6 monovalents and pooled; a pooled reagent and monovalent reagents to non- <i>L. pneumophila</i> spp. Formerly known as BioDx reagents.	Yes
Wampole Laboratories, http://www.wampolelabs.com	Polyclonal, monovalent, and polyvalent	Individual antibodies to <i>L. pneumophila</i> serogroups 1–6 and <i>L. micdadei</i> , as well as a single pooled antibody. Formerly known as Zeus reagents.	Yes
Remel, http://www.remelinc.com/	Polyclonal, polyvalent	Pooled antibody preparation to a number of species	Yes

ANALYTICAL CONSIDERATIONS

IV. QUALITY ASSURANCE

Each time the DFA test is performed, positive and negative controls should be performed. A good negative control is a Formalin suspension of *Escherichia coli* ATCC 25922. This preparation is stable for years, if not decades. A positive control is either one recommended by the manufacturer, or the type strain of the *L. pneumophila* serogroup, or the *Legionella* spp., detected by the antibody; type strain information and the bacteria themselves can be obtained from the ATCC (<http://w.atcc.org>). Many of the commercially available kits provide a set of QC strains. If at all possible, known positive and negative clinical specimens should be used as an additional QC, especially when training new personnel. Sputum or lung homogenates can be suspended in Formalin and a small amount can be used for QC purposes.

In addition to verifying the proper performance of the antibody being used, specimen containers should be tested by examination of known negative sputum specimen placed in the containers. Several different lots of new specimen containers should be tested before wide-scale purchase of the containers. Similarly, although much less of a problem, plastic ware used to prepare bacterial isolate suspensions should be similarly tested.

IV. QUALITY ASSURANCE (continued)

At least 75% of all DFA-positive clinical specimens should be culture positive for the same serogroup or species. In the case of *L. pneumophila* serogroup 1 DFA-positive specimens, the *L. pneumophila* serogroup 1 urinary antigen test should be positive at least 90% of the time. Lower culture or urine antigen positivity rates may indicate a problem with false-positive DFA tests, which are usually due to operator inexperience or cross-contamination of the specimen during processing.

V. PROCEDURE

Instructions for use of the FDA-cleared products are available from the manufacturer, but in other cases, few or no instructions are provided. All of the rabbit polyclonal antibodies use a protocol developed by Cherry and McKinney for the detection of *L. pneumophila* serogroup 1 in clinical specimens and from culture, and the procedure used by any of the manufacturers can be used for any of the polyclonal antibodies made by other manufacturers (reference 1 and references therein). The Bio-Rad monoclonal antibody uses a slightly different protocol, which must be followed exactly to obtain accurate results. Since the CDC protocol may not be readily available, a modified abbreviated version of it follows.

A. Sample application onto a slide

1. For clinical specimens such as expectorated sputum or lower respiratory tract specimens, a very thin layer of the sample is smeared onto a Teflon-ringed or masked slide. The best way to do this is to use a wooden applicator stick to squeegee the sample onto the slide. Fresh lung specimens are best prepared by making a thin impression smear directly onto the slide, and Formalin-fixed lung specimens are best prepared by scraping the lung with a scalpel and then applying the sample to the slide in a very thin layer. It is very important to make the material on the slide one cell layer thick, as thick smears cannot be reliably read using this procedure. Only one clinical specimen should be placed on a slide. All slides must be individually processed to avoid slide-to-slide cross-contamination. The slide is air dried and then heat fixed at 50 to 60°C for 2 to 10 min on a heating block. Methanol fixation has not been studied, and is not recommended as a substitute for heat fixation. Formalin (10% neutral) is added to the slide and the sample is fixed on the slide for 10 min in a moisture chamber at room temperature; this can be omitted for previously Formalin-fixed specimens.
2. Bacterial colonies to be tested must first be suspended in 10% neutral Formalin to approximate the density of a no. 1 MacFarland barium sulfate turbidity standard ($\approx 3 \times 10^8$ cells/ml). Then the suspension is pipetted onto the slide and immediately sucked back into the pipette. Emulsifying bacteria directly onto the slide can cause false-negative results due to a prozone phenomenon. Formalin fixation is not crucial for antigen exposure, so if only a single very small bacterial colony is available for testing, then the suspension can be made in sterile water to facilitate subculture and simultaneous DFA testing; the slide is heat fixed on a heating block to kill the bacteria. Procedures involving the manipulation of live bacterial suspensions must be performed under appropriate biosafety conditions.

B. Slide staining

1. The slides are washed with filter-sterilized distilled water and air dried. It is important to use filter-sterilized water to avoid false-positive results.
2. Antibody is added to the slide, which is incubated at room temperature in individual moisture chambers for 15 to 30 min.

V. PROCEDURE (*continued*)**C. Removal of excess antibody**

1. Wash the slide with filter-sterilized phosphate-buffered saline (PBS), pH 7.4, using a syringe. Perform an additional 5-min soak in PBS, which need not be filter sterilized.
2. Rinse the slides in distilled water, and then air dry.

D. Mounting of coverslips

Alkaline buffered glycerol (Bio-Rad) is applied to the slide, and a coverslip is mounted. Antifade mounting fluid (Molecular Probes, Eugene, Oreg.) can be used but is usually not necessary.

E. Slide examination

1. The slide is examined microscopically using a microscope equipped with the appropriate filters and illumination for FITC microscopy. Optimal total magnification ranges from $\times 200$ to $\times 1,000$. The lower magnification can be used when screening culture isolates and by very experienced technicians when screening clinical samples. Confirmation of positive samples should be at $\times 500$ to $\times 1,000$.
2. Clinical specimens containing more than one brightly staining coccobacillus are considered positive. Some authorities require up to 25 fluorescent bacterial cells to be present to designate a sample as positive, and others require 5. However, both of these criteria are too conservative and will result in an unacceptably high false-negative rate. Only those with months or years of experience in reading these sorts of slides can reliably use ≥ 2 cells/specimen as a cutoff, whereas those with less experience are advised to use the higher cutoff. Positive and negative controls must perform acceptably.
3. Organism suspensions are considered positive when large numbers of brightly fluorescent bacteria are seen. Rare fluorescent bacteria are considered negative.

POSTANALYTICAL CONSIDERATIONS**VI. INTERPRETATION**

Properly performed by experienced laboratorians, the DFA test for detecting *L. pneumophila* in clinical specimens is highly specific but only moderately sensitive (3, 6, 9, 12, 15, 16). With training and experience, the sensitivity of the DFA test for *L. pneumophila* in clinical specimens ranges from 50 to 75%, and the specificity ranges from 94 to 99%. The best performance of the DFA test is with open-lung biopsy specimens or necropsy specimens; providing that the biopsied specimens are from areas with acute pneumonia, the sensitivity and specificity of the DFA test are more than 95 and 99%, respectively, if the antibody being used reacts with the *Legionella* species and serogroup causing the infection.

Use of the test by inexperienced laboratorians may result in a very insensitive and nonspecific test. Several pseudoepidemics of Legionnaires' disease have been reported when nonfiltered Formalin, PBS, or water was used in the test or when there was cross-contamination between clinical specimens and positive controls (8, 10). A number of fluorescent artifacts and cross-reactive bacteria may be present in clinical specimens, which the expert can discriminate from *L. pneumophila* by morphologic appearance. The cross-reactive bacteria are generally gram-positive coccil bacteria, such as staphylococci and streptococci; gram-positive bacilli, such as *Bacillus* spp. and lactobacillus-like bacteria; and *Candida*-like yeasts. In addition, there may be cross-reactions with gram-negative bacilli, including *Pseudomonas aeruginosa*, *Pseudomonas fluorescens*, and *Bacteroides fragilis*; a number of these cross-reactive bacteria are available from the ATCC, for those interested in developing new reagents (ATCC strain numbers 49266 to 49269, 43935 to 43937, and 49270 and 49271). Using polyclonal antibodies, even experts may not be able to

VI. INTERPRETATION (continued)

reliably discriminate between cross-reactive *B. fragilis*, or *P. aeruginosa*, and *L. pneumophila* bacteria. The Bio-Rad monoclonal antibody does not cross-react with other gram-negative bacteria, although it may stain some *Bacillus* spores, or some gram-positive cocci (7, 14).

More than 60 different *Legionella* serogroups have been reported, many with little or no cross-reactivity with one another. This means that the DFA test of clinical specimens will be negative if the antibody being used does not react with the *Legionella* bacterium in the clinical specimen. Fortunately, more than 90% of all cases of community-acquired Legionnaires' disease are caused by *L. pneumophila*, most by *L. pneumophila* serogroup 1. However, the sensitivity and specificity of the DFA test for the detection of other serogroups and species in clinical specimens have not been established. One polyvalent polyclonal reagent cross-reacted with a number of non-*Legionella* bacteria and stained non-*Legionella* bacteria in clinical specimens, mirroring the problems observed with some monovalent polyclonal reagents (4). Use of multiple polyvalent polyclonal pools to screen clinical specimens leads to a high false-positive rate (P. Edelstein, unpublished data). Unfortunately, no genus-specific monoclonal antibody is commercially available. Because of the problems with cross-reactions observed with polyvalent pools, it is inadvisable to use them for testing clinical specimens.

One key for proper interpretation of DFA testing of clinical specimens is that *L. pneumophila* is a small coccobacillus in clinical specimens, not the long filamentous rod sometimes found in positive control reagents. This is in contrast to the appearance of the bacterium when isolated from culture, in which case it varies from a short to a very long filamentous bacillus but is almost never coccobacillary.

Identification of *Legionella* bacteria isolated from culture with DFA reagents can be very useful, but it does have some pitfalls. False-negative results can be obtained if the bacterial suspension put on the slide is too dense (4) or if the serogroup of the bacterium does not match that of the antibody being used. False-positive tests can be obtained if the antibody is allowed to dry on the slide during incubation, if nonfluorescent bacteria are misinterpreted as staining with the antibody, or if the organism cross-reacts with the antibody being used. It is important to view isolated bacterial cells to be certain that they are brightly fluorescent, as sometimes bacterial clumps will be fluorescent because of trapped antibody. Bacteria stained with polyclonal antibodies stain very brightly around their periphery but not at all in the central portion, creating a donut-like appearance. In contrast, the Bio-Rad monoclonal antibody stains *L. pneumophila* bacteria uniformly but less intensely than do the polyclonal antibodies. Since there can be considerable cross-reactivity between some serogroups and species, the DFA test may incorrectly assign a *Legionella* bacterium to the wrong species or serogroup. Identification of *L. pneumophila* serogroup 1 with polyclonal antibodies, and of *L. pneumophila* with the Bio-Rad monoclonal antibody, is quite reliable. However, some *L. pneumophila* serogroup 1 strains may fail to react with the polyclonal antibody made to the Philadelphia strain but will react with antibody made to the Bellingham or Knoxville strain. Rarely, a non-*Legionella* bacterium will stain with the DFA reagent; however, with the exception of *Francisella tularensis*, none of these bacteria have a nutritional requirement for L-cysteine (5, 7, 11). In the case of *F. tularensis* and several other cross-reacting bacteria, review of the colony morphology and Gram stain of the bacterium by an experienced microbiologist quickly discriminates between the cross-reacting and *Legionella* bacteria. Molecular methods are sometimes the only means by which some *Legionella* species may be differentiated and identified.

APPENDIX 11.3–1

Buffered Glycerin Mounting Medium

I. MATERIALS

- A. 250-ml beaker or flask
- B. Magnetic stir bar

II. REAGENTS

glycerin, neutral	10 ml
NaCO ₃	5.3 g
NaHCO ₃	4.2 g
distilled water	200 ml

III. PREPARATION

- A. Add the carbonate and bicarbonate powders to separate flasks, each containing 100 ml of water. Stir to dissolve. This will make 0.5 M solutions of each salt.
- B. Mix 4.4 ml of 0.5 M Na₂CO₃ with 100 ml of 0.5 M NaHCO₃. The final pH should be 9.0; if it is not, adjust by addition of appropriate salt.
- C. Add 1 part buffer, pH 9.0, with 9 parts glycerin.

IV. STORAGE

Store in a small-volume tightly stoppered plastic container at room temperature. Discard if cloudy or if the pH is <9. The shelf life is weeks to months, depending on the amount of CO₂ gas that is absorbed into the buffer.

11.4

Urinary Antigen Detection for *Legionella* spp.

Patients with Legionnaires' disease excrete soluble serogroup-specific *Legionella* antigen into their urine. Urinary antigen tests to detect Legionnaires' disease were developed by several groups soon after the 1976 Philadelphia, Pa., outbreak of Legionnaires' disease (3, 32) and then further refined by Kohler et al. and other groups (5, 13, 21–24, 27–29). The antigen being detected has never been extensively purified, but it is known that it is resistant to boiling, is trypsin resistant, has a molecular mass of approximately 10 kDa, and is most likely a lipopolysaccharide (23, 34).

The first urinary antigen tests developed were designed to detect *Legionella*

pneumophila serogroup 1 infections, and they were initially thought capable of detecting only this serogroup. It is now known that the *L. pneumophila* serogroup 1 antigenuria test will detect an unknown fraction of infections caused by other *L. pneumophila* serogroups and possibly some other species (2, 10). Regardless, the analytical sensitivity of all commercially available test kits is 100- to 1,000-fold greater for the detection of *L. pneumophila* serogroup 1 antigen than for other *L. pneumophila* antigens (2, 8, 18). The vast majority of positive tests will be for patients with *L. pneumophila* serogroup 1 infections, and most specimens from patients with infections caused by other *L. pneu-*

mophila serogroups and other *Legionella* species will be negative. Tang and colleagues developed a polyvalent test for antigenuria produced by multiple *Legionella* spp., but this test has never been commercialized (30, 31).

The Kohler *L. pneumophila* serogroup 1 assay was first commercialized by DuPont, which sold the assay to Binax. Binax subsequently developed an immunochromatographic version of the test, which has had a major impact on the laboratory diagnosis of Legionnaires' disease. Several manufacturers other than Binax now sell a urinary antigen detection kit, all of them based on a microwell EIA method.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Two different methods are used in these tests: EIA antigen capture and immunochromatographic assay. In the EIA method, microtiter plates containing antibody to *L. pneumophila* serogroup 1 (or other *Legionella* species and serogroups, depending on the kit) are provided by the manufacturer. Urine is added to the microwells and allowed to incubate for a short period of time, and the urine is then removed by washing with buffer. If *L. pneumophila* serogroup 1 antigen is present in the urine, it binds to the antibody in the well. The antigen-antibody complex bound to the well is detected by the addition of the same antibody as used to capture the antigen. This detection antibody is supplied already conjugated to an enzyme, such as peroxidase or alkaline phosphatase. The well is again washed to removed unbound

detection antibody, and an enzyme substrate and chromogen are added. If the antigen is present in the specimen, the detection antibody bound to it will cleave the enzyme substrate, which in turn changes the color of the chromogen. A strong acid is added to stop the reaction, and a significant color change is detected either visually (for one kit) or by using a microplate spectrophotometer (for other kits). The test is interpreted based on the intensity of the color change.

In the immunochromatographic assay, capture rabbit antibody to *L. pneumophila* serogroup 1 antigen is bound in a line to a nitrocellulose filter. On a second line on the filter is bound goat anti-rabbit antibody. Dried encapsulated detection rabbit antibody, conjugated to colored particles,

is also applied to an inert fibrous support. Urine is applied to a spot on the fibrous support, and then a citrate-phosphate buffer is applied to the same fibrous support. The urinary antigen and the rehydrated detection antibody migrate to the filter areas containing the capture antibody and anti-rabbit antibody by capillary action. The detection antibody binds to the antigen while both are being eluted onto the filter membrane. The detection antibody-antigen complex binds to the capture antibody in an easily visible colored line, as well as to the anti-rabbit antibody, producing a second line. If the urine contains no antigen, then the detection antibody is eluted past the capture antibody, binding only to the control anti-rabbit antibody, which produces only a single line.

II. SPECIMEN COLLECTION AND TRANSPORT

Only a few milliliters of freshly collected urine is required for the assay. The urine should be collected in a clean screw-top container and does not require refrigeration during short (hours) transport periods. For longer transport, refrigeration of the specimen at 3 to 5°C may be beneficial, although this has never been studied. Addition of boric acid (1% final concentration) preserves the antigen for longer than a week when stored at room temperature and for up to many years when stored at 3 to 5°C. The use of evacuated tubes containing preservative that are designed for preserving urine for bacterial culture has not been studied for the transport of urine used for the antigen test. Freezing the specimen should be avoided if possible, as freeze-thawing can very rarely cause false-positive results. Long-term (months to years) storage of urine at -70°C has been reported to rarely cause false-negative results (6, 26).

III. MATERIALS

Four manufacturers sell kits for urinary antigen detection, three of which are cleared for marketing by the Food and Drug Administration (FDA) (Table 11.4-1). The kit manufacturers provide needed controls. Some kits require making buffer solutions from supplied stock solutions, wash bottles, or plate washers. All of the EIA kits, except the Bartels kit, require the use of a microplate spectrophotometer.

ANALYTICAL CONSIDERATIONS

IV. QUALITY ASSURANCE

Proper performance of the negative and positive kit controls gives assurance of proper test performance. One cost-saving measure for use of the Binax NOW assay is to perform a negative control test only when there is a positive patient sample result, since the vast majority of all tests performed are negative. The positive control should be tested with every test run of the Binax NOW test, or at least once each day the test is performed. The EIA kits should include positive and negative controls with every run. Current Clinical Laboratory Improvement Act (CLIA) regulations and CAP guidelines specify that tests such as the Binax NOW assay have QC testing performed with every test run, or at least once per day if multiple runs are performed on the same day. However, the rationale for this is unclear, as the assay appears to be very stable. My laboratory has never documented a Binax NOW test kit failure after performing this test for many years. Ascertaining the correct performance of each lot of kits on arrival in the laboratory should be sufficient, but this currently does not comply with CAP or CLIA guidelines. In contrast, QC failures with the Binax EIA have been frequent enough to warrant QC testing with each test run, aside from the fact that test interpretation depends on the results of the negative control provided in the kit.

An external QC scheme exists for the urinary antigen test in some countries, including the United States (Medical Laboratory Evaluation, <http://www.mle.org>).

IV. QUALITY ASSURANCE (continued)

www.acponline.org/mle/index.html) and European countries (<http://www.ewgli.org/links.html>). These should be subscribed to if available. If they are not available in a particular country or region, trading blinded specimens with other regional laboratories can help to detect testing problems not detected with the kit control reagents.

Since urine antigen testing may be more sensitive than other means of laboratory diagnosis of Legionnaires' disease, it may be difficult to use the results of other laboratory tests for Legionnaires' disease to determine the proper performance of the urine test, especially for a single case of the disease. However, the majority of patients with a positive urine test should have a positive sputum culture or seroconvert to *L. pneumophila* serogroup 1. Every effort should be made to confirm the laboratory diagnosis of the disease, if at all possible. Also, it should be determined if the patients have an illness compatible with Legionnaires' disease.

V. PROCEDURE

Use of the test kits is straightforward and should be familiar to any laboratorian experienced with EIAs. As with all immunoassays, particular attention must be paid to equilibration of reagents to room temperature before use, to use of proper incubation temperatures, to adequate plate washing, and to use of a calibrated spectrophotometer. The Binax NOW kit is very simple to use, requiring relatively little training or prior experience.

Three modifications of the sample preparation procedure for all of the test kits can enhance test sensitivity and specificity. Test sensitivity can be increased by up to 30% by concentrating urine prior to testing (9, 11). This is done by concentrating the urine 25-fold using an Amicon Minicon B15 concentrator. Concentrating the urine does not appear to affect test specificity. The other modification is to boil urine for 10 min to inactivate rheumatoid-like factors that can rarely cause false-positive tests (about 1 to 5% of positive tests). In addition, clarification of urine by brief low-speed centrifugation can also reduce the frequency of false-positive tests. Whether and when to perform these specimen modifications are dependent somewhat on the test format being used. All urine samples giving a positive result in the assay should be retested after clarification and boiling, in parallel with retesting of the original specimen. Users of an EIA format assay will probably find it most cost-effective and expeditious to boil and clarify all urine specimens prior to testing, as repeating the assay requires several hours and can be quite costly.

Immunochromatographic card assay users will probably find it easiest to boil and clarify only the urine samples giving a positive result, since the vast majority of urine specimens tested will give negative results and because repeating a test is quick and relatively inexpensive. Since concentrating urine samples is expensive because of the cost of the Amicon concentrators, some concentrate only those giving an equivocal result in an EIA (e.g., a ratio between 2 and 3 in the Binax EIA). No one has offered guidelines for when to concentrate urine specimens giving a negative result in the Binax NOW assay. In investigation of an outbreak of Legionnaires' disease, it may be wise to concentrate all urine samples tested.

POSTANALYTICAL CONSIDERATIONS

VI. INTERPRETATION

The urine antigen tests are very specific and sensitive for the detection of *L. pneumophila* serogroup 1. The levels of performance of all kits have been roughly equivalent in published and unpublished studies (<http://www.fda.gov/cdrh/pdf/k991074.pdf>) (1, 2, 6, 8–10, 12, 15–18, 28). One recent retrospective comparison of the Bartels and Binax EIAs showed that the clinical and analytical sensitivity of the Bartels kit was significantly greater than its comparator if nonconcentrated sam-

VI. INTERPRETATION (continued)

ples were tested and that the tests were roughly equivalent when testing concentrated urine samples (8). The sensitivity of the kits for the detection of *L. pneumophila* serogroup 1 is estimated to be somewhere between 75 to 95%, depending on the severity of the illness (1, 23). Test sensitivity is about 80 to 99% for urine specimens taken from patients with *L. pneumophila* serogroup 1 pneumonia severe enough to require hospitalization, especially those with respiratory failure due to pneumonia. Of those patients with culture-proven *L. pneumophila* serogroup 1 pneumonia, 95% have positive urine antigen tests, and 100% have positive tests after urine concentration (1). About 75% of patients with milder disease, especially those with *L. pneumophila* serogroup 1 pneumonia not requiring hospitalization, have a positive test. The test has had its greatest utility in the investigation of outbreaks of Legionnaires' disease, providing rapid diagnoses for far more patients than does culture diagnosis (14, 20, 33).

The specificity of the Binax EIA is extraordinarily high, somewhere in the range of 99.9%, if urine boiling and clarification are performed for initially positive samples (P. Edelstein, unpublished data). The specificities of the other test kits appear to be similar (8, 10, 17). A recent study reported that the specificity of the Binax NOW assay was only 97% but that this could be enhanced by reincubation of the test cards for 60 min, after which very faint lines that were false positive became negative (18). My experience with the NOW assay is that its specificity is $\geq 99\%$, using the specimen clarification and boiling protocol detailed above. The specificity of the Bartels kit may be slightly lower when the test wells are read visually rather than with a spectrophotometer, leading the authors of the paper to recommend that visual reading not be used for this test (17). The very high specificity of these assays means that a patient with a compatible clinical illness has a 75 to 90% chance of truly having Legionnaires' disease.

False-negative tests can occur for several different reasons. Patients with severe renal failure may not concentrate the antigen in the urine, and for those patients with oliguric renal failure, simply obtaining an adequate urine specimen can be difficult. Overly dilute urine may mask the presence of a positive test, especially after a fluid load or administration of diuretics. Concentrating urine or testing another urine specimen may alleviate this problem. Patients with Legionnaires' disease caused by a *Legionella* bacterium other than *L. pneumophila* serogroup 1 may have a negative test with any of the kits. It is claimed, but unproven, that the Biotest kit is more sensitive in this circumstance. In fact the analytical and clinical sensitivities of the Biotest and Binax kits appear to be very similar for non-*L. pneumophila* serogroup 1 *Legionella* antigens, although some claim that the Biotest kit is more sensitive (2, 10, 19). Some patients with very early pneumonia may have a negative urine assay, a cause for repeating negative tests for patients with pneumonia present for less than 2 days (4, 22, 23). Finally, improper test performance or inherent limitations of the assay may also cause false-negative tests.

False-positive tests are usually the result of presence of rheumatoid-like factors in the urine, which can be eliminated by boiling the urine. Freeze-thawing of urine has also been reported to be rarely responsible for false-positive tests (1). A unique case of a false-positive test was reported for a patient with anti-rabbit antibodies, after immunotherapy for kidney transplant rejection with rabbit antibody (7). Although not determined by the authors of the report, boiling of the urine should have eliminated this false-positive reaction. Inherent errors in device performance may also be responsible for some false-positive tests, although this occurs very infrequently. Improper test performance or interpretation of results has been reported to be the cause of a pseudo-outbreak of Legionnaires' disease (25). Patients with very severe pneumonia may excrete detectable urinary antigen for months after recovery from Legionnaires' disease (22). Such patients usually have multilobar pneumonia, accompanied by respiratory failure, and have been hospitalized in intensive care

VI. INTERPRETATION (continued)

units because of the severity of their illness. Such prolonged urinary antigen excretion is not seen in patients with mild pneumonia (Edelstein, unpublished). The concentration of urinary antigen excreted in such severe cases of Legionnaires' disease diminishes fairly quickly, so that if testing both acute- and convalescent-phase urine samples using a EIA method, it is easy to distinguish the two. However, for a patient with two episodes of pneumonia spaced weeks to months apart, it may be difficult to determine if a positive urinary antigen test is due to the first, second, or both episodes of pneumonia, especially if the first episode was severe and no semiquantitative antigen assay was performed with the first pneumonia episode.

There is often a good correlation between the apparent concentration of antigen excreted and the severity of Legionnaires' disease, at least for the Binax EIA. Patients with urine samples testing positive with a sample-to-negative ratio greater than 30 are likely to have severe disease (Edelstein, unpublished).

11.5.1

Introduction

Syphilis is a sexually transmitted disease that is caused by the organism *Treponema pallidum* subsp. *pallidum*. The disease goes through several stages if untreated (2, 13). The primary chancre occurs at the site of inoculation approximately 3 to 4 weeks (range, 10 to 90 days) after the initial exposure. Treponemes may be visualized in lesion exudates using either dark-field microscopy or direct fluorescent antibody for *T. pallidum* (DFA-TP). About 7 to 10 days after the chancre appears, antibodies to *T. pallidum* are detectable using the routine serologic tests for syphilis. The chancre spontaneously heals after 1 to 4 weeks. The symptoms of secondary syphilis appear about 6 weeks later (range, 2 weeks to 6 months). All serologic tests are generally reactive during secondary syphilis. The most common symptoms are a generalized or localized maculopapular rash that occurs on the palms of the hands and soles of the feet (palmar plantar rash) or on the trunk of the body, mucosal membrane lesions, generalized lymphadenopathy, and condylomata lata. These symptoms will resolve without treatment. The patient then enters a period of latency when there are no symptoms. In about 20 to 25% of individuals, secondary symptoms may reoccur during the early part of this latent period. In early latency (<1 year) the results for the serologic tests for syphilis are reactive. As patients progress into late latency, the nontreponemal tests may become nonreactive, but the treponemal tests will remain reactive. About 65% of persons with untreated syphilis will remain in this stage for life (13). In the remaining 35%, late manifestations of syphilis will occur.

Late syphilis can be divided into benign syphilis, cardiovascular syphilis, and neurosyphilis. Benign syphilis and cardiovascular syphilis are rarely seen since

most people receive adequate antimicrobial therapy for some other reason, such as an upper respiratory infection. Neurosyphilis, which is the most common manifestation of late syphilis, can occur during any stage of syphilis, including as a late manifestation of the disease, and is characterized by meningitis, peripheral neuropathy, meningovascular brain lesions, and/or psychiatric illness. Neurosyphilis may be asymptomatic, with the only indication being elevated levels of WBCs (>5 WBCs per ml) and protein (>50 mg per dl) in the CSF. The Venereal Disease Research Laboratory (VDRL) CSF test may or may not be reactive for persons with asymptomatic neurosyphilis, but the fluorescent treponemal antibody absorption (FTA-ABS) test with CSF should be nonreactive for those who do not have syphilis (4). Persons coinfecting with *T. pallidum* and human immunodeficiency virus (HIV) should be evaluated for neurosyphilis.

Syphilis serologies can be complicated by a positive HIV status. For some patients who are coinfecting, syphilis tests may be nonreactive (2), while for others the nontreponemal titers may be higher (10). For patients with HIV infection only, nontreponemal tests may be falsely reactive (5), perhaps due to polyclonal activation of B lymphocytes. This may also be the cause of higher nontreponemal test titers in HIV- and syphilis-coinfecting individuals.

Syphilis is one of the few diseases that can be transmitted from a mother to her unborn child. Rates of transmission to the fetus are dependent on the stage of syphilis in the mother and when in the pregnancy the mother became infected with *T. pallidum* (12). Syphilis contracted in utero may result in fetal death, low birth weight, premature delivery, or various symptoms at birth, or it may be asymptomatic. Diag-

nosis is usually a presumptive one based on the mother's serology and lack of history of adequate treatment. If immunoglobulin M (IgM) antibodies against *T. pallidum* can be detected in the neonate's serum, a stronger case can be made for a diagnosis of congenital syphilis since IgM antibodies do not cross the placenta as IgG antibodies do. Treponemes are frequently demonstrable using Steiner stain, DFA-TP, or immunohistochemical staining of the placenta or umbilical cord of neonates with congenital syphilis. The best prevention for congenital syphilis is identification and treatment of pregnant women who have syphilis.

In the United States, several states (Alabama, Alaska, California, Connecticut, Georgia, New Jersey, Oklahoma, Pennsylvania, West Virginia) and the District of Columbia still require premarital testing for syphilis (3). Screening for syphilis is carried out in sexually transmitted disease clinics, detention centers, and outreach programs. All blood donations are screened for syphilis. Traditionally, the serologic diagnosis of syphilis has been made using a nontreponemal test to screen for the disease and a treponemal test to confirm the results of the nontreponemal test. The rationale for this algorithm is that confirmation of original test results should be done using the more specific test. The most commonly used nontreponemal tests are the rapid plasma reagin (RPR) test or the VDRL test to screen and the *T. pallidum* particle agglutination test (TP-PA) or FTA-ABS to confirm. Outside the United States, screening is frequently done using a treponemal test such as the *T. pallidum* hemagglutination assay followed by a nontreponemal test such as the RPR or VDRL test to distinguish active syphilis from latent or late syphilis. This algorithm is being used more in the

United States, especially in blood banks where the screening is usually done with either a modified hemagglutination test or an EIA. Unfortunately, by screening with a treponemal test, treated cases of syphilis will also be detected, since about 85% of persons with treated syphilis retain treponemal test reactivity for life. The 15% that lose treponemal test reactivity are usually those who had adequately treated primary syphilis and no history of syphilis (1, 11).

Early syphilis is best diagnosed with an antigen detection test to demonstrate the presence of treponemes in the primary chancre (ulcer). The most frequently used method is dark-field microscopy to detect living, motile spirochetes in lesion exudates (6, 7). This does require a light microscope equipped with a dark-field condenser. Smears also must be read within minutes of collection to ensure the motility of the spirochetes in the sample (7, 8). Alternatively, one can use the DFA-TP technique on an air-dried smear (7). This does not require living, motile spirochetes but does require a monoclonal or polyclonal antibody against *T. pallidum* conjugated to fluorescein isothiocyanate (FITC) and a properly working fluorescent microscope. A modification of the DFA-TP can also be used to look for *T. pallidum* in tissues (7). This modification is especially useful in testing for congenital syphilis, with the umbilical cord being one of the easiest tissue samples to obtain.

There are two types of serologic tests for syphilis: the nontreponemal tests, which use a cardioliipin-based antigen, and the treponemal tests, which use either disrupted *T. pallidum* or cloned antigens. Nontreponemal tests, which detect antibodies produced against cardioliipin in response to lipids in the outer membrane of the syphilis spirochete or against host cardioliipin, are either microscopic or macroscopic flocculation tests. The microscopic tests, the VDRL test and unheated-serum reagin (USR) test, require a microscope to read the test results. The USR test uses a stabilized VDRL antigen, which allows unheated serum to be used in the test. The macroscopic tests, the RPR test and toulidine red unheated-serum test (TRUST), also utilize stabilized VDRL antigen as well as colored particles which get caught in the flocculation matrix and make the reaction visible to the naked eye. The RPR test uses sized charcoal particles and the TRUST uses an azo red paint pigment. There was an EIA based on VDRL antigen (Reagin II test), but manufacture of that test has recently been discontinued. It is their reactivity to the host cardioliipin, or as one researcher terms it, "Nontreponemal-infection associated phospholipid antibodies" (14), that gives the nontreponemal tests their nonspecificity. These antibodies may be produced in response to damage by the spirochete, autoimmune disease, acute viral infection, recent im-

munizations, or mechanical damage to the cardiovascular system as occurs in intravenous drug use.

Four treponemal tests are in common use: the FTA-ABS test, FTA-ABS double staining test (FTA-ABS DS), Serodia TP-PA, and EIA. All are available commercially (Table 11.5.1–1). The TP-PA is probably the most commonly used test in clinical laboratories in the United States. The EIA format tests are gaining in popularity, especially in situations where large numbers of tests are performed. The FTA-ABS, FTA-ABS DS, and TP-PA are used only for confirmation of nontreponemal test results. The EIA (IgG only) can be used for confirmation of nontreponemal test results or as a screening test. The IgM EIA is used primarily in diagnosing congenital syphilis. There is also a Western blot test commercially available outside the United States. It can be used to detect either IgG or IgM antibodies. A microhemagglutination test for treponemal antibodies (MHA-TP) had been available in the United States until the end of 1998, when it was replaced by the TP-PA. The TP-PA has been shown to be slightly more sensitive in detecting primary syphilis than the MHA-TP (9). There is a *T. pallidum* hemagglutination assay available outside the United States.

Table 11.5.1–1 lists the manufacturers of various reagents for syphilis diagnosis and their websites. The tests that are dis-

cussed below are the DFA-TP, RPR test, and TP-PA. The RPR test and the TP-PA are the most commonly used tests based on the number of laboratories reporting proficiency testing results. The procedures described here are not detailed; readers should refer to the *Manual of Tests for Syphilis* (7) and the manufacturers' product inserts for detailed instructions. All of

the nontreponemal tests have similar procedures and measure the same type of antibody. However, because they do have slightly different sensitivities, the tests are not interchangeable and the same test as was used for the baseline titer should be used to monitor treatment efficacy. Regardless of the test used, it is the responsibility of the end user to verify that the

test performance meets the laboratory's requirements.

■ **NOTE:** Because of variations in shipping and storage conditions, the results obtained by the manufacturer or by CDC in the premarket evaluation should not be regarded as the definitive QC results. The end user must determine acceptability of the reagents.

11.5.2

Direct Fluorescent-Antibody Test for *Treponema pallidum*

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The direct fluorescent-antibody test for *Treponema pallidum* (DFA-TP) (1) can be used in conjunction with dark-field microscopy or in place of it. The test utilizes either monoclonal antibody or polyclonal antibody conjugated to fluorescein isothiocyanate (FITC). The monoclonal conjugate is specific for the pathogenic treponemes and is the conjugate of choice for ulcers that occur in the oral cavity or rectal

area. Polyclonal antibodies can be absorbed with nonpathogenic treponemes to remove cross-reacting antibodies. Absorbed polyclonal conjugates and the monoclonal conjugate can be used for the same specimens. Unabsorbed polyclonal conjugate can be used on genital ulcer samples with a fair degree of confidence that the organism identified is a pathogenic treponeme. Because the unabsorbed poly-

clonal conjugate cross-reacts with nonpathogenic treponemes, it cannot be used on oral or rectal lesions where other spirochetes are part of the normal microbiota. The FITC-labeled antibody reacts with *T. pallidum* antigen present in the samples. Examination of the smear with a fluorescence microscope reveals fluorescing treponemes with typical morphology.

II. SPECIMEN COLLECTION

Body fluids, lesion or ulcer exudates, tissue impressions, or suspensions of tissue which have been macerated using either scissors to finely mince or a tissue grinder are appropriate samples for DFA-TP. Samples are collected in the same manner as for dark-field microscopy (1, 2). Standard precautions should be observed when collecting samples and preparing slides. Smears are air dried and may be shipped at ambient temperature to an off-site laboratory for staining. However, slides that have been stored frozen should be shipped on dry ice.

III. MATERIALS

A commercial kit is not available, but the conjugates are available commercially (Table 11.5.1-1). In addition, positive and negative control slides are required. Positive control slides can be made from fluorescent treponemal antibody absorption test (FTA-ABS) antigen or impression

smears made using infected rabbit testicular tissue (1). Negative slides can be made using smears of washed nonpathogenic Reiter cultures (1). A fluorescent microscope in good working order with the proper filters for FITC conjugates is also required.

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. The conjugate must be checked for acceptable performance. The nonreactive control should be negative at 2 doubling dilutions below the working dilution specified by the manufacturer. Treponemes in the reactive control should stain with 3 to 4+ intensity when used at the working dilution recommended by the manufacturer.

IV. QUALITY CONTROL (continued)

- B. The pH of the mounting medium and phosphate-buffered saline (PBS) must be within the acceptable ranges.
- C. Positive and negative controls should be included daily.

V. PROCEDURE

Prepare smears and allow them to air dry. If the smears will be stained with polyclonal antibody, they should be fixed in acetone for 10 min and air dried prior to staining. If the monoclonal antibody conjugate is going to be used, the slides need to be fixed with 1 or 2 drops of 100% methanol for 10 s, drained, and allowed to air dry. Cover each smear with 30 μ l of properly diluted conjugate and incubate in a moist chamber at 35 to 37°C for 30 min. Rinse the slides in PBS and then place on a staining rack, cover with PBS, and allow to sit for 10 min. Rinse off the PBS with distilled water. Blot the areas outside the smear with bibulous paper to remove any residual water. Do not allow the smears to completely dry. Add a small amount of mounting fluid and place a coverslip over the smear. Scan the controls and the test smear using the 45 \times or 63 \times objective and the proper filters for FITC conjugates (BG12 or KP490 with K510 or K530 for transmitted light; BG38, K480, KP490, TK510, or K515 for incident light) on the fluorescent microscope. Confirm any treponemes by examining the smear with the 100 \times oil immersion lens. Ensure that the control slides are satisfactory before interpreting the test results.

POSTANALYTICAL CONSIDERATIONS

VI. INTERPRETATION

Observation of treponemes showing 2+ or greater fluorescence and morphology typical of pathogenic treponemes (2) is considered a positive test result. The absence of treponemes is considered a negative test result; however, a negative result does not rule out syphilis.

VII. LIMITATIONS OF THE PROCEDURE

- A. If polyclonal antibody is used and it is not preabsorbed with nonpathogenic treponemes, the test cannot be performed on oral or rectal lesions or ulcers because of other treponemes that are part of the normal microbiota.
- B. If there is precipitate in the conjugate, artifacts may interfere with reading the results.
- C. If the pH of the mounting medium or PBS is incorrect, fluorescence may be quenched, leading to false-negative results.
- D. If smears are too thick, material may wash off the slide, treponemes may not stain, or there may be too much background fluorescence to see treponemes.
- E. Care must be taken to ensure that treponemes from the positive control slide do not contaminate patient samples.
- F. If the lesion is healing, the sample was collected incorrectly, or the sample contains very few treponemes, one may not be able to demonstrate the presence of treponemes.
- G. The test cannot distinguish the treponemes that cause yaws and pinta from those that cause syphilis.

11.5.3

Rapid Plasma Reagin Test

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The rapid plasma reagin (RPR) 18-mm circle card test is a macroscopic nontreponemal test intended as a screening test for syphilis (4). The antigen is Venereal Disease Research Laboratory (VDRL) antigen that has been stabilized with EDTA and has had choline chloride added to eliminate the need for heat inactivation of the serum sample. Sized charcoal particles have been added to make the reaction visible. Charcoal particles get caught in the lattice formed by the stabilized VDRL antigen and antibodies to cardiolipin that are present in the blood of someone who has

syphilis. In the test, unheated serum or plasma is spread within the confines of a circle on a plastic-coated card. A drop of antigen is added, and the card is placed on a rotator at a specified speed for a specified length of time. If antibodies are present, the flocculation reaction takes place. The RPR test measures immunoglobulin G (IgG) and IgM antibodies. These antibodies may be in response to lipoproteins or cardiolipin of the treponeme itself or to host lipoidal antigens exposed by damage from the infection with *Treponema pallidum*. Antilipoidal antibodies may also be

produced in response to tissue damage from other causes such as autoimmune disease or intravenous drug use. A fourfold (2 doubling dilutions) decline in titer following syphilis treatment indicates that treatment has been successful; a fourfold increase indicates either treatment failure or reinfection. Failure of the titer to decline following treatment, in the absence of a rise in titer, does not necessarily indicate a treatment failure and must be considered along with the clinical presentation of the patient.

II. SPECIMEN COLLECTION

When handling serum or plasma, standard precautions must be observed (3). It is recommended that persons who handle blood and body fluids be vaccinated against hepatitis B virus (2).

- A. Serum is the preferred sample, especially if testing is going to be delayed for more than 48 h. However, as the name of the test implies, plasma (with EDTA anticoagulant) is a suitable sample if testing is to take place soon after the sample is collected.
- B. Blood samples should be collected and processed in such a way as to minimize hemolysis or contamination. Samples that are too hemolyzed, extremely lipemic, or contaminated or that contain particulate matter should not be used since these may interfere with the test.

III. MATERIALS

RPR card test reagents, cards, and control sera are all available commercially (Table 11.5.1-1). In addition to the reagents in the kits, persons performing the test will also need the following reagents and supplies.

- A. **0.9% Sodium chloride (0.9 g of NaCl added to 100 ml of distilled water)**

B. Diluent

A 1:50 dilution of serum nonreactive for syphilis prepared in 0.9% NaCl. This diluent should be used in the quantitative procedure for dilutions of 1:32 and higher. A calibrated dropper that delivers 50 μ l should be used.

- C. **Safety pipetting device with disposable tip that delivers 50 μ l**

III. MATERIALS (*continued*)

- D. Rotator, either fixed speed or adjustable to 100 ± 2 rpm, circumscribing a 3/4-in.-diameter circle**
- E. Discard containers and disinfectants**

- F. Disposable latex or nitrile gloves, safety glasses, and protective clothing**

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

It is the responsibility of the laboratory to adhere to Clinical Laboratory Improvement Amendments of 1988 regulations and guidelines. This includes annual calibration of pipettors; daily monitoring of room, water bath, and refrigerator temperatures; calibration of any thermometers used for water baths, etc.; participation and satisfactory results in an approved proficiency testing program; and running and recording controls for new lots of reagents and for daily testing. If the daily controls do not produce expected results, patient results are not valid and cannot be reported.

For lot-to-lot QC, 20 sera of graded reactivity, including minimally reactive, should be tested over a 2-day period using the kit currently in use along with the new kit. For quantitative testing, 6 serum samples of various titers should be tested in parallel on two consecutive work days. For a detailed description of the procedure, refer to *A Manual of Tests for Syphilis* (4).

The revolutions per minute of the rotator, room temperature, and reactivity of the controls should be determined each day that testing is done. In addition, the accuracy of the timer used, whether on the rotator or as a separate timer, should be validated. The needle should be checked each time a new needle is used, when the needle has been dropped or wiped, or when the control pattern is not met.

If the temperature of the room is too warm or cool, or if the reagents and patient samples have not reached room temperature, the accuracy of the test will be compromised (1). Likewise, if the samples or reagents are contaminated, the results may be inaccurate.

V. PROCEDURE

For complete instructions on the test procedure, refer to the manufacturer's product insert or to *A Manual of Tests for Syphilis* (4).

A. Qualitative test

1. Allow all reagents, controls, and samples to reach room temperature.
2. Place 50 μ l of control or patient sample (serum or plasma) onto appropriately labeled circle of the plastic test card. Using the flat end of the Dispensstir or a toothpick, spread the sample to fill the entire circle, taking care not to go outside the circle.
3. Gently shake the antigen-dispensing bottle to resuspend the particles.
4. Holding the dispensing bottle and needle upside down in a vertical position, dispense several drops to clear the needle of air. Add exactly 1 free-falling drop to each circle containing either controls or patient sample. Do not mix.
5. Place the card on the rotator and cover with a humidifying cover. Rotate the card for 8 min at 100 ± 2 rpm.
6. Remove the card from the rotator. Briefly rotate and tilt the card by hand to facilitate differentiation between nonreactive, negative rough, and minimally reactive results.
7. Perform the quantitative test on any samples that had any clumping or roughness.

B. Quantitative test

1. Dilute to endpoint all samples with rough nonreactive and reactive results in the qualitative test.

V. PROCEDURE (*continued*)

2. Place 50 μ l of 0.9% saline in circles 2 through 5 in one row of an RPR test card. Do not spread the saline.
3. Using a safety pipetting device, place 50 μ l of patient sample (serum or plasma) in circle 1 and 50 μ l in circle 2. Mix the saline and sample in circle 2 by drawing the mixture up and down eight times in the safety pipette. Avoid forming bubbles.
4. Transfer 50 μ l from circle 2 to circle 3 and mix. Continue making dilutions through circle 5. Discard 50 μ l from circle 5.
5. Using the flat end of the Dispensir or a toothpick, and starting with circle 5, the highest dilution (1:16), spread the serum dilution to fill the circle. Using the same Dispensir or toothpick, repeat for circles 4 (1:8), 3 (1:4), 2 (1:2), and 1 (undiluted).
6. Gently shake the dispensing bottle to resuspend the antigen and charcoal particles. Hold the dispensing bottle in an inverted vertical position and dispense 1 or 2 drops to clear the needle of air. Add exactly 1 free-falling drop to each circle. Do not mix.
7. Place the card on the rotator. Cover with a humidifying cover and rotate at 100 ± 2 rpm for 8 min.
8. Remove the card from the rotator and gently rotate and tilt the card by hand to and fro several times to aid in differentiating minimally reactive results from nonreactive results.
9. If the 1:16 dilution is still reactive, the sample needs to be diluted further, continuing as follows.
 - a. Prepare a 1:50 dilution of nonreactive serum in 0.9% saline to be used for making the 1:32 and high dilutions of the sample to be tested.
 - b. Prepare a 1:16 dilution of the test sample by adding 0.1 ml of serum to 1.4 ml of 0.9% saline. Mix well.
 - c. Place 50 μ l of the 1:50 nonreactive serum dilution in circles 2 through 5 of the test card.
 - d. Use a safety pipette to dispense 50 μ l of the 1:16 dilution of the test sample in circles 1 and 2.
10. Using the same pipette tip, make twofold serial dilutions. Complete the test as described in steps V.B.4 through 9 above. Use a new pipette tip for each patient sample.
11. At the completion of the day's tests, remove the needle from the dispensing vial, rinse with distilled water, and allow to air dry. Do not wipe the needle, as this removes the silicon coating, which will affect the size of the antigen drop.
12. Recap the dispensing bottle containing the antigen suspension and refrigerate at 2 to 8°C. Do not freeze. Antigen stored in the dispensing bottle will retain its reactivity for 3 months or until the expiration date, whichever occurs first.

POSTANALYTICAL CONSIDERATIONS**VI. INTERPRETATION****A. Qualitative test**

1. Read the reaction immediately under a high-intensity incandescent lamp. Do not allow the reaction to start to dry out, which may lead to misinterpretation of results.
2. Any serum or plasma sample that has characteristic clumping ranging from marked and intense (reactive) to slight but definite (minimally to moderately reactive) is considered reactive.
3. Slight roughness or an absence of clumping is considered nonreactive.

Table 11.5.3–1 Reporting quantitative RPR test results^a

Result with undiluted serum (1:1)	Result at serum dilution of:				Report
	1:2	1:4	1:8	1:16	
Rm or R	N	N	N	N	Reactive, undiluted (1:1)
R	R	N	N	N	Reactive, 2 dilutions or 1:2 or R2
R	R	R	Rm	N	Reactive, 8 dilutions or 1:8 or R8

^a Abbreviations: N, nonreactive; R, reactive; Rm, reactive minimal.

VI. INTERPRETATION

(continued)

B. Quantitative test

1. Read the reaction immediately under a high-intensity incandescent lamp as for the qualitative test. Do not allow the reaction to start to dry out, which may lead to misinterpretation of results.
2. Report the results of the test as the highest dilution showing any reactivity, including minimally reactive, as shown in Table 11.5.3–1.

VII. LIMITATIONS OF THE TEST

- A. False-positive test results can occur in serum or plasma samples from patients who abuse drugs; who have diseases such as lupus erythematosus, human immunodeficiency virus, mononucleosis, malaria, leprosy, viral pneumonia, or hepatitis; or who have recently received antiviral immunizations. Anecdotally, aspirin is thought to cause false-positive reactions, but there is no documented evidence to this effect.
- B. Persons with late latent syphilis or late syphilis may have a nonreactive RPR test. Persons who were treated in the late latent or late stage of syphilis or persons who have a history of syphilis infections may maintain low levels of reactivity for life.
- C. Prozone reactions may occur in undiluted serum samples. This occurs when antibody levels are high and flocculation cannot occur because of antibody excess. These samples will appear either as rough negatives or as weakly reactive. All samples giving this type of reaction must be quantitated. Additionally, if the clinician suspects syphilis and the nontreponemal test is nonreactive, it should be quantitated to rule out a prozone reaction.
- D. The RPR test cannot be used to test CSF for the diagnosis of neurosyphilis. Only the VDRL CSF test can be used for this purpose.
- E. The test has to be performed with all reagent, serum sample, and room temperatures between 23 and 29°C (73 to 85°F). Temperatures below this range will cause false negatives and lower titers, while temperatures above have the opposite effect (1).

11.5.4

Serodia *Treponema pallidum* Particle Agglutination Test

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The Serodia *Treponema pallidum* particle agglutination test (TP-PA) is a treponemal test for the serologic detection of antitreponemal antibodies (3, 4). Partially purified sonicated *T. pallidum* antigens are used to sensitize gelatin particles. If antibodies against syphilis are found in the patient's serum, an agglutination reaction takes place. The TP-PA is intended to be used as a confirmatory test for reactive results in a nontreponemal test such as the RPR test, for patients with nonreactive

nontreponemal tests who have signs or symptoms consistent with late manifestations of syphilis, or for patients for whom clinical history indicates that they may have late latent syphilis. As with all treponemal tests, results of the test remain reactive for life for most patients even when the patients are adequately treated for syphilis.

Serum that contains antibodies to the pathogenic treponemes binds to the antigens on the particles, forming a smooth

mat of particles on the bottom of the microtiter plate well. If no antibodies to *T. pallidum* are present, the particles settle to the bottom of the well, forming a compact button. The unsensitized particle control well for each serum sample should also form a compact button on the bottom of the well, indicating an absence of nonspecific agglutination.

II. SPECIMEN COLLECTION

Serum is the preferred sample, and when handling serum, standard precautions must be observed (2). It is recommended that persons who handle blood and body fluids be vaccinated against hepatitis B virus (1). Blood samples should be collected and processed in such a way as to minimize hemolysis or contamination. Samples that are too hemolyzed or extremely lipemic or that contain microbial contamination should not be used since these may interfere with the test.

III. MATERIALS

A. Reagents

All of the reagents that are required for performance of the test are included in the kit, which is available commercially (Table 11.5.1-1). The user may want to include a minimally reactive control that gives 1+ agglutination for extra QC. Droppers that deliver 25 μ l for delivery of sensitized and unsensitized gelatin particles are included in the kit.

B. Additional materials required

1. Disposable 96-well microtiter plates with round-bottom wells

2. Pipette droppers calibrated to deliver 25 μ l for dispensing sample diluent
3. 100- and 25- μ l automatic safety pipette with disposable tips for adding serum samples and making serum dilutions in the microtiter plate
4. Tray viewer (optional)
5. Automatic vibratory shaker
6. Disposable latex or nitrile gloves, safety glasses, and protective clothing
7. Discard containers and disinfectants

Table 11.5.4–1 Interpretation of agglutination patterns in the TP-PA

Settling pattern of particles	Reading	Interpretation
Smooth mat of particles covering the entire bottom of the well; edges may be folded	4 +	Reactive
Smooth mat of particles covering less than the entire bottom of the well and maybe surrounded by faint ring	3 +	Reactive
Agglutinated particles uniformly covering the bottom of the well, surrounded by a red circle	2 +	Reactive
Particles forming a large ring with an irregular outer margin and peripheral agglutination, surrounded by a red circle	1 +	Reactive
Particles concentrated in the shape of a compact ring with smooth edges and a hole in the center	+ / –	Inconclusive
Particles concentrated in the shape of a button in the center with a smooth round outer margin, with or without a very small hole in the center	–	Nonreactive

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. All new lots of test kits should be tested in parallel with the lot of the kit currently in use before being placed into use. Results of the two lots should be comparable. Reactive and nonreactive controls plus 10 serum samples of graded reactivity (3 reactive, 4 of 1 to 2+ reactivity, 3 nonreactive) should be used for the comparison. The reactive and nonreactive controls included with the kit should be run daily.
- B. Automatic pipettors should be calibrated annually.

V. PROCEDURE

- A. One row of 12 wells is required for the reactive control, four wells are required for the nonreactive control, and four wells are required for all patient samples. Place 100 µl of sample diluent in the first well of each control and patient set of wells. In each additional well per sample or control, add 25 µl of sample diluent.
- B. Make 1:5 dilution of sample by adding 25 µl of sample or control to the first well and serial twofold dilutions made either through well 4 (1:40 dilution) for patient samples and the nonreactive control or through well 12 for the reactive control. Discard 25 µl from the last well.
- C. Using the droppers included with the kit, add 25 µl of sensitized particles to well 4 (final dilution, 1:80) of each patient sample and the nonreactive control and wells 4 through 12 for the reactive control. Add 25 µl of unsensitized particles to well 3 of the controls and patient samples.
- D. Mix the samples by placing on a vibratory shaker for 30 s. Cover with either an empty microtiter plate or microplate cover. Let sit for 2 h at room temperature before reading. The plate may be left overnight to be read the next morning.
- E. Read the plate against a white background and read the pattern of agglutination in each well according to Table 11.5.4–1. Alternatively, a plate viewer can be used to aid in visualizing the results. Results are read as either reactive or nonreactive. The unsensitized particle controls should not show any degree of agglutination.

POSTANALYTICAL CONSIDERATIONS

VI. INTERPRETATION

Read the results of agglutination against a white background. Any degree of agglutination (Table 11.5.4–1) in the wells with sensitized particles should be interpreted as reactive. Control sera and patient sera must show nonreactive results in the wells with the unsensitized particles.

- A. The titer of the reactive control is read as the last dilution reading 1 + . The titer should not vary more than ± 1 doubling dilution from the endpoint titer established for the reactive control. The nonreactive control should not have any agglutination in the 1:80 dilution with sensitized cells. For any sample that shows agglutination in both the unsensitized and sensitized particles, the manufacturer's procedure for absorption should be followed. A reactive test result indicates past or present infection and the test usually remains reactive for life, even with adequate treatment for syphilis.
- B. Any patient sample that shows indeterminate results should be retested or a second sample should be drawn and tested. Repeated inconclusive results should be confirmed with another treponemal test, such as the fluorescent treponemal antibody absorption test.

VII. LIMITATIONS OF THE PROCEDURE

- A. All treponemal tests tend to remain reactive for life for persons who have had treponemal infections. Therefore, the TP-PA cannot be used to evaluate response to therapy or in determining relapse or reinfection.
- B. Tests for syphilis cannot distinguish syphilis from yaws or pinta or endemic syphilis and may be reactive for persons from areas where these other diseases have been endemic.
- C. False-positive reactions may occur in association with other underlying illnesses or conditions such as human immunodeficiency virus infection, rheumatic fever, leprosy, autoimmune diseases, Lyme disease, drug addiction, leprosy, toxoplasmosis, or *Helicobacter pylori* infection.
- D. There is a false-positive rate in healthy persons of about 1%. These false-positive reactions are frequently transient and a second serum sample will be nonreactive.
- E. Nonspecific agglutination, which rarely occurs in the test, may not be resolved by retesting absorbed serum against the sensitized and unsensitized particles.

Lyme disease is a multisystem disease caused by *Borrelia burgdorferi* and transmitted through the bite of infected *Ixodes scapularis* ticks (45). It is currently the most frequent vector-borne infectious disease in the United States, with the highest incidence in the northeastern and midwestern states (13). Lyme disease is also prevalent in Europe, where evidence of the disease existed in the early 1900s and where it is transmitted by *Ixodes ricinus* complex.

B. burgdorferi is a motile spirochete with a complex antigenic composition. It contains a linear chromosome and several linear and circular plasmids that encode outer surface proteins (OspA through OspF). Expression of these outer surface proteins varies depending on environmental conditions allowing the organisms to adapt to different conditions. OspA is preferentially expressed at 25°C in the unfed tick midgut, making it the target of choice for vaccine development (43, 44). OspC is expressed at 37°C after a blood meal has been obtained by the feeding tick and in the mammal host after transmission has occurred (39, 40). This switch in expression of outer surface proteins is important to understand the development of antibodies in humans as is described below. *B. burgdorferi* is composed of several genospecies (genogroups) that cause different manifestations of the disease. The broad group is denominated *B. burgdorferi* sensu lato, which contains the genospecies *B. burgdorferi* sensu stricto (genogroup 1), *Borrelia garinii* (genogroup 2), and *Borrelia afzelii* (genogroup 3). *B. burgdorferi* sensu stricto most frequently causes Lyme disease in the United States, while *B. garinii* and *B. afzelii* cause disease in Europe. While *B. burgdorferi* sensu stricto causes most frequently ery-

thema migrans (EM) and arthritis, *B. garinii* tends to cause more neurological manifestations and *B. afzelii* tends to cause chronic skin infections (48). Recent studies have also suggested that genetic variability among *B. burgdorferi* strains isolated from skin lesions of patients in North America may explain the different clinical manifestations observed in early disease (49).

Lyme disease usually occurs a few days to weeks after the bite of an infected tick and presents in about 80% of individuals with a slowly expanding erythematous skin lesion-denominated EM (45) (Table 11.6–1).

The diagnosis of Lyme disease relies on clinical recognition of the EM lesion during early stages of the disease. When EM is absent, unrecognized, or atypical, other diagnostic modalities are needed. Laboratory tests aimed at detecting the causative agent involve culture, PCR, or microscopy. Unfortunately, these methods are most sensitive in detecting *B. burgdorferi* from EM lesions, for which laboratory tests are theoretically unnecessary (41). *B. burgdorferi* can be cultured in Barbour-Stoenner-Kelly medium, and growth detection can take several weeks of incubation (7). Increased recovery from blood specimens has recently been obtained for patients with early disease by culturing large volumes of blood (50, 51). PCR has been most useful with synovial fluid of patients with late disease and can be used to determine eradication of infection after treatment (35). The use of a urine test to detect *B. burgdorferi* antigens has been questioned in a recent evaluation of its performance (24). Due to the lack of sensitivity and the cumbersome nature of the aforementioned tests, the laboratory confirmation of Lyme disease relies on in-

direct means such as antibody detection methods.

Several immunodominant antigens are present in *B. burgdorferi*. They include OspC (23 kDa), flagellin (41 kDa), and *Borrelia* membrane protein A (BmpA) (39 kDa) in early disease. As the disease progresses, several other antigens become immunoreactive (2, 3, 16, 17, 20). Tremendous knowledge has been gathered in testing for *B. burgdorferi* antibodies since the original assays were developed. First generation immunoassays used organisms highly passaged in culture that are currently known to be devoid of OspC (14, 15). Immunoglobulin (IgM) antibodies to *B. burgdorferi* appear within 2 weeks of infection and may persist for prolonged periods of time after antimicrobial treatment (3, 19). IgG antibodies also appear within weeks of infection but reach their peak months after untreated early infection.

Since antigens such as flagellin and high-molecular-weight antigens, including heat shock proteins, are also present in other bacteria, antibody tests using whole-organism preparations may detect cross-reactive antibodies (18). The facts that available antibody assays have not been standardized and that most assays are conducted in populations with low probability for Lyme disease (32) have contributed to misdiagnosis of *B. burgdorferi* infection and to the belief that serologic assays for *B. burgdorferi* are unreliable.

In 1994 the CDC, in conjunction with the Association of State and Territorial Public Health Laboratory Directors (ASTPHLD), the Food and Drug Administration (FDA), the NIH, the Council of State and Territorial Epidemiologists, and the NCCLS, cosponsored a Conference on the Serological Diagnosis of Lyme Dis-

ease. Among the recommendations was that a two-step testing approach was needed for active disease and for a previous infection using a sensitive EIA or indirect immunofluorescent-antibody assay (IFA) as a first step, followed by Western immunoblotting (12). The first step should detect IgG and IgM antibodies to *B. burgdorferi* and when reactive should be followed by separate IgG and IgM immunoblot tests.

Besides the matrix-based assays, functional antibody assays have also been used (1, 11). Although these assays are more cumbersome, they seem to correlate better with disease activity. Other types of assays

have included specific antibodies bound to immune complexes, reported to be detectable in patients found to be seronegative by standard assays (9, 38). Like the functional borreliacidal-antibody assays, the immune complex antibody assays are still restricted to a few research laboratories.

Between 1994 and 1997 two recombinant OspA vaccines to prevent Lyme disease were evaluated in the United States, and one such preparation was until recently available for use. Their efficacy in disease prevention ranges between 76 and 92% after three doses of vaccine (43, 44). Sera of vaccinated individuals are ex-

pected to react in first-step serological assays that use whole borrelial cells as antigens, since they contain OspA antigens but could be distinguished by Western immunoblots (4). A few assays using preparations of antigens from *B. burgdorferi* strains lacking OspA have been developed but are not currently FDA approved (52).

Since Lyme disease in Europe is caused by different *B. burgdorferi* genogroups and consensus on serology is being developed (22, 23, 37), the discussion on methods that follows is restricted to detection of *B. burgdorferi* antibodies in the United States.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

A. First-step testing

More than 40 commercial assays have been cleared by the FDA, and the majority of them are ELISAs or modifications of EIAs. Since IFAs are less frequently used, as a first-step testing the following description is restricted to ELISA or EIA (Table 11.6–2).

In ELISA, serum is tested for the presence of antibodies reacting with whole-cell sonicates of low-passage *B. burgdorferi* antigens immobilized to a solid surface. Variations to this antigen preparation are the addition of recombinant proteins (p39) or purified antigens and the use of synthetic C6 peptide, derived from the VlsE protein of *B. burgdorferi* (25). The serum specimen is diluted (1:20 to 1:400) in a diluent containing buffer solutions, pre-

servatives, and, in some formats, other bacterial antigens to block nonspecific reactions. Several washing steps remove unbound antibodies. Bound antibodies are detected after the addition of enzyme-conjugated anti-human immunoglobulins (IgG, IgM, and IgA, alone or in combination). After removal of unbound conjugate by several washes, a solution containing the substrate for the bound enzyme-conjugate is added. Color reaction (or fluorescence for Vidas) is read with a spectrophotometer (or luminometer) and absorbance is converted to a numerical value and translated to categories of reactivity (negative, borderline/equivocal, and positive) based on a ratio of patient specimen absorbance over a calibrator absorbance.

Table 11.6–1 Lyme disease stages

Early disease: Few days to few weeks after the bite of an infected *I. scapularis* tick (*I. ricinus* in Europe)

Early localized: EM at the site of the tick bite

Early disseminated: EM, accompanied by fever, influenza-like symptoms, headache, multiple skin lesions

Neurologic manifestations (15%): meningitis, cranial nerve palsies, motor or sensory radiculoneuritis

Cardiac manifestations (5%): atrioventricular blocks, myopericarditis

Late disease: months after onset of illness

Arthritis: about 60% of untreated patients develop intermittent attacks of arthritis

Chronic neuroborreliosis in up to 5% of untreated patients: chronic axonal neuropathy, chronic encephalomyelitis (caused by *B. garinii* in Europe), chronic encephalopathy (cognitive disturbances)

ACA^a chronic skin lesion caused by *B. afzelii* in Europe

^a ACA, achrodermatitis chronica atrophicans.

Wampole	PreVue	Recombinant OspA, OspB, OspC, p93, and flagellin	IgG, IgM	Immunochromatographic test performed in test devices. Use serum or whole blood.
Zeus	<i>Borrelia burgdorferi</i> ELISA test system	Whole borrelial lysate	IgG + IgM, IgG, IgM	

^a List of some of the commercially available tests.

I. PRINCIPLE (continued)

B. Second-step testing: Western blotting

Specimens testing borderline or positive by the first step are assayed in Western blots (immunoblots) where *B. burgdorferi* antigens have been separated electrophoretically by size and transferred (blotted) to membranes. Diluted serum specimens are tested in separate assays for IgG and IgM antibodies to the different antigenic components bound to the membranes, usually in strips. Unbound antibodies are

removed by washing steps. Enzyme-conjugated anti-human IgG and IgM are reacted with the two separate strips, and unbound conjugate is removed by washing. After the addition of a substrate for the bound enzyme, colored bands representing reactivity to the different immobilized antigens will develop. Band recording is visually determined by comparison to the reactivity of a band locator control and of a weak intensity control.

II. SPECIMEN COLLECTION

The most appropriate specimen for testing is serum. Lipemic or hemolyzed specimens should be avoided. Once serum has been separated from whole blood, it should be stored refrigerated (4 to 8°C) for several days or frozen (−20 to −70°C) if testing is delayed beyond a few weeks or for long-term storage.

Since development of antibodies requires a few days to weeks after infection, it is often necessary to test acute- and convalescent-phase sera. The best results are accomplished when both specimens are tested in parallel in the same assay under the same conditions. Testing of other types of specimens, such as synovial fluid or CSF, has not yet been standardized.

III. MATERIALS

As summarized in Table 11.6–2, many formats are currently available for first-step testing for *B. burgdorferi* antibodies.

A. Antigens

Most commercial first-step assays in the United States use whole-cell sonicates of low-passage *B. burgdorferi* B31, the first isolate of *B. burgdorferi* sensu stricto cultured from an *I. scapularis* tick. Several manufacturers have added the recombinant p39 antigen to the whole-cell antigen preparation. Gen-Bio and Alexon have produced dot EIAs using recombinant and purified antigens, and recently Immu-

netics released an ELISA using the C6 peptide, a synthetic peptide derived from the VlsE antigen of *B. burgdorferi* (27). Recombinant antigens have been evaluated in Europe as well as by several investigators in the United States, but few are commercially available (10, 21, 29, 30, 36).

Western blot assays commercially available at this time also use *B. burgdorferi* strain B31, except that of Focus Technologies, formerly MRL, which uses strain CB (a genogroup 1 *B. burgdorferi* sensu stricto human isolate) (Table 11.6–3).

Table 11.6–3 Commercially available Western immunoblots

Manufacturer	Kit name	<i>B. burgdorferi</i> strain used

III. MATERIALS (*continued*)**B. Serum diluent**

Due to the presence in *B. burgdorferi* of antigens common to other bacteria, several manufacturers have added bacterial proteins in some first-step assays in order to absorb cross-reactive antibodies from patient serum.

C. Other materials required as for any immunoassay

1. Calibrated pipettors
2. Rocking platforms or shakers
3. Timers
4. Serological pipettes
5. Multichannel incubating trays for immunoblots

ANALYTICAL CONSIDERATIONS**IV. PROCEDURE**

Commercially available FDA-cleared kits provide instructions for proper performance of assays.

A. Recommendations for testing

Special attention should be paid to the following factors.

1. Use kits within their expiration dates.
2. Avoid interchanging reagents from different lot numbers.
3. The following recommendations are particularly applicable for first-step tests such as ELISAs.
 - a. Positive, low positive, and negative controls as recommended by the manufacturer should be included in every run.
 - b. It is highly recommended that an in-house low positive well-characterized control be included in each run to assess run performance.
 - c. Prior to placing a new kit lot in use, it is advisable to run a panel of well-characterized frozen sera that encompasses all the ranges of reactivity. In our experience differences in detection of IgM antibodies exist when different lots from the same manufacturer are used.
4. The following recommendations are applicable to Western immunoblots.
 - a. Run respective positive, weak positive, and negative controls as recommended by the manufacturer. Some recommend running only the weak and negative controls in every run and the positive (or band locator) only once per new kit.
 - b. Inclusion of in-house controls showing bands of significance not present in the band locator is also suggested.
5. Run paired sera in the same run when comparing reactivities of different specimens obtained from the same patient at different time points.

B. Analytical factors

1. Maintain room temperature conditions (20 to 25°C). Day-to-day variations in room temperature affect the reliability and consistency of results. When room temperature exceeds ranges, the assay should be performed in another area of the laboratory (if possible) where conditions are met.
2. Incubation times and use of rotators and shakers should be adhered to as indicated by manufacturer unless in-house studies have proven them not to affect results.
3. Although Western blot kits are also provided with the appropriate instructions for performance, there are guidelines published by the NCCLS (document M34-A [33]). These guidelines address antigen preparation, electrophoresis, transfer of antigens to the matrix, calibration, and interpretation, among other issues important to this method.

POSTANALYTICAL CONSIDERATIONS**V. INTERPRETATION****A. First-step tests**

Interpretation guidelines are provided by manufacturers. Usually they involve a comparison (ratio) of patient's serum reactivity (absorbance for ELISA) to the reactivity of a calibrator included in the assay (usually a sample testing low positive). This ratio is translated to an index or units such that those samples reacting at about the same intensity of the calibrator are labeled as borderline (equivocal) or positive (reactive). Those with reactivity greater than that of those calibrators are reported as positive. Some in-house tests generate these ratios based on a reactivity that exceeds that of negative controls by 3 standard deviations.

Expected results:

1. Specimens containing cross-reactive antibodies as well as those from patients with early Lyme disease usually test borderline or low positive.
2. Sera from patients with early disseminated disease are low positive to positive (sometimes two to three times above the cutoff).
3. Sera from patients with late disease or those who have received two or three doses of OspA vaccine are high positive (4), usually greater than three times the cutoff.

B. Western immunoblots

If blots are produced in-house, guidelines provided by NCCLS document M34-A are recommended (33). At this writing three commercial sources of Western immunoblots are available (Table 11.6-3), and they provide sufficient guidelines for interpretation. Although this method offers greater specificity than first-step tests, it suffers great limitations due to the subjectivity inherent to visual band scoring. Some investigators have suggested a densitometric analysis of bands, but currently this approach is not widely used (17). Manufacturers have tried to address this issue by including a weak control that usually contains antibodies to the 41-kDa antigen (flagellin).

1. Band scoring

- a. Bands with intensity similar to or greater than that of the 41-kDa antigen of the weak control are scored. Adherence to this is particularly important when scoring IgM bands in sera from patients with early disease. IgM reactivities to the 41- and 23-kDa (OspC) proteins usually exceed the intensity of the weak control for these patients.
- b. Use the band locator provided by the manufacturer to compare the reactive bands in the patient strip and record the bands.

2. Results

- a. A positive IgM blot shows two of these three significant bands: 23 kDa (OspC), 39, or 41 kDa (17).
- b. A positive IgG blot shows 5 of the following 10 significant bands: 18, 23 (OspC), 28, 30, 39, 41, 45, 58, 66, and 93 kDa (16).
- c. CDC-ASTPHLD guidelines state that the IgM criteria should be only of diagnostic use during the first 4 weeks of disease but the IgG criteria can be used to support a clinical diagnosis at any disease stage.
- d. Individuals who have received more than two doses of OspA vaccine develop high titers of IgG to the recombinant antigen of 31 kDa. IgM reactivity is of lesser intensity and duration than the IgG antibodies. In addition, those individuals with high titers of IgG anti-OspA antibodies may show reactivity to other antigens of low molecular size that most likely represent breakdown products of OspA during blot preparation (4, 31).

**VI. POSTANALYTICAL
RECOMMENDATIONS****A. First-step assays**

1. Guidelines established by the manufacturer concerning run acceptability should be followed.
2. Laboratories performing tests for *B. burgdorferi* antibodies should participate in an approved proficiency testing program, such as those offered by different states or the CAP survey.
3. It is important to emphasize that current guidelines recommend that all specimens reactive by first-step tests be referred for second-step IgG and IgM immunoblots and that the final result be that of the immunoblots. Necessary arrangements should be made to refer the specimens to a reference laboratory or establish the Western blot method in the laboratory if the volume of specimens allows it.
4. Absorbance of specimens may vary slightly from run to run; therefore, the numerical values are not as precise as values of chemical blood parameters. This is of particular importance when comparing reactivities of sera obtained from the same individual at different time points. Paired sera should be run in parallel using the same lot of reagents under the same run conditions in order to obtain a meaningful comparison.
5. Since first-step tests are quantitative and the results are derived more objectively than with Western blotting, they better assess the amount of antibodies present. Therefore, these tests are better utilized to determine decline in antibodies than Western immunoblotting.
6. Sensitivity and specificity

Variable levels of sensitivity are observed with the available first-step assays, as has been demonstrated in proficiency testing of the CAP (6). Most frequently, lack of sensitivity involves the detection of IgM antibodies during early disease (2, 3, 8, 16, 26, 46). For a population of patients with culture-confirmed EM of short duration, IgM antibodies were more frequently detected by immunoblotting than by ELISA. The sensitivity of first-step tests during the acute phase is about 30 to 40%, with a specificity of approximately 90% (2, 3, 16). About 60% or more of patients presenting with a disease of more than 1 week's duration show antibodies by first-step tests (3). Sensitivity increases to about 90% if patients are tested within 2 weeks into convalescence.

B. Western immunoblots

1. It is important to assess the blot reactivities of the entire run as a whole, regardless of whether the run met criteria of acceptability based on the control materials. Intensity of immunoblot bands correlates with reactivity as measured by the first-step tests, and usually the specimens included in a blot run have a spectrum of reactivity by ELISA and blotting. If blot bands are present across the board and they do not seem to correlate with the ELISA values, the entire run may need to be questioned. Lack of adherence to procedural details, room temperature, or other factors may have affected the run.
2. If great discrepancies exist between ELISA and immunoblot reactivities, both tests may need to be repeated.
3. Laboratories performing Western immunoblots should participate in an approved proficiency testing program, such as those available through different state health departments or the CAP survey. Although there is not a "gold standard" method to compare results and materials included in proficiency surveys have been questioned (42), proficiency testing programs have contributed to a better understanding of the performance of available tests (6).

VI. POSTANALYTICAL RECOMMENDATIONS

(continued)

4. When immunoblot testing is recently introduced into the laboratory, the use of a panel of monoclonal antibodies to various antigens may aid in identifying the bands of significance. Such panel is available through the CDC and consists of monoclonal antibodies to p93, p62, p41, p39, p37 (FlaA), OspB, OspA, OspD, OspC, and p22. Other monoclonal antibodies have also been produced by a number of investigators.
5. Although the OspA vaccine is no longer commercially available, it is advisable to become familiar with the blot reactivities of sera of those individuals who received such preparations. Since patients who have developed natural antibodies after an infection with *B. burgdorferi* do not usually develop anti-OspA antibodies, the vaccination reactivity observed in blots is quite characteristic. The presence of reactivity to low-molecular-size antigens in vaccinated individuals is different and should not be confused with reactivities to the significant bands used in the IgG blot criteria (23 kDa [OspC] and 18 kDa) (4). Furthermore, vaccination does not seem to affect the interpretation of blots for individuals who failed vaccination and developed Lyme disease (4). Such individuals usually developed low titers of antibody to OspA (4, 28), and as mentioned above, vaccination elicits mostly IgG antibodies and does not affect the IgM blot interpretation (4).

6. Sensitivity and specificity

During early stages of Lyme disease the sensitivity of IgM blots is about 40% in the acute phase and 60 to 80% during convalescence. The sensitivity increases for patients with disseminated disease; in our experience, for patients with early disseminated disease with EM and neurological involvement the sensitivity of IgM blots is close to 100%. In later stages of disease with encephalopathy and arthritis the IgG blots have sensitivities of 84 and 100%, respectively (16).

Methods aimed at detecting antibodies to *B. burgdorferi*, the causative agent of Lyme disease, have many limitations. Contributing factors are the complex antigenic composition of *B. burgdorferi*, the lack of standardization of methods, and their use in unselected patient populations. The American College of Physicians has proposed that antibody tests be restricted to those patients with a pretest probability of Lyme disease of 0.20 to 0.80 (5, 47). Testing of patients with a low probability (<0.20) of Lyme disease will most likely yield false-positive tests. According to their recommendation, patients with a high pretest probability should be treated and not tested (34). The current approach to antibody testing involves the use of two steps: a sensitive ELISA or IFA that should detect both IgG and IgM antibodies, followed by separate IgM and IgG immunoblots. The role of these methods is to support the clinical diagnosis of Lyme disease, and their indiscriminate use should be discouraged.

Future tests to detect *B. burgdorferi* antibodies most likely will include recombinant or synthetic antigens in a quantitative format. Such an approach seems not so distant since such tests are already being developed and evaluated (27).

11.7.1

Introduction

Human rickettsial diseases are divided into those caused by species in the families *Rickettsiaceae* and *Anaplasmataceae*. Members of the genus *Rickettsia* infect endothelial cells and cause vasculitis, whereas those in the *Anaplasmataceae* family include *Ehrlichia chaffeensis*, which infects monocytes and mononuclear phagocytes, and *Anaplasma phagocytophilum* (formerly *Ehrlichia phagocytophila*, *Ehrlichia equi*, and the HGE agent) and *Ehrlichia ewingii*, which infect granulocytes, chiefly neutrophils. Members of the genus *Rickettsia* are further divided into the spotted fever and typhus serologic groups based on the presence (spotted fever group) or absence (typhus group) of rickettsial outer membrane protein A (rOmpA) and lipopolysaccharides. Members of each group are strongly cross-reactive, and infections cannot be differentiated by routine serological testing. Occasionally, reactions across serological groups occur, and differentiation is achieved by comparing titers of antibody to specific rickettsial antigens. Similarly, cross-reactions between *E. chaffeensis* and *A. phagocytophilum* are detected in between 3 and 30% of infections; differentiation is usually achieved by comparison of specific antibody titers.

Among vector-borne infections in North America, next to Lyme disease, tick-borne Rocky Mountain spotted fever (RMSF) caused by *Rickettsia rickettsii* is the second most prevalent and is associated with a case fatality rate of up to 8.5% (1, 3). The next most frequently reported vector-borne infections in North America are human monocytic (HME) and granulocytic (HGE) ehrlichiosis, caused by *E. chaffeensis* and *A. phagocytophilum*. Nationally, these each exceed more than 100 reported cases per year, with regional

prevalences as high as 65 cases of HME per million population in Searcy County, Ark., and 522 cases of HGE per million population in Jackson County, Wis. (6). *E. ewingii* is serologically cross-reactive with *E. chaffeensis*, and a few studies have shown that about 10% of infections diagnosed as HME may actually be due to *E. ewingii* (2). HME is generally more severe than HGE, but both have case fatality rates of up to 2%, and infections are substantially more severe in the context of immunocompromise and human immunodeficiency virus. Of lower national prevalence, but of great local importance, is the flea-borne murine typhus caused by *Rickettsia typhi* and by the recently recognized *Rickettsia felis* (4). This infection is recognized principally in South Texas and southern California, although a wide distribution wherever rats and fleas exist is known. As for RMSF, disease reflects underlying vasculitis because of infection of endothelial cells systemically. Although generally perceived as a mild illness, murine typhus is associated with a case fatality rate approaching 2%. *Orientia tsutsugamushi* is the cause of scrub typhus, a chigger-transmitted rickettsial infection that occurs mostly in eastern parts of Asia, including Indonesia, and northern parts of Australia. Scrub typhus imported to North America and Europe is not infrequent and requires specific serological tools for diagnostic confirmation. In addition, Q fever is caused by *Coxiella burnetii*, an obligate intracellular bacterium not phylogenetically related to either *Rickettsiaceae* or *Anaplasmataceae*, and rarely arthropod transmitted. Diagnoses are often made by referral of sera to public health laboratories that possess the expertise to conduct and interpret the complicated tests required for this infection.

All rickettsial infections present predominantly with fever, headache, myalgias, and malaise, and for RMSF and murine typhus, a maculopapular rash is present in approximately 85 and 50% of patients, respectively. The undifferentiated clinical presentation makes clinical diagnosis difficult, and laboratory studies may be helpful if a normal leukocyte count or leukopenia with a left shift are observed concomitantly with thrombocytopenia and increases in serum hepatic transaminase activities. Since delays in diagnosis and therapy are associated with increased severity and fatality, diagnosis and initiation of therapy based upon clinical suspicion are mandatory; therapy should not be held pending laboratory diagnostic tests. RMSF may be diagnosed in the acute phase by skin biopsy and demonstration of *R. rickettsii* antigens by direct fluorescent antibody or immunohistochemical staining (7); PCR is not widely available and has not demonstrated any additional increase in sensitivity during the acute phase (8, 9). HME and HGE are diagnosed chiefly by specific PCR and less sensitively by examination of Romanowsky-stained peripheral blood or buffy coat smears for the presence of intracytoplasmic bacterial clusters called morulae in monocytes (HME) or neutrophils (HGE). Because of the unavailability or insensitivity of these tests for most clinical laboratories, serologic testing is the method most frequently selected for confirmation of a clinical diagnosis.

The most frequent serologic test for confirmation of rickettsial and ehrlichial infections is the indirect fluorescent-antibody test, although additional tests such as solid-phase EIA (dot blot) and the latex agglutination assay may provide useful diagnostic information and are commer-

cially available. Still available but strongly discouraged owing to a significant lack of sensitivity and specificity is the Weil-Felix agglutination of *Proteus* antigens OX-2, OX-19, and OX-K, which are part of the "febrile agglutinins" panel (5). An increasing variety of alternative serodiagnostic tests and antigen preparations are reported in peer-reviewed literature. Tests that em-

ploy recombinant rickettsial and ehrlichial antigens hold great promise but have not been cleared by the Food and Drug Administration (FDA) for in vitro diagnostic use. Most are not currently commercially available, although some referral laboratories may offer such tests as alternatives to established methods. Current standards generally do not permit acceptance of re-

sults from non-FDA-cleared tests offered through commercial reference laboratories. However, it should be the responsibility of the laboratory director to determine whether the performing referral laboratory's developmental and validation data support acceptance of the diagnostic results.

11.7.2

Indirect Fluorescent-Antibody Test

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The indirect fluorescent-antibody (IFA) test, also called indirect immunofluorescence and microimmunofluorescence, is the most frequently used and best-characterized serological test for rickettsial and ehrlichial infections (1, 3, 7–9, 11–16). IFA detection of human antibodies to *Rickettsia*, *Ehrlichia*, and *Anaplasma* species antigens (rickettsial antigens) is ac-

complished by reacting serum from the patient with rickettsial antigens immobilized onto glass slides; antibodies, if present in the serum, are detected with a fluorescein isothiocyanate (FITC)-labeled anti-human isotype reporter. Reporter signal is detected by UV microscopy using filters appropriate to detect FITC (apple green) fluorescence that highlights the

morphology of the bacteria. For a patient with a consistent clinical illness and epidemiologic history, the detection of a high titer of antibodies in a single serum sample, a seroconversion to a predetermined minimal titer, or a fourfold increase in antibody titer is considered evidence of infection.

II. SPECIMEN COLLECTION

Serum samples for rickettsial serology should be obtained by venipuncture either into standard red-top tubes or into serum separator tubes. Samples should be obtained preferably at the time of acute illness and 2 to 4 weeks later. Some commercial assays may also permit the analysis of antibodies in heparinized plasma, whole blood, and capillary blood. The use of serum is strongly recommended. For Rocky Mountain Spotted Fever (RMSF), antibody may be detected as early as 3 days after onset of illness, and nearly all patients have antibodies demonstrated by 21 days (8, 12, 14). For murine typhus, more than 50% of patients are seropositive within the first 6 days of illness, and 100% are seropositive by 13 to 15 days (10). For both human monocytic (HME) and human granulocytic (HGE) ehrlichiosis, up to 40% of patients are seropositive at presentation, and nearly all will be seropositive within 1 month (2, 9). Aliquots of acute-phase samples should be stored frozen for simultaneous testing with convalescent-phase samples. If serum is unable to be tested within 24 h, it should be stored at -20°C until testing can be conducted.

III. MATERIALS

There are few suppliers of high-quality antigen slides or IFA kits for detection of rickettsial and ehrlichial antibodies (Table 11.7.2–1). In addition, the CDC and some public health laboratories provide or use dimethyl sulfoxide-stabilized frozen infected-cell antigen suspensions that may be applied to glass slides as needed. In general, antigen preparations available range from whole infected cells to highly purified cell-free bacterial suspensions im-

mobilized onto multiwell, Teflon-coated glass slides. Some antigen slide preparations have two or more rickettsial or ehrlichial antigens within a single well on the slide, allowing simultaneous detection of antibodies reactive with multiple species. In addition, some manufacturers will supply individual components of kits, including antigen slides, conjugates, positive control sera, negative control sera, immunoglobulin M (IgM) removal diluent,

III. MATERIALS (continued)

mounting medium, and buffered diluent. The assays will generally require additional supplies, such as coverslips for the antigen slides, test tubes and racks for making serum dilutions, a humidified

chamber for incubation of slides, and a timer. A fluorescent microscope with appropriate excitation filters is required for examination of stained slides.

IV. QUALITY ASSURANCE

A positive and a negative control serum should be tested in parallel with all patient specimens. Most commercially available kits will provide both and will give specific instructions regarding their preparation and use and interpretation of results. In general, positive control samples have been obtained from individual patients recovered or recovering from the rickettsial infection, or pools of samples from such patients; separate controls may be provided for IgG and IgM analyses. Negative control samples are generally derived from healthy individuals without any history of the rickettsial infection and may be supplied as either individual samples or pools from a number of individuals. Controls should be diluted in parallel and at the same time as patient samples, and the test should be conducted at the same time for controls as for test samples. Some manufacturers provide control sera prediluted. Under these circumstances, it is useful for each laboratory to have additional positive and negative control sera of established titer available for testing to control for problems with diluting or dilution buffers. Each positive control serum provided by commercial manufacturers will have a target titer that should be confirmed at least with each new lot of antigen slides and new lot of conjugate. Manufacturers' instructions should be followed and generally call for replication of stated titers within twofold dilutions. Each new lot of conjugate should be tested for reactivity at the recommended dilution in the absence of any primary serum to ensure that direct reaction with the antigen slides is not occurring.

Should positive control serum not react or not achieve the stated range of titer, or if negative control serum should become reactive, patient results should not be accepted and the tests should be repeated after appropriate troubleshooting. It is a reasonable practice to periodically review the clinical records of patients with seroconversion, a fourfold increase in antibody titers, or high IgM titers to ascertain whether the clinical circumstances are consistent with the rickettsial or ehrlichial infection identified. A repetitive pattern of inconsistent clinical manifestations should be an indication for the laboratory director to investigate and/or educate regarding appropriate, sensitive, and specific utilization of rickettsial IFA serology.

Currently, no proficiency testing program is available from the CAP, although a pilot program to assess clinical laboratories' serologic tests for tick-borne path-

IV. QUALITY ASSURANCE (continued)

ogens has had at least one distribution as of this writing. A consortium of clinicians, clinical laboratorians, researchers, and the CDC, called the Consensus Approach for Ehrlichiosis (“CAFÉ”) Society, has made recommendations for clinical and laboratory diagnosis of HME and HGE and has initiated a program of sample sharing to assess the need for standardization (15). It is intended that as the program matures and recommendations are made, it may operate as a repository for corroborated samples to be distributed for proficiency testing.

ANALYTICAL CONSIDERATIONS

V. PROCEDURE

In general, IFA test procedures for the various species are similar and have several steps. It is good practice to record into which well each serum or control will be placed prior to starting the assay.

- A. Slides are allowed to warm to room temperature.
- B. A small volume (usually 10 to 25 μ l) of each appropriate dilution of positive control, negative control, patient serum, and patient serum depleted of IgG (for IgM detection) is added to the appropriate well on a multiwell antigen slide. Some manufacturers supply control sera in a prediluted format. Dilutions are determined by manufacturers, but most agree that a screening dilution of 1:64 should be used for IgG and polyvalent tests; dilutions for IgM tests may vary.
- C. Incubation periods vary by manufacturer but are generally 30 min to 1 h at ambient temperature or at 37°C.
- D. Slides are rinsed in buffer and washed by one or more immersions in buffer, and buffer salts are removed by a brief distilled-water rinse prior to drying.
- E. Each well receives an appropriate volume (usually 10 to 25 μ l) of isotype-specific conjugate.
- F. Repeat the incubation and wash steps (steps V.C and D). Some protocols include a step for counterstaining with reagents such as Evan’s blue or Eriochrome black prior to or during the final wash step.
- G. After the slides are dry, each well receives a small volume (10 to 25 μ l) of mounting medium, usually a glycerol–phosphate-buffered saline mixture.
- H. Coverslips are placed over the wells on the slides, avoiding trapped air bubbles. Care should be taken to avoid excess mounting medium as it will seep from under the coverslip and contaminate the microscope objectives or immersion oil, if used. Excess mounting medium may be removed by capillary action with an absorbent blotting paper.
- I. Slides are examined at a final magnification of between $\times 200$ and $\times 1,000$ using a fluorescent microscope with appropriate filters to allow excitation and emission for FITC.
- J. If the slides cannot be viewed immediately, they may be kept at 4°C in the dark for 24 h.

Since a fourfold change in titer offers the most sensitive seroconfirmation, sera that react at the screening dilution should be titrated. To do so, sera should be serially diluted (after removal of IgG for IgM titer determinations) in doubling dilutions starting at the screening dilution (usually 1:64) until an endpoint titer where no definite fluorescent bacteria are identified is reached.

A reactive sample will allow definite fluorescent visualization of the bacterial morphology. *Rickettsia* spp. appear as small (approximately 0.3 by 1.5 μ m) bacilli and occasionally coccobacilli, whereas *Ehrlichia chaffeensis* and *Anaplasma phagocytophilum* will appear predominantly as tiny (0.2 by 1.0 μ m) coccobacilli and cocci. Some antigen preparations utilize bacteria free of host cells, prepared by

V. PROCEDURE (continued)

growth in chicken embryo yolk sacs or by density gradient purification from infected tissue culture cells. When bacteria are purified from yolk sacs, a diluent that includes normal yolk sac as a 10% suspension in diluting buffer is advisable to absorb any antibodies reactive with yolk sac antigens. Antigen preparations derived from whole infected cells (*Rickettsia rickettsii* or *Rickettsia typhi* grown in Vero or other cell lines, *E. chaffeensis* grown in DH82 or Vero cells, or *A. phagocytophilum* grown in HL-60 cells) may have different appearances from those in cell-free preparations. In general, it is best to only interpret bacteria that are within cells in these preparations. The bacteria will be localized within the cytoplasm as short bacilli for *R. rickettsii* and *R. typhi* (occasionally in nuclei for *R. rickettsii*) and as clusters or inclusions of coccobacilli and cocci in the cytoplasm of the host cells for *E. chaffeensis* and *A. phagocytophilum*.

Slides should be examined for the presence of fluorescent bacteria in several locations, as staining intensity may vary considerably even in a single well. Bacteria at the periphery of the well should not be evaluated. Various intensities of fluorescence may be observed, and many manufacturers suggest recording this in a semi-quantitative manner (0 to 4+). However, the best practice is to assess the morphology of each antigen reacted with each sample for the definition of morphology, the distribution, and the quantity of intracellular bacteria compared with the positive and negative control samples. The positive control sample will provide the approximate distribution and an appropriate comparative morphology, whereas the negative control will provide a meaningful level of background fluorescence. Fluorescence of bacterial morphology in samples that does not exceed that identified on the negative control should be considered negative. Optimally, fluorescent bacteria should not appear in negative control samples.

POSTANALYTICAL CONSIDERATIONS

VI. INTERPRETATION

IFA testing for detection of antibodies to *R. rickettsii*, *R. typhi*, *E. chaffeensis*, and *A. phagocytophilum* is the most sensitive method for confirmation of infection (Table 11.7.2–2). In general, it is good practice to establish appropriate screening and cutoff titers for positive samples in each laboratory, a situation that is not possible for most clinical laboratories owing to the lack of sufficient numbers of well-characterized samples. Thus, most laboratories and laboratory directors will rely upon the validation performed by the manufacturer. In most cases, the CDC case definition provides a serologic cutoff that is widely accepted and corroborated by manufacturers of rickettsial and ehrlichial serodiagnostic tests. For the IFA test, the current CDC seroepidemiologic criterion for diagnostic confirmation of suspected

Table 11.7.2–2 Sensitivities and specificities of serological tests for confirmation of RMSF, murine typhus, HME, and HGE

Disease	Serological assay ^a	Sensitivity (%)	Specificity (%)
RMSF	IFA IgG	89–100	99–100
	IFA IgM	83–85	100
	LA	79–100	94–100
Murine typhus	IFA IgG	≥83	≥93
	IFA IgM	53–85	99
	Dot blot	88	92
HME	IFA IgG	88	Not determined
	IFA IgM	86	Not determined
HGE	IFA IgG	82–100	82–100
	IFA IgM	27–37	83–100

^a IFA, indirect fluorescent-antibody test; LA, latex agglutination.

VI. INTERPRETATION (continued)

RMSF (5) requires a fourfold rise in titer of antibody to *R. rickettsii* antigen; for a serological test that screens samples at a dilution of 1:64, this implies a minimum titer of 128 if the acute-phase titer is <64. The IFA test serological criterion for “probable” infection in a patient with suspected RMSF is a single titer of ≥ 64 . Application of these criteria for diagnosis of individual patients generally requires a “probable” diagnosis with a titer of at least 64. Similar CDC laboratory criteria exist for confirmation of the diagnosis of HME and HGE in clinically suspect cases, but no specific cutoff levels are advocated (6). Some suppliers recommend that initial dilutions of sera begin at 1:8, and a fourfold increase would occur with a minimum titer of 16 or 32. However, prior studies suggest that dilutions lower than approximately 1:64 often result in nonspecific fluorescence; thus, a minimum titer of 64 would be required before any sample is considered specifically reactive with *R. rickettsii*. Although not extensively studied, similar results have been observed in IFA testing for *E. chaffeensis* and *A. phagocytophilum*.

As antibodies are rarely detected in the acute phase of RMSF and murine typhus and infrequently ($\leq 30\%$ of patients) in HME or HGE, a second or convalescent-phase sample must be obtained 2 to 4 weeks later for optimal diagnostic sensitivity (2, 9, 12, 14). More than 99% of patients with HGE and HME are seropositive at 1 month postinfection, and IgG or polyvalent reactions may persist for years. Although IgG antibodies may be frequent in early infection, IgM antibodies are frequently detected only during the first 45 to 60 days postinfection and may be useful to confirm recent exposure or infection; IgM antibodies may infrequently persist for a year or more.

Overall, serologic testing for antibodies reactive with *R. rickettsii*, *R. typhi*, *E. chaffeensis*, and *A. phagocytophilum* should be conducted only when a reasonable level of clinical suspicion exists. Although specificity of the reaction is relatively high ($\geq 92\%$), the predictive value of a positive test is only moderate unless the prevalence of the infection or the pretest probability of infection is relatively high. Likewise, since sensitivity is high in all of these tests (88 to 100%), the predictive value of a negative test is very high when paired acute- and convalescent-phase samples are compared. The predictive value of a negative test is low when only an acute-phase sample is tested, since sensitivity in that phase of infection is low (generally <40%). It is also particularly important to conform with the principle of comparing acute- and convalescent-phase sera since a significantly higher proportion of persons have serologic evidence of infection by *R. rickettsii*, *E. chaffeensis*, and *A. phagocytophilum* than report manifestations of infection. Whether these observations reflect the occurrence of subclinical infections or antigenic stimulation with cross-reactive antigens or “nonpathogenic” species after tick bites is undetermined.

A number of preexisting conditions may dispose patients to false-positive serologic reactions for the various *Rickettsia*, *Ehrlichia*, and *Anaplasma* spp. (Table 11.7.2–3). It must be understood that the *R. rickettsii* IFA test detects antibodies broadly reactive with spotted fever group rickettsiae and more weakly reactive with typhus group rickettsiae; the converse is true for reactions with *R. typhi*. Thus, seroconfirmation of RMSF or murine typhus is dependent upon a strong clinical history consistent with the geographically likely infection or upon more specific serologic tests that are conducted only in reference and public health laboratories. A beneficial aspect of this nonspecificity is the ability to broadly apply the RMSF and murine typhus serologic tests. Thus, these may be used to detect antibodies reactive with other spotted fever group or typhus group rickettsiae that are domestically rare (*Rickettsia akari* or *R. felis*) or may have been acquired during international travel, including such agents as *Rickettsia conorii* (Mediterranean spotted fever), *Rickettsia africae* (African tick bite fever), or *Rickettsia prowazekii* (epidemic typhus), among many. Occasional cross-reactions with other infectious

VI. INTERPRETATION (continued)

agents are also observed, but under ordinary circumstances, the cross-reactive titers are at least fourfold lower than the titer for the homologous rickettsial infectious agent.

In a similar manner, serologic tests for *E. chaffeensis* and *A. phagocytophilum* may yield cross-reactions with each other and related species (6, 16). For example, *Ehrlichia ewingii*, the agent of a newly recognized form of granulocytic ehrlichiosis, induces antibodies reactive with *E. chaffeensis*, as do veterinary infections with other *Ehrlichia* spp. (*E. canis*, *E. muris*, *E. ruminantium*) and some *Anaplasma* spp. (e.g., *A. phagocytophilum*) (4). In general, the majority of infections result in a fourfold higher titer of IFA to the homologous infectious agent, but as antigens are not available for all *Ehrlichia* and *Anaplasma* spp., a high degree of suspicion based upon clinical manifestations and epidemiologic history is required for the highest degree of predictive value. Approximately 3 to 30% of patients with HGE will develop antibodies reactive with *E. chaffeensis*, but only a small proportion (< 10%) will not be resolved by comparison of titers.

A disproportionate number of sera from patients with HGE and HME will also react in some serological tests for Lyme disease (17, 19). The basis for this reaction is still not clear, and it is speculated to result from such diverse circumstances as serological cross-reactivity between antigens of bacteria in different phylogenetic classes or coinfections with multiple tick-transmitted infectious agents. Thus, *Borrelia burgdorferi* and ehrlichial serologies must be carefully interpreted in the context of patient clinical manifestations and epidemiologic history.

Owing to the use of *A. phagocytophilum*-infected HL-60 cells of human derivation, whole-cell-infected antigen preparations may yield false-positive results for

VI. INTERPRETATION (continued)

patients with autoimmune disorders, including those with antinuclear, antiplatelet, and anti-smooth muscle antibodies (18). The false-positive results can be minimized by adherence to careful morphological criteria for interpretation and examination at a high magnification (usually $\times 1,000$).

11.7.3

Solid-Phase (Dot Blot) EIA

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

An alternative method for detection of rickettsial antibodies is based upon reactions of antibodies with rickettsial antigens immobilized to membranes, the solid-phase EIA, or dot blot (1, 2). This method utilizes a principle similar to that for indirect fluorescent antibody (IFA) testing except that serum antibodies are reacted with rickettsial antigens immobilized onto nitrocellulose and in turn these bound antibodies are detected with anti-human antibody isotype reagent coupled to a reporter enzyme. Reporter signal developed from bound enzyme, such as alkaline phosphatase, acting upon a sub-

strate, such as 5-bromo-4-chloro-3-indolylphosphate and *p*-nitroblue tetrazolium chloride, is detected by visual observation of a blue-black reaction on the nitrocellulose. Unlike the situation with IFA testing, where serum titer is determined by serial dilution of serum samples, the EIA takes advantage of the binding properties and kinetics of antibody-antigen interactions by reacting a single dilution of serum with diminishing quantities of rickettsial antigen. Thus, by coupling several diminishing quantities of antigen on a single strip of nitrocellulose and reacting with a single dilution of serum, a quantitative es-

timate of serum antibody concentration, or titer, may be determined. Theoretically, it is possible to develop isotype-specific serological results; however, currently available formats detect only polyvalent responses. The main advantages of this approach are the lack of need for fluorescence microscopy, the relative ease of operation in a dipstick format, the stability of antigen preparations, diminution of subjective fluorescent determinations, and the development of a permanent record. The format is best used when only a limited number of tests are conducted and a rapid turnaround time is desirable.

II. SPECIMEN COLLECTION

Serum samples obtained as described above for immunofluorescence are recommended for use with solid-phase immunoassays. The manufacturer also provides for the ability to test anticoagulated whole blood or capillary blood.

III. MATERIALS

The dot blot kits are provided with reagents mandatory for the reactions, including assay antigen strips, reaction cuvettes, sample diluent, enhancer reagent, conjugate reporter reagent, and developer or substrate solution. While the antigen strips are often stable at room temperature, the liquid reagents require refrigeration.

Additional supplies that are needed to conduct these tests include a heat block or water bath capable of maintaining $50 \pm 1^\circ\text{C}$, a reaction vessel capable of holding at least 50 ml of water, a timer, distilled or deionized water, pipettes, absorbent towels or paper, and control sera.

ANALYTICAL CONSIDERATIONS

IV. QUALITY ASSURANCE

Since the dot blot method has an additional step and reagents not used in IFA testing, each test strip integrates internal reagent controls that ensure that all assay reagents, except for antigen, are working properly. A positive and negative control serum should be tested in parallel with each run to ensure reactivity of human serum with the rickettsial antigen. Currently, no proficiency testing program is available from the CAP.

V. PROCEDURE

Specific instructions are provided by the manufacturer with each kit and should be followed precisely.

- A. Sufficient numbers of assay strips are labeled for patient identification.
- B. Serum is diluted by placing 10 μ l of serum or 20 μ l of whole blood into a premeasured quantity of diluent to achieve a 1:200 dilution.
- C. Assay strips are pretwetted for 4 min and then placed sequentially into each of the following for 5 min, and each step is followed by washing and blotting dry.
 1. Warmed diluted serum
 2. Sodium chloride “enhancer” solution
 3. Reporter conjugate
 4. Substrate
- D. Assay strips are allowed to completely dry prior to reading and result interpretation. The manufacturer does not advocate facilitated drying with instruments such as hair dryers, but drying may be enhanced by ambient airflow or gentle fanning.
- E. Reacted strips are evaluated by visual inspection for the presence of colored end product in each control and patient sample spot on the nitrocellulose strips.

Reaction with diminishing antigen quantities correlates with antibody titer determined by IFA testing and is interpreted as nonreactive (no dots), weakly reactive (one or two dots, equivalent to IFA titers of 16 to 128), or reactive (three- or four dots, IFA titers of ≥ 256). Each strip includes internal positive (human immunoglobulin) and negative (phosphate-buffered saline) reagent controls to ensure proper function of the reporter conjugate and substrate reagents, and these must react appropriately prior to interpretation. Because these internal reagent controls do not adequately control for the antigen, a known positive and negative control should be tested with each run. Although solid-phase EIA results correlate well with IFA titers, for demonstration of either seroconversion or a fourfold change in antibody titer, both acute- and convalescent-phase sera should be tested by the same method, preferably at the same time.

POSTANALYTICAL CONSIDERATIONS

VI. INTERPRETATION

Solid-phase EIA has been developed and is available for *Rickettsia rickettsii*, *Rickettsia conorii*, *Rickettsia typhi*, *Coxiella burnetii* (Q fever), and *Orientia tsutsugamushi* (scrub typhus). Additional formats that allow simultaneous screening for antibodies reactive with several infectious agents, including combined tests for spotted fever, scrub typhus, and murine typhus or dengue, typhoid, leptospirosis, scrub typhus, and salmonella are also available. Favorable comparisons with IFA results have been published for the use of *R. typhi* (2) and the *O. tsutsugamushi* dot blot EIA (3), and anecdotal reports suggest that the *R. rickettsii* assay may also be useful for confirmation of infections with spotted fever group rickettsiae (1). Although no specific criteria for interpretation of solid-phase EIA results are currently recom-

VI. INTERPRETATION*(continued)*

mended by the CDC, good qualitative correlation with IFA testing for antibodies to *R. typhi* exists when performed as a single serum test or when considering a seroconversion as a change from nonreactive to reactive. Thus, a single serum sample reactive by dot blot EIA provides probable evidence of infection in a patient with clinical and epidemiologic histories consistent with suspected rickettsial infection.

Dot blot was compared with IFA testing in only one literature report and only for *R. typhi* (2). Using convalescent-phase sera, sensitivity and specificity compared to immunoglobulin G (IgG) IFA testing where the cutoff titer was 128 were 91.8 and 87.7%, and titers were well correlated overall ($r = 0.84$) with those obtained by IgG IFA testing. Thus, for a 50% pretest probability of infection, the positive predictive value is 88%, and for a 20% pretest probability of infection, the predictive value of a negative test is 81%. Similar predictive values are obtained even if a titer cutoff of 64 is used.

PREANALYTICAL CONSIDERATIONS**I. PRINCIPLE**

Detection of antibodies to *Rickettsia rickettsii* and *Rickettsia typhi* has been accomplished using a rapid and relatively sensitive latex agglutination (LA) method (2, 3). For LA, particles are coated with an extract of purified, cell-free rickettsiae called erythrocyte-sensitizing substance (ESS) that is in part composed of serogroup-reactive lipopolysaccharides (4). This reagent has been prepared only from *Rickettsia* spp.; thus, LA is not available for either *Ehrlichia* or *Anaplasma* spp. Currently, LA reagents are commercially available only for *R. rickettsii*. The coated latex beads are mixed with dilutions of serum. If specific rickettsial antibodies are

present, agglutination of the beads occurs and may be observed macroscopically. Because agglutination of coated latex beads follows the principles of serologic agglutination reactions, it detects immunoglobulin M (IgM) antibodies better than IgG antibodies, is more sensitive as a diagnostic tool early after infection than as a seroepidemiologic tool, and may be prone to prozone reactions.

Unlike the situation for IFA and dot blot assays that sensitively detect both IgG and IgM, comparison of acute- and convalescent-phase sera may not yield an appropriate result, especially if there is a

long interval between sample collections or the convalescent-phase sample is obtained after 45 days. Although sera may be diluted to determine LA titers, as IgM antibodies diminish in convalescence, so will the detected LA titer. Thus, LA is most useful as a screening tool during the early phases of infection, or when early-acute-phase and early-convalescent-phase (7 to 21 days postonset) sera are obtained. The latest case definition for laboratory confirmation of Rocky Mountain spotted fever (RMSF) by LA requires either a fourfold rise in antibody titer or a single LA titer of ≥ 128 (1).

II. SPECIMEN COLLECTION

Serum samples to be tested by LA for *R. rickettsii* are obtained as outlined for IFA testing. Samples should be obtained preferably at the time of acute illness and 14 to 21 days after onset. Some may elect to obtain an intermediate sample 7 to 10 days postonset to help establish an earlier confirmation of infection. Samples should be tested immediately or frozen until used. It is a good practice to test acute- and convalescent-phase samples simultaneously for the most accurate comparison of antibody titers.

III. MATERIALS

The *R. rickettsii* LA kit is provided with reagents required for the reactions, including ESS antigen-coated latex beads, diluting buffer, control sera, black rotation slides, and stirring sticks; control sera may be provided with the kit or purchased separately. Antigen-coated latex beads should

be refrigerated. Additionally required are a rotating platform with a humidified cover, such as the type used for rapid plasma reagin testing, and a 56°C heat block or water bath for complement inactivation.

ANALYTICAL CONSIDERATIONS**IV. QUALITY ASSURANCE**

Each LA test should include a positive and negative control, and the titer of the positive control should be confirmed for each test kit lot. A result ± 1 dilution is acceptable for positive control titer. The antigen-coated latex beads should not be used if aggregation exists prior to mixing with test or control sera or if the reagents are contaminated. Currently, no proficiency testing program is available from the CAP.

V. PROCEDURE

Specific instructions are provided by the manufacturer with each kit and should be followed precisely.

- A. The positive control, negative control serum, and patient sera are diluted 1:16, and all sera are heat inactivated (56°C for 30 min).
- B. Forty microliters of diluted serum is placed onto one corner of a well on the mixing slide and 20 μ l of well-mixed antigen-coated latex beads is placed diagonally in the same well.
- C. The serum and latex beads are mixed with a wooden stick.
- D. The slide is covered to prevent evaporation and rotated for 6 min at 100 to 120 rpm.
- E. After an additional 5 min without rotation, slides are read under a fluorescent lamp or other appropriate illumination.
- F. Agglutination is examined by gently tilting the slide to ascertain the degree of clumping or aggregation, which is recorded as follows.
 1. Negative (no aggregation of latex beads)
 2. Weakly reactive (fine aggregation of latex beads)
 3. Reactive (definite aggregation of latex beads)
- G. All reactive samples are titrated by serial twofold dilutions and each dilution is retested.

The reciprocal of the final dilution with definite agglutination establishes the titer of the sample. A fourfold increase in titer between acute- and convalescent-phase sera from a patient confirms the diagnosis of RMSF in a patient with consistent clinical and epidemiologic findings. Likewise, for a patient with a consistent clinical illness, a single serum with a titer of ≥ 128 provides evidence for probable RMSF. Although LA results correlate well with IFA titers, for demonstration of either seroconversion or a fourfold change in antibody titer, acute- and convalescent-phase sera should be tested by the same method.

POSTANALYTICAL CONSIDERATIONS**VI. INTERPRETATION**

LA has been developed for *R. rickettsii*, *Rickettsia conorii*, and *R. typhi* but is available only for *R. rickettsii*. Favorable comparisons with IFA results have been published for *R. rickettsii* LA (2, 3). Sensitivity and specificity compared to IFA were ≥ 79 and $\geq 96\%$. In a multicenter evaluation study that examined 2,250 sera from areas of endemicity, LA had a positive predictive value of 77 to 94% and a negative predictive value of 96 to 97%.

Immunoassay Detection of Shiga Toxin-Producing *Escherichia coli*

Shiga toxin-producing *Escherichia coli* (STEC) organisms are responsible for a broad range of gastrointestinal illnesses, from mild watery diarrhea to severe hemorrhagic colitis associated with hemolytic-uremic syndrome (HUS) (2, 12, 18). These organisms cause disease primarily through elaboration of one or more Shiga toxins (Stx 1, Stx 2, Stx 2c, Stx 2e) encoded by genes carried on lambda bacteriophages (17). Research supports the fact that hemorrhagic colitis and HUS likely result from the action of these toxins on vascular endothelium (17). Other virulence factors important for pathogenesis include an adhesin, intimin, encoded by an *eae* gene, and enterohemorrhagic *E. coli* (EHEC) hemolysin (*hly* gene), a potent cytolysin (17).

E. coli O157:H7 is the major serotype associated with illness in North America. In the United States, the incidence of *E. coli* O157:H7 is approximately 2.1 to 2.9/100,000 population (5). This is likely an underestimate, since many laboratories do not routinely include selective media for this pathogen in routine stool cultures. O157:H7 is more prevalent in certain geographic areas, such as the western and midwestern United States. In the 1980s, outbreaks of O157:H7 were associated primarily with fast-food restaurants and

undercooked hamburger meat (12, 18). Since then, cases have been more often sporadic. A variety of other food and water sources have been reported as vehicles. Person-to-person spread and contact with animals have emerged as important methods of spread (12, 18). Children and the elderly are the individuals most at risk for development of hemorrhagic colitis and HUS (2, 12, 18).

Over 100 non-O157 serotypes of *E. coli* produce one or both Shiga toxins, and over 50 serotypes have been associated with hemorrhagic colitis or HUS (12). In Europe and Australia, non-O157 serotypes predominate, especially O111:H⁻, O26, and O103:H5, among others (12). Small outbreaks of non-O157 serotypes have been reported in the United States. However, non-O157 serotypes are not systematically and routinely looked for in U.S. laboratories. Those laboratories that have surveyed for them routinely have found that non-O157 STEC may cause disease equal in severity to illness caused by O157 (8, 11, 19).

E. coli O157:H7 can be detected on routine stool screening using sorbitol MAC (SMAC) or other selective media that readily take advantage of the phenotypic differences between O157 (non-sorbitol fermenting) and other *E. coli*

serotypes which are sorbitol fermenting. However, non-O157 STEC organisms that cause disease cannot be readily detected using SMAC (8, 11, 16, 19).

There are several methods available to laboratories for toxin detection. These include cell culture techniques, commercial EIAs, passive latex agglutination methods, and amplification technologies (17). Commercial kits can be used to detect toxins directly in the stool samples, in broth-enhanced stool cultures, and from colony sweeps of confirmed *E. coli* organisms growing on agar media (1, 4, 10, 16).

The advantage of using a method that detects toxins responsible for disease is that theoretically all serotypes associated with hemorrhagic colitis and HUS could readily be detected. Such methods are also rapid, allowing a prompt distinction between STEC diarrhea and diarrhea attributable to other infectious etiologies and noninfectious syndromes. The disadvantage of this procedure when used alone is that an organism is not available for serotyping and additional epidemiologic studies, such as tracing the source of outbreaks. Another issue for laboratories is cost. Commercial kits for the detection of toxins are severalfold more expensive than culture-based screening.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Commercial immunoassays for the detection of Stx 1 and Stx 2 consist of two major methods: (i) EIAs and (ii) latex agglutination. The classic EIAs are performed in a standard microplate format. Available kits use either monoclonal or affinity-purified polyclonal anti-Shiga toxin capture antibodies bound to microwells to bind, or

capture, the toxin present in stool specimens or culture systems. After incubation at room temperature, unbound material is washed from the microtiter wells. A secondary enzyme-conjugated antibody is added, followed by incubation at room temperature and washing to remove unbound conjugate. Substrate for the enzyme

I. PRINCIPLE *(continued)*

is added. If toxin is present a colorimeter reaction ensues as the antibody-enzyme complex converts the substrate to a reaction product. The color development can be detected visually or spectrophotometrically (1, 15, 17).

Reversed passive latex agglutination uses latex particles sensitized with antibodies against Stx 1 and 2. Test samples

are mixed with polymyxin B to enhance toxin release and then added to the latex particles. These particles agglutinate and settle diffusely over the base of a microtiter plate well when mixed with specimens containing toxin. If no toxins are present, the latex particles will settle to form a tight button (10, 17).

II. SPECIMEN TYPES, COLLECTION, AND TRANSPORT

Patients should be instructed to excrete directly into a clean, dry container and not to take a specimen from the toilet water. The specimen should be free of urine. Stool specimens should be transported to the laboratory as quickly as possible at 2 to 8°C (refrigerator temperatures). Diarrheal stool specimens are preferable to rectal swabs. The latter, if collected, should have visible fecal matter and should be placed immediately into transport media. Specimens that will also be cultured for enteric pathogens should be placed in Cary-Blair or other enteric transport media if transport time exceeds 2 h.

Testing can be performed directly on stool samples, on broth samples after overnight incubation, and on culture plates after incubation for 16 to 24 h at 37°C. For EIAs, stool samples may be stored at 2 to 8°C for up to 7 days. If testing is not to be performed within that time frame, samples should be frozen at –20 to –70°C. Repeated freeze-thawing of samples should be avoided because this leads to degradation of toxin.

III. MATERIALS

Commercial monoclonal and polyclonal reagents used in the immunoassays typically come packaged as kits. All reagents necessary for test performance are included. Examples of additional reagents supplied include positive and negative control materials, specimen diluent, wash buffers, color substrates, and stop solution.

Often there are additional supplies required but not provided by the manufacturers. These include, but are not limited to, wooden applicator sticks, pipettes, tubes needed for dilutions, deionized water, squirt bottle, graduated cylinder, and an EIA reader capable of reading absorbance at 450 or 630 nm.

ANALYTICAL CONSIDERATIONS**IV. QUALITY ASSURANCE**

Include QC information on reagent container and in QC records.

At the time of testing, all reagents should be examined for leakage, contamination, and stability. Reagents from different lot numbers should not be mixed or interchanged. Each time an immunoassay is performed, a positive and negative control should be included. Commercial kits contain a set of QC reagents, and each manufacturer defines specific limits for the positive and negative control values. Ideally, previously positive and negative patient specimens should be included as controls, if not with every run then certainly when changing to a new lot of reagents and when training new personnel.

When reading the EIA results visually, it is particularly important to adhere to the manufacturer's guidelines. In the case of colorimetric reactions, an intense color is required for a definitive positive result. A pale color should be considered indeterminate and the assay should then be repeated or, alternatively, the sample can be read using a spectrophotometer. Similarly, when using a spectrophotometer a result should be within the optical density (OD) cutoffs for positivity or negativity. Any indeterminate assay should be repeated. In general, if a laboratory is experiencing a significant number of indeterminates or low positives (~5% of specimen results), the most common reason is insufficient washing of the microwells. As

IV. QUALITY ASSURANCE

(continued)

mentioned above, automated plate washers should be avoided, as sufficient washing cannot be achieved (personal observations).

For interpretation of the latex agglutination results, the agglutination reaction in the control latex wells is compared to that in the sensitized latex wells. Specimens with indeterminate results should be retested, preferably by a different toxin method.

With both EIA and latex agglutination methods, direct stool testing leads to more frequent observations of nonspecific results possibly related to interfering substances. Specificity is enhanced when testing is performed on broth cultures or colonies picked from culture plates.

Since non-*E. coli* pathogens, such as *Enterobacter* and *Shigella dysenteriae*, may also produce verocytotoxins, it is suggested that attempts be made to confirm the source of toxin as one of the serotypes of *E. coli* associated with disease. This may require simultaneous culture with identification of the enterics as *E. coli* and subsequent testing of isolates for toxin production. Alternatively, sending positive stool samples or toxin-positive enrichment broths to a public health or reference laboratory for confirmation is an option.

V. PROCEDURES

It is imperative that these cultures be handled in a biosafety hood.

Instructions on test performance are provided with each Food and Drug Administration (FDA)-cleared kit. All commercially available assays have procedures for direct stool testing, broth culture, and plate culture methods. A brief overview of EIA and latex agglutination methods follows (1, 10, 15).

A. Specimen preparation for EIA methods

1. Direct stool testing
 - a. The stool sample should be mixed thoroughly prior to pipetting.
 - b. For liquid samples, a defined aliquot is added to the manufacturer's specimen diluent using a scored transfer pipette. The volume of stool and the amount of specimen diluent are specified by each manufacturer.
 - c. For solid specimens (nonpipettable) a 3- to 4-mm-diameter portion (pellet sized) is added to specimen diluent and then emulsified using a wooden applicator stick. Samples added to the specimen diluent should be mixed using a vortex.
 - d. Patient samples transported in Cary-Blair medium can be added directly to the microplate without further dilution.
2. Broth methods
 - a. The broth-enhanced method requires fresh stool or stool in Cary-Blair medium to be added to 5 ml of MacConkey broth, TSB, modified TSB, GN broth, or E-Z Coli broth (Difco Laboratories, Detroit, Mich.).
 - b. The sample is incubated overnight at 37°C.
 - c. A defined volume of broth growth is then added to specimen diluent prior to EIA testing.
3. Culture plate methods

After the stool sample has been plated to MAC or a SMAC plate and incubated for 16 to 24 h at 37°C, a colony sweep of a pure subculture or individual colonies can be removed with a loop and placed in the specimen diluent for EIA testing.

B. Addition of specimen to microtiter plates

1. All reagents and microtiter wells should be allowed to reach room temperature (20 to 25°C). Reagents should be thoroughly mixed.
2. The required number of microwells, enough for each patient and the positive and negative control, should be removed from the pouch.

Observe standard precautions.

V. PROCEDURES (continued)

Observe standard precautions.

Observe standard precautions.

Observe standard precautions.

Observe standard precautions.

Observe standard precautions.

3. Add negative control to a test well and a positive control to a second well.
4. Using a transfer pipette, add a measured amount of dilute specimen or undiluted stool in Cary-Blair medium to each well. Care should be taken not to splash into adjacent wells. This can be accomplished by inserting the pipette tip no more than halfway into the well and allowing the sample to slowly run down into the well.
5. Seal or cover the microwells and incubate at room temperature for 1 h.

C. Washing unbound material

1. After incubation, the contents of the wells should be aspirated or shaken out into a biohazard container.
2. Each well is washed with a buffered solution using a squirt bottle. After the wells are filled with buffer, they are aspirated or inverted, and then the plates are forcefully tapped on clean paper towels. This process is critical and should be repeated three or four times as suggested by the manufacturer. The use of an automated plate washer is not recommended (personal observations).

D. Addition of detection antibody-enzyme conjugate

1. Depending upon which manufacturer's kit is used, the addition of detection antibody (usually a few drops) as specified by the manufacturer, followed by enzyme conjugate or enzyme conjugate alone, occurs at this step.
2. The microwells are incubated at room temperature (22 to 27°C) for 30 min and then washed as in step V.C.2 above.

E. Addition of color substrate

Two free-falling drops of color substrate are added, followed by a short incubation period at room temperature.

F. Addition of stop solution

1. One or two drops of stop solution are added to each well.
2. The microwells should be read for the colorimetric reaction either visually or spectrophotometrically within 10 to 30 min after the addition of the stop solution, depending upon the manufacturer.

G. Latex agglutination (10)

1. Specimen preparation

Direct stool testing is currently not recommended by the manufacturer.

 - a. Colony sweep testing
 - (1) After overnight culture of the stool sample on SMAC, a volume of cells equal to a large paper matchstick head is placed into a microcentrifuge tube which contains 0.1 ml of the polymyxin B solution.
 - (2) The sample is incubated at 37°C (35 to 39°C) for 30 min. without shaking.
 - (3) A total of 0.1 ml of 25% kaolin suspension in phosphate-buffered saline is added, and the solution is mixed again and centrifuged at 12,000 rpm for 10 min. The supernatant is used for testing.
 - b. BHI agar enrichment method
 - (1) An aliquot of stool is inoculated onto SMAC or other selective media and incubated overnight at 37°C.
 - (2) Bacterial cells from a dense area of colonies are picked up with a sterilized cotton swab and are inoculated onto a BHI agar plate. The entire plate is inoculated.
 - (3) The plate is incubated at 37°C for 6 h.
 - (4) A volume of growth equivalent to a paper matchstick head is suspended in 0.1 ml of polymyxin solution.
 - (5) The suspension is incubated at 37°C for 30 min, with intermittent shaking (every 5 to 10 min). This ensures optimal extraction of verotoxins.
 - (6) A total of 0.1 ml of kaolin suspension is added.

V. PROCEDURES (*continued*)

- (7) The suspension is mixed briefly and centrifuged at 12,000 rpm for 10 min.
- (8) The supernatant is used for the test specimen.
- c. Stationary culture from BHI agar**
 - (1) A test isolate of *E. coli* is inoculated onto BHI agar and incubated for 16 to 20 h at 37°C.
 - (2) A volume of cells equivalent to three paper matchstick heads is suspended in 0.5 ml of polymyxin solution using a microbiological loop or cotton swab.
 - (3) The suspension is incubated at 37°C for 30 min, with intermittent shaking (every 5 to 10 min). This ensures optimal extraction of verotoxins.
 - (4) The suspension is centrifuged at 12,000 rpm for 10 min.
 - (5) The supernatant is used for the test specimen.
- d. Shaking broth method**
 - (1) An *E. coli* test isolate is inoculated into 5 ml of Casamino Acid yeast extract broth in a test tube.
 - (2) The broth is incubated aerobically, with shaking (120 to 150 strokes/min), at 37°C for 16 to 20 h.
 - (3) The broth is then centrifuged at $900 \times g$ for 15 to 20 min.
 - (4) The supernatant is used for the test specimen.
- 2. Reversed passive latex agglutination (10)**
 - a.** The microtiter plate is arranged so that each specimen is allotted two wells, one for testing with the sensitized latex reagent and the other for testing with the control latex reagent. The positive control and the reagent control (negative control) are allotted to two and one well each, respectively.
 - b.** A total of 25 μ l of the supernatant (test specimen, *see* above) is added to each of the two allotted wells.
 - c.** A total of 25 μ l of sensitized latex is added to the first well and 25 μ l of the control latex is added to the second well for each specimen to be tested.
 - d.** For the positive control, 25 μ l is added to two wells and 25 μ l each of sensitized and the control latex is added to the respective wells. For the negative reagent control, 25 μ l of diluent and 25 μ l of sensitized latex are added to the allotted well.
 - e.** The plates are mixed well using a plate mixer or by carefully tapping by hand.
 - f.** The plates are sealed with a lid and then incubated for 16 h at room temperature.
 - g.** Agglutination patterns are observed by placing the plate over a black surface.

POSTANALYTICAL CONSIDERATIONS**VI. INTERPRETATION**

Before reading patient specimen results, the positive and negative control wells should be examined. Any color in the negative control well with the EIA method constitutes an invalid result and the entire run should be repeated. For reversed passive latex agglutinations if agglutination in the negative control well is seen, this constitutes an invalid result and the kit should not be used.

A. EIA methods (1, 15)

As indicated above, results for an EIA can be read either visually or spectrophotometrically. It is imperative that the manufacturer's guidelines be followed

VI. INTERPRETATION (continued)

implicitly. A negative result is colorless and will yield a low OD reading. A definitive positive is characterized by a strong (usually yellow) color. A positive will demonstrate an OD reading usually well above the cutoff. Some manufacturers have created an “indeterminate” value or range. Results that fall into this category typically have a pale or faint color or an OD reading that falls somewhere between the positive and negative cutoffs. Sample with indeterminate results should be retested (*see* item IV above). A positive result indicates the presence of Stx 1 or Stx 2.

Currently there are two FDA-cleared EIA kits available, the Premier EHEC kit (Meridian Diagnostics, Inc., Cincinnati, Ohio) and the ProSpecT STEC microplate assay (Alexon-Trend, Inc., Ramsey, Minn.) (Table 11.8–1). Only the Premier EHEC assay has been extensively reviewed in the literature (11, 13, 14, 16). Published reports indicate sensitivity in the range of 82 to 100% and specificity in the range of 99 to 100% depending upon the comparative methods and whether O157:H7 alone or all STEC organisms are considered (11, 13, 14, 16). These reported sensitivities are significantly better than SMAC culture results reported in the same studies (50 to 60%), even when only O157:H7 detection is considered (9, 11, 13, 14, 16). Both commercial assays have better sensitivity and specificity when testing is performed on broth-enhanced cultures as opposed to direct stool samples (1, 15).

Clearly, the major advantage of these assays is improved detection of non-O157 serotypes. On the other hand, there have been problems with false-positive results leading to unnecessary public health concerns (6). The Council of State

Table 11.8–1 Commercial EIA reagents

Assay and manufacturer	Method	Notes	FDA cleared?
Premier EHEC; Meridian Diagnostics, Inc., Cincinnati, Ohio	Microwell EIA	Monoclonal capture antibody; polyclonal rabbit antibodies specific for Stx; goat anti-rabbit antibody conjugated to horseradish peroxidase	Yes; approved for direct stool testing and broth and plate cultures
ProSpecT STEC microplate assay; Alexon Trend, Inc., Ramsey, Minn.	Microplate EIA	Rabbit polyclonal anti-Stx 1 and 2 capture antibodies; monoclonal mouse anti-Stx 1 and 2 antibody conjugated to horseradish peroxidase for detection	Yes; approved for direct stool testing and broth cultures
VTEC-Screen (II) Seiken; Denka Seiken Co., Ltd., Tokyo, Japan	Reversed passive latex agglutination	Polymyxin B and kaolin are added to stool samples to increase toxin release and to enhance specificity, respectively. Latex particles are sensitized with Stx 1 and 2 rabbit polyclonal antibodies.	No; multicenter trials are in progress in the United States

VI. INTERPRETATION (continued)

and Territorial Epidemiologists adopted a position paper (9) calling for culture confirmation of positive results from immunoassays (9).

B. Reversed passive latex agglutination

A commercial non-FDA-cleared kit, the VTEC-Screen (II) Seiken (Denka Seiken Co. Ltd, Tokyo, Japan) detects the presence of Stx 1 and Stx 2. The agglutination reactions in the control latex wells are compared to those in the sensitized latex wells.

Preliminary studies (3, 4, 7) indicate a sensitivity slightly less than that of the traditional verocytotoxin assay. One study on 239 strains representing 50 human and animal serotypes noted a clinical sensitivity of 100% and a specificity of 97% compared to the verocytotoxin assay and PCR methods to detect toxin genes (3). This product is currently undergoing clinical trials in the United States.

In 1983, Marshall and Warren proposed the possible association of *Helicobacter pylori* with peptic ulcer disease and gastric cancer (17). In February 1994, the NIH Consensus Development Conference concluded that *H. pylori* infection is the major cause of peptic ulcer disease and that all patients with documented peptic ulcer disease associated with *H. pylori* infection should receive antimicrobial therapy (20).

The prevalence of peptic ulcer disease exceeds 6.5 million cases in the United States, approximating a rate of 2.5%, or 2,500 cases per 100,000 individuals (23). In developed countries, the overall prevalence of *H. pylori* infection ranges from 25 to 30% (5). Seroprevalence increases with age, ranging from 5 to 27% in early childhood to levels exceeding 50% in adults greater than 50 years of age (2, 12, 15, 17, 22). Seroprevalence studies demonstrate an acquisition rate in adults of 3 to 4% per decade. *H. pylori* infection is a likely contributing factor in the development of gastric neoplastic diseases, such as gastric adenocarcinoma and mucosa-associated lymphoid tissue lymphoma (5). *H. pylori* infection is considered to increase the risk of gastric adenocarcinoma, with pooled odds ratios of 1.9 to 2.5 (6, 15). *H. pylori* and its association with mul-

multiple gastroduodenal diseases have emphasized the importance of accurate and prompt diagnosis of symptomatic individuals.

Multiple methods for assessment of *H. pylori* infection are used in the clinical setting (Table 11.9–1). Invasive methods require biopsy by endoscopy and are recommended for patients with complicated infections who are suspected of having peptic ulcer disease. Serologic testing represents a primary screening method for the diagnosis of *H. pylori* infection in individuals with uncomplicated infections. Infection with *H. pylori* results in a vigorous local and systemic humoral response to multiple antigens (14, 24, 25). In contrast to serum immunoglobulin M (IgM), serum IgA and IgG levels persist for months and years and correlate with active infection in untreated individuals (1, 11, 19, 21).

Only a minority of individuals did not show evidence of systemic seroconversion following infection (21). Anti-*H. pylori* serum IgG levels are more consistently elevated than serum IgA levels. Consequently, serum IgG immunoassays yield superior sensitivities and specificities compared with those of serum IgA assays (16).

Commercial ELISAs detecting anti-*H. pylori* serum IgG are the serologic tests of choice for the primary screening of patients with uncomplicated infections. Assays to detect anti-*H. pylori* IgA in sera have reduced and variable sensitivities (39 to 82%) compared to those of serum IgG immunoassays. Serum IgA studies may be useful in testing of symptomatic individuals with equivocal or negative IgG findings. A key advantage of follow-up serum IgA testing is that the same serum specimen may be used. In one study, greater than 7% of patients with negative serum IgG results were found to have detectable anti-*H. pylori* serum IgA and symptoms consistent with *H. pylori* infection (13). As determined by using the IgA immunoassay from HYCOR Biomedical (Irvine, Calif.), five of six IgA-positive, IgG-negative patients had peptic ulcers by endoscopy. Salivary and urinary antibody assays have shown limited utility. Serum IgA assays lack the requisite sensitivity to serve as primary screening tests but may be useful in cases in which infection is strongly suspected and the serum IgG result is negative or equivocal.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE (SERUM IgA OR IgG ELISA)

ELISAs depend on the adsorption of protein or carbohydrate antigens to plastic surfaces such as polystyrene (solid phase). When antigens bound to the solid phase make contact with a patient's serum, *H. pylori*-specific IgG (or IgA), if present,

will bind to specific antigens on the solid phase, forming antigen-antibody complexes. Excess antibody is removed by washing. Washing is followed by the addition of goat anti-human IgG (or anti-human IgA) conjugated with horseradish

peroxidase which then binds to the *H. pylori* antigen-antibody complexes. Excess conjugate is removed by washing and followed by the addition of the chromogenic substrate tetramethylbenzidine (TMB). If specific IgG (or IgA) antibodies to *H. py-*

lori antigens are present in the patient's serum, TMB is altered and a blue color develops. When the enzymatic reaction is stopped with 1 N sulfuric acid (H₂SO₄), the contents of the wells turn yellow. The

color change is indicative of the presence of anti-*H. pylori* IgG in the patient's serum and can be detected by absorbance spectrophotometry in an ELISA microwell

plate reader. ELISA-based detection of serum anti-*H. pylori* IgG is the preferred approach for antibody screening in assessment of chronic *H. pylori* infection.

II. SPECIMEN COLLECTION

Table 11.9-1 Diagnostic and follow-up testing approaches for assessment of *H. pylori* infection

Testing approach
Diagnostic testing
Noninvasive
IgG serology
IgA serology
Fecal antigen detection
Urea breath testing
Invasive ^a
Histopathology (special stains)
Rapid urease testing
Follow-up testing
Noninvasive
Fecal antigen detection
Urea breath testing

^a Requires biopsy sampling by esophagogastro-duodenal endoscopy.

Optimal detection of anti-*H. pylori* IgG antibodies depends upon the presence of fresh serum samples. Although point-of-care testing (POCT) kits for detection of anti-*H. pylori* IgG and total antibodies in whole blood are available, assay sensitivities are reduced compared to those of serum-based ELISAs (8). Recommended laboratory-based ELISAs include HM-CAP (Enteric Products, Westbury, N.Y.), *H. pylori* IgG ELISA (Wampole Laboratories, Cranbury, N.J.), and Premier IgG ELISA (Meridian Biosciences, Cincinnati, Ohio). A minimum volume of 50 µl is recommended for collection in case repeat testing is required to clarify equivocal findings. Ten microliters of serum is used for testing. Serum specimens should be stored at 2 to 8°C if testing will occur within 48 h of collection. If prolonged storage is required for batch testing, storage at -20°C or lower is recommended to minimize proteolysis of antibodies. Caution must be exercised to avoid hemolyzed, lipemic, or bacterially contaminated sera, as these samples may yield spurious results (e.g., false positive). Sera should not be heat inactivated prior to testing.

In order to facilitate in-office POCT for *H. pylori* infection, rapid serum and whole-blood IgG immunoassays have recently been developed by several manufacturers (e.g., Quickvue *H. pylori* test by Quidel, San Diego, Calif., and Flexsure HP by Beckman Coulter, Palo Alto, Calif.). Whole-blood assays may use small volumes (drops) of capillary blood for POCT. A rapid latex agglutination test format (Pyloriset, Orion Diagnostics, Espoo, Finland) is also available to detect serum anti-*H. pylori* IgG. Such immunoassays produce a qualitative result in 4 to 10 min using heparinized whole-blood or capillary blood specimens. Compared to those of serum EIAs, whole-blood serologic assays have reduced sensitivities (80 to 90% versus >90%), with comparable specificities (70 to 80%) and lower overall accuracy (5). Therefore, negative results must be confirmed by a laboratory-based serum IgG or IgA ELISA, fecal antigen testing, or urea breath testing.

III. MATERIALS

H. pylori antigens (derived from strain ATCC 43504 and others) are commonly used as reagents bound to solid phase for detection of *H. pylori*-specific antibodies. Pooled *H. pylori* antigens of high-molecular-weight surface-associated proteins, acid extracts, or whole-cell lysates (sonicates) are used in most serologic assays. Various cytosolic and cell surface-associated proteins (18) represent immunodominant antigens recognized by serum antibodies of infected individuals (14). Immunodominant antigens include housekeeping enzymes such as ATP synthase Fl, RecA, and heat shock proteins HspA and HspB. Essential colonization factors such as urease subunit UreB and flagellar protein FlaA also comprised a group of

greater than 20 different immunogenic proteins identified in *H. pylori* (14).

Goat anti-human IgG is commonly used for detection of *H. pylori*-specific antibodies in human serum. Goat IgG is conjugated with enzymes such as horseradish peroxidase to facilitate chromogen detection. Chromogenic substrates such as TMB are included for colorimetric detection by absorbance spectrophotometry. A single- or dual-wavelength microplate reader capable of absorbance spectrophotometry at the appropriate wavelength (e.g., 450 nm for TMB) is necessary for quantitative optical density determinations. If dual-wavelength spectrophotometry is performed, the reference filter is fixed at 600 to 650 nm.

ANALYTICAL CONSIDERATIONS

IV. QUALITY ASSURANCE AND QUALITY CONTROL

Blank reagent, positive, and negative controls must be included with each assay. Commercial kits also provide calibrators and controls that should be included with each assay. All of the kits described in this procedure provide serum controls. Calibrators for verifying cutoff values should be provided in commercial serologic kits and are useful for maintaining reproducible assay performance. The reagent blank (usually the serum diluent provided in the kit) should be included with each assay to set the baseline for optical density readings on an ELISA plate reader. When read against an air blank, the absorbance should remain below 0.200 unit at the recommended wavelength. Negative controls (provided in kit) and patient serum negative controls should be included with each assay and yield readings below 0.200 absorbance unit. Positive controls should include low and high positive controls and may include prior reactive patient sera. Dilutions of known positive sera may provide useful low positive controls. Popular *H. pylori* serologic kits, such as the Wampole Laboratories *H. pylori* IgG ELISA kit, recommend verification of immune status ratios and stated ranges for high positive, low positive, and negative controls. Proficiency testing is available by subscribing to the VR3 (serology) survey of the CAP.

V. PROCEDURE (SERUM IgG ELISA)

Serologic testing for assessment of *H. pylori* infection depends upon the detection of serum antibodies (IgA, IgG, or total antibodies) by EIAs. The recommended approach for primary screening in the clinical laboratory is serum IgG detection by ELISA (16). Samples for which the results are negative or equivocal may be retested with serum IgA ELISA.

A. Serum preparation

Dilute the test sera from each individual patient in serum diluent provided by the manufacturer. Typically, 10 μ l of patient or control sera will be diluted in 200 μ l of diluent (1:21 dilution) prior to testing.

B. Primary *H. pylori* antigen-serum antibody binding

1. Add calibrators, controls, and patient sera (dilutions) to individual wells. Serum diluent must be added to reagent blank well for optical density calibration.
2. Incubate each well at room temperature for 20 to 30 min.
3. Wash strips of wells by light agitation or shaking liquid from wells. Alternatively, wells may be aspirated by vacuum-assisted suction using a Pasteur pipette tip at an angle. Repeat procedure a minimum of three times for sufficient removal of nonspecific antigen-antibody interactions.

C. Detection of anti-*H. pylori* antibodies

1. Add conjugate to each well. Conjugate or conjugated antibody usually is goat anti-human IgG linked covalently with horseradish peroxidase as reporter enzyme.
2. Incubate secondary antibodies in each well for 20 to 30 min.
3. Wash strips of wells by light agitation and aspiration as described above. Repeat procedure a minimum of three times for sufficient removal of nonspecific antigen-antibody interactions.
4. Add chromogenic substrate (e.g., TMB) solution to each well and incubate at room temperature for 10 to 15 min.
5. Stop reaction with 1 N H₂SO₄.

V. PROCEDURE (SERUM IgG ELISA) (continued)

- Chromogenic reactions should be read on an ELISA plate reader equipped with an appropriate filter (e.g., for horseradish peroxidase-TMB, 450 nm). If dual-wavelength absorbance spectrophotometry will be performed, the reference filter should be used at 600 to 650 nm.

POSTANALYTICAL CONSIDERATIONS

VI. INTERPRETATION

Commercial EIAs detecting anti-*H. pylori* serum IgG are the tests of choice (16) for primary screening of patients with uncomplicated infections. Patients with mild dyspeptic symptoms or asymptomatic patients at risk may be screened by serologic testing. A positive serology should be confirmed with direct detection of *H. pylori* by fecal antigen testing or urea breath testing to verify the presence of active infection. Patients with severe symptoms or “alarm” features such as weight loss or bleeding should be diagnosed by endoscopy. Serologic results should be interpreted qualitatively as the presence or absence of antibodies. Overall, the medians of the sensitivity and specificity for *H. pylori* serology kits were 92 and 83%, respectively (16). Performance varied significantly among commercial serologic kits, with top performers exceeding 90% in sensitivity and specificity and bottom performers failing to reach 90% in sensitivity or 80% in specificity (16). Anti-*H. pylori* serologic assays from various commercial sources have variable sensitivities (57 to 100%) and specificities (31 to 100%) (16). Importantly, positive (95 to 100%) and negative (84 to 89%) predictive values for serology were comparable to those of histology, rapid urease testing, and urea breath testing (4). ELISA serologic testing had the lowest cost per correct diagnosis, but overall accuracy was reduced compared to that of stool antigen or urea breath testing (25). Patients infected with “*Helicobacter heilmannii*” were usually negative by anti-*H. pylori* IgG assays (9). Serum IgG immunoassays have markedly reduced sensitivities (50 to 60% versus >90%) with samples from human immunodeficiency virus type 1-infected patients (7). Therefore, a negative result in this setting must be confirmed by urea breath testing or gastric biopsy. In addition to qualitative serologic approaches, notable decreases in titer may be obtained within 6 to 12 months of completion of antimicrobial therapy with quantitative serologies (3). However, at least 50% of patients remain seropositive 6 months or longer following successful treatment (3, 10, 21).

11.10

Total Viable Cell Counting Procedure

I. PRINCIPLE

Trypan blue allows rapid observation of nonviable cells present in a peripheral blood mononuclear cell suspension (PBMCS). A count of viable cells present in a PBMCS allows the suspension to be adjusted accordingly for further use in assays.

II. SPECIMEN

A PBMCS in a known volume of cell culture medium

III. MATERIALS

- A. Trypan blue (0.4%; Sigma catalog no. T81540, 100-ml bottle)**
 - 1. Filter as needed.
 - 2. Store at room temperature.
- B. Hemacytometer with appropriate coverslip**
- C. Pipettes**

IV. QUALITY CONTROL

- A.** Perform daily.
- B.** A drop of trypan blue is mixed with a drop of distilled water. The preparation is screened for contamination by bacteria.

V. PROCEDURE

- A.** In a 5-ml test tube, add 90 μ l of the 0.4% trypan blue solution to 10 μ l of the cell suspension.
- B.** Mix cells and trypan blue and let stand for 1 to 3 min.
- C.** Make sure hemacytometer is clean; place appropriate clean coverslip on empty unit.
- D.** Load one chamber of the double-sided hemacytometer with 10 to 12 μ l of cell-trypan blue mixture. Avoid air bubbles.
- E.** Allow cells to settle; let stand for at least 1 min.

VI. READING AND REPORTING RESULTS

- A. Screen chamber under low power.
- B. Use 40× high-power magnification to count cells.
- C. The blue-tinged cells are counted as dead, nonviable cells. The translucent cells are counted as live, viable cells.
- D. Count all the cells present inside the large four corner squares of the hemacytometer. Record as viable or nonviable.
- E. Calculate percentages of viable and nonviable cells.
- F. Report total viable cell count.

VII. CALCULATIONS
A. Total viable cell count

$$\left(\frac{\text{Total no. of cells in 4 large squares}}{4 \text{ [number of squares counted]}} \right) \times 10^4 \times \text{volume of cell suspension} \\ \times \text{dilution factor}$$

B. Dilution factor

$$\frac{90 \mu\text{l of trypan blue} + 10 \mu\text{l of cells}}{10 \mu\text{l of cells}} = 10 \text{ (dilution factor)}$$

SUPPLEMENTAL READING

Kruse, P. F., and M. K. Patterson. 1973. *Tissue Culture—Methods and Applications*, p. 406. Academic Press, New York, N.Y.

11.11

Peripheral Blood Mononuclear Cell Cryopreservation Method

I. PRINCIPLE

To be able to cryopreserve peripheral blood mononuclear cells (PBMCs) for utilization in future testing

II. SPECIMEN

Blood collected in heparin or acid citrate dextrose

III. MATERIALS AND REAGENTS

- A. Fetal calf serum (heat inactivated at 56°C for 30 min)
- B. RPMI 1640 medium
- C. Ficoll-Hypaque
- D. Dimethyl sulfoxide (DMSO) (catalog no. 27,043-1; Aldrich, Milwaukee, Wis.)

DMSO must be fresh. Once the bottle is opened, the shelf life of DMSO should not exceed 6 months.
- E. Cryogenic vials (cryovials): 2-ml polyethylene vial with screw cap (catalog no. 03-341-20; Fisher Scientific)
 - ☑ **NOTE:** Polypropylene cryovials are not recommended for storage in liquid nitrogen unless sealed in Cryoflex tubing (catalog no. 12-565-177; Fisher) using a heat sealer (catalog no. 01-812-15; Fisher).
- F. Nalgene “Mr. Frosty” (catalog no. 288-383; Curtis Matheson Scientific, Houston, Tex.)
- G. Optional: cryotube holder that stabilizes tubes on ice (Corning workstation from Fisher Scientific; catalog no. 03-374-37A)
- H. Plasticware, pipettes
- I. Sterile phosphate-buffered saline, Ca²⁺ and Mg²⁺ free
Use for washing cells.

IV. PROCEDURE

- A. Label cryovials and chill at -20°C for 30 min.
- B. Prepare freezing solution (90% fetal calf serum plus 10% DMSO); chill on ice.
- C. Prepare PBMCs by Ficoll-Hypaque density centrifugation; wash twice at 4°C. Adjust cells, and wash again at 4°C. (After Ficoll separation, keep cells chilled or on ice at all times.)
- D. Resuspend cells in freezing solution at 10⁷ cells/ml; aliquot 0.5 to 1.0 ml of the cell suspension per cryovial. Be sure cryovial caps are securely tightened.
- E. Immediately place cryovials in “Mr. Frosty” and transfer to a -70°C freezer. Alternatively, place cryovials in a Cryomed freezing chamber, lowering the temperature at -1°C per minute to -70°C.
- F. Transfer cryovials to liquid nitrogen within 24 h.

V. THAWING PROCEDURE

- A.** Transfer cryovial from liquid nitrogen to a 37°C water bath. If liquid nitrogen has seeped into the cryovial, loosen the cap slightly to allow the nitrogen to escape during thawing.
- *Some cryovials have been reported to explode during the thawing process. To minimize this risk, use only unbreakable polyethylene vials for storage in liquid nitrogen (see item III above). If polypropylene tubes are used, they should be sealed in Cryoflex tubing.*
- B.** Hold the cryovial in the surface of the water bath with an occasional gentle flick during thawing. Do not leave cryovial unattended during the thawing process. (It is important for cell viability that the cells are thawed and processed quickly.) When a small bit of ice remains in the cryovial, transfer the cryovial to the biosafety hood. Dry off the outside of the cryovials before opening to prevent contamination.
- C.** Add RPMI 1640 plus 10% fetal calf serum dropwise into the cryovial containing the cell suspension, slowly (over 2 min), up to a volume which doubles the original volume (e.g., add 1 ml of medium to a vial containing 1 ml of cell suspension).
- D.** Transfer the cell suspension to a 15-cc conical-bottom centrifuge tube containing 8 ml of RPMI 1640 plus 10% fetal calf serum; wash twice by centrifugation, gently resuspending the cells between washes.
- E.** Determine cell number and viability.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Measuring the proliferative capability of lymphocytes is important in the evaluation of an individual's immune system. This can be achieved in an assay in which lymphocytes are cultured with either a mitogen or antigen that can stimulate a proliferative response and then are labeled with a radioactive marker, to allow for measurement of such a response (1).

The lymphocyte proliferation assay (LPA) exposes lymphocytes to mitogens

such as phytohemagglutinin or pokeweed mitogen (PWM), recall antigens such as *Candida albicans*, tetanus toxoid, and other antigens which may be of specific interest (such as human immunodeficiency virus proteins gp120 and p24). Separated peripheral blood mononuclear cells (PBMCs) are incubated at 37°C for 6 days in a 96-well plate with a mitogen or antigen in triplicate wells. [³H]thymidine is

then added to each well. The isotope is incorporated into the newly synthesized DNA of the proliferating cells, and after a 6-h incubation the cells are harvested. A scintillation counter is used to measure the activity of the tritiated thymidine, expressed as counts per minute. This measurement is directly proportional to the level of lymphocyte proliferation (2).

II. SPECIMEN

Whole blood is collected in an acid citrate dextrose (ACD) or heparin tube. These samples must be processed within 30 h of draw time.

III. REAGENTS AND SUPPLIES

A. Reagents

1. LPA medium (*see* Appendix 11.12-1 for preparation)
2. Ficoll-Paque PLUS
3. 1× Phosphate buffer solution (PBS)
4. Crystal violet (*see* appendix 11.12-1 for preparation)
5. [³H]thymidine, 6.7 Ci/mmol
6. Pooled human AB serum
7. Mitogens (assay dependent)
8. Recall antigens (assay dependent)
9. Specific antigens of interest (assay dependent)

B. Supplies

1. Pipet-Aid
2. 10-ml sterile plastic pipettes
3. 5-ml sterile plastic pipettes
4. 2-ml sterile plastic aspirating pipettes
5. 20-, 100-, and 200- μ l pipettors
6. Pipette tips to deliver 5 to 200 μ l

7. 15-ml sterile plastic centrifuge tubes with conical bottoms
8. 12- by 75-mm sterile plastic culture tubes with closures (snap cap)
9. Glass microfiber filter paper
10. Scintillation fluid (Betafluor)
11. 6-ml glass scintillation vials with caps
12. ³H waste containers (check with your institution regarding what type of waste container for ³H you are to use)
13. Hemacytometer with coverslip

C. Equipment

1. Variable-speed centrifuge
2. Cell harvester
3. Liquid scintillation counter (Packard, model U2200)
4. Biosafety cabinet with vacuum trap system for aspiration
5. Incubator, 37°C, 5% CO₂

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

Include QC information on reagent container and in QC records.

A. Medium

The color of the LPA medium should be orange. If the LPA medium turns a dark pink color, it should be discarded.

B. Calibration

1. Scintillation counter

- a. Normalization of scintillation counter must be done once a week.
- b. High and low standards must be assayed with each run.
- c. Preventive maintenance should be performed twice per year.

2. Pipettors

Pipettors should be calibrated twice per year.

3. Equipment

All laboratory equipment should have preventive maintenance performed according to the manufacturers' instructions.

V. PROCEDURE

☑ **NOTE:** All of the pipetting and filtering should take place in a biosafety cabinet using sterile technique, and all reagents should be at room temperature when used. All radioactive materials must be used in designated areas and must be disposed of properly per the institutions' radiation safety guidelines.

A. PBMC separation

1. Centrifuge ACD or heparin tube for 10 min at $200 \times g$ at room temperature.
2. Gently invert the Ficoll-Paque PLUS bottle twice.
3. Using a pipette, remove the plasma from the ACD or heparin tube and place into a snap-cap tube. This can be aliquoted and frozen, or it can be discarded if desired.
4. Dilute the blood twofold using $1 \times$ PBS. Mix gently by pipetting up and down.
5. Pipette 5 ml of Ficoll-Paque PLUS into a 15-ml conical tube.
6. Carefully layer the blood onto the 5 ml of Ficoll-Paque PLUS. Be sure not to let the diluted blood penetrate the Ficoll-Paque PLUS.
7. Centrifuge the conical tube containing the diluted blood on Ficoll-Paque PLUS at 300 to $400 \times g$ for 30 min at room temperature.
8. After centrifugation, four layers will be visible. Gently aspirate the top clear layer, which contains PBS and any remaining plasma. Be careful not to disturb the cloudy layer underneath, which contains the mononuclear cells.
9. The cloudy mononuclear cell layer is removed next by placing the tip of a pipette over the layer and gently moving the pipette in a circular motion while applying suction with the pipette. The entire layer should be removed and transferred to a 15-ml conical tube containing 5 ml of $1 \times$ PBS. Care should be taken to remove as little as possible of the Ficoll-Paque PLUS layer below the mononuclear cells. Centrifuge the conical tube at $200 \times g$ for 10 min at room temperature.
10. After centrifugation, aspirate the supernatant, making sure not to disturb the cell pellet.
11. Pipette 10 ml of $1 \times$ PBS into the conical tube containing the pellet. Using the pipette, thoroughly mix to resuspend the pellet.
12. Centrifuge the conical tube at $200 \times g$ for 10 min at room temperature.
13. After centrifugation, aspirate the supernatant without disturbing the pellet.
14. Pipette 1 ml of LPA medium into the conical tube containing the pellet. Using the pipette, thoroughly mix to resuspend the pellet.

V. PROCEDURE (*continued*)

15. Count the number of PBMCs using the total viable cell counting procedure (procedure 11.10). This procedure uses trypan blue dye to determine the viability and number of PBMCs. To better distinguish mononuclear cells, it is recommended to perform the cell count using crystal violet.
16. Adjust the concentration of the cells to 10^6 /ml with LPA medium. The total number of cells needed for a plate can be found by multiplying the number of wells by 100,000. A minimum of 600,000 is usually required, which allows you to do one control triplicate and one mitogen triplicate.

B. Plate preparation

1. LPA plates can be made in advance and stored at -70°C in Ziploc plastic bags until they are needed. LPA plates consist of triplicate wells containing either 100 μl of a medium control (background) or 100 μl of an antigen or mitogen prepared at $2\times$ in medium. The medium used is LPA medium plus 20% pooled human AB serum to yield a final concentration of 10% pooled human AB serum after the PBMCs are added. Some commonly used final concentrations are 2.5 and 1.25 $\mu\text{g}/\text{ml}$ for tetanus toxoid, 50 and 10 $\mu\text{g}/\text{ml}$ for *C. albicans*, and 10 $\mu\text{g}/\text{ml}$ for PWM. Titration may be required to determine the optimal concentrations for particular stimulants.
2. Retrieve the appropriate premade LPA plate from the freezer. After removing the plastic bag, put the plate in the incubator to defrost.
3. Once the plate is fully defrosted, label it appropriately with patient information, study information, and the date.
4. Mix PBMCs well and add 100 μl of the PBMC suspension to each well of the plate that contains a stimulant, changing tips every triplicate. Also add 100 μl in triplicate to the medium control wells. This effectively adds 10^5 cells/well.
5. Tap plate gently to mix.
6. Place the plate in the incubator for 6 days.
7. On the sixth day, add 1 μCi of [^3H]thymidine (which is purchased at a concentration of 1 mCi/ml) per well.
8. Tap plate gently to mix.
9. Return the plate to the incubator for 6 h.
10. After 6 h, harvest the plate using a cell harvester.
11. Leave the filters to dry overnight. The following day, put the filters in 6-ml glass scintillation vials and add 2 ml of scintillation fluid such as Betafluor to each of these vials.
12. Count each vial for 1 min using a liquid scintillation counter.

POSTANALYTICAL CONSIDERATIONS**VI. CALCULATIONS****A. To determine net counts (2)**

Net counts = experimental counts per minute – background unstimulated counts per minute

B. To determine stimulation index (SI) (2)

SI = experimental counts per minute/background unstimulated counts per minute

VII. INTERPRETATION

An SI greater than 3 (antigens) to 5 (mitogens) is generally considered to be a significant response to the specific antigenic or mitogenic stimulus.

11.13

Natural Killer Cell Assay

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Natural killer (NK) cells mediate the spontaneous lysis of virus-infected or tumor cells. The functional capability of NK cells can be determined by exposing them to a known NK-specific target that is radioactively labeled. NK cell activity is quantified in this assay by using the K-562 cell line (*see* Appendix 11.13–1), which is

known to be NK sensitive. K-562 target cells are incubated for 1 h with ^{51}Cr . The targets are then incubated with several different serial dilutions of peripheral blood mononuclear cells (PBMCs) (effectors) for 4 h at 37°C in a 96-well plate. The effectors lyse the target cells, releasing ^{51}Cr into the medium. At the end of the

incubation, the plate is centrifuged and the supernatants are collected. The amount of ^{51}Cr released into these supernatants, which is measured with a gamma counter, can be used to determine the lytic capability of the NK cells at each effector-to-target (E:T) ratio.

II. SPECIMEN

Whole blood is drawn into a heparin (green top) tube; 10 ml is usually sufficient to perform this assay. These samples must be processed within 30 h of draw time.

III. REAGENTS AND SUPPLIES

A. Reagents (*see* Appendix 11.13–1 for preparation)

1. ^{51}Cr (chromium)
2. K-562 cell line
3. RPMI 1640 (stored at 4°C)
4. Filtered R10 (stored at 4°C)
5. Ficoll-Paque PLUS (stored at 4°C)
6. 1% Triton X-100
7. Crystal violet
8. Trypan blue

B. Supplies

1. Sterile pipette tips to deliver 5 to 200 μl
2. 10-ml sterile plastic pipettes
3. 5-ml sterile plastic pipettes
4. 1-ml sterile plastic pipettes
5. 2-ml sterile plastic aspirating pipettes
6. 15-ml sterile plastic conical tubes

7. 12- by 75-mm sterile plastic culture tubes with closures (snap caps)

8. 12- by 75-mm sterile plastic culture tubes without closures

9. Hemacytometer with coverslip

10. Polyethersulfone filter unit, 150 ml (0.2- μm pore size; 50-mm-diameter membrane)

11. 96-well round-bottom plate

C. Equipment

1. 20-, 100-, and 200- μl pipettors
2. Pipet-Aid
3. Vacuum setup in biosafety cabinet
4. Centrifuge
5. Serofuge
6. ^{51}Cr radiation safety waste containers
7. Gamma counter
8. 37°C , 5% CO_2 incubator

IV. CALIBRATION

A. Gamma counter

1. Cesium control should be included with each run.
2. Preventive maintenance should be performed according to the manufacturer's recommendations.

IV. CALIBRATION *(continued)***B. Pipettors**

Pipettors should be calibrated twice per year.

- C.** All laboratory equipment should have preventive maintenance performed according to the manufacturers' instructions.

ANALYTICAL CONSIDERATIONS**V. QUALITY CONTROL**

Include QC information on reagent container and in QC records.

A. Media

1. The color of the R10 and plain RPMI 1640 should be orange. If the R10 or plain RPMI 1640 turns a dark pink color, it should be discarded.
2. When R10 is first made, it should be tested for the presence of contamination by pipetting 2 ml into 5 ml of BHI broth and placed in a 37°C, 5% CO₂ incubator for 5 days.

B. Assay validity

In order for the assay to be considered valid, the spontaneous release must be ≤15% of the maximum release.

VI. PROCEDURE

▣ **NOTE:** All of the pipetting and filtering should take place in a biosafety cabinet using sterile technique, and all reagents should be at room temperature when used. All radioactive materials must be used in designated areas and must be disposed of properly per the institutions' radiation safety guidelines.

A. PBMC preparation

1. Centrifuge the heparin tube for 10 min at $200 \times g$ at room temperature.
2. Gently invert the Ficoll-Paque bottle twice.
3. Pipette 5 ml of Ficoll-Paque into a sterile 15-ml conical tube.
4. Using a 5-ml pipette, remove the plasma from the heparin tube and place into a sterile snap-cap tube. This can be aliquoted and frozen, or it can be discarded if desired.
5. Dilute the blood twofold using RPMI 1640. Mix gently by pipetting up and down.
6. Carefully layer the blood onto the 5 ml of Ficoll-Paque. Be sure not to let the diluted blood penetrate the Ficoll-Paque.
7. Centrifuge the conical tube containing the diluted blood on Ficoll-Paque at 300 to $400 \times g$ for 30 min at room temperature.
8. After centrifugation, four layers will be visible. Using a sterile aspirating pipette connected to the in-house vacuum system, gently aspirate the top clear layer, which contains RPMI 1640 and any remaining plasma. Be careful not to disturb the cloudy layer underneath, which contains the mononuclear cells. If you do not have an in-house vacuum system, then use a 5-ml pipette to remove the top clear layer. Eject fluid into a waste container, such as an empty 15-ml conical tube, and treat as biohazardous waste.
9. The cloudy mononuclear cell layer is removed next by placing the tip of a 5-ml pipette over the layer and gently moving the pipette in a circular motion. The entire layer should be removed and transferred to a sterile 15-ml conical tube containing 5 ml of RPMI 1640. Care should be taken to remove as little as possible of the Ficoll-Paque layer below the mononuclear cells. Centrifuge the conical tube at $200 \times g$ for 10 min at room temperature.
10. After centrifugation, aspirate the supernatant, making sure not to disturb the pellet.
11. Pipette 10 ml of RPMI 1640 into the conical tube. Thoroughly mix to resuspend the pellet.
12. Centrifuge the conical tube at $200 \times g$ for 10 min at room temperature.

VI. PROCEDURE (*continued*)

13. After centrifugation, aspirate the supernatant, making sure not to disturb the pellet.
14. Pipette 1 ml of R10 into the conical tube. Using the pipette, thoroughly mix to resuspend the pellet, being careful not to make bubbles.
15. Count the PBMCs using the total viable cell counting procedure (procedure 11.10). This procedure uses trypan blue dye to determine the viability and number of PBMCs. To better distinguish mononuclear cells, it is recommended that the cell count be performed using crystal violet.
16. If lytic units are to be determined, the NK cells should be enumerated by flow cytometry.
17. Determine the amount of R10 and cell suspension required to have 1 ml of the first E:T ratio. The E:T ratio is how many PBMCs there are for each K-562 cell. Typically, 2.5×10^6 PBMCs/ml are used for the 50:1 E:T ratio, so adjust the number you need for the first desired E:T ratio accordingly. If you have 12.5×10^6 PBMCs, the calculation is as follows: $2.5/12.5 = 0.20$ ml of cell suspension (from step VI.A.14) + 0.80 ml of R10.
18. Label four sterile snap caps for the serial dilutions of PBMCs (effector cells). Commonly used E:T ratios are 50:1, 25:1, 12.5:1, and 6.25:1.
19. Pipette the appropriate amount of R10 calculated in step VI.A.17 into the starting E:T ratio snap cap.
20. Pipette 0.5 ml of R10 into the next three snap caps.
21. Mix the cell suspension thoroughly and pipette the appropriate amount as calculated in step VI.A.17 into the starting E:T ratio snap cap.
22. With a new pipette, mix well, and pipette 0.5 ml from the first snap cap into the second one. Discard pipette.
23. Repeat this procedure until you come to the last snap cap, which will have a final volume of 1 ml after the addition of cells.
24. Label the first 6 wells on the first row of a 96-well plate as "S." These wells are used to identify any spontaneous lysis of the target cells. (This creates two sets of triplicate wells.)
25. Label the next six wells as "M." These wells are used to demonstrate the maximum chromium released by the target cells. (This creates two sets of triplicate wells.)
26. Skip one row and mark off the patient row(s) in triplicate.
27. Pipette 100 μ l of R10 into each of the S wells.
28. Pipette 100 μ l of 1% Triton X-100 into each of the M wells.
29. Pipette 100 μ l of the first E:T ratio into each of the first three wells for that patient.
30. Changing tips between triplicates, pipette the remaining E:T ratios into the appropriate triplicate wells.

B. K-562 preparation

1. Thoroughly mix the contents of the K-562 flask and pipette 2 ml into a sterile snap cap.
2. Count the number of K-562 cells using the total viable cell counting procedure (procedure 11.10). Live K-562 cells appear translucent, while dead K-562 cells appear blue, because of the trypan blue dye.
3. Add or remove K-562 suspension from the original snap cap as needed to obtain 2×10^6 to 3×10^6 K-562 cells to label. This is the recommended number of cells to label with 100 μ l of 1-mCi/ml ^{51}Cr .
4. Serofuge the snap cap at 3,500 rpm for 3 min.
5. Decant the supernatant, making sure not to disturb the pellet.
6. Resuspend the K-562 pellet in 100 μ l of R10.
7. Add 100 μ l of ^{51}Cr to the resuspended K-562 cells. It is recommended that this be timed so that the K-562 cells will be ready close to when the PBMCs will be ready, due to the highly cytotoxic nature of ^{51}Cr .

VI. PROCEDURE (*continued*)

8. Put the snap cap into an empty lead container containing warm water, and place in a 37°C CO₂ incubator for 1 h. The ⁵¹Cr should arrive in a lead container from the manufacturer. After you have either used or disposed of the contents, you will have an empty lead container which you can use for this incubation.
9. Gently shake the snap cap after 30 min to resuspend the K-562 cells.
10. After the incubation, add 2 ml of R10 to the snap cap containing the K-562 cells. Mix well.
11. Spin in a serofuge for 3 min at 3,500 rpm.
12. Decant the supernatant into an appropriate radioactive waste container, making sure not to disturb the pellet.
13. Add 2 ml of R10 to the snap cap. Mix well.
14. Spin in the serofuge for 3 min at 3,500 rpm.
15. Decant the supernatant into an appropriate radioactive waste container.
16. Repeat steps VI.B.13 through 15 two more times.
17. After the suspension is decanted for the fourth time, pipette 1 ml of R10 into the snap cap. Mix thoroughly.
18. Count the K-562 cells using the total viable cell counting procedure (procedure 11.10).
19. An NK assay utilizing one plate requires 5×10^5 K-562 cells in 10 ml. Remove from the snap cap the necessary amount of K-562 cells and dilute to 10 ml with R10 in a sterile 15-ml conical tube to obtain 5×10^4 K-562 cells/ml.
20. Invert the 15-ml conical tube several times to mix it.
21. Pipette 100 μ l of K-562 suspension to each of the S wells, changing tips between triplicates.
22. Pipette 100 μ l of K-562 suspension to each of the M wells, changing tips between triplicates.
23. Pipette 100 μ l of K-562 final suspension to each of the patient E:T ratio wells, changing tips between triplicates.
24. Spin plate in centrifuge for 5 min at $80 \times g$.
25. After centrifugation, incubate plate at 37°C for 4 h.
26. After the incubation, spin plate in centrifuge for 10 min at $300 \times g$.
27. Label one nonsterile 12- by 75-mm plastic culture tube without a closure for each well of the plate containing K-562 cells.
28. Tilt the plate slightly, pipette 100 μ l of supernatant from each well, and eject into appropriate tube. Be careful not to disturb the pellet. Repeat this procedure for all wells, changing tips every triplicate.
29. Load tubes into gamma counter to count for 1 min each.
30. Discard plate and tubes into ⁵¹Cr radioactive waste container after counting.

POSTANALYTICAL CONSIDERATIONS**VII. CALCULATIONS**

The mean of the triplicate counts per minute (cpm) is determined for each E:T ratio and for the spontaneous and maximum release wells. Percent specific target cell lysis is calculated for each E:T ratio as follows:

$$\begin{aligned} \% \text{ Specific lysis} = & \frac{(\text{mean cpm of experimental release} - \text{mean cpm of spontaneous release})}{(\text{mean cpm of maximum release} - \text{mean cpm of spontaneous release})} \\ & \times 100 \end{aligned}$$

VIII. INTERPRETATION

The percent NK cell lysis at each E:T ratio can be used to determine the effectiveness of the subject's NK cells via comparison with the results of a normal control. It should be noted, however, that variation in ^{51}Cr absorption and K-562 percent spontaneous release is to be expected, as the health of the K-562 cell line does have some minor variability.

APPENDIX 11.13–1

A. K-562 cell line

1. According to the *ATCC Catalogue of Cell Lines and Hybridomas* (1), the K-562 cell line was established by Lozzio and Lozzio (2) from the pleural effusion of a 53-year-old female with chronic myelogenous leukemia in terminal blast crises. The K-562 cell line can be purchased from the *ATCC Catalogue of Cell Lines and Hybridomas* as CCL 243.
2. The culture medium is 90% RPMI 1640 and 10% fetal bovine serum and is antimicrobial agent free.
3. The cell line is maintained in T₂₅ flasks. When a concentration of 750,000 to 10⁶/ml is reached, the flask is split 1:10 with culture medium.

B. Reagent information and preparation

1. R10-FBS
 - a. 87% RPMI 1640
 - b. 1% 2 mM L-glutamine
 - c. 1% 100-U/ml penicillin and 100- $\mu\text{g}/\text{ml}$ streptomycin
 - d. 1% 1 mM HEPES buffer
 - e. 10% fetal bovine serum
2. 1% Triton X
 - a. 1% Triton X-100
 - b. 99% 1X phosphate buffer solution
3. Crystal violet
 - a. 98 ml of deionized H₂O
 - b. 2 ml of glacial acetic acid
 - c. 0.05 g of crystal violet dye (powder form)
4. Reagent information
See table on next page.

Quantitation of Human Interleukin 4, Interleukin 6, and Gamma Interferon

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Interleukin 4 (IL-4), IL-6, and gamma interferon (IFN- γ) are cytokines with many cellular effects, including mediation of the immune response to infection. Among other biological activities, IL-4 and IL-6 stimulate B cells and IFN- γ has antiviral activities (6). There is an increasing interest in using cytokine levels to monitor disease progression (2). There are several commercially prepared kits available to

quantify cytokines by ELISA. This procedure is written for use with kits manufactured by Pierce Endogen. If IL-4, IL-6, or IFN- γ is present in the clinical specimen, it will bind to an ELISA plate that is precoated with antibody specific for that cytokine. After the patient specimen is incubated with a biotinylated detection antibody, the plate is washed and then streptavidin conjugated to horseradish per-

oxidase (HRP) is added. After another incubation, tetramethylbenzidine (TMB) substrate is added to the plate. The enzyme-substrate reaction produces a color change that can be measured spectrophotometrically. The unknown values can be determined from a standard curve in which the color intensity is directly proportional to the standard concentration.

II. SPECIMEN

Serum, EDTA plasma, heparin plasma, sodium citrate plasma, and urine are acceptable specimens for cytokine measurement. In addition, *in vitro* cytokine production can be measured in peripheral blood mononuclear cell culture supernatants or whole blood culture supernatants (1, 7). Specimens should be stored at -70°C . If more than one ELISA is to be performed, the specimen or supernatant should be split into an appropriate number of 150- μl aliquots prior to freezing.

III. REAGENTS AND SUPPLIES

A. Reagents

1. Human IL-4, IL-6, or IFN- γ kit (Pierce Endogen, Rockford, Ill.)
2. Distilled water

B. Supplies

1. 5- and 10-ml nonsterile plastic pipettes
2. 20-, 100-, 200-, and 1,000- μl pipettors
3. Multichannel pipettor
4. 2-liter nonsterile flask or bottle to dilute wash buffer
5. Nonsterile pipette tips to deliver 5 to 1,000 μl

6. 12- by 75-mm nonsterile polypropylene tubes

7. Disposable reagent reservoirs

8. 15-ml nonsterile plastic centrifuge tubes with conical bottoms

9. Squirt bottle

10. Empty box to fit a 96-well plate

C. Equipment

1. Vortex

2. ELx800 microplate reader (Bio-Tek Instruments, Inc., Winooski, Vt.)

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A.** All reagents and samples should be brought to room temperature before use. Do not place in a water bath.
- B. Reagents**
1. Do not use any reagent that appears cloudy. This may indicate microbial contamination.
 2. Do not mix reagents from different kits.
 3. Use a new reagent reservoir for each reagent.
 4. When using the multichannel pipettor, use new tips for each row to avoid cross contamination and bubble formation.
 5. TMB substrate solution should be colorless. If it appears blue, discard it.
 6. The standard diluent and biotinylated antibody reagent contain sodium azide as a preservative. If leftover reagent is poured down the drain, it must be flushed with water for several minutes.
- C. Specimens**
If any specimen is cloudy, lipemic, hemolyzed, or otherwise unusual, a note should be made on the plate plan or worksheet and the result should be reported with this notation.
- D. Calibration**
1. **Standard curve**
Each ELISA plate is specific for only one cytokine. This is identified by the kit being used. A curve using the enclosed standard must be run on each plate.
 2. **Medium validation**
 - a. Medium validation must be performed in order to run culture supernatants and patient specimens (serum, etc.) on the same plate.
 - b. A standard curve diluted in culture medium is run in parallel with a standard curve diluted in the Pierce Endogen standard diluent. If the optical density (OD) values of the two curves are within 10% of the mean for each standard point of both curves then the culture medium is validated. For example, the average OD values for a particular point of a standard curve are 0.605 for the medium-diluted curve and 0.685 for the curve diluted in standard diluent. The mean for these OD values would be 0.645. The difference between the mean and the OD values would be 0.040, or 5.8%. This means that culture supernatants can be run on a plate with a curve diluted in standard diluent. If the difference is greater than 10%, culture supernatants must be run on a separate plate with a curve diluted in the culture medium.
 3. **Plate reader**
The plate reader must be calibrated in accordance with the specific manufacturer's instructions.

V. PROCEDURE

It is imperative that these cultures be handled in a biosafety hood.

Plate setup

A plate plan or worksheet should be filled out completely for each plate to be run. This can be a diagram of a 96-well plate or a listing of each well. The standards and specimens to be run should be written in the places where they will be on the plate. The standards should always be run at the beginning of the plate (Fig. 11.14-1). All standards and samples are to be run in duplicate.

- A.** Remove the plate from the foil envelope. If a partial plate is being run, the unused strips should be resealed in the envelope with the desiccant and refrigerated as soon as possible.

Figure 11.14–1 Plate plan for Endogen IL-6 ELISA with 10 samples

	1	2	3	4	5	6	7	8	9	10	11	12
A	Standard 1 400 pg/ml	Standard 5 10.24 pg/ml	Sample 3	Sample 7								
B	Standard 1 400 pg/ml	Standard 5 10.24 pg/ml	Sample 3	Sample 7								
C	Standard 2 160 pg/ml	Standard 6 0 pg/ml	Sample 4	Sample 8								
D	Standard 2 160 pg/ml	Standard 6 0 pg/ml	Sample 4	Sample 8								
E	Standard 3 64 pg/ml	Sample 1	Sample 5	Sample 9								
F	Standard 3 64 pg/ml	Sample 1	Sample 5	Sample 9								
G	Standard 4 25.6 pg/ml	Sample 2	Sample 6	Sample 10								
H	Standard 4 25.6 pg/ml	Sample 2	Sample 6	Sample 10								

V. PROCEDURE (*continued*)

- B.** Add 50 μ l of the biotinylated antibody reagent to each well using a multichannel pipettor. This reagent is slightly foamy, so it will be necessary to use new tips frequently to avoid air bubbles.
- C.** Mix all samples by gently inverting the tubes.
- D.** Make 1:2.5 serial dilutions of the appropriate standard. See Appendix 11.14–1 for details.
- E.** Add 50 μ l of standards or samples to the appropriate wells in duplicate. Check that no air bubbles are in the pipette tip.
- F.** Cover the plate with a new adhesive plate sealer and incubate at room temperature (20 to 25°C) for 2 h.
- G.** At the end of 2 h, wash the plate with wash buffer. See Appendix 11.14–1 for instructions to dilute wash buffer.
1. Empty the plate into the sink and use a squirt bottle to add wash buffer vigorously.
 2. Empty the plate and repeat two more times.
 3. After the third wash, pat the plate on paper towels to absorb all excess liquid.
 4. An automated plate washer can be used for this process.
- H.** Add 100 μ l of streptavidin-HRP solution to each well. See Appendix 11.14–1 for preparation instructions.
- I.** Cover the plate with a new adhesive plate sealer and incubate at room temperature for 30 min.
- J.** After 30 min, wash the plate (*see* steps V.G.1 to V.G.4).
- K.** After washing the plate, add 100 μ l of TMB substrate solution to each well.
 This reagent is extremely sensitive to light. Do not pour into reagent reservoir until immediately before use. Do not pour out more reagent than necessary.
- L.** Allow the plate to develop in the dark at room temperature for 30 min (e.g., place plate in empty box on lab bench). Do not use a plate sealer for this step.
- M.** After 30 min, add 100 μ l of stop reagent to each well.
- N.** Read the plate using an automated plate reader at 450 nm. The plate must be read within 30 min after the addition of the stop reagent.

POSTANALYTICAL CONSIDERATIONS

VI. CALCULATIONS

- A.** The standard curve can be created manually or with curve-fitting software. The cytokine concentration is plotted on the x axis, and the average OD of the standards is plotted along the y axis. The average OD of each specimen is used to interpolate its concentration from the standard curve. If curve-fitting software is used, a linear or point-to-point curve can be chosen. All OD values must agree within 10% of the duplicate value for that patient, control, or standard.

Example: A patient whose samples have been set up in duplicate has OD values of 0.123 and 0.167. Average these numbers.

$$0.123 + 0.167 = 0.29 \quad 0.29/2 = 0.145$$

Calculate the difference between the mean and one of the values.

$$0.145 - 0.123 = 0.022$$

Divide the difference by the mean and multiply by 100 to calculate the percent difference.

$$0.022/0.145 = 0.152 \times 100 = 15.2\%$$

These OD values are greater than 10% from the mean, and this sample would have to be retested on another run.

- B.** The results for any diluted specimens must be multiplied by the dilution factor.

VII. INTERPRETATION

- A.** In the absence of disease, cytokines are nearly undetectable in body fluids (6). See Table 11.14–1.

B. Sensitivity

1. The IL-4 and IFN- γ assays are sensitive to <2 pg/ml.
2. The IL-6 assay is sensitive to <1 pg/ml.

VIII. PROCEDURE NOTES

- A.** If the reader does not give an OD value for a specimen or if the cytokine concentration is greater than the highest standard, that specimen must be diluted and retested on another run.
- B.** Culture supernatants are diluted in the culture medium. Serum, plasma, or urine is diluted in the provided sample diluent.

Table 11.14–1 Pierce Endogen observed cytokine values in body fluids^a

Body fluid	Concn (pg/ml) of cytokine		
	IL-4	IL-6	IFN- γ
Serum	Not detected (8)	0–149 (14)	0–1.5 (35)
Plasma	Not detected (8)	0–5 (14)	0–2.6 (45)
Urine	Not detected (5)	0–0.6 (5)	0.5–1.2 (5)

^a The number of subjects evaluated is in parentheses (3–5).

APPENDIX 11.14–1

Include QC information on reagent container and in QC records.

Reagent Preparation

Instructions for reagent preparation and standard dilutions from Pierce Endogen (1, 2, 3)

A. Wash buffer

In a clean flask or bottle, dilute 50 ml of the 30× wash buffer concentrate with 1.45 liters of distilled water. Label the buffer with the lot number, date made, expiration date, and initials of the person who made it. Store unused wash buffer in a bottle at 4°C.

B. Streptavidin-HRP solution

1. Do not prepare more than 15 min before it will be used. Do not prepare more than necessary. There is no extra reagent in the kit.
2. Gently vortex the streptavidin-HRP concentrate.
3. In a plastic 15-ml tube, dilute the streptavidin-HRP concentrate 1:40 with streptavidin-HRP dilution buffer.
4. If an entire plate is being assayed, add 30 µl of concentrate to 12 ml of diluent. If less than a whole plate is being assayed, add 2.5 µl of concentrate to 1 ml of diluent for each strip used.

C. Standards

1. Reconstitute one vial of standard with the volume of distilled water listed on the standard vial. The standard will take about 1 min to dissolve. Use standard within 1 h of reconstitution. Do not store reconstituted standard.
2. Gently invert standard to mix.
3. Make a 1:2.5 serial dilution of the standard. Label six polypropylene tubes for the standard dilutions as follows.
 - a. For IL-4 and IL-6, label the tubes 400 pg, 160 pg, 64 pg, 25.6 pg, 10.24 pg, and 0 pg.
 - b. For IFN-γ, label the tubes 1,000 pg, 400 pg, 160 pg, 64 pg, 25.6 pg, and 0 pg.
4. If the specimens to be run are plasma, serum, or urine, the standard is diluted with the provided standard diluent. If the specimens are culture supernatants, the standard is diluted with the culture medium unless validation has been performed (*see* item IV.D.2 in procedure 11.14). If validation has been done, all specimen types can be analyzed on the same plate.
 - a. Add 240 µl of the appropriate diluent to each of the six tubes.
 - b. Pipette 160 µl of the reconstituted standard to the first tube and gently vortex to mix.
 - c. Using the same pipette tip, transfer 160 µl to the second tube and gently vortex to mix.
 - d. Continue this for the next three tubes, being careful that there are no air bubbles during the transfers.

APPENDIX 11.14–1 *(continued)*

- e. Do not transfer anything into the sixth tube. This is the 0 standard tube and will contain only diluent or culture medium.
- f. If more than one plate is being run, the standard dilutions can be made by increasing all volumes two- or threefold.

Flow Cytometry Whole-Blood Intracellular-Cytokine Assay Using Phorbol Myristate Acetate, Ionomycin, and Brefeldin A

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Cytokines are soluble proteins produced by T and B lymphocytes, natural killer cells, monocytes, macrophages, and granulocytes. Specifically, cytokines regulate growth, differentiation, and function of a wide variety of cells and mediate normal and pathological responses. Most cytokine bioassays examine cytokines at the cell population level, but they cannot provide information concerning the phenotype of cytokine-producing cells or mechanism of

cytokine products. The flow cytometry method described here measures production of cytokines by T-cell subsets using whole blood. Heparinized blood is stimulated with the polyclonal activator phorbol myristate acetate plus ionomycin (induces intracellular signal cascades for polyclonal leukocyte activation) and the protein transport inhibitor brefeldin A (BFA) (a fungal metabolite that interferes with ve-

sicular transport from the rough endoplasmic reticulum to the Golgi complex) for 4 h at 37°C and 5% CO₂. Activated cells are stained with monoclonal antibodies for lymphocyte surface markers, followed by lysing of RBCs. WBCs are fixed and permeabilized simultaneously and stained with monoclonal antibodies to intracellular cytokines. Stained cells are analyzed by flow cytometry.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

A. Specimen collection

1. Peripheral blood in sodium heparin anticoagulant (2 ml)
2. Vacutainers or other collection tubes should be filled properly to account for the amount of anticoagulant.
3. Since all specimens should be regarded as potentially infectious, standard precautions for blood collection and handling should be properly followed.

B. Specimen transport

1. Specimens should be placed in well-stoppered tubes and should be placed with adequately absorbent material, preferably in a closed leakproof container, for delivery.
2. If delivery to reference laboratories is possible within the first 24 h, follow federal guidelines (International Air Transport Association Dangerous Goods Regulations, January 2001 [*see procedure 15.5*]).
3. Specimens should be maintained at room temperature (18 to 22°C) during transportation and storage.
4. *Testing must be performed within 24 h from the time of collection.*

C. Specimen labeling and request submission

1. Each patient sample must be properly labeled.
2. Each sample should be accompanied by some type of procurement form which should contain appropriate identifiers, e.g., patient's name, date of birth, and gender; date and time of collection, clinician; and other relevant patient information.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

(continued)

D. Rejection criteria

1. Inadequate sample volume
2. Clotted specimen
3. Hemolyzed blood specimen
4. Specimen more than 24 h old
5. Specimen exposed to cold temperatures

III. MATERIALS

Include QC information on reagent container and in QC records.

A. Reagents (see Appendix 11.15–1 for reagent concentrations and preparation)

1. Dulbecco's phosphate-buffered saline without calcium, magnesium, or phenol red (dPBS) (Invitrogen, Grand Island, N.Y.)
2. Dimethyl sulfoxide (DMSO) (Sigma Chemical Co., St. Louis, Mo.)
3. RPMI 1640 with glutamine (Invitrogen)
4. Heat-inactivated fetal bovine serum (FBS) (Invitrogen)
5. Monoclonal antibodies including isotype markers against cell surface and cytokine markers—stored according to manufacturer's instructions
6. Wash buffer (0.5% FBS, 0.1% sodium azide)
7. Sodium azide (J.T. Baker, Phillipsburg, N.J.)
8. Phorbol 12 myristate 13 acetate (PMA) (Sigma)
9. Ionomycin (Sigma)
10. BFA (Sigma)
11. Lysing solution
 - a. NH_4Cl (Sigma)
 - b. NaHCO_3 (Fisher Scientific, Fair Lawn, N.J.)
 - c. EDTA (Fisher Scientific)
 - d. Sterile distilled water
12. Permeabilization buffer
 - a. 10% Methanol-free formaldehyde (Polysciences, Inc., Warrington, Pa.)

b. Hanks balanced salt solution without calcium, magnesium, or phenol red (HBSS) (Invitrogen)

c. Saponin (Sigma)

d. HEPES buffer (Invitrogen)

13. Flow cytometer calibration beads or other calibration reagents (follow manufacturer's directions)

B. Supplies

1. Adjustable-volume pipette and tips
2. 12- by 75-mm polypropylene tubes (BD Biosciences, Franklin Lakes, N.J.)
3. 12- by 75-mm polystyrene tubes (BD Biosciences)
4. Liquid-waste container with bleach
5. Disposable gloves
6. Disposable lab coat
7. Protective eyewear

C. Equipment

1. Centrifuge with swinging bucket rotor, capable of centrifugation at $300 \times g$ and equipped with aerosol containment canisters
2. Vacuum source with pipette attached
3. Flow cytometer
4. Class II biosafety cabinet
5. Timer/stop watch
6. CO_2 incubator (5% CO_2)
7. Vortex

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

Controls

- A. Surface and intracellular markers (e.g., CD4 and interleukin-2 [IL-2]) from a healthy volunteer donor. These cells should be stained in the same manner and with the same monoclonal antibodies as the patient specimens. These cells should be run with every cytokine assay.
- B. Various blocking reagents may be used to ensure positivity.
- C. Unstimulated control sample containing BFA.
- D. Commercially available QC substance that is positive for particular cytokine

V. CALIBRATION

A. Optical alignment

The flow cytometer must be optically aligned. Follow manufacturer's directions. (Some cytometers require a company engineer.)

B. Calibration

Depending on the flow cytometer manufacturer, either standardized fluorescent beads or chicken RBCs may be used for calibration and to assess instrument function. Follow manufacturer's procedures.

C. Verification with whole-blood preparation

Electrical fluorescent compensation on single stained cells. Follow manufacturer's procedures.

VI. CYTOKINE ASSAY

It is imperative that these cultures be handled in a biosafety hood.

Observe standard precautions.

A. Procedure

1. Label each of two 12- by 75-mm polypropylene tubes "Unstimulated" and "Activated."
2. Add 500 μ l of RPMI 1640 to each tube.
3. Add 10 μ l of BFA to the unstimulated tube.
4. Add 20 μ l of PMA, 10 μ l of ionomycin, and 10 μ l of BFA to the activated tube.
5. Add 500 μ l of heparinized (sodium heparin) whole blood. Vortex to mix.
6. Incubate for 4 h at 37°C in the 5% CO₂ incubator. (*Note:* One milliliter of activated blood provides enough cells for staining 10 samples, based on 100 μ l/test.)
7. Aliquot 100 μ l of activated blood into 12- by 75-mm polystyrene tubes preloaded with monoclonal antibody for surface antigens. (Follow manufacturer's instructions for appropriate volume. Antibody may have to be titered.)
8. Incubate for 15 min at room temperature in the dark.
9. Add 2 ml of prewarmed (37°C) lysing solution per tube. Vortex and incubate for 5 min at room temperature.
10. Centrifuge at 300 \times *g* for 5 min, and aspirate supernatant. Vortex lightly to loosen cell pellet. Wash twice with 2 ml of wash buffer and centrifuge at 300 \times *g* for 5 min.
11. Aspirate supernatant. Vortex lightly to loosen pellet. Add 500 μ l of permeabilization buffer. Vortex lightly to mix. Incubate for 15 min at room temperature.
12. Wash twice with 2 ml of wash buffer. Spin at 300 \times *g* for 5 min. Aspirate supernatant. Vortex lightly to loosen pellet.
13. Add cytokine monoclonal antibody for intracellular staining. (Follow manufacturer's instructions for appropriate volume. Antibody may have to be titered.) Vortex lightly.
14. Incubate for 25 to 30 min at room temperature in the dark.
15. Wash once with wash buffer. Spin at 300 \times *g* for 5 min.
16. Aspirate supernatant to loosen pellet, and fix with 300 μ l of 1% formaldehyde.

B. Flow cytometry analysis

1. Collect 5,000 events in the gate (small nongranular cells) on the flow cytometer. Cells can be stored at 4°C and collected the following day.
2. Gate lymphocytes using forward versus side light scatter parameters. Analyze fluorescent parameters for appropriate surface and cytokine markers. Negative markers will be set on unstimulated stained cells for the same antibodies.

POSTANALYTICAL CONSIDERATIONS

VII. REPORTING RESULTS

Report percentage of surface marker that expresses a particular cytokine (e.g., if the total percentage of CD4 is 25% and the CD4⁺ IL-2⁺ is 10%, then 10% divided by 25% would equal 40%, which is the percentage of CD4 that expresses IL-2).

VIII. INTERPRETATION

Normal values

- A. Values for at least 50 healthy donors should be ascertained by each laboratory performing this test.
 - B. Compare percentage to means and standard deviations of healthy donors.
-

IX. LIMITATIONS OF TESTING

Stimulation with PMA and ionomycin does not occur in vivo.

SUPPLEMENTAL READING

APPENDIX 11.15–1

Include QC information on reagent container and in QC records.

Reagent Preparation

- A. PMA
 1. Stock solution of 1 mg/ml is prepared in DMSO, with aliquots frozen at 70°C.
 2. Working solution is prepared from stock solution diluted in dPBS for a 1-μg/ml concentration. Final concentration in assay is 20 ng/ml.
- B. Lysing solution
 1. Stock solution is prepared using 8.02 g of NH₄Cl (Sigma), 0.84 g of NaHCO₃ (Fisher), and 0.37 g of EDTA (Fisher) and bringing to a volume of 100 ml with sterile distilled water. Store at 4°C. Keeps for 6 months.
 2. Working solution is prepared by adding 10 ml of stock solution to 90 ml of sterile distilled water. Keeps for a week.
- C. Ionomycin
 1. Stock solution of 1 mg/μl is prepared in DMSO, with aliquots frozen at –70°C.
 2. Working solution is diluted in PBS for a 100-μg/ml concentration. Final concentration in assay is 1 μg/ml.
- D. BFA
 1. Stock solution of 5-mg/ml is prepared in DMSO, with aliquots frozen at –70°C.
 2. Working solution is diluted in PBS for a 1-μg/ml concentration. Final concentration of assay is 10 μg/ml.
- E. Permeabilization buffer
 1. Dilute 10% methanol-free formaldehyde in HBSS to make a 4% solution.
 2. Dissolve 0.1 g of saponin in 100 ml of 4% formaldehyde.
 3. Filter and add 1 ml of 1 M HEPES buffer.
 4. Cover in foil and store at 4°C. Keeps for 2 weeks.
- F. Buffer

Add 2.5 ml of heat-inactivated FBS and 0.5 g of sodium azide to 500 ml of PBS for a 0.5% FBS–0.1% sodium azide solution.

11.16

Whole-Blood Lymphocyte Immunophenotyping Using Cell Surface Markers by Flow Cytometry

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Whole blood can be stained with fluorochrome-labeled monoclonal antibodies against antigen markers found on the surfaces of lymphocytes. The stained samples are treated with a lysing solution to destroy erythrocytes. The flow cytometer is an instrument capable of rapid, quantita-

tive, multiparameter analysis of heterogeneous cell populations on a cell-by-cell basis (single-cell analysis). During acquisition, the cells travel past the laser beam and scatter the laser light. The stained cells fluoresce. These scatter, and fluorescence signals provide information about the

cells' size, internal complexity, and relative fluorescence intensity. The percentage of fluorescent cells is determined for each antibody. In addition, the use of the light scatter measurements from the individual cells along with fluorescence allows identification of the lymphocyte population.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. Peripheral blood in EDTA (acid citrate dextrose or heparin may also be used) anticoagulant
2. Vacutainers or other collection tubes should be filled properly to account for the amount of anticoagulant.
3. Since all specimens should be regarded as potentially infectious, standard precautions for blood collection and handling should be properly followed.

B. Specimen transport

1. Specimens should be placed in well-stoppered tubes and should be placed with adequately absorbent material, preferably in a closed leakproof container, for delivery.
2. Specimens should be maintained at room temperature (18 to 22°C) during transportation and storage.

C. Specimen labeling and request submission

1. Each patient sample must be properly labeled.
2. Each sample should be accompanied by some type of procurement form which should contain appropriate identifiers, e.g., patient's name, date of birth, and gender; date and time of collection; clinician; and other relevant patient information.

D. Rejection criteria

1. Inadequate sample volume
2. Clotted specimen
3. Hemolyzed blood specimen
4. Specimen more than 24 h old
5. Specimen exposed to cold temperatures

III. MATERIALS

- A. Reagents** (*see* Appendix 11.16–1 for reagent concentrations and preparation)
1. Lysing reagent (depends on manufacturer of flow cytometer)
 2. Dulbecco's phosphate-buffered saline (dPBS) without calcium, magnesium, or phenol red (Invitrogen, Grand Island, N.Y.)
 3. Monoclonal antibodies against cell surface markers—stored according to manufacturer's instructions
 4. 2% Working solution of 10% Formalin neutral buffered solution (Sigma, St. Louis, Mo.) or 2% working solution of 10% methanol-free Formaldehyde (PolySciences, Inc., Warrington, Pa.)
 5. Flow cytometer calibration beads or other calibration reagents (follow manufacturer's directions)
- B. Supplies**
1. Adjustable-volume pipette and tips
 2. 12- by 75-mm polystyrene tubes (BD Biosciences, Franklin Lakes, N.J.)
 3. Liquid-waste container with bleach
 4. Disposable gloves
 5. Disposable lab coat
 6. Protective eyewear
- C. Equipment**
1. Vortex
 2. Centrifuge with swinging bucket rotor, capable of centrifugation at $300 \times g$ and equipped with aerosol containment canisters
 3. Vacuum source with pipette attached
 4. Flow cytometer
 5. Class II biosafety cabinet
 6. Timer/stop watch

IV. CALIBRATION

- A. Optical alignment**
Flow cytometer must be optically aligned. Follow manufacturer's directions. (Some cytometers require a company engineer.)
- B. Calibration**
Depending on the flow cytometer manufacturer, either standardized fluorescent beads or chicken RBCs may be used for calibration and to assess instrument function. Follow manufacturer's procedures.
- C. Verification with whole-blood preparation**
Electrical fluorescent compensation on single stained cells (unless not required due to calibration software specifications in which beads mimic the actual specimens). Adjust FL1-FL2 and FL2-FL1, FL2-FL3 and FL3-FL2, and FL3-FL4 and FL4-FL3. Parameters depend on the number of lasers present and which panel is being used. Follow manufacturer's procedure.

ANALYTICAL CONSIDERATIONS

V. QUALITY CONTROL

Controls

- A. Surface-stained cells (e.g., CD3⁺ CD4⁺) from a healthy donor**
These cells should be stained in the same manner and with the same monoclonal antibodies as the patient specimens.
- B. Commercially available QC substance (usually stabilized blood cells) that mimics actual specimens**
These cells are stained with the same monoclonal antibodies as patient specimens. Results can be compared to expected values.
- C. Frequency**
The healthy donor blood should be drawn and run daily. If there are several working shifts, the blood should be stained and run for each shift. The QC cells should be stained and run daily.

V. QUALITY CONTROL

(continued)

D. Expected results

1. Healthy donor results should be compared to normal values ascertained by each laboratory.
2. QC substances should be compared to the individual company's published ranges.

E. Corrective action

1. All control results falling outside of the expected ranges should be considered suspect and should be brought to the attention of the person in charge.
2. Results of cell surface markers performed on blood from apparently healthy donors may be dependent on the current health of the individual or due to individual variation. They do not necessarily signify a failure of the test system. These results should be reviewed to determine if patient results are reportable. There must be documentation of these reviews.
3. In the event that a serious problem is found in the test system, corrective action should be performed and documented. If patient's values are suspect, they should not be released and a request should be made for submission of a new specimen.

VI. FLOW CYTOMETRY TWO-COLOR STAINING

It is imperative that these cultures be handled in a biosafety hood.

Observe standard precautions.

A. Panel

Isotype, CD45/CD14, CD3/CD4, CD3/CD8, CD3/CD19, CD3/CD(16 + 56), or CD3/CD16

B. Procedure (done in a laminar hood with the lights out)

1. Label a set of six tubes for each patient and one set for the normal control.
2. Pipette 100 μ l (or amount specified by the monoclonal antibody manufacturer's directions) of the control's or patient's blood into each tube.
3. Pipette the appropriate volume of antibodies into all the tubes, changing pipette tips between each antibody vial to prevent contamination. Gently vortex to mix.
4. Incubate at room temperature in the dark for the appropriate time (check manufacturer's recommendations).
5. During the incubation time, remove any blood adhering to the walls of the tubes with a cotton swab moistened with PBS.
6. After incubation, vortex each sample tube and add appropriate amount of lysing reagent (per manufacturer's instructions).
7. Incubate for appropriate time (per manufacturer's instructions).
8. After the incubation period, centrifuge tubes at $300 \times g$ for 5 min at room temperature.
9. Using an aspirating unit, remove the supernatant from the tubes to within 1/8 in. of the bottom. There should be about 200 μ l of liquid left in the tube.
10. Gently vortex to resuspend the pellet.
11. Add 3 ml of PBS to all tubes. Centrifuge tubes at $300 \times g$ for 5 min at room temperature.
12. Using the aspirating unit, remove the supernatant from the tube to within 1/8 in. of the bottom. There should be about 200 μ l of liquid left in the tube.
13. Gently vortex each tube to resuspend the cell pellet.
14. Add at least 0.5 ml of a 2% formaldehyde fixative solution to each sample tube and vortex gently. Cap tubes, place in rack, and cover with aluminum foil to protect from light.
15. Store at 2 to 8°C until tubes can be acquired. This should be no longer than 48 h after they are completed.

VII. FLOW CYTOMETRY TWO-COLOR ANALYSIS

Observe standard precautions.

A. Purity and recovery

1. Specimen must be properly mixed before collection.
2. Draw an electronic gate using forward versus side light scatter around the small nongranular population (lymphocytes). Care should be taken to include large granular lymphocytes and at the same time to exclude monocytes and granulocytes.
3. Draw a second, relatively larger light scatter gate to also include debris and monocytes.
4. Collect 20,000 total events or sufficient events so that there are at least 2,500 events collected in the lymphocyte population for each tube.
5. Using the first gate (lymphocyte gate), analyze the CD45 CD14 tube on a dual-parameter histogram plot. The CD45 should be on the x axis, and the CD14 should be on the y axis. Set quadrants so that they separate the bright CD45-positive cells from CD45-dim and -negative cells and the CD14-positive cells from the CD14-negative cells on the y axis (Fig. 11.16-1A and B). The purity of the lymphocyte gate is the percentage of cells within the gate that express bright CD45⁺ and CD14⁻ cells. The lymphocyte purity should optimally be at least 90% but may be as low as 85%. If it is less than 85%, the initial gate should be checked and if possible redrawn.
6. Using a dual dot plot for the larger gate, set the same quadrants as used for the smaller lymphocyte gate.
7. Determine the number of cells that meet both criteria for both gates (bright CD45⁺ CD14⁻ = total number of lymphocytes).
8. To determine the lymphocyte recovery (Fig. 11.16-1C and D), divide the number of lymphocytes determined from the analysis regions of the smaller gate by the total number of lymphocytes in the analysis regions of the larger gate and multiply by 100.
9. The lymphocyte recovery should optimally be at least 95% but may be as low as 90%. Optimal gates include as many lymphocytes and as few contaminants as possible.

B. Isotype tube

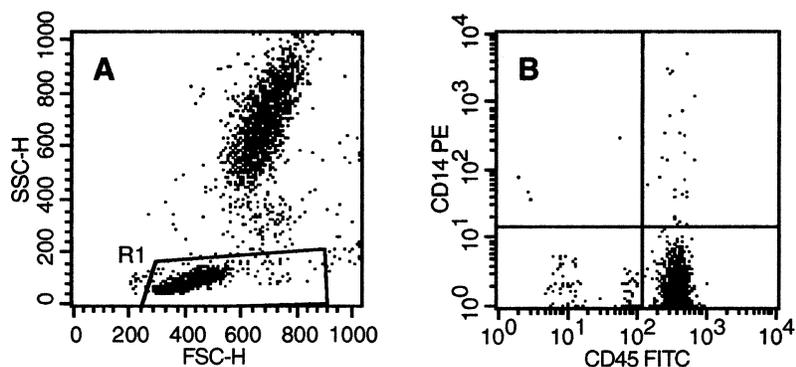

Using the smaller gate, analyze the isotype on a two-parameter dot plot. Set the quadrant markers to read between no more than 1 to 2% positive in quadrants 1, 2, and 4. If the background is above 2% and found to be present throughout the rest of the samples, it should be subtracted.

C. Remaining tubes

1. Read the remaining tubes for the same specimen using the isotype quadrant markers. If it is necessary, the quadrant markers may be optimized.
2. Correct all percentages of markers by dividing the percent positive of gated cells by the percent lymphocyte purity.

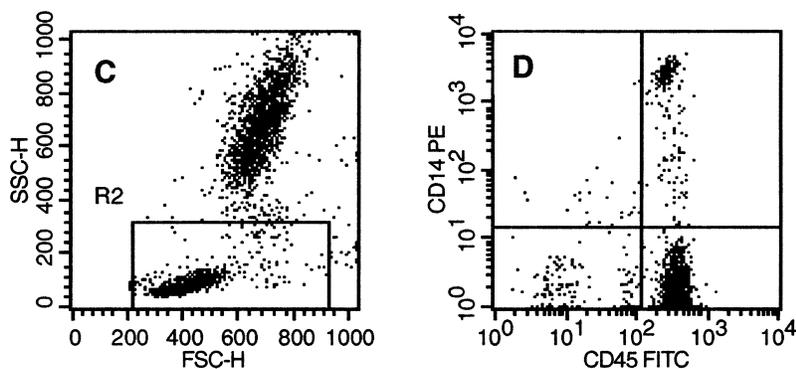

D. QA

1. Check lymphosum (total T cells plus B cells plus natural killer [NK] cells). Results should be between 95 and 100%.
2. Helper (CD3⁺ CD4⁺) plus suppressor (CD3⁺ CD8⁺) cells should equal total T (CD3⁺) cells within $\pm 10\%$. (The presence of gamma delta cells could affect these results. In that case, the values could be less than -10% .)
3. The difference between CD3⁺ cells in all four tubes should be within 0 to 3%.
4. If any of these values are out of range, try regating or restaining.

Gate: G1

Quad	Events	% Gated	% Total	X Mean	X Geo Mean	Y Mean	Y Geo Mean
UL	4	0.10	0.04	16.46	5.45	115.40	80.77
UR	28	0.71	0.25	385.39	363.65	660.36	144.74
LL	104	2.63	0.94	47.96	29.74	1.84	1.59
LR	3812	96.56	34.43	374.14	366.28	1.42	1.26

Gate: G2

Quad	Events	% Gated	% Total	X Mean	X Geo Mean	Y Mean	Y Geo Mean
UL	29	0.68	0.26	48.22	30.91	178.00	47.95
UR	206	4.86	1.86	297.35	285.51	1851.88	925.51
LL	157	3.70	1.42	37.22	19.26	2.18	1.76
LR	3847	90.75	34.75	373.93	365.85	1.43	1.27

Figure 11.16–1 (A) Forward versus side light scatter histogram showing the smaller light scatter gate (lymphocytes) which is used for analyzing the remaining tubes from that specimen. (B) CD45/CD14 histogram from gated R1. The lymphocyte purity is the percentage of positive cells within the gate that express bright CD45-positive cells that are negative for CD14 (quadrant LR). The purity in this sample is 97%. The number of cells in quadrant LR which are bright CD45 positive and negative for CD14 is the number of gated lymphocytes (3,812 cells). (C) The same light scatter gate as in panel A except that it has a rather large light scatter region drawn around the lymphocytes (R2). (D) The two-parameter histogram of CD45/CD14 fluorescence is gated on R2. The number of cells in quadrant LR which are bright CD45 positive and negative for CD14 is the total number of lymphocytes (3,847 cells). The lymphocyte recovery is 99%, obtained as follows: $(3,812 / 3,847) \times 100$. FITC, fluorescein isothiocyanate; PE, phycoerythrin.

VIII. CD45 GATING AND THREE-COLOR ANALYSIS

It is easier to distinguish lymphocytes based on CD45 fluorescence and 90° (side) scatter. Many nonlymphocyte contaminants of a light scatter gate (e.g., unlysed RBCs) can be easily eliminated from a CD45 side scatter gate. The presence of nonlymphocyte elements within the boundaries of the lymphocyte gate is assumed to be negligible. Using a low side scatter and bright CD45 fluorescence for identification of lymphocytes, an assumption is made that the only cells meeting these criteria are lymphocytes and that therefore the lymphocyte purity of the gate is close to 100%. Therefore, it is not necessary to stain cells for determination of purity. An isotype control is not necessary, as the negatively labeled populations can serve this function.

A. Panel

CD45/CD3/CD4, CD45/CD3/CD8, CD45/CD3/CD19, CD45/CD3/CD(16 + 56), or CD16

B. Staining

Follow two-color procedure using four tubes instead of six.

C. Flow cytometry analysis

1. Set a lymphocyte gate using linear 90° side scatter and log of CD45 fluorescence. Lymphocytes are defined as CD45^{bright} with low side scatter.
2. Set threshold to CD45 fluorescence and adjust so populations of interest are visible.
3. Collect a minimum of 2,500 events in the CD45^{bright} low-scatter gate.
4. Analyze each tube using the negative and positive populations to determine cursor settings.
5. Ensure lymphocyte recovery by determining the lymphosum (total T cells plus B cells plus NK cells). Results should fall within 95 to 100%. If not, try regating.
6. The presence of nonlymphocyte elements within the boundaries of the lymphocyte gate is assumed to be negligible. Therefore, it is not necessary to report purity (percentage of lymphocytes in analysis gate).

D. QA

Follow two-color procedure.

IX. FLOW CYTOMETRY FOUR-COLOR ANALYSIS (Fig. 11.16–2)**A. Panel**

CD45/CD3/CD4/CD8, CD45/CD3/CD19/CD(16 + 56), or CD16

B. Staining

Follow three-color procedure.

C. Flow cytometry analysis

Follow three-color procedure.

D. QA

Follow three-color procedure, except that the difference between the total T cells (CD3) in the two tubes should be 0 to 2%.

X. FLOW CYTOMETRY NO-WASH METHOD

By using fluorescence triggering on CD45 (setting a threshold on fluorescence instead of forward and side scatter), which stains all WBCs, it is possible to reduce contamination of unlysed or nucleated RBCs in the gate and analyze the lymphocyte population.

A. Staining using CD45 gating three- or four-color panel

1. Label a set of two or four tubes, depending on which panel you are using.
2. Pipette 100 µl (or monoclonal antibody manufacturer's directions) of the control's or patient's blood into each tube.

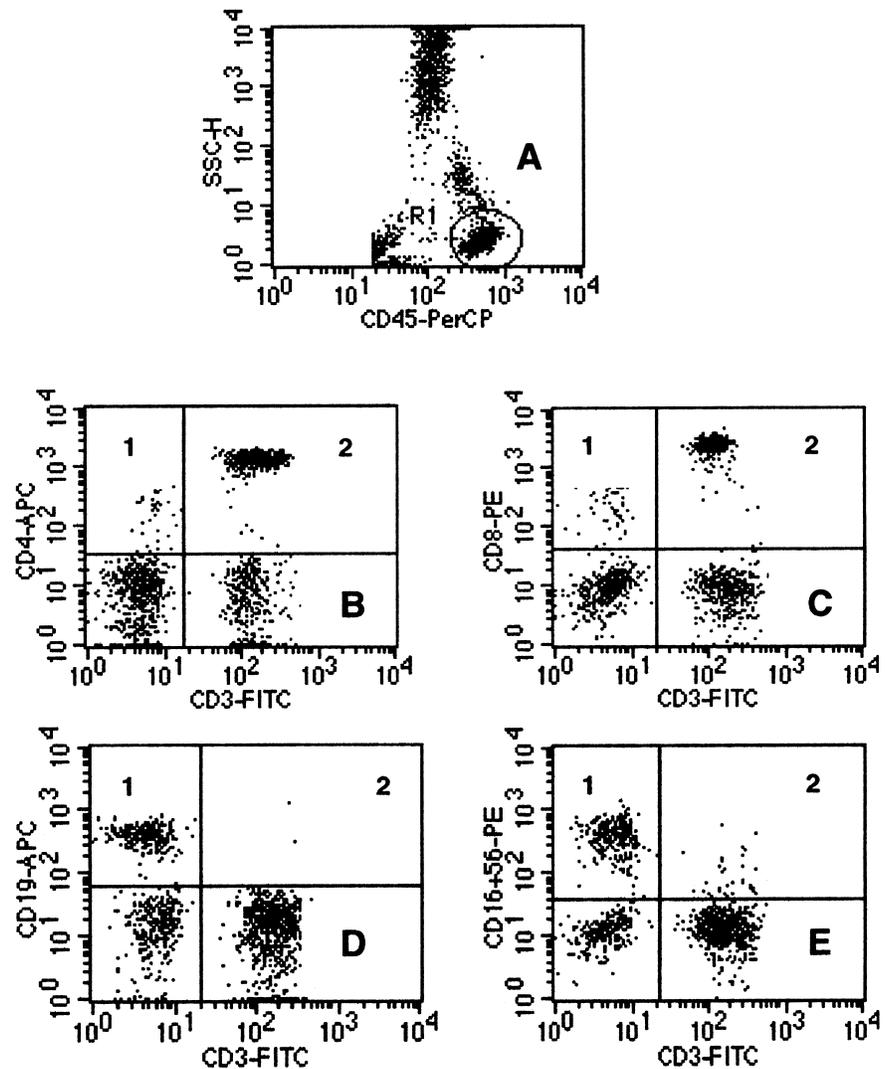

Figure 11.16-2 Four-color immunophenotyping using CD45 and side scatter gating. (A) Gate (R1) on the bright CD45 nongranular population (lymphocytes). This is the region used for analysis of both tubes 1 and 2. (B) CD3⁺ CD4⁺ (quadrant 2) from tube 1. (C) CD3⁺ CD8⁺ (quadrant 2) from tube 1. (D) CD⁻ CD4⁺ (quadrant 1) from tube 2. (E) CD3⁻ CD(16⁺56⁺) (quadrant 1) from tube 2. FITC, fluorescein isothiocyanate; APC, allophycocyanin; PE, phycoerythrin.

X. FLOW CYTOMETRY NO-WASH METHOD *(continued)*

3. Pipette the appropriate volume of antibodies into all the tubes as in the three- and four-color procedures.
4. Incubate at room temperature in the dark for the appropriate time as in the three- and four-color procedures.
5. After incubation, add lysing reagent and incubate as in the three- and four-color procedures. Do not wash.

B. Flow cytometry analysis

Follow procedure for three- and four-color acquisition.

C. QA

Follow three- or four-color procedure.

POSTANALYTICAL CONSIDERATIONS

XI. REPORTING RESULTS

Reference range

- A. Reference range values, including percent positive and absolute numbers, should be calculated from at least 50 healthy adult donors. Pediatric reference ranges should also be established.
- B. Patient values should be compared to healthy donor ranges and reported as increased or decreased.

XII. INTERPRETATION

- A. Patient values should be compared to healthy donor values. Increases or decreases in values may be related to a variety of diseases. A physician should be able to interpret these results based on patient symptoms and other clinical data.
- B. New sample required if
 1. Lymphosum (total T cells plus B cells plus NK cells) is out of range. Results should be between 95 and 100%.
 2. The differences in CD3 values in tubes are not within the matching range (0 to 3% for two- or three-color staining and 0 to 2% for four-color staining).
 3. Helper (CD3⁺ CD4⁺) plus suppressor (CD3⁺ CD8⁺) cells do not equal total T (CD3⁺) cells within $\pm 10\%$. (The presence of gamma delta cells could affect these results. In that case the values could be less than -10% .)

APPENDIX 11.16–1

Reagent Preparation

Working solution of methanol-free 2% formaldehyde—stock solution from PolySciences or Sigma

- A. 10% Formaldehyde solution (PolySciences no. 0418), which must be diluted 1:5 with dPBS to obtain a working concentration of 2% formaldehyde
- B. 10% Formalin neutral buffered solution from Sigma (no. HT50-1-1) that is diluted 1:2 with dPBS to obtain a working concentration of 2% formaldehyde
- C. Store diluted 2% formaldehyde in an amber glass container or wrap container in aluminum foil to avoid exposure to light. May be stored for up to 1 week at 2 to 8°C.

Neutrophil Function Whole-Blood Flow Cytometric Test for Leukocyte Adhesion Deficiency

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Normal neutrophil function is of great importance in the host defense against bacterial and fungal infections. As neutrophils recognize, adhere to, and phagocytose an invading microbe they generate an oxidative burst, which kills the pathogen. In the leukocyte adhesion deficiency (LAD) states, there are defects in the ability of neutrophils to adhere to both the vascular

endothelium and opsonized microorganisms due to the absence or reduced expression of a group of cell surface leukocyte adhesion markers. This group of surface glycoproteins includes LFA-1 (CD11b/CD18), Cr3 (CD11b/CD18), and P150,95 (CD11c/CD18). Patients with this deficiency manifest recurrent infections involving the skin, subcutaneous tissues,

middle ear, and oropharyngeal mucosa. In the assay described here, neutrophils are stimulated with phorbol 12 myristate 13 acetate (PMA) and stained with CD11b plus corresponding isotypic monoclonal antibody. Cellular fluorescence is measured on resting and stimulated neutrophils using flow cytometry.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

A. Specimen collection

1. Peripheral blood in EDTA anticoagulant (2 ml)
2. Vacutainers or other collection tubes should be filled properly to account for the amount of anticoagulant.
3. Since all specimens should be regarded as potentially infectious, standard precautions for blood collection and handling should be properly followed.

B. Specimen transport

1. Specimens should be placed in well-stoppered tubes and should be placed with adequately absorbent material, preferably in a closed leakproof container, for delivery.
2. Specimens should be maintained at room temperature (18 to 22°C) during transportation and storage.
3. *Testing must be performed within 4 h from the time of collection.*

C. Specimen labeling and request submission

1. Each patient sample must be properly labeled.
2. Each sample should be accompanied by some type of procurement form which should contain appropriate identifiers, e.g., patient's name, date of birth, and gender; date and time of collection; clinician; and other relevant patient information.

D. Rejection criteria

1. Inadequate sample volume
2. Clotted specimen
3. Hemolyzed blood specimen
4. *Specimen more than 4 h old*
5. Specimen exposed to cold temperatures

III. MATERIALS

Include QC information on reagent container and in QC records.

- A. Reagents** (see Appendix 11.17–1 for reagent concentrations and preparation)
1. BD FACS Lysing Solution—working solution diluted 1:10 with distilled water (BD Biosciences, San Jose, Calif.). (If using different lysing reagent, follow manufacturer's instructions.)
 2. Dulbecco's phosphate-buffered solution (dPBS) without calcium or magnesium (Invitrogen, Grand Island, N.Y.)
 3. Hanks balanced salt solution (HBSS) without calcium, magnesium, or phenol red (Invitrogen)
 4. CD11b and isotype immunoglobulin G2a (IgG2a) phycoerythrin (PE)-labeled monoclonal antibodies, stored according to manufacturer's instructions
 5. PMA (Sigma Chemical Co., St. Louis, Mo.)
 6. 2% Working solution of 10% methanol-free formaldehyde
 7. Flow cytometer calibration beads or other calibration reagents (follow manufacturer's directions)
- B. Supplies**
1. Adjustable-volume pipette and tips
 2. 12- by 75-mm polystyrene tubes (BD Biosciences, Franklin Lakes, N.J.)
 3. Liquid-waste container with bleach
 4. Disposable gloves
 5. Disposable lab coat
 6. Protective eyewear
- C. Equipment**
1. Vortex
 2. Centrifuge
 3. CO₂ incubator (5% CO₂)
 4. Vacuum source with pipette attached
 5. Centrifuge with swinging bucket rotor, capable of centrifugation at 300 × *g* and equipped with aerosol containment canisters
 6. Class II biosafety cabinet
 7. Timer/stop watch
 8. Flow cytometer

IV. CALIBRATION

- A. Optical alignment**
Flow cytometer must be optically aligned. Follow manufacturer's directions. (Some cytometers require a company engineer.)
- B. Calibration**
Depending on the flow cytometer manufacturer, either standardized fluorescent beads or chicken RBCs may be used for calibration to assess instrument function. Follow manufacturer's procedures.
- C. Verification with whole-blood preparation**
Electrical fluorescent compensation on single stained cells. Follow manufacturer's procedures.

ANALYTICAL CONSIDERATIONS

V. QUALITY CONTROL

Controls

- A.** Surface-stained cells (e.g., CD11b) from a healthy donor. These cells should be stained and stimulated in the same manner and with the same monoclonal antibodies as the patient specimens. Values should fall within established normal ranges.
- B.** If for some reason the results for the healthy donor are abnormal (such as response to stimulants), then the patient's results should not be reported. Instruments and reagent integrity should be checked, and if necessary, service on the flow cytometer should be requested. A new patient sample should be submitted.

VI. LAD ASSAY

It is imperative that these cultures be handled in a biosafety hood.

Observe standard precautions.

A. Procedure

1. Set four tubes per run for both a healthy donor and the patient, labeled as follows.
 - a. IgG2a PE
 - b. CD11b PE
 - c. IgG2a PE + PMA
 - d. CD11b PE + PMA
2. Add 100 μ l of whole blood to each tube.
3. Add 10 μ l of HBSS to tubes a and b. Add 10 μ l of PMA to tubes c and d. Vortex lightly.
4. Incubate for 15 min at 37°C in a CO₂ incubator.
5. Add 20 μ l of monoclonal antibody (or follow amount suggested in monoclonal antibody manufacturer's directions) to appropriate tubes. Vortex lightly.
6. Incubate for 15 min in the dark at room temperature.
7. Add 2 ml of BD FACS Lysing Solution. Incubate for 10 min (follow appropriate amount and manufacturer's instructions if using a different lysing agent).
8. Centrifuge at 300 \times g for 5 min. Aspirate supernatant.
9. Wash one time with 2 ml of HBSS. Aspirate supernatant.
10. Fix with 0.5 ml of 2% methanol-free formaldehyde.
11. Acquire as soon as possible on the flow cytometer.

B. Flow cytometry analysis

1. Using forward versus side light scatter parameters, set a region around the large granular cells (neutrophils).
2. Set the mean channel of the histogram from tube a (IgG2a) at around 2.0 on the log scale and collect specimen.
3. Collect 10,000 events for all four tubes.
4. Using the region around the neutrophils, print the histograms from all four tubes.
5. Record the mean fluorescence intensities (MFI) for CD11b, CD11b plus PMA, IgG2a, and IgG2a plus PMA and determine the upregulation index (UI).

UI =

$$\frac{\text{MFI for CD11b stimulated with PMA} / \text{MFI for IgG2a stimulated with PMA}}{\text{MFI for unstimulated CD11b} / \text{MFI for unstimulated IgG2a}}$$

POSTANALYTICAL CONSIDERATIONS

VII. REPORTING RESULTS

Report the MFI for CD11b stimulated with PMA divided by the MFI for IgG2a stimulated with PMA, the MFI for unstimulated CD11b divided by the MFI for unstimulated IgG2A, and the UI.

VIII. INTERPRETATION

Normal values

- A. Values for at least 50 healthy donors should be ascertained by each laboratory performing this test.
- B. Compare the following values.
 1. The MFI for stimulated CD11b divided by the value for stimulated IgG2a
 2. The MFI for unstimulated CD11b divided by the value for unstimulated IgG2a
 3. UI

VIII. INTERPRETATION

(continued)

- C. Values for patients should fall within ranges for healthy donors. However, sometimes values may be slightly off for various reasons, e.g., the patient's MFI for unstimulated CD11b is increased. In cases such as these, it is important to ascertain that there was a sufficient increase in the MFI for stimulated CD11b. Patients with LAD will have very little increase in the MFI for CD11b when the cells are stimulated.
- D. Increased values compared to the healthy donor ranges have no significance.

IX. LIMITATION OF TESTING

Stimulation with PMA does not occur in vivo.

SUPPLEMENTAL READING

APPENDIX 11.17–1

Include QC information on reagent container and in QC records.

Reagent Preparation

- A. PMA
Stock solution of 1 mg/ml is prepared in dimethyl sulfoxide, with aliquots frozen at –70°C. Working solution is diluted in HBSS for a 1-μg/ml concentration. Final concentration in assay is 90 ng/ml.
- B. Working solution of methanol-free 2% formaldehyde—stock solution from PolySciences or Sigma
1. 10% Formaldehyde solution (PolySciences no. 0418), which must be diluted 1:5 with dPBS to obtain a working concentration of 2% formaldehyde
 2. 10% Formalin neutral buffered solution from Sigma (no. HT50-1-1) that is diluted 1:2 with dPBS to obtain a working concentration of 2% formaldehyde
 3. Store diluted 2% formaldehyde in an amber glass container or wrap container in aluminum foil to avoid exposure to light. May be stored for up to 1 week at 2 to 8°C.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Normal neutrophil function is of great importance in the host defense against bacterial and fungal infections. As neutrophils recognize, adhere to, and phagocytose an invading organism, they generate an oxidative burst which results in the reduction of molecular oxygen to superoxide. The superoxide produced is rapidly converted

to hydrogen peroxide (H_2O_2 , which kills the pathogen). In chronic granulomatous disease (CGD), microbial killing is defective because neutrophils from patients with CGD lack a respiratory burst. The assay described here uses dihydrorhodamine-123 (DHR-123) and phorbol 12 myristate 13 acetate (PMA) to measure

oxidative burst activity, which is easily converted to hydrogen peroxide. DHR, a nonfluorescent compound, reacts with hydrogen peroxide and is oxidized to rhodamine-123, a green fluorescent compound. Cellular fluorescence is measured using flow cytometry.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

A. Specimen collection

1. Peripheral blood in EDTA anticoagulant (2 ml)
2. Vacutainers or other collection tubes should be filled properly to account for the amount of anticoagulant.
3. Since all specimens should be regarded as potentially infectious, standard precautions for blood collection and handling should be properly followed.

B. Specimen transport

1. Specimens should be placed in well-stoppered tubes and should be placed with adequately absorbent material, preferably in a closed leakproof container, for delivery.
2. Specimens should be maintained at room temperature (18 to 22°C) during transportation and storage.
3. *Testing must be performed within 4 h from the time of collection.*

C. Specimen labeling and request submission

1. Each patient sample must be properly labeled.
2. Each sample should be accompanied by some type of procurement form which should contain appropriate identifiers, e.g., patient's name, date of birth, and gender; date and time of collection; clinician; and other relevant patient information.

D. Rejection criteria

1. Inadequate sample volume
2. Clotted specimen
3. Hemolyzed blood specimen
4. *Specimen more than 4 h old*
5. Specimen exposed to cold temperatures

III. MATERIALS

Include QC information on reagent container and in QC records.

A. Reagents (see appendix 11.18–1 for reagent concentrations and preparation)

1. Ammonium chloride lysing solution
 - a. NH_4Cl (Sigma Chemical Co., St. Louis, Mo.)
 - b. NaHCO_3 (Fisher Scientific, Fair Lawn, N.J.)
 - c. EDTA (Fisher Scientific)
2. Hanks balanced salt solution (HBSS) without calcium, magnesium, or phenol red (Invitrogen, Grand Island, N.Y.)
3. DHR-123 (Molecular Probes, Eugene, Oreg.)
4. Dimethyl sulfoxide (DMSO) (Sigma)
5. PMA (Sigma)
6. Flow cytometer calibration beads or other calibration reagents (follow manufacturer's directions)

B. Supplies

1. Adjustable-volume pipette and tips
2. 12- by 75-mm polystyrene tubes (BD Biosciences, Franklin Lakes, N.J.)
3. Liquid-waste container with bleach
4. Disposable gloves
5. Protective eyewear

C. Equipment

1. Vortex
2. Timer/stop watch
3. Centrifuge with swinging bucket rotor, capable of centrifugation at $300 \times g$ and equipped with aerosol containment canisters
4. CO_2 incubator (5% CO_2)
5. Vacuum source with pipette attached
6. Class II biosafety cabinet
7. Flow cytometer

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

Observe standard precautions.

Controls

- A. Cells from a healthy donor. These cells should be treated in the same manner as the patient specimens. Values should fall within established normal ranges.
- B. If for some reason the results for the healthy donor are abnormal (e.g., the neutrophil oxidative index [NOI]), then the patient's results should not be reported. Instruments and reagent integrity should be checked, and if necessary, service on the flow cytometer should be requested. A new patient sample should be submitted.

V. CALIBRATION

A. Optical alignment

Flow cytometer must be optically aligned. Follow manufacturer's directions. (Some cytometers require a company engineer.)

B. Calibration

Depending on the flow cytometer manufacturer, either standardized fluorescent beads or chicken RBCs may be used for calibration and to assess instrument function. Follow manufacturer's procedures.

VI. CGD ASSAY

It is imperative that these cultures be handled in a biosafety hood.

A. Procedure

1. Set two tubes per run for both a healthy donor and the patient, labeled as follows.
 - a. DHR-123
 - b. DHR-123 + PMA
2. Add 100 μl of whole blood to each tube.
3. Add 3 ml of lysing solution (prewarmed to 37°C) to each tube. Vortex and let stand at room temperature for 5 min.
4. Spin at $300 \times g$ for 5 min. Aspirate supernatant.
5. Wash twice with 2 ml of HBSS. Aspirate supernatant.
6. Add 400 μl of HBSS. Vortex tubes lightly.

Observe standard precautions.

VI. CGD ASSAY (*continued*)

7. Add 10 μ l DHR-123. Vortex lightly. Incubate in 5% CO₂ incubator at 37°C for 5 min.
8. Add 40 μ l of HBSS to tube a. Add 40 μ l of PMA to tube b. Vortex lightly and incubate in 5% CO₂ incubator at 37°C for 15 min.
9. Collect immediately on the flow cytometer.

B. Flow cytometry analysis

1. Using forward versus side light scatter parameter, set a region around the large granular cells (neutrophils).
2. Set the mean channel of the histogram from tube a (DHR) at around 10.0 on the log scale and collect specimen.
3. Collect 10,000 events for both tubes.
4. Using the region around the neutrophils, print the histograms from both tubes.

POSTANALYTICAL CONSIDERATIONS**VII. REPORTING RESULTS**

Record the mean fluorescence intensity (MFI) from both the DHR tube and the tube with DHR plus PMA. Calculate the NOI. The NOI is the MFI of the cells with DHR plus PMA (stimulated) divided by the MFI of cells with DHR alone (unstimulated).

VIII. INTERPRETATION

Normal values

- A. NOIs for at least 50 healthy donors should be ascertained by each laboratory performing this test.
- B. Compare the NOIs to established normal ranges. Patients with CGD have a lack of oxidative burst function and will have a very low NOI (e.g., ~0 to 10). If the patient has an intermediate value, repeat studies should be done. A normal value indicates that there is no evidence of lack of oxidative burst function.

IX. LIMITATION OF TESTING

Stimulation with PMA does not occur *in vivo*.

12.1

Introduction

The techniques of molecular biology have contributed tremendously to our understanding of the pathogenesis and epidemiology of infectious diseases. The molecular diagnosis of infectious diseases requires the isolation of nucleic acids from microorganisms and clinical material and the use of restriction endonuclease enzymes, gel electrophoresis, and nucleic acid hybridization techniques. Increasingly, newer techniques for amplification of nucleic acids are applied to clinical material. Although DNA sequence analysis is

not practical for use in the clinical laboratory at the present time, it does provide the ultimate means of characterizing organisms and when coupled with amplification techniques has provided the means to identify uncultivable organisms previously unknown in infectious disease (1, 3, 5, 6, 8).

The use of molecular methods for identification and direct detection of microorganisms in clinical microbiology is evolving gradually. Several products are now available commercially and are becoming

integrated into the routine practice of diagnostic laboratories of all sizes (12, 13). Practical applications of molecular methods include the use of nucleic acid probes and amplification-based techniques for direct detection of organisms in clinical material (Tables 12.1–1 to 12.1–3) or for identification of previously isolated organisms (Table 12.1–4). Furthermore, molecular fingerprinting methods provide a powerful means of characterizing organisms to the subspecies level in epidemiologic investigations (Table 12.1–5). Fi-

^g Available in both qualitative and quantitative formats.

nally, molecular techniques may be used to define specific characteristics of organisms, such as genes encoding toxin production or antimicrobial resistance factors (Table 12.1–6).

As molecular techniques become routine, the critical questions of cost and potential for contribution to patient care must be addressed. In the area of diagnosis of infectious diseases, improved patient outcomes and reduced costs of antimicrobial agents and duration of hospital stay may outweigh increases in laboratory costs which are sure to accompany the use of these more sophisticated testing methods (1, 13). For transmissible infections, the cost of molecular diagnosis and characterization of pathogens may be justified by improved infection control measures to

protect patients and health care workers. Molecular epidemiology may make a real contribution to the detection and control of nosocomial spread of infection, with the potential to reduce infection rates and the requirement for expensive antimicrobial agents to treat resistant organisms (1, 7, 13). Although the use of molecular diagnostic methods for infectious diseases is attractive, one must remember that the value of any of these methods is a function of the degree to which it addresses the limitations of current methods. Presently, much of the justification for expenditures on molecular diagnostics and epidemiology is speculative, and we must continue to critically examine the role of these methods in the care of patients (11–13).

The molecular methods and applications presented in this section are those that either are available commercially for individual laboratories or are accessible through reference laboratories. In most instances the procedures presented address infectious agents or characteristics of microorganisms that are difficult to detect and identify in a timely fashion by conventional methods. The protocols provided are merely representative of the ever-increasing array of molecular techniques that can be applied to the diagnosis of infectious diseases. The interested reader is referred to several excellent manuals that provide additional protocols for use in both diagnostic and research laboratories (4, 9, 10).

Table 12.1–3 Clinically important viral, fungal, and bacterial pathogens tested for by noncommercial nucleic acid amplification-based tests^a

Organism(s)	Specimen type(s)	Clinical indication(s)
EBV	CSF	EBV lymphoproliferative disorder
HSV types 1 and 2	CSF and vitreous humor	Encephalitis and ocular herpes
VZV	Various tissues	VZV reactivation
JC virus	CSF	Progressive multifocal leukoencephalopathy
Enterovirus	CSF	Aseptic meningitis
Parvovirus B19	Amniotic fluid Serum	Hydrops fetalis Anemia
Adenovirus	Urine, tissues, blood	Immunocompromised patients and transplant recipients
<i>Ehrlichia</i>	Blood	Human granulocytic and monocytic ehrlichiosis
<i>Bordetella pertussis</i>	Nasopharyngeal aspirate	Whooping cough
<i>Legionella pneumophila</i>	Respiratory	Atypical pneumonia
<i>Chlamydia pneumoniae</i>	Respiratory	Atypical pneumonia
<i>Mycoplasma pneumoniae</i>	Respiratory	Atypical pneumonia
<i>Helicobacter pylori</i>	Gastric fluid, stool	Peptic ulcer disease
<i>Candida</i>	Blood	Hematogenous candidiasis
<i>Aspergillus</i>	Respiratory and blood	Invasive aspergillosis

^a All tests use PCR. The list is not all-inclusive. Abbreviations: EBV, Epstein-Barr virus; HSV, herpes simplex virus; VZV, varicella-zoster virus.

Table 12.1–5 Molecular methods for epidemiologic typing of microorganisms^a

Method	Substrate	Principal characteristics	Examples
Plasmid analysis	Plasmid DNA	Potentially unstable owing to loss of plasmids. May be augmented by restriction endonuclease digestion.	<i>Staphylococcus aureus</i> , coagulase-negative staphylococci, <i>Klebsiella</i> , <i>Serratia</i> , <i>Enterobacteriaceae</i>
Restriction endonuclease analysis of chromosomal DNA with conventional electrophoresis	Chromosomal DNA	Broadly applicable. Large numbers of bands. Not amenable to computer analysis.	Enterococci, <i>S. aureus</i> , <i>Clostridium difficile</i> , <i>Candida</i> spp.
Pulsed-field gel electrophoresis	Chromosomal DNA	Broadly applicable. Uses infrequently cutting restriction enzymes to generate large DNA fragments (10–800 kb). Fewer bands. Excellent reproducibility and discriminatory power. Expensive equipment	Staphylococci, enterococci, <i>Enterobacteriaceae</i> , <i>Pseudomonas</i> , <i>Candida</i>
Genome restriction fragment length polymorphism analysis with DNA probes	Chromosomal DNA	Broadly applicable. Multistep process. Amenable to computer analysis. Includes IS6110 analysis of <i>M. tuberculosis</i> and ribotyping	<i>Mycobacterium tuberculosis</i> , <i>Candida</i> spp., <i>Enterobacteriaceae</i> , staphylococci, <i>Pseudomonas</i>
PCR-based methods: repetitive-element PCR spacer typing, selective amplification of genome restriction fragments, multilocus allelic sequence-based typing	Chromosomal DNA	Broadly applicable. Rapid and moderately easy to perform. Crude extracts and small amounts of DNA may suffice.	<i>Enterobacteriaceae</i> , <i>Acinetobacter</i> , staphylococci, <i>M. tuberculosis</i> , hepatitis C virus
Library probe genotypic hybridization schemes: multilocus probe dot blot patterns, high-density oligonucleotide patterns	Chromosomal DNA	Unambiguous yes-no result. Less discrimination than with other methods. Couple with DNA chip technology.	<i>Burkholderia cepacia</i> , <i>S. aureus</i> , <i>M. tuberculosis</i>

^a This table contains examples of available methods and applications and is not intended to be all-inclusive. It has been adapted from reference 12.

	Ethambutol	Point mutations in <i>embB</i>	PCR and sequencing
	Streptomycin	Point mutations in <i>rpsL</i> and <i>rrs</i>	PCR and RFLP
Herpesviruses ^g	Acyclovir and related drugs	Mutations or deletions in the TK gene	PCR and sequencing
	Foscarnet	Point mutations in the DNA polymerase gene	PCR and sequencing
HIV	Nucleoside RT inhibitors	Point mutations in the RT gene	PCR and sequencing; PCR and LIPA
	Protease inhibitors	Point mutations in the PROT gene	PCR and sequencing

^a Adapted from reference 12. Abbreviations: bDNA, branched-chain DNA; RFLP, restriction fragment length polymorphism; SSCP, single stranded conformational polymorphism; LIPA, line probe assay; TK, thymidine kinase; RT, reverse transcriptase; PROT, protease; HIV, human immunodeficiency virus.

^b *mecA* encodes the altered penicillin binding protein PBP2a; phenotypic methods may require 48 h of incubation or more to detect resistance and are less than 100% sensitive. Detection of *mecA* has potential for clinical application in specific circumstances.

^c Vancomycin resistance in enterococci may be related to one of four distinct resistance genotypes of which *vanA* and *vanB* are of the most importance. Genotypic detection of resistance is useful in validation of phenotypic methods.

^d Penicillin and cephalosporin resistance in *S. pneumoniae* is due to the alteration of one or more penicillin binding proteins.

^e The genetic basis of resistance to β-lactam antimicrobial agents among *Enterobacteriaceae* is extremely complex. The *bla*_{TEM} and *bla*_{SHV} genes are the two most common sets of plasmid-borne β-lactamase genes. The presence of either a *bla*_{TEM} or *bla*_{SHV} gene implies ampicillin resistance. Variants of the *bla*_{TEM} and *bla*_{SHV} genes (extended-spectrum β-lactamases) may also encode resistance to a range of broad-spectrum cephalosporins and to monobactams.

^f *M. tuberculosis* is a very slow-growing organism. Four weeks or more may be required to obtain phenotypic susceptibility test results. Detection of resistance genes in *M. tuberculosis* has potential for clinical application in the short term.

^g There are no phenotypic methods sufficiently practical for routine clinical detection of resistance to antiviral agents. Genotypic methods represent a practical approach to the routine detection of antiviral resistance.

12.2.1

Introduction

The detection of pathogenic microorganisms directly in clinical specimens by molecular methods has been investigated extensively using a variety of nucleic acid probe hybridization, target amplification, and signal-generating formats. Commer-

cial product development has focused on direct diagnosis of blood-borne and sexually transmitted diseases and respiratory pathogens using solid- and solution-phase hybridization with nonisotopic nucleic

acid probes and several different target amplification methods, including PCR, ligase chain reaction, strand displacement amplification, and transcription-mediated amplification (Table 12.1–1).

12.2.2

Nucleic Acid Probe-Based Methods

Direct diagnosis by nucleic acid probe hybridization is simple, rapid, and relatively free of the contamination and inhibition problems associated with target amplification methods. The sensitivity of probe hybridization methods is limited by the relatively large number of copies ($\sim 10^4$)

of the target sequence required to generate a positive signal. Efforts to improve the sensitivity of the nucleic acid probe-based methods include the use of RNA targets, various signal amplification formats, and reduction of the background signal (1–3).

PART 1

Gen-Probe PACE 2 Nucleic Acid Hybridization Test for Detecting *Chlamydia trachomatis* and *Neisseria gonorrhoeae*

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The Gen-Probe PACE 2 systems (Gen-Probe, Inc., San Diego, Calif.) for *Chlamydia trachomatis* and *Neisseria gonorrhoeae* are rapid DNA probe tests that utilize the technique of nucleic acid hybridization for the detection of *C. trachomatis* and *N. gonorrhoeae*, respectively, in

endocervical and male urethral swab specimens. The test for *C. trachomatis* may also be applied to conjunctival specimens. The Gen-Probe PACE 2 systems use a chemiluminescently labeled DNA probe that is complementary to the rRNA of the

target organism. The labeled DNA-RNA hybrid is separated from nonhybridized probe and the luminescence of the hybrid is measured in a luminometer.

■ **NOTE:** This procedure had been adapted from that of Cintron (1).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

Specimens from the urogenital tract (endocervical, male urethra) and conjunctiva must be obtained using the Gen-Probe specimen collection kit (containing a transport tube and swab).

B. Time of specimen collection

There are no particular timing issues to consider in collection of these specimens; however, the time of collection should be recorded.

C. Specimen transport

Collection tubes containing the appropriate swab specimens must be transported to the laboratory at 2 to 25°C and may be stored at 2 to 25°C for up to 7 days before testing. If longer storage is necessary, process the specimen as described in section VA below, and freeze at -20 to -70°C.

D. Specimen labeling and request submission

The laboratory should determine a mechanism to ensure that the specimen type and time of collection are recorded.

E. Rejection criteria

1. Test only the indicated specimen types (endocervical, urethral, conjunctival) in the indicated transport medium. Testing of other specimen types or use of other transport media has not been validated.
2. Grossly bloody specimens (greater than 80 µl of whole blood in 1 ml of transport medium) could interfere with the assay. A repeat specimen should be requested if possible.
3. Repeat testing to evaluate efficacy of therapy is not indicated for nonculture tests.
4. Request a repeat specimen, or obtain the information, when the collection time or specimen type has not been provided.
5. Reject specimens that arrive in leaky containers.
6. Nonculture methods should not be used in cases of suspected sexual abuse.
7. If an improperly collected, transported, or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised.

III. MATERIALS

☑ **NOTE:** Do not freeze reagents contained in PACE 2 kits.

A. Reagents

1. Gen-Probe PACE 2 system for *C. trachomatis*
2. Gen-Probe PACE 2 system for *N. gonorrhoeae*
3. Gen-Probe PACE 2 detection reagent kit

B. Supplies

1. Gen-Probe PACE 2 specimen collection kit
 - a. Urethral-conjunctival collection kit
 - b. Endocervical collection kit
2. Wash bottle and cap assembly (provided)

3. Sealing cards (provided)

☑ **NOTE:** Items 4 to 7 are required but not provided

4. Disposable polystyrene tubes (12 by 75 mm)
5. Pipette tip (1 to 5 ml)
6. Pipette tip (100 µl)
7. Absorbent paper

C. Equipment (required but not provided)

1. Leader I luminometer
2. Covered water bath (60 ± 1°C)
3. Vortex mixer
4. Magnetic rack
5. Certified thermometer
6. Micropipettor (100 µl)
7. Pipettes capable of delivering 1 to 25 ml

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. Verify that transport media and kits meet expiration date and QC parameters per NCCLS document M22-A2 (2).
- B. Negative reference
 - 1. The response of each negative reference should be <200 but >20 relative light units (RLU).
 - 2. All negative reference values should fall within 30% of the mean response of the negative reference.
 - 3. If one value falls outside these ranges, it may be deleted.
 - 4. If two values fall outside these ranges, the results should not be reported, and the assay must be repeated.
- C. Positive control (provided)
 - 1. The difference in the response of the positive control and the mean response of the negative reference should be >600 RLU.
 - 2. If the positive control value is not in the required range, the test results are not acceptable, and the assay must be repeated.

V. PROCEDURE

- A. **Sample preparation**
 - 1. Allow the transport tubes containing the swab specimens to come to room temperature and then vortex for 5 to 10 s.
 - 2. Express all liquid from the swab by pressing the swab against the wall of the tube. Discard the swab.
 - 3. Vortex the tubes for 5 to 10 s to ensure homogeneity.
- B. **Reagent preparation**
 - 1. Probe reagent
 - a. Remove hybridization buffer from the kit, vortex for 10 s, warm in a water bath (60°C) for 3 to 4 min, and then vortex for 10 s to ensure homogeneity.
 - b. Pipette 6.0 ml of the buffer into lyophilized probe reagent, let stand at room temperature for 2 min, and vortex for 10 s. Visually inspect the mixture to ensure complete rehydration and homogeneity.
 - c. Record the expiration date of the preparation on the label. Reagent is stable for 3 weeks at 2 to 8°C.
 - 2. Separation suspension
 - a. Determine number of tests to be performed.
 - b. Calculate volume of selection reagent and separation reagent needed as follows:
 - (1) Volume (milliliters) of selection reagent
 - (a) When using an Eppendorf pipettor = number of tests + two extra tests
 - (b) When using a bottle top dispenser = number of tests + 10 extra tests
 - (2) Volume (milliliters) of separation reagent = volume of selection reagent divided by 20.
 - c. Pour required volume of selection reagent into a clean, dry container.
 - d. Add the required volume of separation reagent to the selection reagent, and mix well. The separation suspension is stable at room temperature for 6 h.
- C. **Hybridization**
 - 1. Label tubes with sample identification numbers and insert into magnetic rack. Include three tubes for negative reference and one for the positive control.
 - 2. Vortex each specimen for 5 s.

V. PROCEDURE (*continued*)

3. Pipette 100 μ l of each control and each specimen into the bottoms of the appropriate tubes.
4. Pipette 100 μ l of the probe reagent to the bottom of each tube, taking care not to touch the top or sides of the tube.
5. Seal the tubes with sealing cards and shake the rack three to five times to mix the contents.
6. Incubate the rack with tubes in a water bath ($60 \pm 1^\circ\text{C}$) for 1 h.

D. Separation

1. Remove the tube rack from the water bath, and pipette 1 ml of the separation solution into each tube.
2. Cover the tubes with sealing cards, shake three to five times, and incubate in a water bath ($60 \pm 1^\circ\text{C}$) for 10 min.
3. Place tube rack on the base of the Gen-Probe magnetic separation unit for 5 min at room temperature.
4. Holding the tube rack and base of magnetic separation unit together, invert to decant the supernatants, shake the unit two or three times, and then blot the inverted tubes on absorbent paper.
5. *Do not remove the tube rack from the magnetic separation base.* Fill each tube to the rim with wash solution and let sit on magnetic separation base for 20 min at room temperature.
6. Holding the tube rack and base together, decant wash fluid. *Do not blot.* Approximately 50 to 100 μ l of wash solution should remain in each tube.
7. Separate the tube rack from the base, and shake to suspend the pellets.

E. Equipment preparation

1. Prepare the Gen-Probe Leader luminometer for operation. Make sure there are sufficient volumes of detection reagents 1 and 2 to complete the tests.
2. Select the appropriate protocol from the instrument software.

F. Detection

1. Wipe each tube to ensure that no residue is present on the outside of the tube.
2. Mix each tube to suspend the pellets, and insert into the instrument based on the prompts provided by the software.
3. Read the tubes in the following order.
 - a. Negative reference: three tubes
 - b. Positive control: one tube
 - c. Specimen tubes
4. When the analysis is completed, remove the last tube, replace it with an empty tube, and follow the instrument prompts.

G. Calculation of results

1. Results are calculated on the basis of the difference between the response in RLU of the specimen and the mean of the negative reference.
2. The mean of the negative reference equals the sum of the three negative reference replicates divided by 3.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. Report results as positive or negative for the presence of *C. trachomatis* and/or *N. gonorrhoeae*.
- B. A positive direct test for *N. gonorrhoeae* should prompt the collection of an additional specimen for culture and antimicrobial susceptibility testing.
- C. Document all testing in hard copy or computerized work card.

VII. INTERPRETATION

- A. The luminometer prints the specimen response (in RLU) and compares this response to an assigned assay cutoff. A positive or negative interpretation resulting from this comparison is printed.
- B. A positive result indicates that the target organism is present in the specimen and strongly supports a diagnosis of chlamydial or gonococcal infection.
- ▣ **NOTE:** A positive direct test for *N. gonorrhoeae* should prompt the collection of an additional specimen for culture and antimicrobial susceptibility testing.
1. Positive for *C. trachomatis*. The response difference is ≥ 350 RLU.
 2. Positive for *N. gonorrhoeae*. The response difference is ≥ 300 RLU.
- C. A negative result indicates that the target organism is not present in the specimen.
1. Negative for *C. trachomatis*. The response difference is < 350 RLU.
 2. Negative for *N. gonorrhoeae*. The response difference is < 300 RLU.

VIII. LIMITATIONS OF TESTING

- A. Only standard culture methods for *N. gonorrhoeae* and *C. trachomatis* should be used for evaluation of suspected sexual abuse and for other medico-legal indications.
- B. Additional testing is recommended in any circumstance when false-positive results could lead to adverse medical, social, or psychological consequences. Test results should be interpreted with consideration of clinical and laboratory findings.
- C. The presence of blood in cervical specimens may cause erroneous results (usually false positives).
- D. A negative result does not exclude the possibility of infection, because reliable results are dependent on adequate specimen collection.
- E. Therapeutic success or failure cannot be determined, because target organism nucleic acids may persist after appropriate antimicrobial agent therapy.

PART 2**Solution Hybridization Antibody Capture Assay for the Chemiluminescent Detection and Quantitation of Human Cytomegalovirus DNA in WBCs****PREANALYTICAL CONSIDERATIONS****I. PRINCIPLE**

The Digene Hybrid Capture CMV DNA assay (Digene Diagnostics, Inc., Silver Spring, Md.) is a solution hybridization antibody capture assay for the chemiluminescent detection and quantitation of human cytomegalovirus (CMV) in WBCs. Specimens containing the target DNA hybridize with a specific CMV RNA probe

cocktail. The resultant RNA-DNA hybrids are captured onto the surface of a tube coated with antibodies specific for RNA-DNA hybrids. Immobilized hybrids are then reacted with alkaline phosphatase-conjugated antibodies specific for the RNA-DNA hybrids and detected with a

chemiluminescent substrate. As the substrate is cleaved by the bound alkaline phosphatase, light is emitted and is measured as relative light units (RLU) on a luminometer. The intensity of the light emitted is proportional to the amount of target DNA in the specimen.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING**A. Specimen collection**

Whole blood, 7 to 10 ml, collected in an EDTA-lavender tube. The test requires a minimum of 3.5 ml of blood.

B. Timing of specimen collection

There are no particular timing issues to consider in collecting these specimens; however, the time of collection should be recorded.

C. Specimen transport

Whole blood (4 to 7 ml) collected in an EDTA tube must be processed within 48 h from the time of collection. After 48 h, adequate cell recovery may not occur. Immediately after collection, whole blood may be stored for up to 24 h at 20 to 25°C. Thereafter, the blood should be stored at 2 to 8°C until processing.

D. Specimen labeling and request submission

The laboratory should determine a mechanism to ensure that the specimen type and time of collection are recorded.

E. Rejection criteria

1. Test only whole blood collected in EDTA. Test performance characteristics with other anticoagulants have not been determined.
2. Test performance characteristics with neonatal specimens have not been determined.
3. Repeat testing to monitor antiviral therapy is not indicated with this test.
4. Request a repeat specimen, or obtain the information, when the collection time has not been specified.
5. Specimens submitted more than 48 h after collection should be rejected.
6. Reject specimens that arrive in leaky containers.
7. If an improperly collected, transported, or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised.

III. MATERIALS**A. Reagents (items 1 to 11 provided)**

1. Lysis buffer concentrate
2. Negative control (NC)
3. Positive standards 1 to 3 (PS1, PS2, PS3)
4. Positive control (PC)
5. Sample diluent
6. Denaturation reagent
7. Indicator dye

8. CMV probe

9. Probe diluent
10. Detection reagents 1 and 2
11. Wash buffer pack
12. Sodium hypochlorite solution (household bleach [required but not provided])

III. MATERIALS (continued)

- B. Supplies (items 3 through 13 required but not provided; items 8, 12, and 13 available from Digene Diagnostics, Inc.)**
1. Hybridization tubes and caps (provided)
 2. Capture tubes (provided)
 3. Graduated polypropylene conical vials (15 ml) with screw caps
 4. Disposable transfer pipettes (5 ml) with standard tips
 5. Disposable pipettes (5 ml) with extra fine tips
 6. Sterile, RNase-free disposable micropipettor tips
 7. Disposable pipette tips (25, 50, 75, and 250 μ l)
 8. Disposable 1-ml plastic transfer pipettes
 9. Parafilm or equivalent
 10. Polystyrene tubes (12 by 75 mm)
 11. Specimen test tube racks
 12. Hybridization racks
 13. Decanting racks
- C. Equipment (required but not provided; items 5 and 6 available from Digene Diagnostics, Inc.)**
1. Clinical centrifuge with swinging bucket rotor
 2. $70 \pm 2^\circ\text{C}$ water bath
 3. Vortex mixer
 4. Rotary shaker with adjustable speed setting
 5. Wash apparatus
 6. DCR-1 luminometer or equivalent
 7. Micropipettor with variable settings (20 through 200 μ l)
 8. Repeating positive-displacement pipettor

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. Verify that kits and reagents meet expiration date and QC parameters per NCCLS document M22-A2 (1).
- B. As a validation procedure, users must test PSs in triplicate until satisfactory results have been obtained in several consecutive assays.
- C. For a qualitative assay, the NC must be tested in triplicate and PS1 must be tested in duplicate for each test run.
- D. For a quantitative assay, the NC and PS1, -2, and -3 must be tested in duplicate for each test run.
- E. The detection reagent 2 blank should have an RLU value of $<5,000$ and less than all control values. Values above 5,000 RLU suggest detection reagent 2 contamination. Specimen results cannot be interpreted in this case.
- F. All control results should demonstrate a variability of $\leq 30\%$. If the variability of any triplicate result is $>30\%$, discard the control value with an RLU value furthest from the mean as an outlier and recalculate the mean using the remaining two control values. If the difference between the mean and each of the two values is $\leq 30\%$, proceed to the next step; otherwise, the assay is invalid and must be repeated.
- G. The mean of the NC results should be $\leq 12,000$ RLU. If the mean of the NC is $>12,000$ RLU, the assay is invalid and must be repeated.
- H. The PS mean (PS_{mean}) and NC mean (NC_{mean}) results are used to calculate the ratios that validate the assay. These results must be within the following acceptable ranges to validate the assay before the specimen results can be interpreted.

Assay	Calculation	Acceptable range
Qualitative	$PS1_{\text{mean}}/NC_{\text{mean}}$	1.5–10.0
Quantitative	$PS1_{\text{mean}}/NC_{\text{mean}}$	1.5–10.0
	$PS2_{\text{mean}}/NC_{\text{mean}}$	10.0–200
	$PS3_{\text{mean}}/NC_{\text{mean}}$	100–1,200

- I. Calculate the appropriate ratios shown above using the mean values on the luminometer printout tape. If all of the results are within their respective ranges, proceed to the next step. If any of the calculated values fall outside its expected range, the assay is invalid and must be repeated.

IV. QUALITY CONTROL (continued)

- J. The PC contains a defined concentration of CMV DNA that is detectable using the CMV DNA assay. This sample may be tested to meet the QC requirements of the testing laboratory. Acceptable values for the PC are as follows.

Assay	Calculation	Acceptable range
Qualitative	PC/NC _{mean}	1.8–15
Quantitative		10.5–42 pg/ml

V. PROCEDURE

A. Sample preparation

1. Add 3.5 ml of whole blood to 10 ml of 1 × lysis buffer. Mix and incubate for 15 min at 20 to 25°C. Centrifuge at 1,000 × g for 15 min. Discard supernatant.
2. Label hybridization tubes.
3. Suspend cell pellet in 1.5 ml of 1 × lysis buffer. Transfer to hybridization tubes and incubate for 10 min at 20 to 25°C.
4. Centrifuge hybridization tubes to pellet cells. Discard supernatant.
 - **NOTE:** At this point the specimens (cell pellets) may be tested immediately in the CMV DNA assay or may be stored at –20°C for future testing.

B. Denaturation

1. Place specimen hybridization tubes (containing specimen) in a hybridization rack.
2. Place labeled NC, PS1 (from kit), PS2 (no. 4 from Digene CMV test panel), PS3 (no. 6 from Digene CMV test panel), and PC tubes in hybridization tube rack (three NC, three PS1, three PS2, three PS3, and one PC). Use a clean pipette tip for each transfer to avoid contamination of controls.
3. Pipette 75 µl of sample diluent and 50 µl of denaturation reagent into each specimen hybridization tube. Cap and vortex each specimen.
4. Pipette 100-µl controls or standards into the bottoms of control and standard hybridization tubes.
5. Pipette 50 µl of denaturation reagent into control and standard hybridization tubes.
6. Tighten caps on hybridization tubes and shake rack to mix on a rotary shaker set at 1,100 ± 100 rpm for 5 ± 2 min. *Standards will be dark purple; specimens will be purple to greenish-purple.*
7. Incubate in a 70 ± 2°C water bath for 25 ± 5 min (label a new set of hybridization tubes for each specimen during this incubation).
8. Remove hybridization rack from water bath. Visually inspect to ensure that pellets have dissolved. Vortex individual tubes to suspend any remaining material.
9. Transfer specimens to fresh hybridization tubes.
10. Return hybridization rack to a 70 ± 2°C water bath and incubate for 25 ± 5 min (prepare CMV probe mix).

C. Hybridization

1. Loosen hybridization tube caps. Pipette 50 µl of CMV probe mix into each tube. Recap hybridization tubes with same caps and shake on a rotary shaker at 1,100 ± 100 rpm for 5 ± 2 min. *Controls, standards, and specimens should turn yellow.*
2. Incubate in a 70 ± 2°C water bath for 120 ± 5 min (label capture tubes).

D. Hybrid capture

1. Transfer contents from each hybridization tube to corresponding capture tube. Cover with Parafilm or equivalent. Shake at 1,100 ± 100 rpm at 20 to 25°C for 60 ± 5 min (prepare wash buffer).
2. Decant and blot capture tubes.

V. PROCEDURE (*continued*)**E. Hybrid detection**

1. Pipette 250 µl of detection reagent 1 into each capture tube. Cover capture tubes and shake side to side and back to front by hand. Incubate at 20 to 25°C for 30 ± 3 min.
2. Decant and blot capture tubes.
3. Wash five times with wash buffer. Drain for 5 min on absorbent paper.

F. Signal generation and reading

1. Pipette 250 µl of detection reagent 2 into each capture tube and incubate at 20 to 25°C for 30 ± 3 min.
2. Wipe and read capture tubes on a luminometer.
3. Validate assay and calculate specimen results.

G. Calculation of results

1. Once the test run has been validated, the positive cutoff value (PCV) is calculated using the following formula: $PCV = NC_{\text{mean}} \times 2$.
2. To determine the actual concentration of CMV in the specimen, the number of genome equivalents detected must be calculated from the concentration of DNA (in picograms per milliliter) reported by the luminometer using the following formula:

$$\frac{\text{CMV genomes}}{\text{Assay}} = \text{Reported CMV DNA concentration (pg/ml)} \\ \times 2,410 \frac{\text{genomes-ml}}{\text{assay-pg}}$$

The number of CMV genomes per milliliter of specimen may be calculated as follows:

$$\frac{\text{CMV genomes}}{\text{assay}} \times \text{initial specimen volume (ml)} = \frac{\text{CMV genomes}}{\text{ml of specimen}}$$

3. Only specimens with RLU values between PS1 and PS3 RLU values can be quantitated accurately since this is the linear range of the test.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. Specimens with RLU values that are greater than or equal to the PC value should be reported as positive for CMV DNA.
- B. Specimens with RLU values that are <90% of the PC value contain CMV DNA levels that are below the detection limit of the assay or do not contain CMV DNA. These should be reported as “no CMV DNA detected.”
- C. Specimens with RLU values between 90 and 99.9% of the PC value should be reported as “equivocal.” A second sample should be obtained and tested.
- D. When the quantitative assay is performed, only specimens with RLU values between PS1 and PS3 values can be quantified accurately since this is in the linear range of the assay. Samples with RLU values within the linear range of the assay should be reported as the number of CMV genomes per milliliter of specimen. Samples giving RLU values greater than the PS3 value should be reported as “high positive,” and positive samples giving RLU values below the PS1 value but greater than the PCV should be reported as “low positive.”
- E. For patients with WBC counts of <400 mm³, footnote the phrase “interpret negative results with caution due to low WBC count.”
- F. Call positive results to requesting area. Note on the worksheet the name of the person called, date, and time, and initial.
- G. Document all testing in hard copy or computerized work card.

VII. INTERPRETATION

- A. The qualitative tests provide evidence for or against the presence of CMV viremia.
- B. Specimens with levels of CMV DNA below the detection limits of the test or those with equivocal values should be followed up with repeat testing if indicated clinically.
- C. Quantitative results reported as CMV genomes per milliliter of specimen may serve as an estimate of the viral load in the patient.

VIII. LIMITATIONS OF THE PROCEDURE

- A. Digene Hybrid Capture CMV DNA assay procedure, QC, and the interpretation of specimen results must be followed closely to obtain reliable results.
- B. Test performance characteristics with anticoagulants other than EDTA and acid citrate dextrose have not been determined. The Digene Hybrid Capture assay can be used only with whole-blood specimens collected and processed as described under item II above.
- C. It is important to pipette the exact reagent volume indicated and to mix well after each reagent addition. Failure to do so could result in erroneous test results. Ensuring that the noted color changes occur will help to confirm that these conditions have been met.
- D. A negative result does not exclude the possibility of CMV infection, since very low levels of infection or sampling error may cause a false-negative result.
- E. The Digene CMV DNA assay is not intended for antiviral drug monitoring.
- F. Performance characteristics of this assay with patient populations other than immunosuppressed and immunocompromised patients have not been determined.

PART 3**Solution Hybridization Antibody Capture Chemiluminescent Assay for the Detection of Human Papillomavirus Types in Cervical Specimens****PREANALYTICAL CONSIDERATIONS****I. PRINCIPLE**

The Digene Hybrid Capture HPV DNA assay (Digene Diagnostics, Inc., Silver Spring, Md.) is a hybridization antibody capture assay using chemiluminescence to qualitatively detect the presence of 14 human papillomavirus (HPV) types: 6, 11, 16, 18, 31, 33, 35, 42, 43, 44, 45, 51, 52, and 56. The HPV DNA assay can differentiate between two HPV DNA groups

based upon their risk of cervical neoplasm (low-risk HPV types 6, 11, 42, 43, and 44 and high- or intermediate-risk HPV types 16, 18, 31, 33, 35, 45, 51, 52, and 56) in cervical specimens (cervical swabs and fresh cervical biopsy samples) collected using the Digene specimen collection kit or Digene specimen transport medium. Specimens containing the target DNA hy-

bridize with a specific HPV RNA probe cocktail. The resultant RNA-DNA hybrids are captured onto the surface of a tube coated with antibodies specific for RNA-DNA hybrids. Immobilized hybrids are then reacted with alkaline phosphatase-conjugated antibodies specific for the hybrids and detected with a chemiluminescent substrate.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING**A. Specimen collection**

Cervical specimens (cervical swabs and cervical biopsy specimens) must be collected by using the Digene specimen collection kit and transported in Digene specimen transport medium. Specimens taken with other sampling devices or transported in other transport media are not suitable for this assay.

B. Timing of specimen collection

There are no particular timing issues to consider in collecting these specimens; however, the time of collection and specimen type should be recorded.

C. Specimen transport

1. Appropriately collected cervical swab specimens may be held for up to 2 weeks at room temperature and shipped without refrigeration to the testing laboratory. At the testing laboratory, specimens should be stored at 2 to 8°C if the assay is to be performed within 1 week of collection. If the assay will be performed later than 1 week, store specimens at -20°C.
2. Freshly collected cervical biopsy specimens up to 5 mm in cross section may also be analyzed with the HPV DNA assay. The biopsy specimen must be placed immediately into 1 ml of Digene specimen transport medium and stored at -20°C. Biopsy specimens may be shipped at 20 to 25°C for overnight delivery to the testing laboratory and stored at -20°C until processed. Biopsy specimens less than 2 mm in diameter should not be used.

D. Specimen labeling and request submission

The laboratory should determine a mechanism to ensure that the specimen type and time of collection are recorded.

E. Rejection criteria

1. Test only those specimens that have been collected using the Digene specimen collection kit and transported in Digene specimen transport medium.
2. Cervical biopsy specimens less than 2 mm in diameter should not be tested.
3. Request a repeat specimen, or obtain the information, when the specimen type and the collection time have not been specified.
4. Reject specimens that arrive in leaky containers.
5. If an improperly collected, transported, or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised.

III. MATERIALS

- A. Reagents (items 1 through 11 provided)**
1. Negative control (NC)
 2. Positive control A (PCA)
 3. Positive control B (PCB)
 4. Denaturation reagent
 5. Indicator dye
 6. Probe diluent
 7. HPV probe A (HPV 6, 11, 42, 43, and 44 RNA probe cocktail)
 8. HPV probe B (HPV 16, 18, 31, 33, 35, 45, 51, 52, and 56 RNA probe cocktail)
 9. Detection reagent 1
 10. Detection reagent 2
 11. Wash buffer pack
 12. Sodium hypochlorite solution (household bleach [required but not provided])
- B. Supplies (items 5 through 13 required but not provided; items 6, 7, and 13 available from Digene Diagnostics, Inc.)**
1. Specimen transportation tube vent caps (provided)

 7. Decanting racks
 8. Disposable bench cover, paper towels, powder-free gloves, Kim-wipes or equivalent
 9. Parafilm or equivalent
 10. Polystyrene tubes (12 by 75 mm)
 11. Sterile RNase-free disposable pipette tips (20 to 200 μ l)
 12. Disposable pipette tips (50, 250, and 500 μ l)
 13. Disposable 1-ml transfer pipettes
- C. Equipment (required but not provided; items 4 and 5 available from Digene Diagnostics)**
1. $65 \pm 2^\circ\text{C}$ water bath
 2. Vortex mixer
 3. Rotary shaker with adjustable speed setting
 4. Wash apparatus
 5. DCR-1 luminometer or equivalent
 6. Micropipettor with variable settings for 20- to 200- μ l delivery volumes
 7. Repeating positive-displacement pipettor

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A.** Verify that kits and reagents meet expiration date and QC parameters per NCCLS document M22-A2 (1).
- B.** Combined probe cocktail method
1. Three replicates of NC, PCA, and PCB must be tested with the combined probe cocktail for each test run.
 2. PCA and PCB should be assayed separately.
- C.** Two-probe method
1. Three replicates of PCA and NC must be tested with HPV probe A for each test run.
 2. Three replicates of PCB and NC must be tested with HPV probe B for each test run.
- D.** Both methods
1. The detection reagent 2 blank should have a relative light unit (RLU) value that is $<5,000$ and less than all control values.
 2. All control results should have a demonstrated variability of $\leq 30\%$.
 3. The PC mean (PC_{mean}) and NC mean (NC_{mean}) results are used to calculate the $PC_{\text{mean}}/NC_{\text{mean}}$ ratio for each probe. These ratios must all be ≥ 1.5 in order to validate the assay and before the specimen results can be interpreted.

V. PROCEDURE

- A. Setup**
1. Specimens
 - a. Remove specimens and all required reagents from refrigerator prior to beginning assay.
 - b. Allow specimens to reach 20 to 25°C for at least 15 to 30 min.
 - c. Mix specimens thoroughly by vortexing.

V. PROCEDURE (*continued*)

- d. Specimens may be tested once with the combined probe cocktail or once with HPV probe A cocktail and once with HPV probe B cocktail if using the two-probe method.

2. Controls

- a. If using the combined probe cocktail method, PCA, PCB, and NC should be each tested in triplicate with the combined probe cocktail.
- b. If using the two-probe method, PCA and NC should be tested in triplicate with HPV probe A cocktail. PCB and NC should be tested in triplicate with HPV probe B cocktail.

B. Denaturation and hybridization: combined probe cocktail and two-probe method

1. Pipette 500 μ l of denaturation reagent into bottoms of control and specimen tubes. Cap tubes with vent caps and vortex to mix thoroughly. Check that all tubes show a purple color.

■ **NOTE:** Some cervical specimens may contain blood or other material which may mask the color changes upon addition of denaturation reagent and probe. In these cases, failure to exhibit the proper color change will not affect the results of the assay.

2. Incubate at $65 \pm 2^\circ\text{C}$ for 45 ± 5 min.
3. Label hybridization tubes and prepare probe cocktails.
4. Pipette 50 μ l of appropriate probe cocktail (combined, probe A, or probe B) into the bottoms of the hybridization tubes.
5. Mix denatured specimen well, remove swab, vortex, and pipette 150 μ l into the bottoms of hybridization tubes.
6. Recap tubes and shake on a rotary shaker at $1,100 \pm 100$ rpm for 3 ± 2 min. Check that all tubes show a yellow color.
7. Incubate at $65 \pm 2^\circ\text{C}$ for 60 ± 5 min.
8. Label capture tubes.

C. Hybrid capture

1. Transfer contents from each hybridization tube to corresponding capture tube.
2. Cover tubes with Parafilm or equivalent and shake at $1,100 \pm 100$ rpm at 20 to 25°C for 60 ± 5 min. Prepare wash buffer.
3. Decant and blot tubes.

D. Hybrid detection

1. Pipette 250 μ l of detection reagent 1 into each capture tube. Cover tubes and shake by hand several times side to side and back to front.
2. Incubate at 20 to 25°C for 30 ± 3 min.
3. Decant and blot tubes.
4. Wash five times with wash buffer and drain for 5 min on absorbent paper.

E. Signal generation

1. Pipette 250 μ l of detection reagent 2 into each capture tube. Include detection reagent 2 blank at this time.
2. Incubate in the dark at 20 to 25°C for 20 ± 3 min.
3. Wipe and read tubes in a luminometer.
4. Validate assay (QC) and interpret specimen results.

F. Calculation of results

1. Once the assay has been validated, the cutoff values for determining positive specimens are as follows.
 - a. Combined probe cocktail method

$$\frac{0.8 \times (\text{PCA}_{\text{mean}} + \text{PCB}_{\text{mean}})}{2}$$

V. PROCEDURE *(continued)***b. Two-probe method**

$$\text{Probe A cutoff} = 1 \times \text{PCA}_{\text{mean}}$$

$$\text{Probe B cutoff} = 1 \times \text{PCB}_{\text{mean}}$$

2. All specimen RLU values should be converted into a ratio to the appropriate cutoff value. For example, all assays tested with HPV probe A should be expressed as specimen RLU divided by cutoff value A.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. Specimens with RLU/cutoff value ratios of ≥ 1.0 with the combined probe cocktail are considered positive for one or more of HPV types 6, 11, 16, 18, 31, 33, 35, 42, 43, 44, 45, 51, 52, and 56.
- B. Specimens with RLU/cutoff value ratios of ≥ 1.0 with HPV probe A only are considered positive for one or more of HPV types 6, 11, 42, 43, and 44.
- C. Specimens with RLU/cutoff value ratios of ≥ 1.0 with HPV probe B only are considered positive for one or more of HPV types 16, 18, 31, 33, 35, 45, 51, 52, and 56.
- D. Specimens with RLU/cutoff value ratios of ≥ 1.0 with both probe A and probe B are considered positive for one or more HPV types from each group of probes.
- E. Specimens with RLU/cutoff value ratios of < 1.0 for combined probe cocktail or both HPV probe A and probe B are considered negative (can be reported as “none detected”) for the 14 HPV types tested.
- F. Call positive results to requesting area. Note on the worksheet the name of the person called, date, and time, and initial.
- G. Document all testing in hard copy or computerized work card.

VII. INTERPRETATION

- A. The results provide evidence for or against HPV infection of cervical tissue.
- B. HPV types 6, 11, 42, 43, and 44 are considered low risk for cervical neoplasia (HPV probe A).
- C. HPV types 16, 18, 31, 33, 35, 45, 51, 52, and 56 are considered high or intermediate risk for cervical neoplasia (HPV probe B).
- D. An RLU/cutoff value ratio of < 1.0 means that either HPV DNA sequences are absent or the HPV DNA levels are below the detection limit of the assay.

VIII. LIMITATIONS OF THE PROCEDURE

- A. Digene Hybrid Capture HPV DNA assay procedure, QC, and the interpretation of specimen results must be followed closely to obtain reliable results.
- B. Test performance characteristics with specimens other than cervical swabs and cervical biopsy samples have not been determined. The Digene Hybrid Capture assay can be used only with cervical specimens collected and processed as described under item II above.
- C. Biopsy specimens < 2 mm in diameter should not be tested.
- D. It is important to pipette the exact reagent volume indicated and to mix well after each reagent addition. Failure to do so could result in erroneous test results. Ensuring that the noted color changes occur will help to confirm that these conditions have been met.
- E. A negative result does not exclude the possibility of HPV infection since very low levels of infection or sampling error may cause a false-negative result.

12.2.3

Amplification-Based Methods

Nucleic acid target amplification has the potential to overcome the lack of sensitivity that is the primary limitation of probe hybridization methods when used for direct detection of infectious agents in clinical material. As the first amplification technique to be developed, PCR remains the most widely applied molecular method for diagnosis of infectious diseases. Commercial kits employing PCR technology

for detection of *Mycobacterium tuberculosis*, hepatitis C virus, human immunodeficiency virus, *Neisseria gonorrhoeae*, and *Chlamydia trachomatis* have been developed and are available. The availability of commercial products with built-in contamination controls, standardized reagents, and potential for automation has certainly increased the reproducibility and

ease of application of this technology. The newer amplification technologies such as ligase chain reaction, transcription-mediated amplification, strand displacement amplification, and nucleic acid strand-based amplifications form the basis of additional diagnostic systems that are available for use in the clinical laboratory (Table 12.1–2).

PART 1

Detection of *Chlamydia trachomatis* in Genitourinary Specimens by Using the Roche Amplicor PCR Kit

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The Amplicor *Chlamydia trachomatis* test is a direct DNA probe test that uses PCR and nucleic acid hybridization for detection of *C. trachomatis* plasmid DNA in endocervical, urethral (male), and urine (male and female) samples. *C. trachomatis* contains, in addition to its chromosomal DNA, a cryptic plasmid (ca. 7,500 bp)

that is common to all serovars of *C. trachomatis*. For the detection of *C. trachomatis* DNA in the Amplicor *C. trachomatis* test, the specific target sequence DNA is located on the cryptic plasmid and is 207 bp in length. Each elementary body of *C. trachomatis* contains about 10 copies of this plasmid, and the reticulate body

stage contains at least 10 copies of the plasmid, depending on its state of replication. The Amplicor *C. trachomatis* test is based upon three major processes: PCR amplification, hybridization of the amplified product to a specific nucleic acid probe, and detection of the amplified product by color formation.

12.2.3.1

Because of the sensitivity of the PCR method, it is necessary to limit the potential for contamination by performing each step of the process in a *separate area* (preferably separate rooms) of the laboratory and to dedicate equipment to each of the areas. Work flow in the laboratory must proceed in a unidirectional manner, beginning in the reagent preparation area and moving to the specimen preparation

area and then to the amplification and detection area. Preamplification activities must begin with reagent preparation and proceed to specimen preparation. Reagent preparation activities and specimen preparation activities must be performed in separate, segregated areas. Supplies and equipment must be dedicated to each activity and not used for other activities or moved between areas. Lab coats and

gloves must be worn in each area and must be changed before leaving that area. Equipment and supplies used for reagent preparation must not be used for specimen preparation activities or for pipetting or processing amplified DNA or other sources of target DNA. Amplification and detection supplies and equipment must be confined to the amplification and detection area at all times.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. Specimens from the urogenital tract (female endocervical and male urethral swabs) and male and female first-catch urinary specimens must be obtained using the Amplicor STD specimen collection and transport kit.
2. Endocervical and urethral swab specimens should be inserted into the transport medium provided and the swab should be left in the transport medium during transport to the laboratory.
3. Male and female first-catch urine specimens should be collected in a clean *plastic* container.

B. Time of specimen collection

The first portion (~15 ml) of the urine stream should be collected. Patients must not have urinated during the previous 2 h. There are no other particular timing issues to consider in collection of these specimens; however, the time of collection and the type of specimen should be recorded.

C. Specimen transport

1. Transport the specimen at room temperature. *It is stable for 24 h at room temperature. Do not freeze! Urine specimens that have been frozen are not acceptable for testing. Upon receipt the specimen should be stored at 2 to 8°C. Process swab specimen within 10 days of collection. Process urine specimens within 4 days of collection.*
2. Specimens that require shipment to off-site test centers must be stored at 2 to 8°C until shipment. Specimens should be shipped with guaranteed arrival within 24 h.

D. Specimen labeling and request submission

The laboratory should determine a mechanism to ensure that the specimen type and time of collection are recorded.

E. Rejection criteria

1. Test only the indicated specimen types (endocervical, urethral, urine) in the indicated transport medium. Testing of other specimen types or use of other transport media has not been validated.
2. Specimens that are received without the swab still in the transport medium may give false-negative results.
3. Urine specimens that have been frozen are unacceptable for testing.
4. Repeat testing to evaluate efficacy of therapy is not indicated.
5. Request a repeat specimen, or obtain the information, when the collection time or specimen type has not been provided.
6. Reject specimens that arrive in leaky containers.
7. Nonculture methods should not be used in cases of suspected sexual abuse.
8. If an improperly collected, transported, or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised.

III. MATERIALS

- A. Area 1: reagent preparation**
1. Amplicor *C. trachomatis* amplification kit (provided)
 2. Biological safety cabinet or dead-air box equipped for UV irradiation
 3. Dedicated lab coat (store in area 1)
 4. Powder-free gloves
 5. 10% Bleach
 6. 70% Ethanol
 7. Pipette with plugged pipette tips (100 µl)
 8. MicroAmp tray, base, and tray and retainer
 9. Repeat pipettor with 1.25-µl sterile Combitips
 10. Plastic baggie
- B. Area 2: specimen preparation**
1. Amplicor STD swab specimen preparation kit (provided)
 2. Amplicor STD urine preparation kit (provided)
 3. Amplicor PCR controls (positive and negative) (provided)
 4. Dedicated lab coat (store in area 2)
 5. Powder-free gloves
 6. 10% Bleach
 7. 70% Ethanol
 8. Pipetaide
 9. Sterile 2-ml serologic pipettes
 10. Sterile transfer pipettes
 11. 37°C (± 2°C) incubator
- C. Area 3: amplification and detection**
1. Amplicor *C. trachomatis* detection kit (provided)
 2. Dedicated lab coat (store in area 3)
 3. Powder-free gloves
 4. 10% Bleach
 5. Thermal cycler with printer
 6. Spatula or tool to remove tube caps
 7. Multichannel pipette with plugged pipette tips (100 µl)
 8. Pipette with plugged pipette tips (25 µl)
 9. Disposable reagent reservoirs
 10. Erlenmeyer flask (1 liter)
 11. Graduated cylinder (100 ml)
 12. 37°C (± 2°C) incubator
 13. Disposable 96-well plate with lid
 14. Microwell plate washer
 15. Sterile 15-ml polypropylene centrifuge tubes
 16. ELISA plate reader
12. Vortex mixer
 13. Test tube racks
 14. 15 ml conical polypropylene centrifuge tubes
 15. Centrifuge
 16. 4 by 4 gauze
 17. Pipette with plugged pipette tips (50 and 1,000 µl)
 18. MicroAmp tube caps and capping tool

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that transport media and reagents meet expiration date and QC parameters per NCCLS document M22-A2 (1).
- B. All three negative control values *must* be <0.25 optical density units (ODU). If not, the test (entire batch) must be repeated.
- C. Each of the three negative control values *should* be within ± 25% of the negative control mean.
- D. The positive control value *must* be >2.000 ODU. If not, the test must be repeated.
- E. The thermal cycler run QC log *must* show that there was a successful run.
- F. The test must be repeated if any of the following conditions apply.
 1. A negative control of >0.25 ODU
 2. A positive control of <2.000 ODU
 3. A failed thermal cycler run
- G. A sample processing control should be run monthly. McCoy cells (10³ to 10⁴) infected with *C. trachomatis* should be added to a fresh tube of specimen transport medium (provided in the collection and transport kit) for 1 h and treated as a normal clinical specimen. A positive signal of >0.25 ODU at 450 nm should be obtained.

V. PROCEDURE**A. Area 1: reagent preparation**

■ **NOTE:** To minimize contamination, the use of a biological safety cabinet (hood) or dead-air box equipped for UV irradiation is suggested. All reagent preparation should be performed in this cabinet.

1. Wipe out dead-air box or hood with 10% bleach followed by 70% ethanol.
2. Add 100 µl of AmpErase to each tube of master mix (one tube is sufficient for 32 amplifications).
3. Recap and mix by inverting 10 to 15 times. Discard AmpErase tube when empty. Record date of preparation on master mix tube.
4. Determine the number of PCR tubes needed, place in MicroAmp sample tray, and lock in place with retainer. (Run one positive and three negative controls with each run. Well locations for controls are as follows: positive, A1; negatives, B1, H1, and A2.)
5. Pipette 50 µl of working master mix into each PCR tube by using a repeat pipettor with sterile Combitip or a micropipette with plugged tips.
6. Place tray in a baggie and transport to area 2.

B. Area 2: specimen preparation**1. Control preparation**

- a. Add 0.75 ml of diluent to the tube containing the negative control. Recap the tube and vortex well to mix. Incubate at room temperature for 10 min.
- b. Add 0.75 ml of diluent to the tube containing the positive control. Recap the tube and vortex well to mix. Incubate at room temperature for 10 min.

2. Urine preparation

- a. Check urine for precipitates. If present, warm the specimen for up to 30 min at 37°C and mix to dissolve. If some precipitate remains after heating, it will not interfere with the test.
- b. Vortex specimen for 3 to 10 s.
- c. Transfer 7 to 8 ml to a conical *polypropylene* 15-ml centrifuge tube.
- d. Centrifuge at 1,500 × *g* for 10 min at room temperature.
- e. Discard supernatant. Tap tube on clean 4-by-4 gauze. (Use new gauze for each specimen.)
- f. Add 2 ml of urine resuspension buffer. Cap and vortex for 3 to 10 s to suspend the pellet. (A multitube vortexer may be used.)
- g. Let stand for 1 h at room temperature.
- h. Add 2 ml of urine diluent to each tube. Cap and vortex for 3 to 10 s.
- i. Let stand at room temperature for 10 min.

3. Swab preparation

- a. Check the transport tube for swab. If a specimen has been transported without a swab still in the transport medium, contact the lead scientist or section manager. Verify that the seal has been broken on transported specimens.
- b. Pipette 1 ml of specimen diluent to each tube with a sterile serologic pipette.
- c. Recap the tube and vortex for 5 to 10 s.
- d. Incubate at room temperature for 10 min.

4. Tray preparation

- a. Using a clean plugged tip for each sample, pipette 50 µl of processed sample into appropriate MicroAmp tubes. Be careful not to pipette any precipitated material that may not have been resuspended.
- b. Cap the tubes tightly with the capping tool.
- c. Move the prepared samples in tray to area 3.

V. PROCEDURE (continued)

C. Area 3: amplification and detection

1. Amplification

- a. Remove MicroAmp tray from base.
- b. Place MicroAmp tray into the thermal cycler block. Check to make sure the notch in the sample tray is at the left of the block and that the rim of the tray is seated in the channel around the block.
- c. Slide the cover forward.
- d. Turn the knob clockwise until hand tight. (The white mark on the cover knob should line up with the white mark on the cover.)
- e. Program the thermal cycler as follows.
Program 1, CYCLE program (1 cycle): 5 min, 95°C; 1 min, 60°C
Program 2, CYCLE program (29 cycles): 30 s, 95°C; 1 min, 60°C
Program 3, HOLD program: 5 min, 72°C
Program 4, HOLD program: 72°C constant
In CYCLE programs, the ramp times are left at 0:00. Link the four programs together into METHOD program 5.
- f. Start the METHOD program (program runs about 1.5 h).
- g. Remove the completed PCR sample tray from the thermal cycler and place in tray base. *Do not remove from area 3.*
- h. Remove caps carefully to avoid aerosolizing PCR products.
- i. *Immediately* add 100 µl of denaturation solution to each PCR tube with a multichannel pipette (program 1 on Amplicor pipettor) with plugged tips.
- j. Incubate for 10 min at room temperature. Store the denatured, amplified samples at room temperature only if the detection test will be performed within 1 to 2 h. If not, store the samples at 2 to 8°C for up to 1 week.
- k. Review the thermal cycler run parameters for "HISTORY FILE" and record on "RUN QUALITY CONTROL LOG," or print run parameters on printer during run.

2. Detection

- a. Prepare working wash solution by adding 1 volume of wash concentrate (10×) to 9 volumes of distilled, deionized water. Mix well.
- b. Allow microwell plate to warm to room temperature before removing from the foil pouch. Remove the appropriate number of eight-well strips and set into microwell plate frame. Return unused strips to foil pouch and reseal bag, making sure desiccant pillow remains in the pouch.
- c. Add 100 µl of hybridization buffer to each well (program 2 on Amplicor pipettor). If the amplified samples were stored at 2 to 8°C, it may be necessary to incubate them at 37°C for 2 to 4 min to reduce viscosity.
- d. Using plugged pipette tips, pipette 25 µl of denatured amplified samples to the appropriate microtiter well. (A multichannel pipettor may be used.) Place lid on tray and gently tap the plate 10 to 15 times until the color changes from blue to light yellow.
- e. Cover plate and place in 37°C ($\pm 2^\circ\text{C}$) incubator for 1 h.
- f. Wash plate five times manually or with a microwell plate washer, using the prepared 1× washing solution.
 - (1) Manually (do not use squirt bottle)
 - (a) Empty contents of plate and tap on paper towel.
 - (b) Pipette working wash solution to fill each well (400 to 450 µl).
 - (c) Soak for 30 s. Empty contents and tap dry on a paper towel.
 - (d) Repeat steps V.C.2.f.(1).(b) and (c) four additional times.

V. PROCEDURE (*continued*)

- (2) Automated (program washer)
 - (a) Aspirate contents of well.
 - (b) Fill each well to top with working wash solution (350 to 450 μ l), soak for 30 s, and aspirate dry.
 - (c) Repeat step V.C.2.f.(2).(b) four additional times.
 - (d) Tap plate dry.
- g. Add 100 ml of avidin-horseradish peroxidase conjugate to each well. Cover plate and incubate for 15 min at 37°C (\pm 2°C).
- h. Wash plate as described in step V.C.2.f.
- i. Prepare working substrate by mixing 2 ml of substrate A and 0.5 ml of substrate B into a polypropylene tube for each pair of eight-well strips. Prepare substrate no more than 3 h before use, and protect from the light.
- j. Pipette 100 μ l of prepared working substrate into each well. Check wells for uneven blue color and note these wells on the worksheet.
- k. Allow color to develop for 10 min at room temperature *in the dark*.
- l. Add 100 μ l of stop reagent to each well.
- m. Measure the OD at 450 nm within 1 h of adding stop reagent.

D. Protocol for repeat testing

Store specimens at 4°C and retest within 4 days of initial processing. Warm specimens to room temperature and vortex each specimen for 10 to 15 s to mix.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. Report results as positive or negative for the presence of *C. trachomatis*.
- B. Document all testing in hard copy or computerized work card.
- C. Call positive results to physician of record or designee. Note on the worksheet the name of the person called, date, and time, and initial.

VII. INTERPRETATION

- A. The presence of *C. trachomatis* in the sample is determined by relating the absorbance of the unknown specimen to the cutoff value.
- B. The analytical sensitivity of this assay is 1 inclusion-forming unit (approximately 10 plasmid copies) of any *C. trachomatis* serovar (including serovars responsible for lymphogranuloma venereum).
- C. A clinical specimen with an A_{450} reading of <0.2 ODU should be reported as negative for *C. trachomatis*.
- D. A clinical specimen with an A_{450} reading of >0.5 ODU should be reported as positive for *C. trachomatis*.
- E. A clinical specimen with an A_{450} between 0.2 and 0.5 ODU should be considered equivocal. The specimen should be repeated in duplicate. The final test result should be determined as follows.
 1. Compile all three results (initial and duplicate repeat) of the sample.
 2. If two of the three results are <0.250 ODU, the sample is negative.
 3. If two of the three results are >0.250 ODU, the sample is positive.

VIII. LIMITATIONS OF TESTING

- A. The Amplicor *C. trachomatis* test will not detect plasmid-free variants of *C. trachomatis*.
- B. Only standard chlamydial cell culture methods should be used for evaluation of suspected sexual abuse and for other medico-legal indications.
- C. Additional testing is recommended in any circumstance when false-positive results could lead to adverse medical, social, or psychological consequences.

VIII. LIMITATIONS OF TESTING (continued)

Test results should be interpreted with consideration of clinical and laboratory findings.

- D. The presence of PCR inhibitors may cause false-negative results.
- E. The presence of spermicides in excess of 1%, or surgical lubricants in excess of 10%, in the specimen for testing may have an inhibitory effect.
- F. The presence of mucus in cervical specimens may inhibit PCR and cause false-negative results. Samples containing >5% (vol/vol) blood may give false-positive results.
- G. A negative result does not exclude the possibility of infection, because reliable results are dependent on adequate specimen collection.
- H. Therapeutic success or failure cannot be determined, because chlamydial plasmid DNA may persist after appropriate antimicrobial agent therapy.

PART 2

Detection of *Mycobacterium tuberculosis* in Respiratory Specimens by Using the Roche Amplicor PCR Kit

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The Amplicor *Mycobacterium tuberculosis* test is a direct DNA probe test that utilizes PCR and nucleic acid hybridization for the detection of *M. tuberculosis* complex in digested, decontaminated sputum and bronchoalveolar lavage (BAL) samples. The test is based on three major processes: PCR target amplification, hybridization of the amplified product to a

specific nucleic acid probe, and detection of the amplified product by color formation. Genus-specific primers located in a highly conserved region of the 16S rRNA gene of mycobacteria are biotinylated and used to amplify a 584-bp sequence. After PCR, the amplicons are denatured and captured by oligonucleotide probes bound to the wells of a microwell plate. The cap-

ture probes were selected from the hyper-variable region of the 16S rRNA gene and are specific for the *M. tuberculosis* complex. The bound amplicons are then detected by a color reaction with an avidin-horseradish peroxidase (HRP) conjugate.

Work flow in the laboratory must proceed in a unidirectional manner, beginning in the reagent preparation area and moving

to the specimen preparation area and then to the amplification and detection area. Pre-amplification activities must begin with reagent preparation and proceed to specimen preparation. Reagent preparation and specimen preparation activities must be performed in separate, segregated

areas. Supplies and equipment must be dedicated to each activity and not used for other activities or moved between areas. Laboratory coats and gloves must be worn in each area and must be changed before leaving that area. Equipment and supplies used for reagent preparation must not be

used for specimen preparation activities or for pipetting or processing amplified DNA or other sources of target DNA. Amplification and detection supplies and equipment must be confined to the amplification and detection area at all times.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. Acceptable specimens include sputum (induced or expectorated) or bronchial (e.g., bronchial lavage specimens or aspirates) or tracheal aspirates that are acid-fast-smear positive.
2. The efficacy of this test has not been demonstrated (and it is not Food and Drug Administration [FDA] approved) for the direct detection of *M. tuberculosis* in other clinical specimens (e.g., blood, urine, stool, or tissue).
3. The Amplicor *M. tuberculosis* test has been FDA approved for testing acid-fast-smear-positive respiratory specimens only.

B. Timing of specimen collection

Generally, an early-a.m. expectorated sputum should be collected each day for 3 days. The time of collection and the type of specimen (expectorated or induced sputum, BAL specimen) should be recorded.

C. Specimen transport

1. Specimens must be collected in sterile, plastic containers and stored at 2 to 8°C until transported or processed.
2. Specimens should be processed (decontaminated and concentrated) within 24 h of collection (including transport time) in a proper biosafety hood (*see* section 7) as recommended by the CDC.
3. Specimens that are grossly bloody should not be tested.
4. The Amplicor *M. tuberculosis* test is designed to detect nucleic acids from *M. tuberculosis* complex by using sediments from generally accepted current adaptations of the *N*-acetyl-L-cysteine (NALC)-NaOH and NaOH decontamination protocols described by the CDC, with 1 to 1.5% NaOH for 15 to 20 min and centrifugation at $\geq 3,000 \times g$. *See* section 7 for complete description of sputum concentration.
5. Processed specimens may be stored at 2 to 8°C for up to 3 days before testing.

D. Specimen labeling and submission

The laboratory should determine a mechanism to ensure that the specimen type and time of collection are recorded.

E. Rejection criteria

1. Test only the indicated specimen types (acid-fast-smear-positive sputum, bronchial or tracheal aspirate) submitted within 24 h of collection in the proper container.
2. Reject specimens that arrive in leaky containers.
3. Request a repeat specimen, or obtain the information, when the collection time or specimen type has not been provided.
4. Repeat testing to evaluate efficacy of therapy is not indicated.
5. If an improperly collected, transported, or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised.

III. MATERIALS

- A. Materials provided** (see Amplicor *M. tuberculosis* test package insert)
1. Sputum preparation kit
 - a. Wash solution
 - b. Lysis reagent
 - c. Neutralization reagent
 2. Amplification kit
 - a. Master mix
 - b. AmpErase
 - c. Tuberculosis positive control
 - d. Negative control
 3. Detection kit
 - a. Denaturation solution
 - b. Hybridization buffer
 - c. Avidin-HRP conjugate
 - d. Substrate A
 - e. Substrate B
 - f. Stop reagent
 - g. 10× wash concentrate
 - h. *M. tuberculosis* DNA probe-coated microwell plate
- B. Materials required but not provided** (see Amplicor *M. tuberculosis* test package insert)
1. Area 1: reagent preparation
 - a. Consumables for thermal cycler
 - (1) Reaction tubes
 - (2) Caps
 - (3) Base
 - (4) Trays/retainers
 - b. Repeat pipettor
 - c. Individually wrapped Combitips (1.25 ml)
 - d. Micropipettes
 - e. Plugged (aerosol barrier) or positive-displacement pipette tips (50, 100, and 1,000 µl)
 2. Area 2: specimen preparation
 - a. Microcentrifuge
 - b. Sterile screw-cap tubes
 - c. Tube racks
 - d. Sterile fine-tip transfer pipettes
 - e. Repeat pipettor with 12.5-ml individually wrapped Combitips
 - f. Vortex mixer
 - g. Thermal cycler base and capping tool
 - h. Micropipettes with plugged (aerosol barrier) or positive-displacement tips (50 and 100 µl)
 - i. Dry-heat blocks, 60°C (± 2°C)
 3. Area 3: amplification and detection
 - a. Micropipettes with plugged (aerosol barrier) tips (25 and 100 µl) and unplugged tips (100 µl)
 - b. Thermal cycler
 - c. Multichannel pipettor (25 and 100 µl) with plugged (aerosol barrier) tips (25 and 100 µl) and unplugged tips (100 µl)
 - d. Disposable reagent reservoirs
 - e. Microwell plate lid
 - f. ELISA well key for strip removal
 - g. Incubator, 37°C (± 2°C)
 - h. Distilled or deionized water
 - i. Microwell plate washer
 - j. Microwell plate reader and printer

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. It is recommended that at least one positive control and three negative controls be run each time the test is performed.
- B. Negative control
 1. The assay result of each negative control should be less than 0.25 A_{450} unit.
 2. If one or more of the negative control values are greater than 0.25 A_{450} unit, the entire run should be discarded and the entire assay, including amplification, should be repeated.
- C. Positive control
 1. The response of the positive control should be greater than 3.0 A_{450} units.
 2. If the value of the positive control falls below 2.0 A_{450} units, the entire run should be discarded and the entire assay, including amplification, should be repeated.
- D. Sample processing control
 1. To test the effectiveness of sample processing (recommended on a monthly basis), 10^4 *M. tuberculosis* cells (determined by quantitative plating or turbidimetric methods) should be processed as described for specimen preparation and then treated as a normal clinical specimen.

IV. QUALITY CONTROL (continued)

2. A positive signal above 3.0 A_{450} units should be obtained on the microwell plate if the sample is properly processed.
- E. Verify that all reagents and material meet expiration date and QC parameters per NCCLS document M22-A2 (1).

V. PROCEDURE

■ **NOTE:** This procedure should be performed in three areas of the laboratory as dictated by the instructions below. Before starting this procedure, turn on the thermal cycler to allow it to warm up. All reagents must be at ambient temperature before use. Use micropipettes with plugged (aerosol barrier) or positive displacement tips. *Use extreme care to ensure selective amplification.*

A. Reagent preparation

1. Performed in reagent preparation area (area 1)
2. If reagent preparation (part A), specimen preparation (part B), and amplification (part C) cannot be completed within 1 day, complete specimen preparation on day 1. Reagent preparation (part A) and amplification and detection (part C) should then be performed on day 2.
3. Prepare master mix with AmpErase by adding 100 μ l of AmpErase to one tube of master mix (sufficient for 32 amplifications).
4. Determine the appropriate number of PCR tubes for patient specimen and control testing. It is recommended that one positive and three negative controls be run with each amplification. Place tubes in sample tray and lock in place with retainer.
5. Pipette 50 μ l of master mix with AmpErase into each tube using a repeat pipettor and 1.25-ml Combitip or a micropipette with a plugged tip.
6. Cover tubes loosely with caps and move to specimen preparation area (area 2). Store sample tray at 2 to 8°C until specimen preparation is complete.

B. Specimen preparation

1. Performed in a biosafety hood in specimen preparation area (area 2).
2. Add 100 μ l specimen of concentrated sputum or BAL specimen to 500 μ l of sputum wash solution in a 1.5-ml screw-cap tube. Ascertain that screw cap is airtight. Vortex.
3. Centrifuge at $12,500 \times g$ for 10 min.
4. Aspirate supernatant and discard in an appropriate vessel with tuberculocidal disinfectant (*see* section 7). Add 100 μ l of lysis reagent to the cell pellet. Replace screw cap securely and vortex to suspend pellet.
5. Prepare positive and negative control stocks.
 - a. Pipette 100 μ l of negative control into a tube using a micropipette with a plugged tip. Add 400 μ l of lysis reagent. Vortex. This is the negative control stock.
 - b. Pipette 100 μ l of positive control into a tube using a micropipette with a plugged tip. Add 400 μ l of lysis reagent. Vortex. This is the positive control stock.
 - c. Pipette 100 μ l from each control stock and place into a 1.5-ml screw-cap tube to be processed.
6. Incubate specimens and controls in a 60°C (\pm 2°C) dry-heat block for 45 min.
7. Remove tubes from heat block and pulse centrifuge for 5 s.
8. Add 100 μ l of neutralization reagent. Vortex.
9. Pipette 50 μ l of prepared patient specimens and prepared controls (one positive and three negative) to appropriate PCR tubes by using a micropipette with plugged tips. Record positions of the tubes in the tray. Cap the tubes.

V. PROCEDURE (*continued*)

10. Move the prepared specimens in the sample tray to the amplification and detection area (area 3).

C. Amplification and detection

1. Performed in amplification and detection area (area 3).

2. Amplification

- a. Place sample tray into the thermal cycler sample block.
- b. Make certain that the cover knob of the thermal cycler is turned completely counterclockwise. Slide the cover forward.
- c. Turn the thermal cycler cover knob clockwise until hand tight.
- d. Program the thermal cycler for amplification of the Amplicor *M. tuberculosis* test as follows.

HOLD program: 2 min, 50°C

CYCLE program (2 cycles): 20 s, 98°C; 20 s, 62°C; 45 s, 72°C

CYCLE program (35 cycles): 20 s, 94°C; 20 s, 62°C; 45 s, 72°C

HOLD program: 5 min, 72°C

HOLD program: 72°C constant

In the CYCLE programs, the ramp times should be left at the default setting (0:00) which is the maximum rate, and the allowed setpoint error should be at the default setting (2°C). Link the five programs together into a METHOD program.

- e. Start the METHOD program. The program runs approximately 1.5 h. Specimens may be removed at any time during the final HOLD program but must be removed within 24 h.
- f. Remove completed PCR amplification specimen from the thermal cycler. *Do not bring amplified DNA into area 1 or area 2. The amplified specimens and controls should be strictly confined to area 3.*
- g. Immediately pipette 100 µl of denaturation solution to the first column (or row) of PCR tubes by using a multichannel pipettor with plugged tips, and mix by pipetting up and down. For each column (or row), repeat this procedure with a fresh set of tips. Incubate for 10 min at room temperature to allow complete denaturation.
- h. Store denatured, amplified specimens at room temperature only if the detection will be performed within 1 to 2 h. If not, store the specimens at 2 to 8°C until the detection assay is performed. Amplicons may be stored for up to 1 week at 2 to 8°C.

3. Detection

- a. Warm all reagents to room temperature.
- b. Prepare working wash solution by adding 1 volume of 10× wash concentrate to 9 volumes of distilled or deionized water.
- c. Allow the microwell plates to warm to room temperature before removing from the foil pouch.
- d. Add 100 µl of hybridization buffer to each well to be tested on the microwell plate.
- e. With plugged tips, pipette 25 µl of denatured amplification specimen into the appropriate well. Gently tap the plate approximately 10 to 15 times until the color changes from blue to light yellow (indicating that sufficient mixing has occurred).
- f. Cover the plate and incubate for 1.5 h at 37°C ($\pm 2^\circ\text{C}$).
- g. Wash plate five times manually or by using a microwell plate washer. Use the prepared washing solution for washing the plate.
- h. Add 100 µl of avidin-HRP conjugate to each well. Cover the plate and incubate for 15 min at 37°C ($\pm 2^\circ\text{C}$).
- i. Wash plate as in step V.C.3.g above.

V. PROCEDURE (*continued*)

- j.** Prepare working substrate by mixing 2.0 ml of substrate A and 0.5 ml of substrate B for each multiple of two eight-well microwell plate strips (16 tests). Prepare this reagent no more than 3 h before use, and protect from exposure to direct light.
- k.** Pipette 100 μ l of prepared working substrate reagent into each well being tested.
- l.** Allow color to develop for 10 min at room temperature (20 to 25°C) in the dark.
- m.** Add 100 μ l of stop reagent to each well.
- n.** Measure the optical density at 450 nm within 1 h of adding the stop reagent. Record the absorbance value for each patient specimen and control tested.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A.** Report results as positive or negative for the presence of *M. tuberculosis* complex.
- B.** Document all testing in hard copy or computerized work card.
- C.** Call positive results to physician of record or designee and to infection control. Note on the worksheet the name of the person called, date, and time, and initial.

VII. INTERPRETATION

- A.** The presence of *M. tuberculosis* in the specimen is determined by relating the absorbance of the unknown specimen to the cutoff value.
- B.** An A_{450} of 0.35 has been selected as the cutoff value for this assay.
- C.** A clinical specimen with an A_{450} reading equal to or greater than 0.35 is positive for the presence of *M. tuberculosis* group.
- D.** A clinical specimen with an A_{450} reading less than 0.35 is considered negative for *M. tuberculosis* group.

VIII. LIMITATIONS OF TESTING

- A.** The Amplicor *M. tuberculosis* test has been validated by using sputum or BAL specimens that have been liquefied, concentrated, and decontaminated using either NALC-NaOH or NaOH. Performance with other specimens has not been evaluated and may result in false-negative or -positive results.
- B.** The addition of AmpErase to master mix enables selective amplification of target DNA; however, reagent purity is maintained only by good laboratory practices and careful adherence to the recommended procedure.
- C.** Detection of *M. tuberculosis* is dependent on the number of organisms present in the specimen. This may be affected by specimen collection methods and patient factors such as age, history of respiratory disease, presence of symptoms, etc. This test is FDA approved for acid-fast-smear-positive specimens only.
- D.** A negative test does not exclude the possibility of infection.
- E.** Therapeutic success or failure cannot be determined using this assay.

PART 3

Detection of *Mycobacterium tuberculosis* in Respiratory Specimens by Using the Gen-Probe Amplified *Mycobacterium tuberculosis* Direct Test

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The Gen-Probe Amplified *Mycobacterium tuberculosis* Direct (MTD) test is a target-amplified nucleic acid probe test for the in vitro diagnostic detection of *M. tuberculosis* complex rRNA in acid-fast bacillus (AFB) smear-positive and smear-negative concentrated sediments prepared from sputum, bronchial specimens (e.g., bronchoalveolar lavage specimens or bronchial aspirates) or tracheal aspirates.

The MTD test is a two-part test in which amplification and detection take place in a single tube. After nucleic acid

extraction, the MTD test utilizes transcription-mediated amplification (TMA) and the hybridization protection assay to detect *M. tuberculosis* complex rRNA. In contrast to PCR, which requires thermal cycling and uses a thermostable polymerase to produce multiple copies (amplicons) of DNA, TMA uses a constant 42°C temperature and amplifies a specific rRNA target by using RNA polymerase and reverse transcriptase enzymes to produce multiple RNA amplicons. Detection of the amplicons is accomplished with a chemi-

luminescence-labeled DNA probe that is complementary to the RNA amplicons. When stable RNA-DNA hybrids are formed, separation of the hybridized from the unhybridized probe is accomplished by adding a selection reagent that hydrolyzes the chemiluminescent label on the unhybridized probe. The label on the hybridized probe is *protected* (hybridization protection) and may be detected in a luminometer. The entire assay is performed in a single tube.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. Acceptable specimens include sputum (induced or expectorated) or bronchial (e.g., bronchoalveolar lavage specimens or aspirates) or tracheal aspirates.
2. The efficacy of this test has not been demonstrated (and it is not Food and Drug Administration [FDA] approved) for the direct detection of *M. tuberculosis* rRNA with other clinical specimens (e.g., blood, urine, stool, or tissue).
3. The Gen-Probe MTD test (enhanced) has been FDA approved for testing AFB smear-positive and -negative respiratory specimens.

B. Timing of specimen collection

Generally, an early-a.m. expectorated sputum should be collected each day for 3 days. The time of collection and type of specimen (expectorated or induced sputum, bronchoalveolar lavage specimen, or tracheal aspirate) should be recorded.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

C. Specimen transport

1. Specimens must be collected in sterile, plastic containers and stored at 2 to 8°C until transported or processed.
2. Specimens should be processed (decontaminated and concentrated) within 24 h of collection (including transport time) in a proper biosafety hood (*see* section 7) as recommended by the CDC.
3. Specimens that are grossly bloody should not be tested with the MTD test.
4. The MTD test is designed to detect rRNA from members of the *M. tuberculosis* complex by using sediments prepared from generally accepted current adaptations of the *N*-acetyl-L-cysteine-NaOH or NaOH decontamination protocols, described by the CDC, with 1 to 1.5% NaOH for 15 to 20 min and centrifugation at $\geq 3,000 \times g$.

■ **NOTE:** See Section 7 for complete description of sputum concentration.

5. Processed sediments may be stored at 2 to 8°C for up to 3 days before testing.

D. Specimen labeling and submission

The laboratory should determine a mechanism to ensure that the specimen type and time of collection are recorded.

E. Rejection criteria

1. Test only the indicated specimen types (sputum, bronchial and tracheal aspirates) submitted within 24 h of collection in the proper container.
2. Reject specimens that arrive in leaky containers.
3. Request a repeat specimen, or obtain the information, when the collection time or specimen type has not been provided.
4. Repeat testing to evaluate efficacy of therapy is not indicated.
5. If an improperly collected, transported, or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised.

III. MATERIALS

A. Materials provided (*see* package insert)

1. Specimen dilution buffer
2. Amplification reagent
3. Reconstitution buffer
4. Lysing tubes
5. Oil reagent
6. Enzyme reagent
 - a. Reverse transcriptase
 - b. RNA polymerase
7. Enzyme dilution buffer
8. Termination reagent
9. Hybridization positive control
10. Hybridization negative control
11. Probe reagent
12. Hybridization buffer
13. Selection reagent
14. Sealing cards

B. Materials required but not provided (*see* package insert)

1. Luminometer
2. Sonicator
3. Detection reagent kit
4. Dry-heat bath (95°C [$\pm 5^\circ\text{C}$])
5. Sonicator rack
6. Pipette tips with hydrophobic plugs

7. Polypropylene tubes (12 by 75 mm)
8. Micropipettes capable of dispensing 20, 25, 50, 100, 200, and 300 μl
9. Snap-top polypropylene caps for 12- by 75-mm tubes
10. Water bath and/or dry heat bath (42°C [$\pm 1^\circ\text{C}$] and 60°C [$\pm 1^\circ\text{C}$])
11. Vortex mixer
12. Sterile water
13. Culture tubes
14. Glass beads (3 mm)
15. Screw-cap microcentrifuge tubes
16. Positive cell controls (e.g., *M. tuberculosis* ATCC 25177 or ATCC 27294)
17. Negative cell controls (e.g., *Mycobacterium gordonae* ATCC 14470 or *Mycobacterium terrae* ATCC 15755).
18. Household bleach (5.25% hypochlorite solution)
19. Plastic backed bench covers

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. The amplification cell negative control and amplification cell positive control should produce the following values.
 - 1. Amplification cell negative control, <20,000 relative light units (RLU)
 - 2. Amplification cell positive control, $\geq 500,000$ RLU
- B. The hybridization negative control and hybridization positive control should produce the following values.
 - 1. Hybridization negative control, <5,000 RLU
 - 2. Hybridization positive control, $\geq 15,000$ RLU
- C. Patient test results must not be reported if the MTD test control values do not meet the criteria above.
- D. Target values for amplification cell positive and cell negative controls should be determined in each laboratory by using test results for each batch of prepared controls.
- E. Verify that all reagents and materials meet expiration date and QC parameters per NCCLS document M22-A2 (1).

V. PROCEDURE

- A. **Equipment preparation**
 - 1. Degas water in sonicator.
 - 2. Adjust one dry-heat bath to 95°C, one dry-heat or water bath to 60°C, and another dry-heat or water bath to 42°C ($\pm 2^\circ\text{C}$).
 - 3. Wipe down work surfaces, equipment, and pipettors with a 1:1 dilution of household bleach (2.6% NaOCl) before starting. Cover work surfaces with plastic-backed laboratory bench covers.
 - 4. Prepare luminometer for operation. Make sure there are sufficient volumes of detection reagents 1 and 2 to complete the tests.
- B. **Reagent preparation**
 - 1. Reconstitute one vial (25 tests) of lyophilized *M. tuberculosis* amplification reagent with 750 μl of mycobacterium reconstitution buffer. Vortex and let sit at room temperature until clear.
 - 2. The reconstituted amplification reagent may be stored at 2 to 8°C for 2 months.
 - 3. The reconstituted amplification reagent should be allowed to come to room temperature before use.
- C. **Controls**
 - 1. Lysis and amplification controls
 - a. Cells used for the cell positive control should be a member of the *M. tuberculosis* complex, such as *M. tuberculosis* ATCC 25177 or ATCC 27294, suspended in sterile water. Cells used for the cell negative control should be mycobacteria other than the tuberculosis complex, such as *M. goodii* ATCC 14470 or *M. terrae* ATCC 15755.
 - b. Preparation and storage of amplification controls.
 - (1) Place three to five sterile 3-mm glass beads in a clean screw cap culture tube.
 - (2) Add several 1- μl loopfuls of growth from the appropriate culture to 1 to 2 ml of sterile water, cap, and vortex several times.
 - (3) Allow the suspension to settle, and transfer the supernatant to a clean culture tube. Adjust turbidity to that of a no. 1 McFarland standard.
 - (4) Make a 1:100 dilution (dilution 1) of the suspension into sterile water. Cap and vortex.
 - (5) Make a 1:100 dilution (dilution 2) of dilution 1.

V. PROCEDURE (*continued*)

- (6) Take 100 μ l of dilution 2 and place into 6 ml of sterile water (dilution 3). This contains approximately 25 CFU per 50 μ l.
 - (7) Plate 50 μ l of each dilution onto Lowenstein-Jensen culture medium and freeze the remaining stock at -20 or -70°C . Test all dilutions using the MTD test.
 - (8) The dilutions that give between 25 and 150 CFU per 50 μ l on plated culture medium should be thawed, aliquoted, and used as controls.
 - (9) The dilutions must be aliquoted into clean 1.5-ml screw-cap microcentrifuge tubes as single-use aliquots (100 μ l). The tubes may be stored frozen at -20°C for 6 months or -70°C for 1 year. Frost-free freezers must *not* be used.
- c.** A single replicate of the positive and negative cell controls must be tested with each run.
 - d.** Each laboratory should determine target values and means for the controls.
- 2.** Hybridization controls
 - a.** Hybridization positive controls and hybridization negative controls are provided in the MTD test kit.
 - b.** A single replicate of each of the hybridization controls should be tested with each run for QC purposes.
 - 3.** Specimen inhibition controls
 - a.** When the AFB smear is positive and the MTD test is negative for untreated patients, one must consider the following possibilities.
 - (1) The specimen is inhibitory.
 - (2) The specimen contains mycobacteria other than *M. tuberculosis*.
 - (3) The specimen contains a mixture of high number of nontuberculosis mycobacteria and a low number of *M. tuberculosis* organisms.
 - b.** Testing patient sediments for inhibition in the MTD test
 - (1) Place 200 μ l of specimen dilution buffer into two lysing tubes.
 - (2) Add 50 μ l of amplification positive cell control and 50 μ l of sediment from patient specimen to one tube (seeded). Add 50 μ l of sediment to the second tube (unseeded). Proceed with the test as usual.
 - (3) If the luminometer reading of the seeded tube is $\geq 30,000$ RLU, then the sample is not inhibitory to amplification and there apparently was no target available for amplification.
 - (4) If the number of RLU of the seeded tube is below 30,000, then the sample is inhibitory to amplification, and another sample should be evaluated.
 - 4.** Laboratory contamination monitoring control
 - a.** Place 2 ml of sterile water in a clean tube.
 - b.** Wipe the area of bench or equipment to be tested using a premoistened sterile polyester or Dacron swab.
 - c.** Place the swab in the water and swirl gently. Remove the swab and express fluid along the side of the tube.
 - d.** Add 25 μ l of the water to an amplification tube containing 25 μ l of amplification reagent and 200 μ l of oil reagent.
 - e.** Follow the test procedure for amplification and detection.
 - f.** If the results are $\geq 30,000$ RLU, the surface is contaminated and should be decontaminated with bleach.

V. PROCEDURE (*continued*)**D. Sample preparation**

1. Pipette 200 μl of specimen dilution buffer into labeled lysing tubes.
2. Transfer 50 μl of decontaminated, well-vortexed specimen or cell control from its container to the correspondingly labeled lysing tube.
 NOTE: The enhanced MTD test uses 500 μl of decontaminated sediment.
3. Cap the tubes and vortex for 3 s.

E. Sample lysis

1. Push the lysing tubes through the sonicator rack so that the reaction mixture in the bottom of the tubes is submerged but the caps are above water. Place sonicator rack on water bath sonicator. Do not allow the tubes to touch the bottom or sides of the sonicator.
2. Sonicate for 15 min but no more than 20 min. Samples and controls that have been sonicated are referred to as "lysates."

F. Amplification

1. Add 25 μl of reconstituted amplification reagent to each appropriately labeled amplification tube by using a repeat pipettor. Add 200 μl of oil reagent to each tube by using a repeat pipettor.
2. Transfer 50 μl of lysate to the bottom of the appropriately labeled amplification tube using a separate extended-length, hydrophobically plugged pipette tip for each transfer.
3. Incubate tubes at 95°C for at least 15 min, but for no more than 20 min, in the dry-heat bath.
4. Prepare the enzyme mix by adding 1.4 ml of enzyme dilution buffer to the lyophilized enzyme reagent. Swirl to mix. Do not vortex.
5. Transfer the tubes to the 42°C ($\pm 1^\circ\text{C}$) dry-heat bath or water bath and incubate for 5 min. Do not allow tubes to cool at room temperature. Do not cover the water bath.
6. Add 25 μl of enzyme mix to each amplification tube while the tubes are at 42°C ($\pm 1^\circ\text{C}$). Shake to mix. Incubate at 42°C for at least 2 h but no more than 3 h. Sealing cards or snap caps should be used during this step. Do not cover the water bath.
7. After the 2-h incubation, tubes may be placed at 2 to 8°C for up to 2 h or at -20°C overnight.

G. Termination

1. Add 20 μl of termination reagent to each tube. Cover tubes and shake to mix. Incubate at 42°C for 10 min.
2. Tubes may be covered and placed at 2 to 8°C for up to 2 h or at -20°C overnight.

H. Hybridization

1. Reconstitute lyophilized probe reagent with hybridization buffer. Vortex the solution until clear. The reconstituted probe reagent is stable for 1 month at 2 to 8°C.
2. Place 100 μl of hybridization positive control and 100 μl of hybridization negative control into correspondingly labeled 12- by 75-mm polypropylene tubes.
3. Add 100 μl of reconstituted probe reagent to each tube. Cover the tubes and vortex eight times until the reaction mixture is uniformly yellow.
4. Incubate 60°C for at least 15 min, but no more than 20 min, in a dry-heat or water bath.

I. Selection

1. Remove tubes from the 60°C water bath or dry-heat bath and add 300 μl of selection reagent. Cover tubes and vortex three times until the reaction mixture is uniformly pink.

V. PROCEDURE (*continued*)

2. Incubate tubes at 60°C for at least 10 min, but no more than 11 min, in a dry-heat or water bath.
3. Remove tubes from water bath or dry-heat bath and cool at room temperature for at least 5 min but no more than 1 h.

J. Detection

1. Select the appropriate protocol from the menu of the luminometer software. Use a 2-s read time.
2. Wipe each tube and insert into the luminometer. Tubes must be read within 1 h of step V.I.3.
3. When the analysis is complete, remove the tubes from the luminometer.
4. Decontaminate tubes and work surfaces with bleach.

K. Procedure notes

1. Reagents
 - a. Enzyme reagent should not be held at room temperature for more than 15 min after it is reconstituted.
 - b. Hybridization buffer may precipitate. Warming and mixing at 60°C will dissolve the precipitate.
2. Temperature
 - a. The amplification, hybridization, and selection reactions are temperature dependent; ensure that the water bath or dry-heat bath is maintained within the specified temperature range.
 - b. The tubes must be cooled at 42°C for 5 min before addition of enzyme mix for optimal performance.
 - c. The temperature is critical for the amplification (42 ± 1°C).
3. Water bath
 - a. The level of water in the water bath must be maintained so that the entire liquid volume in the tubes is submerged.
 - b. During the amplification step, water bath covers should not be used to ensure that condensation cannot drip into or onto the tubes.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. If the MTD test result is positive, report the following: “*Mycobacterium tuberculosis* complex rRNA detected. AFB culture pending. Specimen may contain *M. tuberculosis* alone or in combination with a nontuberculosis mycobacterium.”
- B. If the MTD test is negative, report the following: “No *Mycobacterium tuberculosis* complex rRNA detected. AFB culture pending. Specimen may not contain *M. tuberculosis*, or result may be falsely negative owing to low numbers of *M. tuberculosis* organisms in the presence of other mycobacterial species, or interference with assay detection by specimen inhibitors.”
- C. Document all testing in hard copy or computerized work card.
- D. Call positive results to requesting area and to infection control. Note on the worksheet the name of the person called, date, and time, and initial.

VII. INTERPRETATION

The results of the MTD test are based on a 30,000-RLU cutoff. Samples producing signals greater than or equal to the cutoff value are considered positive. Samples producing signals less than the cutoff value are considered negative.

- A. If the controls do not yield the expected results, test results on patient specimens in the same run must not be reported.
- B. A value of ≥30,000 RLU is considered positive for *M. tuberculosis*.
- C. A value of <30,000 RLU is considered negative for *M. tuberculosis*.

VIII. LIMITATIONS OF TESTING

- A. The Gen-Probe MTD test has been validated by using sputum or bronchoalveolar lavage specimens that have been liquefied, concentrated, and decontaminated with either *N*-acetyl-L-cysteine-NaOH or NaOH. Performance with other specimens has not been fully evaluated and may result in false-negative or -positive results.
- B. Detection of *M. tuberculosis* is dependent on the number of organisms present in the specimen. This may be affected by specimen collection methods and patient factors such as age, history of respiratory disease, presence of symptoms, etc. The enhanced MTD test (500 ml of decontaminated sediment) is FDA approved for testing both AFB-positive and -negative respiratory specimens.
- C. A negative test does not exclude the possibility of infection.
- D. Therapeutic success or failure cannot be determined by using this assay.

PART 4

Detection of *Mycobacterium tuberculosis* Complex in Respiratory Specimens by Using the BD ProbeTecET Direct Detection Assay

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The BD ProbeTecET Direct Detection Assay (DTB) is a target-amplified nucleic acid probe test for the *in vitro* diagnostic detection of *Mycobacterium tuberculosis* complex (MTBC) nucleic acids in acid-fast bacillus smear-positive and smear-negative concentrated sediments prepared from sputum, bronchial specimens (e.g., bronchoalveolar lavage fluid or bronchial aspirates), or tracheal aspirates. The DTB test has not yet been Food and Drug Ad-

ministration (FDA) approved for use in the United States.

The DTB test uses strand displacement amplification (SDA). In this novel DNA amplification method, segments of the insertion sequence *IS6110* specific to MTBC, together with a sequence of the 16S rRNA gene common to most mycobacterial species, are amplified isothermally. The DTB test employs a fully automated walkaway system that couples

SDA to a fluorescent-energy transfer detection system in a closed, high-throughput assay format. An internal amplification control (IAC) is run with each sample to detect the presence of inhibiting substances.

Work flow in the laboratory must proceed in a unidirectional manner, beginning in the reagent preparation area and moving to the specimen preparation area and then to the amplification and detection area.

Preamplification activities must begin with reagent preparation and proceed to specimen preparation. Reagent preparation and specimen preparation activities must be performed in separate, designated areas. Supplies and equipment must be

dedicated to each activity and not used for other activities or moved between areas. Lab coats and gloves must be worn in each area and must be changed before leaving that area. Equipment and supplies used for reagent preparation must not be used for

specimen preparation activities or for pipetting or processing amplified DNA or other sources of target DNA. Amplification and detection supplies and equipment must be confined to the amplification and detection area at all times.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. Acceptable specimens include sputum (induced or expectorated), bronchial specimens (e.g., bronchoalveolar lavage fluid or aspirates), or tracheal aspirates that are acid-fast smear positive or negative.
2. The efficacy of this test has also been demonstrated for the direct detection of MTBC in other nonpulmonary specimens (e.g., urine, stool, or tissue; *see Supplemental Reading*).

B. Timing of specimen collection

Generally, an early-a.m.-expectorated sputum should be collected each day for 3 days. The time of collection and the type of specimen (expectorated or induced sputum, bronchoalveolar lavage specimen) should be recorded.

C. Specimen transport

1. Specimens must be collected in sterile, leakproof plastic containers (preferably a centrifuge tube and collection container set [Sage Collection Kit, Becton Dickinson Microbiology System]) and stored at 2 to 8°C until transported or processed.
2. Specimens should be processed (decontaminated and concentrated) within 24 h of collection (including transport time) as recommended by the CDC.
3. Specimens that are grossly bloody should not be tested.
4. The DTB test is designed to detect nucleic acids from MTBC by using sediments from generally accepted current adaptations of the *N*-acetyl-L-cysteine-NaOH and NaOH decontamination protocols described by the CDC, with 1 to 1.5% NaOH for 15 to 20 min and centrifugation at $\geq 3,000 \times g$.
5. Processed specimens may be stored at 2 to 8°C for up to 3 days before testing.

D. Specimen labeling and submission

The laboratory should determine a mechanism to ensure that the specimen type and time of collection are recorded.

E. Rejection criteria

1. Test only the indicated specimen types (sputum or bronchial or tracheal aspirates) submitted within 24 h of collection in the proper container.
2. Reject specimens that arrive in leaky containers.
3. Request a new specimen, or obtain the information, when the collection time or specimen type has not been provided.
4. Repeat testing to evaluate efficacy of therapy is not indicated.
5. If an improperly collected, transported, or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised.

III. MATERIALS

- | | |

Microcentrifuge with aerosol containment and standard rotors 6. 2-ml sample tubes and caps <p>C. Materials required but not provided</p> <p>P100 and P1000 pipettors and aerosol-resistant tips</p> |
|---|--|

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. BD ProbeTecET System Direct Detection Assay Controls consist of one negative control and one positive control, which must be included with each assay run. The positive control monitors for reagent failure, completion of essential procedural elements (pipetting and incubations), amplification, and detection. The negative control monitors for reagent and/or environmental contamination.
- B. The BD ProbeTecET *M. tuberculosis* Procedural Control consists of a 1:100 dilution of *M. tuberculosis* H37Ra ATCC 25177 and is processed as routine samples.

V. PROCEDURE

- A. Aliquot 1.0 ml of DTB wash buffer into 2-ml sample tubes.
- B. Add 500 µl of the processed sediment to each sample tube; vortex.
- C. Centrifuge at $12,200 \times g$ for 3 min; immediately decant and recap.
- D. Place tubes into oven; perform heating cycle run 1.
- E. Quick spin in centrifuge.
- F. Dispense 100 µl of DTB lysis buffer to each tube; vortex.
- G. Sonicate for 45 min at $65 \pm 5^\circ\text{C}$.
- H. Quick spin in centrifuge.
- I. Dispense 600 µl of DTB neutralization buffer to each tube, vortex, and quick spin.
- J. Using the automated pipettor, add 150 µl of sample to priming wells.
- K. Cover plate and incubate for 20 min at room temperature.
- L. Place priming wells on priming heater and amplification wells on warming heater for 10 min.
- M. Pipette 100 µl from priming wells to amplification wells; seal plate.
- N. Insert plate into BD ProbeTecET instrument and initiate run.
- O. Results are printed out in 1 h.

VI. RESULTS AND INTERPRETATIONS

The BD ProbeTecET system automatically calculates values called MOTA (method other than acceleration) for both the specific target and the IAC for each specimen. These results are reported on the plate layout report with numerical values representing the test result printed for each well location. The MOTA is a qualitative value and should not be interpreted for quantity of nucleic acid. The MOTA values obtained are compared to predetermined threshold values and are automatically reported as positive, negative, or indeterminate. The assay result report shows the test results of the plate with symbols representing positive, negative, or indeterminate and a pass or fail symbol for each control. When both the specific signal

VI. RESULTS AND INTERPRETATIONS *(continued)*

and the IAC signal fail to reach their preset thresholds, an indeterminate assay result is reported, indicating inhibition or procedural error.

POSTANALYTICAL CONSIDERATIONS

VII. REPORTING RESULTS

The BD ProbeTecET has not been approved for sale in the United States.

- A. If the result is positive, report the following: "Probe assay positive for the presence of *M. tuberculosis* complex DNA."
- B. If the result is negative, report the following: "Probe assay negative for the presence of *M. tuberculosis* complex DNA."
- C. If the result is indeterminate, repeat probe assay from processed specimen. If positive or negative, use appropriate statement given above. If still indeterminate, report the following: "Initial and repeat probe assay results are indeterminate. Please submit a new specimen for testing."
- D. Include the following additional information in all reports: "Nucleic acid amplification results are preliminary, pending culture results."

VIII. LIMITATIONS

- A. The DTB assay does not detect MTBC variants that lack the insertion sequence IS6110.
- B. The DTB assay cannot be used to assess therapeutic success or failure, since nucleic acids from MTBC organisms may persist following antimicrobial therapy.
- C. The DTB assay provides qualitative results. No correlation can be drawn between the magnitude of the MOTA score and the number of cells in a positive sample.
- D. The effect of other potential variables, such as antimicrobial therapy or coinfecting samples, has not been determined.

PART 5

Quantitative Measurement of Human Immunodeficiency Virus Type 1 RNA by Using the Roche Amplicor PCR Kit

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The Amplicor HIV-1 Monitor test is an *in vitro* nucleic acid amplification test for the quantitation of human immunodeficiency virus type 1 (HIV-1) RNA in human plasma. The Amplicor HIV-1 Monitor test is based on five major processes: specimen preparation, reverse transcription (RT) of target RNA to generate cDNA, PCR amplification of target cDNA using HIV-1-specific complementary primers, hybridization of the amplified products to oligonucleotide probes specific to the target(s), and detection of the probe-bound amplified products by colorimetric determination. The Amplicor HIV-1 Monitor test amplifies and detects a 142-base target sequence located in a highly conserved region of the HIV-1 gag gene, defined by the primers SK431 and SK462. The test quantitates viral load by utilizing a second

target sequence (quantitation standard [QS]) that is added to the amplification mixture at a known concentration. The QS is a noninfectious 219 base *in vitro*-transcribed RNA molecule that contains SK431 and SK462 primer binding sites and generates a target of the same length (142-bp) as the HIV-1 target. The probe binding region of QS has been modified to differentiate QS-specific amplicons from HIV-1 target amplicons. HIV-1 levels in the test specimen are determined by comparing the absorbance of the specimen to the absorbance obtained for the QS.

Work flow in the laboratory must proceed in a unidirectional manner, beginning in the reagent preparation area and moving to the specimen preparation area and then to the amplification and detection area.

Preamplification activities must begin with reagent preparation and proceed to specimen preparation. Reagent preparation activities and specimen preparation activities must be performed in separate, segregated areas. Supplies and equipment must be dedicated to each activity and not used for other activities or moved between areas. Laboratory coats and gloves must be worn in each area and must be changed before leaving that area. Equipment and supplies used for reagent preparation must not be used for specimen preparation activities or for pipetting or processing amplified DNA or other sources of target DNA. Amplification and detection supplies and equipment must be confined to the amplification and detection area at all times.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. The Amplicor HIV-1 Monitor test is for use with plasma samples only.
2. Blood should be collected in sterile tubes with EDTA or acid citrate dextrose (ACD) as the anticoagulant.
3. EDTA (lavender top) tubes are acceptable but will yield test results that are approximately 15% higher than those collected in ACD. If only EDTA blood is available, add the following footnote to the final report: "Specimen collected in EDTA rather than ACD. ACD is the anticoagulant of choice. Use of EDTA anticoagulant will yield result 15% higher than test results obtained with ACD anticoagulant."
4. Specimens anticoagulated with heparin are not suitable for this test.

B. Timing of specimen collection

There are no particular timing issues to consider in collecting these specimens; however, the time of collection should be recorded.

C. Specimen transport

1. Whole blood must be transported at 20 to 25°C and processed within 3 h of collection. Do not refrigerate whole blood.
2. Plasma may be transported at 2 to 8°C or frozen.
3. Separate plasma within 3 h by centrifugation at 800 to 1,600 × *g* for 20 min at room temperature.
4. Plasma samples may be stored at room temperature for 24 h or at 2 to 8°C for up to 5 days. For longer periods store at -20° to -80°C.
5. Plasma specimens may be frozen and thawed up to three times.

D. Specimen labeling and submission

The laboratory should determine a mechanism to ensure that the time of collection is recorded.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

E. Rejection criteria

1. Test only plasma.
2. Reject heparinized specimens.
3. Reject specimens that arrive in leaky containers.
4. Reject whole-blood specimens that have been refrigerated and/or are received more than 3 h after collection.
5. Request a repeat specimen, or obtain the information, when collection time has not been provided.
6. If an improperly collected, transported, or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised.

III. MATERIALS

A. Materials provided

1. Specimen preparation reagents
 - a. Lysis reagent
 - b. QS
 - c. Specimen diluent
2. Controls
 - a. Negative plasma (human)
 - b. Negative control
 - c. Positive control, low
 - d. Positive control, high
3. Amplification reagents
 - a. Monitor master mix
 - b. Monitor manganese solution
4. Detection reagents
 - a. Denaturation solution
 - b. Hybridization buffer
 - c. Avidin-horseradish peroxidase (HRP) conjugate
 - d. Substrate A
 - e. Substrate B
 - f. Stop reagent
 - g. 10× wash concentrate
 - h. Oligonucleotide probe-coated microwell plate (MWP)

B. Materials required but not provided

1. Area 1: preamplification reagent preparation
 - a. Consumables for thermal cycler
 - (1) Reaction tubes
 - (2) Caps
 - (3) Trays/retainers
 - (4) Base
 - b. Plastic resealable bag
 - c. Repeating pipettor with 1.25-ml reservoir
 - d. Micropipettes (adjustable volume, 20 to 200 µl)
 - e. Plugged (aerosol barrier) pipette tips (50 and 200 µl)
 - f. Latex gloves
 - g. Vortex mixer

2. Area 2: preamplification specimen preparation

- a. Microcentrifuge
- b. Sterile screw-cap tubes (2.0 ml)
- c. Tube racks
- d. Ethyl alcohol, absolute (freshly diluted to 70% using deionized water)
- e. Isopropanol, reagent grade (100%)
- f. Fine-tip, sterile transfer pipettes
- g. Vortex mixer
- h. Latex gloves
- i. Sterile, disposable polystyrene pipettes (5, 10, and 25 ml)
- j. Micropipettes with plugged (aerosol barrier) or positive-displacement tips (50, 100, 200, 400, 600, 800, and 1,000 µl)

3. Area 3: postamplification area, amplification and detection

- a. Multichannel pipettor (25 and 100 µl)
- b. Plugged (aerosol barrier) micropipette tips (25 and 100 µl) and unplugged tips (100 µl)
- c. Thermal cycler (Perkin-Elmer GeneAmp PCR System 9600 or GeneAmp PCR System 2400)
- d. MicroAmp base (Perkin-Elmer GeneAmp PCR System 9600 or GeneAmp PCR System 2400)
- e. MWP washer
- f. MWP reader
- g. Disposable reagent reservoirs
- h. MWP lid
- i. Incubator, 37 ± 2°C
- j. Graduated vessels (25 to 100 ml)
- k. Distilled or deionized H₂O

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. It is recommended that one replicate of the HIV-1 Monitor (–) Control, one replicate of the HIV-1 Monitor Low (+) Control, and one replicate of the HIV-1 Monitor High (+) Control be included in each test run.
- B. All controls and patient specimens should yield optical density (OD) values for the QS that meet the criteria described in item V.F below, demonstrating that the specimen processing, RT, amplification, and detection steps were performed correctly.
 1. If any specimen has a QS OD value that does not meet the criteria described below, the *result for that specimen* is invalid, but the run is still acceptable.
 2. If *any control* has a QS OD value that does not meet the criteria described below, *the entire run is invalid*.
- C. The expected range for each of the HIV-1 Monitor (+) Controls is specific for each lot of control and is provided on the HIV-1 Monitor data card supplied with the kit.
 1. The HIV-1 RNA copy number per milliliter for both the Low (+) and High (+) Controls should fall within the range indicated on the Control data card.
 2. The HIV-1 Monitor (–) Control should yield a “not detected” result; i.e., all HIV OD values should be <0.20.
- D. Verify that all reagents and materials meet expiration date and QC parameters per NCCLS document M22-A2 (1).

V. PROCEDURE**A. Reagent preparation**

1. Performed in the preamplification reagent preparation area
2. Prepare working master mix by adding 100 µl of HIV-1 Monitor manganese solution to one tube of HIV-1 Monitor master mix.
3. Place reaction tubes in tray and lock in place with tube retainer.
4. Pipette 50 µl of working master mix into each tube.
5. Place tray in plastic resealable bag, and move to specimen preparation area.
6. Store the tray at 2 to 8°C until specimen preparation is completed. *Amplification must begin within 4 h of preparation of working master mix.*
7. Remember to change gloves and coats before moving to next area.

B. Specimen and control preparation

1. Performed in the preamplification specimen preparation area
2. Prepare 70% ethanol.
3. Prepare working lysis reagent. A precipitate forms in the HIV-1 lysis reagent upon storage at 2 to 8°C. Prior to use, dissolve precipitate by warming the lysis reagent to 25 to 37°C and mixing thoroughly. Add 100 µl of HIV-1 Monitor QS to one bottle of lysis reagent and mix (enough for 12 specimens).
4. Label a 2.0-ml screw-cap microcentrifuge tube for each specimen and control.
5. Thaw plasma specimens at room temperature and vortex for 3 to 5 s.
6. Spin tube briefly to collect specimen in base of tube.
7. Dispense 600 µl of working lysis reagent into each tube.
8. Add 200 µl of each patient specimen to appropriate tube, cap, and vortex for 3 to 5 s.
9. For each negative and positive control, add 200 µl of negative plasma (human) to the appropriate tubes. Cap the tubes and vortex for 3 to 5 s, and then add 50 µl of HIV-1 Monitor (–) Control, HIV-1 Monitor Low (+) Control, and HIV-1 Monitor High (+) Control to the appropriate tubes. Cap the tubes and mix.

V. PROCEDURE (*continued*)

10. Incubate tubes for 10 min at room temperature.
11. Add 800 μ l of 100% isopropanol to each tube, cap, and vortex for 3 to 5 s.
12. Using a permanent marker, put a mark on each tube and place tubes into microcentrifuge with the mark facing outward, so that the pellet will align with the orientation mark. Centrifuge specimens at maximum speed (at least $12,500 \times g$) for 15 min at room temperature (begin timing from the moment of reaching maximum speed).
13. Using a new, fine-tip disposable transfer pipette for each tube, carefully remove and discard supernatant from each tube into an appropriate bio-safety container, being careful not to disturb the pellet.
14. Add 1.0 ml of 70% ethanol to each tube, cap, and vortex for 3 to 5 s.
15. Centrifuge tubes for 5 min at maximum speed (at least $12,500 \times g$) at room temperature.
16. Carefully remove supernatant without disturbing the pellet. Remove as much of the supernatant as possible. Residual ethanol can inhibit amplification.
17. Add 400 μ l of HIV-1 Monitor specimen diluent to each tube, cap, and vortex for 10 s to resuspend extracted RNA.
18. Amplify the processed specimens within 2 h of preparation or store frozen at -20°C or colder for up to 1 week.
19. Pipette 50 μ l of each prepared control and patient specimen to appropriate reaction tubes using a micropipettor with plugged tips. Cap and seal the tubes.
20. Transfer the tray with sealed tubes containing the processed specimens and controls in working master mix to the amplification and detection area.
21. Change gloves and coats before moving to next area.

C. RT and amplification

1. Performed in the amplification and detection area
2. Turn on the thermal cycler at least 30 min prior to amplification.
3. Place the tray/retainer assembly into the thermal cycler block.
4. Program the thermal cycler as follows.
HOLD program: 2 min at 50°C
HOLD program: 30 min at 60°C
CYCLE program (4 cycles): 10 s at 95°C , 10 s at 55°C , 10 s at 72°C
CYCLE program (26 cycles): 10 s at 90°C , 10 s at 60°C , 10 s at 72°C
HOLD program: 15 min at 72°C
5. Link the five programs into a METHOD program.
6. Start the METHOD program. The program runs approximately 30 min.
7. Remove the tray from the thermal cycler at any time during the final HOLD program, place in MicroAmp base, and continue immediately with step V.C.8. Do not allow the reaction tubes to remain in the thermal cycler beyond the end of the final HOLD program, and do not extend the final HOLD program beyond 15 min.
NOTE: Do not bring amplified samples into the preamplification area. Amplified controls and specimens should be considered a major source of contamination.
8. Remove caps from the reaction tubes and immediately pipette 100 μ l of Monitor denaturation solution into each tube and mix by pipetting up and down five times.
9. The denatured amplicon can be held at room temperature no more than 2 h before proceeding to the detection reaction. If the detection reaction cannot be performed within 2 h, recap the tubes and store at 2 to 8°C for up to 1 week.

V. PROCEDURE (*continued*)**D. Detection**

1. Performed in the amplification and detection area
2. Warm all reagents to room temperature prior to use.
3. Prepare working wash solution as follows. Add 1 volume of 10× wash concentrate to 9 volumes of distilled, deionized water and mix well. Store in a clean, closed plastic container at 2 to 25°C for up to 2 weeks.
4. Allow the HIV-1 Monitor MWP to warm to room temperature before removing from the foil pouch. Add 100 µl of hybridization buffer to each well. Rows A through F of the MWP are coated with the HIV-specific oligonucleotide probe; rows G and H are coated with the QS-specific oligonucleotide probe.
5. Add 25 µl of the denatured amplicon to the HIV wells in row A of the MWP, and mix up and down 10 times with a 12-channel pipettor with plugged tips. Make serial fivefold dilutions in the HIV wells in rows B through F as follows. Transfer 25 µl from row A to row B and mix as before, and continue through row F. Mix row F and remove and discard 25 µl. Discard pipette tips.
6. Add 25 µl of the denatured amplicon to the QS wells in row G of the MWP and mix. Transfer 25 µl from row G to row H. Mix as before, and then remove 25 µl from row H and discard.
7. Cover the MWP and incubate 1 h at 37 ± 2°C.
8. Wash the MWP five times with the working wash solution using an automated MWP washer.
 - a. Fill each well to the top (400 to 450 µl). Let soak for 30 s. Aspirate.
 - b. Repeat step V.D.8.a four additional times.
 - c. Invert the plate over a layer of paper towels and gently tap the plate dry.
9. Add 100 µl of avidin-HRP conjugate to each well. Cover the MWP and incubate for 15 min at 37 ± 2°C.
10. Wash the MWP as described in step V.D.8.
11. Prepare the working substrate solution. For each MWP, mix 12 ml of substrate A with 3 ml of substrate B. Protect working substrate solution from direct light. Working substrate solution must be kept at room temperature and used within 3 h of preparation.
12. Pipette 100 µl of working substrate solution into each well.
13. Allow color to develop for 10 min at room temperature in the dark.
14. Add 100 µl of stop reagent to each well.
15. Measure the OD at 450 nm (OD₄₅₀) (single wavelength) within 10 min of adding stop reagent.

E. Procedure precautions

1. Work flow in the laboratory must proceed in a unidirectional manner, beginning in the reagent preparation area and moving to the specimen preparation area and then to the amplification and detection area. Reagent preparation activities and specimen preparation activities must be performed in separate, segregated areas. Supplies and equipment must be dedicated to each activity.
2. Owing to the analytical sensitivity of this test and the potential for contamination, extreme care should be taken to preserve the purity of kit reagents and amplification mixtures. All reagents should be closely monitored for purity. Discard any reagents that may be suspect.
3. All pipettors, pipettes, bulbs, pipette tips, etc., should be dedicated to, and used only for, each PCR laboratory activity.

F. Calculation of results

1. For each specimen and control, calculate the HIV-1 RNA level.
2. Choose the appropriate HIV-1 well.

V. PROCEDURE (*continued*)

- a. The HIV wells in rows A to F represent the HIV-1 amplicon undiluted and in 1:5, 1:25, 1:125, 1:625, and 1:3,125 serial dilutions, respectively. The absorbance values should decrease with the serial dilutions, with the highest OD₄₅₀ for each specimen or control in row A and the lowest OD₄₅₀ in row F.
- b. Choose the well with the lowest OD₄₅₀ that is ≥ 0.20 and ≤ 2.00 OD units.
- c. If any of the following conditions exist, see item VII.E below.
 - (1) All HIV OD values are < 0.20 .
 - (2) All HIV OD values are > 2.00 .
 - (3) HIV OD values are not in sequence (OD values do not decrease from well A to well F).
3. Subtract background from selected HIV OD value (background = 0.07 OD unit).
4. Calculate the total HIV OD by multiplying the background-corrected OD value of the selected HIV well by the dilution factor associated with that well.
5. Choose the appropriate QS well.
 - a. The QS wells in rows G and H represent the QS amplicon neat and in a 1:5 dilution, respectively. The absorbance value in row G should be greater than the value in row H.
 - b. Choose the well with the lowest OD₄₅₀ that is ≥ 0.30 and ≤ 2.00 OD units.
 - c. If the following conditions exist, see item VII.E below.
 - (1) Both QS OD values are < 0.30 .
 - (2) Both QS OD values are > 2.00 .
 - (3) QS OD values are not in sequence (well H has a higher OD than well G).
6. Subtract background from the selected QS OD values (background = 0.07 OD unit).
7. Calculate the total QS OD by multiplying the background-corrected OD value of the selected QS well by the dilution factor associated with that well.
8. Calculate the number of HIV-1 RNA copies per milliliter of plasma as follows.

$$\frac{\text{Total HIV OD}}{\text{Total QS OD}} \times \text{Input QS copies/PCR} \times 40$$

where input QS copies per PCR is specific to each lot of QS (*see* the Amplicor HIV-1 Monitor test data card for the input QS copies per PCR). Verify that the QS lot number matches the lot number on the Amplicor HIV-1 Monitor test data card. The number 40 is a factor to convert copies per PCR to copies per milliliter of plasma.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. The presence of HIV RNA in the sample is determined by relating the absorbance of the unknown specimen to the cutoff value.
- B. Report the number of HIV copies per milliliter of specimen.
- C. Call positive results to physician of record or designee. Note on the worksheet the name of the person called, date, and time, and initial.
- D. Document all testing in hard copy or computerized work card.

VII. INTERPRETATION

- A.** Quantitative results reported as HIV RNA copies per milliliter serve as an estimate of the viral load of the patient.
- B.** Limit of detection
Studies demonstrate that the Amplicor HIV-1 Monitor test can detect fewer than 2 copies of HIV RNA per reaction and that 7.5 or more copies were detected 100% of the time. Five copies of HIV RNA per PCR are equivalent to 200 HIV RNA copies per ml of sample.
- C.** Limit of quantitation
Studies demonstrate that the HIV-1 Monitor test can quantitate virion-associated HIV-1 RNA in plasma at concentrations as low as 400 RNA copies/ml of plasma provided that the OD of the selected microwell is within the specified OD range (0.2 to 2.0).
- D.** Linear range
The HIV-1 Monitor test was found to give a linear response between 400 and 750,000 HIV-1 RNA copies per ml. Samples with results greater than 750,000 HIV-1 RNA copies per ml must be diluted with HIV-negative human plasma and tested.
- E.** Unexpected results
1. All HIV OD values are <0.20 . If QS wells have the expected values, use 0.20 as the raw HIV-1 OD and 1 as the dilution factor. Calculate the result as described above and report the result as "No HIV-1 RNA detected, less than . . ." (the calculated value).
 2. All HIV OD values are >2.0 . This means that the HIV-1 copy number is above the linear range of the assay. Report the result as "Not Determined." Prepare a 1:50 dilution of the original specimen with HIV-negative human plasma and repeat the test. Calculate the HIV-1 result as described above, and then multiply the final result by 50.
 3. HIV OD values are out of sequence. The OD values for HIV wells should follow a pattern of decreasing OD values with increasing dilution factor, except for wells that are saturated ($OD > 2.3$) and wells with background values ($OD < 0.1$). If this pattern is not observed, a dilution error may have occurred and the test procedure should be repeated.
 4. Both the QS OD values are <0.30 . This suggests that either the specimen was inhibitory to the amplification or the RNA was not recovered during specimen processing. Repeat the entire test procedure.
 5. Both QS OD values are >2.0 . This indicates that an error has occurred and the result for that specimen is invalid.
 6. QS OD values are out of sequence. An error has occurred and the result for that specimen is invalid.

VIII. LIMITATIONS OF TESTING

- A.** This test has been validated for use only with human plasma anticoagulated with EDTA or ACD. Heparin inhibits PCR; specimens collected using heparin as the anticoagulant should *not* be used with this test.
- B.** The presence of AmpErase in the master mix reduces the risk of amplicon contamination. However, contamination from HIV-positive controls and HIV-positive clinical specimens can be avoided only by good laboratory practices and careful adherence to the procedures specified by the manufacturer.
- C.** Use of this product should be limited to personnel trained in the techniques of PCR.
- D.** As with any diagnostic test, results from the Amplicor HIV-1 Monitor test should be interpreted with consideration of all clinical and laboratory findings.

VIII. LIMITATIONS OF TESTING (continued)

- E. Interfering substances
1. Elevated levels of lipids, bilirubin, and hemoglobin in specimens have been shown to *not* interfere with the quantitation of HIV-1 RNA by this test.
 2. The following drug compounds have been shown to not interfere with the quantitation of HIV-1 RNA by this test: zidovudine, dideoxyinosine, dideoxycytosine, stavudine, HBV097, nevirapine, saquinavir, isoniazid, fos-carnet, and ganciclovir.
 3. Heparin inhibits PCR.

PART 6

Quantitative Measurement of Human Immunodeficiency Virus Type 1 RNA by Using the Roche Amplicor Ultrasensitive PCR Kit

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The Amplicor HIV-1 Ultrasensitive test is an in vitro nucleic acid amplification test for the quantitation of human immunodeficiency virus type 1 (HIV-1) RNA in human plasma. In order to monitor the effectiveness of the highly active antiretroviral therapy regimens now in use, the sensitivity of the HIV-1 Ultrasensitive test has been increased so that quantitation of viral load down to 40 copies per ml is now possible.

The Amplicor HIV-1 Ultrasensitive test is based on five major processes: spec-

imen preparation, reverse transcription of RNA to generate a cDNA, PCR to target cDNA using HIV-1-specific primers, hybridization of the amplified products to specific oligonucleotide probes, and detection of the probe-bound amplified product by colorimetric determination.

The amount of HIV-1 RNA in each specimen is calculated from the ratio of the total optical density (OD) for the HIV-1-specific well to the total OD for the quantitation standard (QS)-specific well and the input number of QS RNA mole-

cules using the following equation:

$$\left(\frac{\text{Total HIV-1 OD}}{\text{Total QS OD}} \right) \times \text{Input QS copies per PCR} \times 4 = \text{HIV-1 RNA copies/ml}$$

Because of the sensitivity of the PCR method, it is necessary to limit the potential for contamination by performing each step of the process in a separate area of the laboratory and to dedicate equipment to each of the areas.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. Plasma only, collected in acid citrate dextrose (ACD) (yellow top)
2. EDTA (lavender top) tubes are acceptable but will yield test results that are approximately 15% higher than those collected in ACD. If only EDTA blood is available, add the following footnote to the final report: "Specimen collected in EDTA rather than ACD. ACD is the anticoagulant of choice. Use of EDTA anticoagulant will yield result 15% higher than test results obtained with ACD anticoagulant."
3. Store whole blood at 2 to 25°C for no longer than 3 h.
4. Patients must have a previous result by the standard HIV method of <400 copies/ml. For other requests refer to the laboratory director.

B. Timing of specimen collection

There are no particular timing issues to consider in collecting these specimens; however, the time of collection should be recorded.

C. Specimen transport

1. Transport the specimen at room temperature.
2. Within 3 h of blood draw, blood collection tubes must be centrifuged at 800 to 1,600 × *g* for 20 min at room temperature.
3. Make four aliquots by transferring a minimum of 600 µl of plasma to a sterile 1.5-ml polypropylene tube and store at 2 to 8°C for up to 5 days. For longer periods, store at -20 to -80°C.

D. Specimen labeling and submission

The laboratory should determine a mechanism to ensure that the time of collection is recorded.

E. Rejection criteria

1. Test only plasma.
2. Reject heparinized specimens.
3. Reject specimens that arrive in leaky containers.
4. Reject whole-blood specimens that have been refrigerated and/or are received more than 3 h after collection.
5. Request a repeat specimen, or obtain the information, when collection time has not been provided.
6. If an improperly collected, transported, or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised.

III. MATERIALS

(See Part 4 above for materials provided.)

A. Area 1: reagent preparation

1. Amplicor HIV-1 amplification kit
2. Dedicated lab coat
3. Powder-free gloves
4. 10% Bleach, prepared fresh daily
5. Sanicloth disposable wipes
6. Pipette with plugged pipette tips (100 µl)
7. MicroAmp tray, base, and tray and retainer
8. Repeat pipettor with 1.25-ml sterile Combitips
9. Plastic baggie

B. Area 2: specimen preparation

1. Juon high-speed refrigerated centrifuge
2. Amplicor HIV specimen preparation kit

3. HIV Accurun Control Series 100 (Boston Biomedica)
4. HIV Accurun Control Series 400 (Boston Biomedica)
5. HIV Accurun Negative Control (Boston Biomedica)
6. Dedicated lab coat
7. Powder-free gloves
8. 10% Bleach, prepared fresh daily
9. Sanicloth disposable wipes
10. 95% Ethyl alcohol in glass (Sigma) (freshly diluted to 70% using sterile tissue culture-grade water)
11. Isopropyl alcohol, reagent grade (Fisher)
12. Pipetaide

III. MATERIALS *(continued)*

- | | |
|---|---|
| <ul style="list-style-type: none"> 13. Sterile disposable polystyrene pipettes (5 and 10 ml) 14. 1.5-ml screw-cap microcentrifuge tubes 15. 60 ± 2°C dry-heat block 16. Sterile fine-tip transfer pipettes (graduated) 17. Vortex mixer 18. Test tube racks 19. Microcentrifuge (maximum relative centrifugal force [RCF], 16,000 × g; minimum RCF, 12,500 × g) 20. Pipette with plugged pipette tips (50, 200, and 1,000 µl) 21. MicroAmp tube caps and capping tools | <ul style="list-style-type: none"> 3. 10% Bleach, prepared fresh daily 4. Powder-free gloves 5. Thermal cycler with printer 6. Spatula or tool to remove tube caps 7. Multichannel pipette with plugged pipette tips (200 µl) 8. Pipette with plugged pipette tips (25 µl) 9. Disposable reagent reservoirs 10. 1-liter Erlenmeyer flask 11. 100-ml graduated cylinder 12. Type 1 water 13. 37°C (± 2°C) incubator 14. Sterile disposable 96-well plate lid 15. Microwell plate washer 16. Sterile 15-ml polypropylene centrifuge tubes 17. ELISA plate reader |
|---|---|
- C. Area 3: amplification and detection**
- 1. Amplicor HIV detection kit
 - 2. Dedicated lab coat

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. For each batch of specimen processed include a low positive control, a high positive control, and one negative control. Process the controls in the exact same manner as the patient specimens.
- B. Specimens and controls from separate preparation batches may be amplified and detected at the same time. Each separate specimen batch is validated individually by the set of serum controls for that batch.
- C. All test specimens and controls prepared in the same batch should be amplified and detected in adjacent positions in the thermal cycler and on the detection plate. The exact order of the placement is not critical.
- D. All controls should yield OD values from the QS that meet the criteria described in V.E and VII.C. If any control has QS OD values that do not meet the criteria, the entire run is invalid.
- E. The negative control must be <40 copies/ml. The high positive control must be between 10,000 and 24,000 copies/ml, and the low positive control must be between 40 and 100 copies/ml.
- F. The thermal cycler run QC log must show that there was a successful run.
- G. Verify that all reagents and materials meet expiration date and QC parameters as per NCCLS document M22-A2 (1).

V. PROCEDURE

- A. Area 1: reagent preparation**
- 1. Wipe out dead-air box with 10% bleach. Wipe out with a Sanicloth wipe.
 - 2. Prepare working master mix by adding 100 µl of manganese solution to one tube of master mix. Recap the tube and mix well by inverting the tube 10 to 15 times. Discard the remaining manganese solution into an appropriate bio-safety container.
 - 3. Determine the number of PCR tubes needed for patient samples and controls, and place in MicroAmp sample tray and lock in place with retainer.
 - 4. Pipette 50 µl of master mix into each PCR tube using a repeat pipettor with sterile Combitip or a micropipette with plugged tips. Inspect the reaction tubes after pipetting to ensure that the same volume was pipetted into each tube. Discard unused working master mix into an appropriate biosafety container.

V. PROCEDURE (continued)

5. Place tray in baggie and transport to area 2. Store at 2 to 8°C. Amplification must begin within 4 h of preparation of working master mix.
6. Clean out dead-air box with 10% bleach and wipe with a Sanicloth. Turn on UV light for 10 min.
 - ☑ **NOTE:** Do not operate the UV light with the enclosure doors open. Do not place arms or hands in the enclosure when UV light is on. Do not look at the UV bulb while in operation without protective eyewear.
7. Record hood cleaning on hood QC sheet.

B. Area 2: specimen preparation

A precipitate forms in the HIV-1 lysis reagent upon storage at 2 to 8°C. Prior to use, dissolve the precipitate by warming the lysis reagent to 25 to 37°C and mixing thoroughly.

1. Precool the Juon high-speed centrifuge by turning it on, closing the lid, and setting the temperature gauge to 2 to 8°C. It will take approximately 45 min to cool down. To speed up the cooldown process, secure an empty rotor in the centrifuge and run on low speed at 2 to 8°C for 15 to 30 min.
2. Turn on the blower to the biologic safety cabinet and allow it to run for 30 min prior to use.
3. Clean out the biologic safety cabinet with 10% bleach and wipe with a Sanicloth.
4. Prepare 70% ethanol (mix 11.0 ml of ethanol, in glass, with 4.0 ml of tissue culture-grade water). One milliliter of 70% ethanol is needed for each sample processed.
5. Prepare the Ultrasensitive working lysis reagent.
 - a. Check that all crystals are dissolved in the lysis reagent.
 - b. Vortex the QS for at least 10 s.
 - c. Add 25 µl of QS to one bottle of lysis reagent.
 - ☑ If processing only a partial plate, prepare only enough lysis reagent for the number of specimens being processed (i.e., for six samples add 12.5 µl of QS to 4.5 ml [1/2 bottle] of lysis reagent). Note on the remainder of the lysis reagent the volume that is left and the quantity of QS to add.
 - d. Mix working lysis reagent.
6. Label one 1.5-ml microcentrifuge tube for each specimen and control. Make a mark on the side of the tube to help in orientation in the centrifuge.
7. Fill out an HIV-Ultra worksheet. Record lot number and expiration dates. Record number of QS copies added.
8. Thaw controls and patient samples. Controls may be thawed three times without deleterious effects. Vortex all samples and controls for 3 to 5 s when thawed.
9. Spin patient samples and controls briefly to collect sample at the bottom of the tube.
10. Pipette 500 µl of each patient sample and control into the appropriately labeled tube using aerosol barrier pipette tips.
11. Place tubes in the high-speed centrifuge with the orientation mark facing out. Centrifuge for 1.5 h at 16,000 × g at 2 to 8°C.
12. Remove the tubes from the centrifuge. Leave the centrifuge lid open to warm up. Wipe out condensation with a paper towel.
13. Using a sterile fine-tip transfer pipette, carefully draw off the supernatant without disrupting the pellet. Maintain a continuous negative pressure as you draw off the liquid. *Up to 25 µl of the supernatant can remain in the tube without affecting the performance of the test.* Leaving fluid may be necessary to not disturb the pellet.
14. Add 600 µl of Ultrasensitive working lysis reagent to each tube. Cap the tubes and vortex for 10 to 15 s.

V. PROCEDURE (*continued*)

15. Incubate all tubes for 10 min at room temperature.
16. Add 600 μ l of 100% isopropanol to each tube. Mix well by vortexing for 3 to 5 s.
17. Place tubes in the Eppendorf centrifuge with the orientation mark facing out. Centrifuge at 12,500 to 16,000 $\times g$ for 15 min at room temperature.
18. Using a new sterile fine-tip transfer pipette for each tube, carefully remove and discard the supernatant from each tube, being careful not to disturb the pellet. (Pellets may not be visible at this point.) Remove as much fluid as possible. Do not use vacuum aspiration.
19. Add 1.0 ml of 70% ethanol to each tube.
20. Place the tubes in the Eppendorf centrifuge with the orientation mark facing out. Centrifuge at 12,500 to 16,000 $\times g$ for 15 min at room temperature.
21. Using a new sterile fine-tip transfer pipette for each tube, carefully remove and discard the supernatant from each tube, being careful not to disturb the pellet. The pellet should be visible at this point. Do not use vacuum aspiration.
22. Place tubes in the Eppendorf centrifuge with the orientation mark facing out. Pulse spin for 1 to 2 s.
23. Remove residual ethanol with an aerosol barrier pipette tip and Pipetman pipettor. *Removing residual ethanol is important, as ethanol may inhibit amplification.*
24. Add 100 μ l of specimen diluent to each tube. Recap the tubes and vortex for 10 to 15 s. Some insoluble material will remain.
25. Amplify the processed specimens within 2 h of preparation or store the processed samples at -20°C for up to a week.
26. If samples have been frozen, completely thaw, vortex for 1 to 10 s, and allow particulate material to settle.
27. Pipette 50 μ l of prepared samples to the appropriate MicroAmp reaction tube. Do not transfer any precipitated material.
28. Cap the tubes and place in a baggie to transfer to area 3.
29. Clean out the biologic safety cabinet with 10% bleach and wipe with a Sanicloth. Allow blower to run for at least 30 min after cleaning.
30. Record hood cleaning on hood QC sheet.

C. Area 3: amplification

1. Turn the thermal cycler on.
2. Remove MicroAmp tray from base.
3. Place MicroAmp tray into the thermal cycler block. Check to make sure the notch in the sample tray is at the left of the block and that the rim of the tray is seated in the channel around the block.
4. Slide the cover forward.
5. Turn the knob clockwise until hand tight. (The white mark on the cover knob should line up with the white mark on the cover.)
6. Program the thermal cycler as follows.
 - Program 13, HOLD program: 2 min at 50°C
 - Program 14, HOLD program: 30 min at 60°C
 - Program 36, CYCLE program (4 cycles): 10 s at 95°C , 10 s at 55°C , 10 s at 72°C
 - Program 37, CYCLE program (26 cycles): 10 s at 90°C , 10 s at 60°C , 10 s at 72°C
 - Program 18, HOLD program: 15 min at 72°C
7. Start the METHOD program (program runs about 1.7 h).
- **NOTE:** Specimens must be removed within 15 min of the start of the final HOLD program.
8. Remove the completed PCR sample tray from the thermal cycler and place in tray base. *Do not remove from area 3.*

V. PROCEDURE (*continued*)

9. Remove caps carefully to avoid aerosolizing PCR products.
10. *Immediately* add 100 μ l of denaturation solution to each PCR tube using a multichannel pipette (program 1 on Amplicor pipettor) with plugged tips. The program will mix the samples up and down five times.
11. Incubate for 10 min at room temperature.
Store the denatured, amplified samples at room temperature only if the detection test will be performed within 1 to 2 h. If not, recap the samples and store at 2 to 8°C for up to 1 week.
12. Review the thermal cycler run parameters for HISTORY FILE and record on RUN QUALITY CONTROL LOG, or print run parameters on printer during run.

D. Area 3: detection

Warm all reagents to room temperature prior to use.

1. Prepare working wash solution by adding 1 volume of wash concentrate (10 \times) to 9 volumes of type 1 water. Mix well. If necessary, warm the concentrate at 30 to 37°C to redissolve any precipitate. The working wash solution should be made fresh weekly.
2. Allow reagents and microwell plate to warm to room temperature before using.
3. Add 100 μ l of hybridization buffer to each well (program 2 on Amplicor pipettor). If the amplified samples were stored at 2 to 8°C, it may be necessary to incubate them at 37°C for 2 to 4 min to reduce viscosity. Rows A to F of the microwell plate are coated with HIV-specific probe; rows G and H are coated with the QS-specific probe.
4. Using plugged pipette tips and a multichannel pipettor (program 3), pipette 25 μ l of denatured amplified samples from the amplification tray into row A of the microwell plate. Place the pipette tips at a 45° angle in the corner of the well. Mix by pipetting up and down 10 to 15 times, and then transfer 25 μ l to the next row of wells. Repeat this procedure four more times, so as to generate five fivefold dilutions (1:5, 1:25, 1:125, 1:625, and 1:3,125) in rows B to F. Discard 25 μ l from the last well after mixing.
5. Add 25 μ l of denatured amplification reaction mixture from the amplification tray into the first row of green-rimmed microwells, row G, using the multichannel pipettor (program 3). Place the pipette tips at a 45° angle in the corner of the well. Mix by pipetting up and down 10 to 15 times, and then transfer 25 μ l to the next row of wells. Repeat this procedure one more time, so as to generate one fivefold dilution (1:1, 1:5) in rows G to H. Discard 25 μ l from the last well after mixing.
6. Place lid on tray and gently tap the plate 10 to 15 times until the color changes from blue to light yellow.
7. Cover plate and place in 37°C (\pm 2°C) incubator for 1 h. Plates may be incubated for up to 1 h 30 min if time is necessary to stagger plate washing.
8. Wash plate five times manually or by microwell plate washer, using the prepared 1 \times washing solution.
 - a. Manually (do not use squirt bottle):
 - (1) Empty contents of plate, invert, and tap dry on paper towel.
 - (2) Pipette working wash solution to fill each well (400 to 450 μ l).
 - (3) Soak for 30 s. Empty contents, invert plate, and tap dry on a paper towel.
 - (4) Repeat steps V.D.8.a.(2) and (3) four additional times.
 - b. Automated (program washer; Costar):
 - (1) Aspirate contents of well.
 - (2) Fill each well to top with working wash solution (400 to 450 μ l), soak for 30 s, and aspirate dry.

V. PROCEDURE (*continued*)

- (3) Repeat step V.D.8.b.(2) four additional times.
- (4) Tap plate dry.
9. Add 100 μ l of avidin-horseradish peroxidase conjugate to each well using the multichannel pipettor (program 2). Cover plate and incubate for 15 min at 37°C (\pm 2°C). Do not extend the incubation period beyond 15 min.
10. Wash plate as described in step V.D.8.
11. Prepare working substrate by mixing 2 ml of substrate A and 0.5 ml of substrate B into a polypropylene tube for each two eight-well strips. Prepare substrate no more than 3 h before use, and protect from the light.
12. Pipette 100 μ l of prepared working substrate into each well.
13. Allow color to develop for 10 min, at room temperature, *in the dark*. Do not extend the incubation period beyond 10 min.
14. Add 100 μ l of stop reagent to each well.
15. Measure the OD at 450 nm within 10 min of adding stop reagent.

E. Calculation of results

1. For each sample, select the highest dilution of the amplicon that gives an OD between 0.2 and 2.0 on the HIV microwells (rows A to F). For the QS, select the highest dilution of the amplicon that gives an OD between 0.3 and 2.0 on the microwells (rows G and H). Enter the OD and the dilution factors for the HIV and QS microwells in the worksheet. These values will be used to calculate the number of HIV copies per ml.
2. To calculate results on the computer, do the following.
 - a. Enter OD values and dilution determined as described above into worksheet template on the computer.
 - b. Enter the number of QS copies added. This is unique to each lot. Find the value on the test data card included in the kit.
 - c. Print a copy of the completed worksheet to keep with patient result worksheet.
3. To manually calculate the results, follow the instructions below.
 - a. Choose the appropriate HIV well that has an OD value in the range of 0.2 to 2.0 OD units. If more than one well is in this range, choose the well with the larger dilution factor (i.e., the smaller OD).
 - b. Subtract the background from the selected HIV OD value. Background = 0.07 OD unit.
 - c. Calculate the total HIV OD by multiplying the OD background value of the selected HIV well by the dilution factor associated with that well.
 - d. Choose the appropriate QS well that has an OD value in the range of 0.3 to 2.0 OD units. If more than one well is in the range, choose the well with the larger dilution factor (i.e., the smaller OD).
 - e. Subtract the background from the selected QS OD value. Background = 0.07 OD unit.
 - f. Calculate the total QS OD by multiplying the OD background of the selected QS well by the dilution factor associated with that well.
 - g. Calculate the HIV-1 RNA copies per milliliter of plasma as follows:

$$\left(\frac{\text{Total HIV OD}}{\text{Total QS OD}} \right) \times \text{input copies of QS} \times 4$$

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. The presence of HIV RNA in the sample is determined by relating the absorbance of the unknown specimen to the cutoff value.
- B. Report the number of HIV copies per milliliter of specimen.
- C. Call positive results to physician of record or designee. Note on the worksheet the name of the person called, date, and time, and initial.
- D. Document all testing in hard copy or computerized work card.

VII. INTERPRETATION

- A. Quantitative results reported as HIV RNA copies per milliliter serve as an estimate of the viral load of the patient.
- B. The linear range of the HIV ultrasensitive test is 40 to 750,000 copies/ml. Results outside this range should be reported as <40 or >750,000 copies/ml.
- C. Unexpected results
 1. All HIV values are <0.20 OD units. If all HIV wells have OD values less than 0.2, but the QS wells have the expected values, use 0.2 as the OD and 1 as the dilution factor. The result should be reported as <40 copies/ml.
 2. All HIV wells are >2.0 OD units. If all HIV wells have OD values greater than 2.0 but the QS wells have the expected values, then either an error occurred in the test or the HIV copy number is above the dynamic range of the assay. Report values as 750,000 copies/ml. If the doctor requests, repeat the test using a 1:50 dilution of the specimen with the negative control plasma. Calculate the results as described above, and then multiply the final result by 50.
 3. HIV OD values are out of sequence. If HIV wells do not follow the general pattern of decreasing OD values from row A to row F, an error in dilution may have occurred. The result for that specimen is invalid and the test should be repeated.
 4. Both QS values are <0.3 OD unit. If all QS wells are less than 0.3, then either the processed sample was inhibitory to the amplification or the RNA was not recovered during sample preparation. Repeat the entire test, including sample preparation and amplification and detection.
 5. Both QS values are >2.0 OD units. If all QS wells are greater than 2.0, then an error occurred. Repeat the tests.
 6. QS values are out of sequence. If the absorbance of row H is greater than the absorbance in row G, then an error occurred. The result for that specimen is invalid. Repeat the entire test.

PART 7

Qualitative Detection of Hepatitis C Virus RNA by Using the Roche Amplicor Reverse Transcriptase PCR Kit

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The major cause of posttransfusion non-A, non-B hepatitis is hepatitis C virus (HCV). The entire genome of HCV has been cloned and sequenced. The 5' untranslated region of the virus is remarkably well conserved and serves as the target sequence for several molecular detection assays, including the Roche Amplicor HCV test. Detection of HCV RNA in serum or plasma has been applied to the acute diagnosis of the disease, to supplement results obtained by immunoassays, and as a monitor of therapeutic protocols. The Amplicor HCV test is based on four major processes: reverse transcription of RNA to generate a cDNA, PCR target amplification, hybridization of the amplified prod-

uct to a specific oligonucleotide probe, and detection of the amplified product by color formation.

Because of the sensitivity of the PCR method, it is necessary to limit the potential for contamination by performing each step of the process in a separate area (preferably separate rooms) of the laboratory and to dedicate equipment to each of the areas. Work flow in the laboratory must proceed in a unidirectional manner, beginning in the reagent preparation area and moving to the specimen preparation area and then to the amplification and detection area. Pre-amplification activities must begin with reagent preparation and proceed

to specimen preparation. Reagent preparation activities and specimen preparation activities must be performed in separate, segregated areas. Supplies and equipment must be dedicated to each activity and not used for other activities or moved between areas. Lab coats and gloves must be worn in each area and must be changed before leaving that area. Equipment and supplies used for reagent preparation must not be used for specimen preparation activities or for pipetting or processing amplified DNA or other sources of target DNA. Amplification and detection supplies and equipment must be confined to the amplification and detection area at all times.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. Serum or plasma collected in acid citrate dextrose or EDTA
2. Specimens anticoagulated with heparin are not suitable for this test.

B. Timing of specimen collection

There are no particular timing issues to consider in collecting these specimens; however, the time of collection should be recorded.

C. Specimen transport

1. Transport the specimen at room temperature.
2. Within 3 h of blood draw, blood collection tubes must be centrifuged at $1,500 \times g$ for 20 min at room temperature.
3. Collect serum or plasma and store in 150- μ l aliquots at 2 to 8°C for 72 h. For longer periods, store at -20 to -80 °C.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

D. Specimen labeling and submission

The laboratory should determine a mechanism to ensure that the time of collection is recorded.

E. Rejection criteria

1. Test only serum or plasma.
2. Reject heparinized specimens.
3. Reject specimens that arrive in leaky containers.
4. Reject whole blood specimens that have been refrigerated and/or are received more than 3 h after collection.
5. Request a repeat specimen, or obtain the information, when collection time has not been provided.
6. If an improperly collected, transported, or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised.

III. MATERIALS

A. Area 1: reagent preparation

1. Amplicor HCV amplification kit (provided)
2. Biological safety cabinet or dead-air box equipped for UV irradiation
3. Dedicated lab coat (store in area 1)
4. Powder-free gloves
5. 10% Bleach
6. 70% Ethanol
7. Pipette with plugged pipette tips (100 μ l)
8. MicroAmp tray, base, and tray and retainer
9. Repeat pipettor with 1.25- μ l sterile Combitips
10. Plastic baggie

B. Area 2: specimen preparation

1. Amplicor HCV specimen preparation kit (provided)
2. Amplicor HCV PCR controls (positive and negative) (provided)
3. Amplicor HCV serum control kit (provided)
4. Dedicated lab coat (store in area 2)
5. Powder-free gloves
6. 10% Bleach
7. 70% Ethanol
8. Pipetaide
9. 1.5- μ l attached screw-cap microcentrifuge tubes, conical bottom
10. 60 \pm 2°C dry-heat block
11. 95% Ethyl alcohol

12. Isopropyl alcohol

13. Sterile transfer pipettes (graduated)
14. Vortex mixer
15. Test tube racks
16. Microcentrifuge
17. Pipettes with plugged pipette tips (50, 100, and 1,000 μ l)
18. MicroAmp tube caps and capping tool

C. Area 3: Amplification and detection

1. Amplicor HCV detection kit (provided)
2. Dedicated lab coat (store in area 3)
3. Powder-free gloves
4. 10% Bleach
5. 70% Ethanol
6. Thermal cycler with printer
7. Spatula or tool to remove tube caps
8. Multichannel pipette with plugged pipette tips (100 μ l)
9. Pipette with plugged pipette tips (25 μ l)
10. Disposable reagent reservoirs
11. 1-liter Erlenmeyer flask
12. 100- μ l graduated cylinder
13. 37°C (\pm 2°C) incubator
14. Disposable 96-well plate with lid
15. Microwell plate washer
16. Sterile 15- μ l polypropylene centrifuge tubes
17. ELISA plate reader

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. For each batch of specimens processed, include three replicates of the positive serum control and one replicate of the negative serum control. Process the controls in the exact same manner as the patient specimens.
- B. Specimens and controls from separate preparation batches may be amplified and detected at the same time. Each separate specimen batch is validated individually by the set of serum controls for that batch.
- C. All test specimens and controls prepared in the same batch should be amplified and detected in adjacent positions in the thermal cycler and on the detection plate. The exact order of the placement is not critical.
- D. For each PCR amplification, run one positive reagent control and one negative reagent control.
- E. Verify that all reagents and materials meet expiration date and QC parameters as per NCCLS document M22-A2 (1).

V. PROCEDURE**A. Area 1: reagent preparation**

■ **NOTE:** To minimize contamination, the use of a biological safety cabinet (hood) or dead-air box equipped with UV irradiation is suggested. All reagent preparation should be performed in this cabinet.

1. Warm all reagents to room temperature before beginning.
2. Wipe out dead-air box or hood with 10% bleach followed by 70% ethanol.
3. Add 100 µl of AmpErase to one tube of master mix (one tube is sufficient for 32 amplifications).
4. Recap and mix by inverting 10 to 15 times. Discard AmpErase tube when empty. Record date of preparation on master mix tube.
5. Determine the number of PCR tubes needed and place in MicroAmp sample tray and lock in place with retainer. (*See* item IV above for number of controls.)
6. Pipette 50 µl of working master mix into each PCR tube using a repeat pipettor with sterile Combitip or a micropipette with plugged tips.
7. Place tray in a baggie and transport to area 2. Store at 2 to 8°C until use.

B. Area 2: specimen preparation

■ **NOTE:** Prewarm the HCV lysis reagent by placing it in a 37°C incubator. Ensure that crystals have gone into solution.

1. Wipe out hood with 10% bleach followed by Sanicloth disinfectant.
2. Reagent control preparation

■ **NOTE:** Do not extract the reagent controls with lysis reagent. These reagent controls are added directly to the PCR tubes.

- a. Add 50 µl of HCV (–) control to a tube containing 200 µl of control diluent. Recap and vortex *well*. Incubate at room temperature for 10 min. Negative reagent control must be amplified within 5 h of preparation. Do not reuse.
 - b. Add 50 µl of HCV (+) control to a tube containing 200 µl of control diluent. Recap and vortex *well*. Incubate at room temperature for 10 min. Positive reagent control must be amplified within 5 h of preparation. Do not reuse.
3. Serum control preparation
 - a. Using a permanent marker, label three 1.5-µl microcentrifuge tubes as positive serum controls and one as a negative serum control. Draw a vertical line on the tubes for pellet orientation during centrifugation. Add 400 µl of lysis reagent to each tube.

V. PROCEDURE (*continued*)

- b. Add 100 μ l of normal serum and mix well by vortexing for 10 s.
NOTE: The normal serum is not included with the kit. Use a serum which has previously been tested as negative by PCR.
- c. Vortex controls and add 50 μ l of the appropriate control to each tube. Vortex well.
4. For each patient specimen, label a 1.5- μ l microcentrifuge tube with indelible ink and draw a vertical line for orientation of the pellet after centrifugation. Add 400 μ l of lysis reagent to each tube.
5. Thaw specimens at room temperature and vortex. Add 100 μ l to the appropriate tube and mix well by vortexing.
6. Incubate all tubes for 10 min at $60 \pm 2^\circ\text{C}$, and then mix well by vortexing.
7. Using a new tip for each specimen, add 500 μ l of 100% isopropyl alcohol to each tube and mix well by vortexing.
8. Incubate all tubes for 2 min at room temperature.
9. Centrifuge tubes for 15 min at $13,000$ to $16,000 \times g$ at room temperature. Position tubes so that all are in the same orientation in the rotor.
10. Using a different transfer pipette for each specimen, remove and discard the supernatant into a container containing 10% bleach. Let bleach stand for 24 h and discard down the drain. Flush sink with running water after discarding bleach.
11. Add 1.0 ml of 70% ethanol (made fresh) and vortex.
12. Centrifuge for 5 min at $13,000$ to $16,000 \times g$ at room temperature. Position tubes so that all are in the same orientation in the rotor.
13. Remove the supernatant from each tube with a different transfer pipette and discard into a container with 10% bleach. Let the bleach solution sit for 24 h before discarding down the drain. Flush sink with running water after discarding bleach.
14. Resuspend the pellet in 1.0 ml of specimen diluent by carefully, but thoroughly, dislodging the pellet with a pipette tip from the *side* of the tube.
NOTE: The specimens and controls should be held at room temperature until ready to use. RNA preparations should be amplified within 3 h of preparation. If this is not possible, the RNA preparations can be stored at -20°C for up to 1 month. Thaw frozen RNA preparations at room temperature before proceeding to tray preparation.
15. Tray preparation
 - a. Using a clean plugged tip for each sample, pipette 50 μ l of processed sample into appropriate MicroAmp tubes. Be careful not to pipette any precipitated material that may not have been resuspended.
 - b. Cap the tubes tightly with the capping tool.
 - c. Move the prepared samples in tray to area 3.

C. Area 3: amplification and detection

1. Amplification
 - a. Remove MicroAmp tray from base
 - b. Place MicroAmp tray into the thermal cycler block. Check to make sure the notch in the sample tray is at the left of the block and that the rim of the tray is seated in the channel around the block.
 - c. Slide the cover forward.
 - d. Turn the knob clockwise until hand tight. (The white mark on the cover knob should line up with the white mark on the cover.)
 - e. Program the thermal cycler as follows.
Program 13, HOLD program: 2 min at 50°C
Program 14, HOLD program: 30 min at 60°C
Program 15, HOLD program: 1 min at 95°C
Program 16, CYCLE program (2 cycles): 15 s at 95°C , 20 s at 60°C

V. PROCEDURE (*continued*)

Program 17, CYCLE program (38 cycles): 15 s at 90°C, 20 s at 60°C
Program 18, HOLD program: 72°C (at least 5 min; do not exceed 15 min)

In CYCLE programs, the ramp times are left at 0:00. Link the programs together into METHOD program 19.

- f. Start the METHOD program (program runs about 1 h 45 min).
- **NOTE:** Specimens must be removed within 15 min of the start of the final HOLD program.
- g. Remove the completed PCR sample tray from the thermal cycler and place in tray base. *Do not remove from area 3.*
- h. Remove caps carefully to avoid aerosolizing PCR products.
- i. *Immediately* add 100 µl of denaturation solution to each PCR tube using a multichannel pipette (program 1 on Amplicor pipettor) with plugged tips.
- j. Incubate for 10 min at room temperature.
Store the denatured, amplified samples at room temperature only if the detection test will be performed within 1 to 2 h. If not, store the samples at 2 to 8°C for up to 1 week.
- k. Review the thermal cycler run parameters for HISTORY FILE and record on RUN QUALITY CONTROL LOG, or print run parameters on printer during run.

2. Detection

- a. Prepare working wash solution by adding 1 volume of wash concentrate (10×) to 9 volumes of distilled, deionized water. Mix well.
- b. Allow microwell plate to warm to room temperature before removing from the foil pouch. Remove the appropriate number of eight-well strips and set into microwell plate frame. Return unused strips to foil pouch and reseal bag, making sure desiccant pillow remains in the pouch.
- c. Add 100 µl of hybridization buffer to each well (program 2 on Amplicor pipettor). If the amplified samples were stored at 2 to 8°C, it may be necessary to incubate them at 37°C for 2 to 4 min to reduce viscosity.
- d. Using plugged pipette tips, pipette 25 µl of denatured amplified samples to the appropriate microtiter well. (A multichannel pipettor may be used.) Place lid on tray and gently tap the plate 10 to 15 times until the color changes from blue to light yellow.
- e. Cover plate and place in 37°C (± 2°C) incubator for 1 h.
- f. Wash plate five times manually or by microwell plate washer, using the prepared 1× washing solution.
 - (1) Manually (do not use squirt bottle):
 - (a) Empty contents of plate, invert, and tap dry on paper towel.
 - (b) Pipette working wash solution to fill each well (400 to 450 µl)
 - (c) Soak for 30 s. Empty contents of plate, invert, and tap dry on a paper towel.
 - (d) Repeat steps V.C.2.f.(1).(b) and (c) four additional times.
 - (2) Automated: (program washer):
 - (a) Aspirate contents of well.
 - (b) Fill each well to top with working wash solution (350 to 450 µl), soak for 30 s, and aspirate dry.
 - (c) Repeat step V.C.2.f.(2).(b) five additional times.
 - (d) Invert plate and tap plate dry on a paper towel.
- g. Add 100 µl of Avidin-horseradish peroxidase conjugate to each well. Cover plate and incubate for 15 min at 37°C (± 2°C).
- h. Wash plate as described in step V.C.2.f.

V. PROCEDURE *(continued)*

- i. Prepare working substrate by mixing 2 ml of substrate A and 0.5 ml of substrate B into a polypropylene tube for each two eight-well strips. Prepare substrate no more than 3 h before use, and protect from the light.
- j. Pipette 100 μ l of prepared working substrate into each well. Check wells for uneven blue color and note these wells on the worksheet.
- k. Allow color to develop for 10 min, at room temperature, *in a darkened room*.
- l. Add 100 μ l of stop reagent to each well.
- m. Measure the optical density (OD) at 450 nm within 1 h of adding stop reagent.

D. Assay validation

1. The absorbance of the negative serum control should be less than or equal to 0.25. If the negative serum control in a specimen batch is greater than 0.25, that batch of specimens should be invalidated and the entire test procedure for that batch should be repeated.
2. The absorbance of at least two of the three positive serum controls in each batch must be greater than or equal to 1.50. If this criterion is not met, the entire test procedure for that batch should be invalidated and repeated.
3. The absorbance of the negative reagent control should be less than or equal to 0.25. If this criterion is not met, the entire amplification and detection run should be invalidated and repeated.
4. The absorbance of the positive reagent control should be greater than or equal to 2.00. If this criterion is not met, the entire amplification and detection run should be invalidated and repeated.
5. The thermal cycler run QC log *must* show that there was a successful run.
6. The test must be repeated if any of the following conditions applies.
 - a. A negative control of >0.25 OD unit (ODU)
 - b. Two of three positive serum controls of <1.50 ODU
 - c. A positive reagent control of <2.00 ODU
 - d. A failed thermal cycler run

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. The presence of HCV RNA in the sample is determined by relating the absorbance of the unknown specimen to the cutoff value.
- B. A clinical specimen with an A_{450} reading of <0.25 ODU should be reported as negative for HCV RNA.
- C. A clinical specimen with an A_{450} reading of >0.60 ODU should be reported as positive for HCV RNA.
- D. A clinical specimen with an A_{450} between 0.25 and 0.60 ODU should be considered equivocal. The test should be repeated in duplicate. The final test result should be determined as follows.
 1. Compile all three results (initial and duplicate repeat) of the sample.
 2. If two of the three results are <0.40 , the sample is negative.
 3. If two of the three results are >0.40 , the sample is positive.
- E. Call positive results to the requesting area. Note on the worksheet the name of the person called, date, and time, and initial.
- F. Document all testing in hard copy or computerized work card.

VII. INTERPRETATION

- A. Test results indicate the presence or absence of circulating HCV virions.
- B. A positive result is indicative of active infection.
- C. A negative result does not rule out infection entirely.

VIII. LIMITATIONS OF TESTING

- A. This test is not Food and Drug Administration approved.
- B. Specimens anticoagulated with heparin should not be used.
- C. Contamination from HCV-positive controls and clinical specimens can be avoided only by good laboratory practices and careful adherence to the procedures specified by the manufacturer.
- D. Use of this product should be limited to personnel trained in the techniques of PCR.
- E. As with any diagnostic test, results from the Amplicor HCV test should be interpreted with consideration of all clinical and laboratory findings.

PART 8

Quantitative Measurement of Hepatitis C Virus RNA by Using the Roche Amplicor HCV Monitor Reverse Transcriptase PCR Kit

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The Amplicor HCV Monitor test is a PCR assay for the quantitative measurement of hepatitis C virus (HCV) viral RNA in serum or plasma. The test includes an RNA quantitation standard (QS) of known copy number that is coamplified with the target and is used to assign the copy level to the specimen. The QS is a synthetic RNA molecule with primer binding sites identical to the HCV target RNA and with a unique internal sequence specific for the QS probe. The test is based on four major processes: reverse transcription of RNA to generate a cDNA, PCR target amplification, hybridization of the amplified product to a specific oligonucleotide probe, and

detection of the amplified product by a color formation.

Because of the sensitivity of the PCR method, it is necessary to limit the potential for contamination by performing each step of the process in a separate area (preferably separate room) of the laboratory and to dedicate equipment to each of the areas. Work flow in the laboratory must proceed in a unidirectional manner, beginning in the reagent preparation area and moving to the specimen preparation area and then to the amplification and detection area. Preamplification activities must begin with reagent preparation and proceed to specimen preparation. Reagent prepara-

tion activities and specimen preparation activities must be performed in separate, segregated areas. Supplies and equipment must be dedicated to each activity and not used for other activities or moved between areas. Lab coats and gloves must be worn in each area and must be changed before leaving that area. Equipment and supplies used for reagent preparation must not be used for specimen preparation activities or for pipetting or processing amplified DNA or other sources of target DNA. Amplification and detection supplies and equipment must be confined to the amplification and detection area at all times.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. Serum or plasma collected in acid citrate dextrose or EDTA.
2. Heparinized specimens are not suitable for this test.

B. Timing of specimen collection

There are no particular timing issues to consider in collecting these specimens; however, the time of collection should be recorded.

C. Specimen transport

1. Transport the specimen at room temperature.
2. Within 3 h of blood draw, blood collection tubes must be centrifuged at $1,500 \times g$ for 20 min at room temperature.
3. Collect serum or plasma and store in 150- μ l aliquots at 2 to 8°C for 72 h. For longer periods, store at -20 to -80°C.

D. Specimen labeling and submission

The laboratory should determine a mechanism to ensure that the time of collection is recorded.

E. Rejection criteria

1. The quantitative HCV test is not indicated if the qualitative test is negative.
2. Test only serum or plasma.
3. Reject heparinized specimens.
4. Reject specimens that arrive in leaky tubes.
5. Reject whole-blood specimens that have been refrigerated and/or are received more than 3 h after collection.
6. Request a repeat specimen, or obtain the information, when collection time has not been provided.
7. If an improperly collected, transported, or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised.

III. MATERIALS

A. Area 1: reagent preparation

1. Amplicor HCV amplification kit (provided)
2. Biological safety cabinet or dead-air box equipped for UV irradiation
3. Dedicated lab coat (store in area 1)
4. Powder-free gloves
5. 10% Bleach
6. 70% Ethanol
7. Pipette with plugged pipette tips (100 μ l)
8. MicroAmp tray, base, and tray and retainer
9. Repeat pipettor with 1.25- μ l sterile Combitips
10. Plastic baggie

B. Area 2: specimen preparation

1. Amplicor HCV specimen preparation kit (provided)
2. Amplicor HCV PCR controls (positive and negative) (provided)
3. Amplicor HCV serum control kit (provided)
4. Dedicated lab coat (store in area 2)
5. Powder-free gloves

6. 10% Bleach

7. 70% Ethanol

8. Pipetaide

9. 1.5- μ l attached screw-cap microcentrifuge tubes, conical bottom

10. 60 \pm 2°C dry-heat block

11. 95% Ethyl alcohol

12. Isopropyl alcohol

13. Sterile transfer pipettes (graduated)

14. Vortex mixer

15. Test tube racks

16. Microcentrifuge

17. Pipettes with plugged pipette tips (50, 100, and 1,000 μ l)

18. MicroAmp tube caps and capping tool

C. Area 3: amplification and detection

1. Amplicor HCV detection kit (provided)

2. Dedicated lab coat (store in area 3)

3. Powder-free gloves

4. 10% Bleach

5. 70% Ethanol

6. Thermal cycler with printer

7. Spatula or tool to remove tube caps

III. MATERIALS (continued)

- | | |
|--|--|
| 8. Multichannel pipette with plugged pipette tips (100 µl) | 13. 37°C (±2°C) incubator |
| 9. Pipette with plugged pipette tips (25 µl) | 14. Disposable 96-well plate with lid |
| 10. Disposable reagent reservoirs | 15. Microwell plate washer |
| 11. 1-liter Erlenmeyer flask | 16. Sterile 15 µl polypropylene centrifuge tubes |
| 12. 100-µl graduated cylinder | 17. ELISA plate reader |

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. For each batch of specimens processed, include one replicate of the positive serum control and one replicate of the negative serum control. Process the controls in the same manner as the patient specimens.
- B. Specimens and controls from separate preparation batches may be amplified and subjected to detection at the same time. Each separate specimen batch is validated individually by the set of serum controls for that batch.
- C. All test specimens and controls prepared in the same batch should be amplified and subjected to detection in adjacent positions in the thermal cycler and on the detection plate. The exact order of the placement is not critical.
- D. Verify that all reagents and materials meet expiration date and QC parameters as per NCCLS document M22-A2 (1).

V. PROCEDURE**A. Area 1: reagent preparation**

■ **NOTE:** To minimize contamination, the use of a biological safety cabinet (hood) or dead-air box equipped for UV irradiation is suggested. All reagent preparation should be performed in this cabinet.

1. Wipe out dead-air box or hood with 10% bleach followed by 70% ethanol.
2. Remove HCV lysis reagent from 4°C. Mix by inversion to dissolve any precipitate. Vortex the internal QS and add the appropriate volume. The copy number of the internal QS varies with the kit lot. Check the kit insert for the amount of internal QS specified.
3. Determine the number of PCR tubes needed for patient samples and controls, place in MicroAmp sample tray, and lock in place with retainer.
4. Pipette 50 µl of working master mix into each PCR tube using a repeat pipettor with a sterile Combitip or a micropipette with plugged tips. Inspect the reaction tubes after pipetting to ensure that the same volume was pipetted into each tube.
5. Place tray in a baggie and transport to area 2. Store at 2 to 8°C until used.

B. Area 2: specimen preparation

1. Prepare aliquots of isopropanol and 70% ethanol, made fresh daily.
2. Label 1.5 ml microcentrifuge tubes for one positive serum control, one negative serum control, and patient samples. Draw a vertical line on the tubes for pellet orientation during centrifugation. Add 400 µl of lysis reagent to each tube.
3. Control preparation
 - a. Mix normal serum well by vortexing and add 100 µl to the lysis reagent in the control tubes. Vortex well after mixing.

■ **NOTE:** The normal serum is not included with the kit. Use serum which has previously been tested as negative by PCR.
 - b. Add 100 µl of the appropriate control to each tube.
4. Vortex the patient serum or plasma after thawing, add 100 µl to the appropriate tube, and mix well by vortexing.
5. Incubate all tubes for 10 min at 60 ± 2°C, and then mix well by vortexing.

V. PROCEDURE (*continued*)

6. Add 500 μ l of 100% isopropyl alcohol to each tube and mix well by vortexing.
 7. Incubate all tubes for 2 min at room temperature.
 8. Centrifuge tubes for 15 min at 13,000 to 16,000 $\times g$ at room temperature. Position tubes so that all are in the same orientation in the rotor. The RNA pellet may not be visible at this point.
 9. Remove and discard the supernatant from each tube with a different transfer pipette.
 10. Add 1.0 ml of 70% ethanol (made fresh) and vortex.
 11. Centrifuge for 5 min at 13,000 to 16,000 $\times g$ at room temperature. Position tubes so that all are in the same orientation in the rotor.
 12. Remove the supernatant from each tube with a different transfer pipette. Discard into a container with 10% bleach. Let discarded supernatant sit for 24 h before discarding down the drain. Flush sink with running water after discarding bleach.
 13. Resuspend the pellet in 1.0 ml of specimen diluent by carefully dislodging the pellet with a pipette tip from the side of the tube. Break it apart as much as possible by scraping the tube wall with a P200 pipettor fitted with a P200 plugged pipette tip. Scrape the top third, the middle third, the bottom third, and then the entire area of the tube wall. Vortex for 5 s. Let the undissolved particles settle to the bottom of the tube. Do not vortex just before adding to the master mix. Pipette samples from near the top of the preparation and avoid pipetting the chunks of precipitate.
- **NOTE:** The specimens and controls should be held at room temperature until ready to use. RNA preparations should be amplified within 3 h of preparation. If this is not possible, the RNA preparations can be stored at -20°C for up to 1 month.
14. Tray preparation
 - a. Using a clean plugged tip for each sample, pipette 50 μ l of processed sample into appropriate MicroAmp tubes. Be careful not to pipette any precipitated material that may not have been resuspended.
 - b. Cap the tubes tightly with the capping tool.
 - c. Move the prepared samples in tray to area 3.
 15. Remember to change coat and gloves before moving to the next area.

C. Area 3: amplification and detection

1. Amplification
 - a. Remove MicroAmp tray from base.
 - b. Place MicroAmp tray into the thermal cycler block. Check to make sure the notch in the sample tray is at the left of the block and that the rim of the tray is seated in the channel around the block.
 - c. Slide the cover forward.
 - d. Turn the knob clockwise until hand tight. (The white mark on the cover knob should line up with the white mark on the cover.)
 - e. Program the thermal cycler as follows.
 - Program 13, HOLD program: 2 min at 50°C
 - Program 14, HOLD program: 30 min at 60°C
 - Program 15, HOLD program: 1 min at 95°C
 - Program 16, CYCLE program (2 cycles): 15 s at 95°C , 20 s at 60°C
 - Program 17, CYCLE program (38 cycles): 15 s at 90°C , 20 s at 60°C
 - Program 18, HOLD program 72°C (at least 5 min; do not exceed 15 min)

In CYCLE programs, the ramp times are left at 0:00. Link the programs together into METHOD program 19.

V. PROCEDURE (continued)

- f. Start the METHOD program (program runs about 1 h 45 min).
 - ☑ **NOTE:** Specimens must be removed within 15 min of the start of the final HOLD program.
- g. Remove the completed PCR sample tray from the thermal cycler and place in tray base. *Do not remove from area 3.*
- h. Remove caps carefully to avoid aerosolizing PCR products.
- i. *Immediately* add 100 μ l of denaturation solution to each PCR tube using a multichannel pipette (program 1 on Amplicor pipettor) with plugged tips.
- j. Incubate for 10 min at room temperature.
Store the denatured, amplified samples at room temperature only if the detection test will be performed within 1 to 2 h. If not, store the samples at 2 to 8°C for up to 1 week.
- k. Review the thermal cycler run parameters for HISTORY FILE and record on RUN QUALITY CONTROL LOG, or print run parameters on printer during run.

2. Detection

- a. Prepare working Wash Solution by adding 1 volume of wash concentrate (10 \times) to 9 volumes of distilled, deionized water. Mix well.
- b. Allow microwell plate to warm to room temperature before removing from the foil pouch. Remove the appropriate number of eight-well strips and set into microwell plate frame.
- c. Add 100 μ l of hybridization buffer to each well (program 2 on Amplicor pipettor).
- d. Using plugged pipette tips, pipette 25 μ l of denatured amplified samples to the appropriate microtiter well. (A multichannel pipettor may be used.) Place lid on tray and gently tap the plate 10 to 15 times until the color changes from blue to light yellow.
- e. Cover plate and place in 37°C (\pm 2°C) incubator for 1 h.
- f. Wash plate five times manually or by microwell plate washer, using the prepared 1 \times washing solution.
 - (1) Manually (do not use squirt bottle):
 - (a) Empty contents of plate and tap on paper towel.
 - (b) Pipette working wash solution to fill each well (400 to 450 μ l).
 - (c) Soak for 30 s. Empty contents and tap dry on a paper towel.
 - (d) Repeat steps V.C.2.f.(1).(b) and (c) four additional times.
 - (2) Automated (program washer):
 - (a) Aspirate contents of well
 - (b) Fill each well to top with working wash solution (350 to 450 μ l), soak for 30 s, and aspirate dry.
 - (c) Repeat step V.C.2.f.(2).(b) five additional times.
 - (d) Tap plate dry.
- g. Add 100 μ l of avidin-horseradish peroxidase conjugate to each well. Cover plate and incubate for 15 min at 37°C (\pm 2°C).
- h. Wash plate as described in step V.C.2.f.
- i. Prepare working substrate by mixing 2 ml of substrate A and 0.5 ml of substrate B into a polypropylene tube for each pair of eight-well strips. Prepare working substrate no more than 3 h before use, and protect from the light.
- j. Pipette 100 μ l of prepared working substrate into each well. Check wells for uneven blue color and note these wells on the worksheet.
- k. Allow color to develop for 10 min at room temperature, *in the dark*.
- l. Add 100 μ l of stop reagent to each well.

V. PROCEDURE *(continued)*

m. Measure the optical density (OD) at 450 nm within 1 h of adding stop reagent.

D. Assay validation

1. The absorbance of the negative serum control should be less than or equal to 0.25. If the negative serum control in a specimen batch is greater than 0.25, that batch of specimens should be invalidated and the entire test procedure for that batch should be repeated.
2. The absorbance of at least two of the three positive serum controls in each batch must be greater than or equal to 1.50. If this criterion is not met, the entire test procedure for that batch should be invalidated and repeated.
3. The absorbance of the negative reagent control should be less than or equal to 0.25. If this criterion is not met, the entire amplification and detection run should be invalidated and repeated.
4. The absorbance of the positive reagent control should be greater than or equal to 2.00. If this criterion is not met, the entire amplification and detection run should be invalidated and repeated.
5. The thermal cycler run QC log *must* show that there was a successful run.
6. The test must be repeated if any of the following conditions applies.
 - a. A negative control of >0.25 OD unit (ODU)
 - b. Two of three positive serum controls of <1.50 ODU
 - c. A positive reagent control of <2.00 ODU
 - d. A failed thermal cycler run

E. Calculation of results

1. For each sample select the highest dilution of the amplicon that gives an OD between 0.2 and 2.0 on the HCV microwells (rows A to E). Repeat the same determination for the QS microwells (rows F to H). Enter the OD and the dilution factors for the HCV and QS microwells in the worksheet. These values will be used to calculate the number of HCV copies per milliliter.

NOTE: For each sample, the OD for the internal QS must be above 0.5 in at least one of the wells for the determination to be valid. If it is not, then both the specimen preparation and amplification and detection must be repeated for that sample.
2. To manually calculate the results, follow the instructions below.
 - a. Choose the appropriate HCV well that has an OD value in the range of 0.2 to 2.0 ODU. If more than one well is in this range, choose the well with the larger dilution factor (i.e., the smaller OD).
 - b. Subtract the background from the selected HCV OD value. Background = 0.07 ODU.
 - c. Calculate the total HCV OD by multiplying the OD background value of the selected HCV well by the dilution factor associated with that well.
 - d. Choose the appropriate QS well that has an OD value in the range of 0.2 to 2.0 ODU. If more than one well is in this range, choose the well with the larger dilution factor (i.e., the smaller OD). The OD value of QS in row F must be greater than or equal to 0.5 for the test result to be valid. If it is not, then both the specimen preparation and amplification and detection must be repeated for that sample.
 - e. Subtract the background from the selected QS OD value. Background = 0.07 ODU.
 - f. Calculate the total QS OD by multiplying the OD background of the selected QS well by the dilution factor associated with that well.
 - g. Calculate the HCV RNA copies per milliliter as follows:

$$\left(\frac{\text{Total HCV OD}}{\text{Total QS OD}} \times \text{Input copies of QS} \right) \times 200$$

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. The presence of HCV RNA in the sample is determined by relating the absorbance of the unknown specimen to the cutoff value.
- B. Round all values to the nearest thousand.
- C. Report the number of HCV copies per milliliter of specimen.
- D. The linear range of the HCV Monitor test is 1,000 to 1,000,000 copies/ml. Results outside this range should be reported as <1,000 or >999,999 copies/ml.
- E. Call positive results to requesting area. Note on the worksheet the name of the person called, date, and time, and initial.
- F. Document all testing in hard copy or computerized work card.

VII. INTERPRETATION

- A. Quantitative results reported as HCV RNA copies per milliliter serve as an estimate of the viral load of the patient.
- B. Unexpected results
 - 1. All HCV values are <0.20 ODU. If all HCV wells have OD values less than 0.2, but the QS wells have the expected values, the result should be reported as undetectable.
 - 2. All HCV wells are >2.0 ODU. If all HCV wells have OD values greater than 2.0 but the QS wells have the expected values, then either an error occurred in the test or the HCV copy number is above the dynamic range of the assay. Report the result as “not determined.” If it is suspected that the sample has a very high titer, repeat the entire test using 10 μ l of serum instead of 100 μ l. Calculate the results as described above, and then multiply the final result by 10.
 - 3. All QS values are <0.2 ODU. If all QS wells are less than 0.2, then either the processed sample was inhibitory to the amplification or the RNA was not recovered during sample preparation. Report the result as “not determined” and repeat the entire test, including sample preparation and amplification and detection.
 - 4. All QS values are >2.0 ODU. If this is the case, then an error occurred. Report the result as “not determined” and repeat the assay.

VIII. LIMITATIONS OF TESTING

- A. This test is not Food and Drug Administration approved.
- B. Specimens anticoagulated with heparin should not be used.
- C. The HCV Monitor test is less sensitive than the HCV Amplicor qualitative test and should not be used for the initial diagnosis of HCV infection.
- D. Contamination from HCV-positive controls and clinical specimens can be avoided only by good laboratory practices and careful adherence to the procedures specified by the manufacturer.
- E. Use of this product should be limited to personnel trained in the techniques of PCR.
- F. As with any diagnostic test, results from the HCV Monitor test should be interpreted with consideration of all clinical and laboratory findings.

PART 9

Detection of Herpes Simplex Virus in CSF by PCR

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Herpes simplex encephalitis (HSE) is a rare complication of herpetic infection (both herpes simplex virus types 1 and 2) and is associated with significant morbidity and mortality. Antiviral therapy is successful if administered early in the course of the infection. The clinical presentation of HSE is one of focal encephalitis associated with headache, fever, behavioral disorders, altered levels of consciousness, focal seizures, and hemiparesis. While the clinical picture will lead physicians to treat

empirically for HSE, the presentation is not pathognomonic for HSE.

Infectious HSV is rarely present in CSF during encephalitis. HSV is cultured from CSF in only about 5% of adult patients and in up to 50% of neonatal cases of HSE. Isolation of HSV from brain tissue after biopsy has been considered the reference standard for the diagnosis of HSE. Recent studies have shown that HSV DNA was detected by PCR in CSF of 53 (98%) of 54 patients with biopsy-proven HSE. In

this study the specificity of HSV PCR for the diagnosis of HSE was 94% compared to culture of brain tissue. Thus, PCR detection of HSV DNA should be considered the standard for diagnosis of HSE (2, 3).

In this HSV PCR assay, the target is a 290-bp region of the polymerase gene which is common to both HSV types 1 and 2 (Table 12.2.3–1). This primer pair does not amplify cytomegalovirus, varicella-zoster virus, or Epstein-Barr virus DNA (1).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. The assay requires the sterile collection of at least 500 μ l (0.5 ml) of CSF.
2. This assay may be performed on eye specimens (vitreal or aqueous), but this must be approved by either the supervisor or director.

B. Timing of specimen collection

There are no particular timing issues to consider in collecting these specimens; however, the specimen type and time of collection should be recorded.

C. Specimen transport

1. Specimens should be transported to the laboratory at room temperature.
2. Samples are stored at 4°C until testing.
3. An aliquot of 200 μ l of CSF is required for testing; the remaining specimen is stored at –70°C for repeat testing if necessary.

D. Specimen labeling and submission

The laboratory should determine a mechanism to ensure that the specimen type and time of collection are recorded.

E. Rejection criteria

1. Test only CSF or ocular specimens (director approval).
2. Reject specimens that arrive in leaky tubes or specimen containers.

Table 12.2.3–1 PCR primers for detection of HSV types 1 and 2 in CSF

Primer designation	Nucleotide sequence, 5'–3'	Product size (bp)
HSV-3	TAC ATC GGC GTC ATC TGC GGG G	290
HSV-4	CAG TTC GGC GGT GAG GAC AAA G	290

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

3. Testing of volumes of CSF as little as 100 μ l brought up to a 200- μ l volume with phosphate-buffered saline requires director approval. Such cases should be noted when reporting results, with the approximate volume entered as a qualifier.
4. Request a repeat specimen, or obtain the information, when collection time or specimen type has not been provided.
5. If an improperly collected, transported, and/or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised.

III. MATERIALS

A. Specimen supplies and equipment

1. Area 1
 - a. Repeat pipettor with tips
 - b. Perkin-Elmer 9600 reaction tray and retainer sets
 - c. Perkin-Elmer 200- μ l reaction tubes
 - d. Ziploc baggies
 - e. Dead-air box
 - f. 2.0-ml Sarstedt screw-top tubes
 - g. Low-speed microcentrifuge
 - h. Rainin Gilson P20, P200, and P1000 Pipetman
 - i. 20-, 200-, and 1,000- μ l plugged DNase-free aerosol-resistant pipette tips
 - j. Spray/squirt bottles—bleach, ethanol
 - k. Refrigerator
 - l. -20°C freezer
- m. Microtube racks
 - n. 50-ml conical tubes
 - o. 1.7-ml microcentrifuge flip-top tubes
 - p. 2-ml microcentrifuge tubes
 - q. QIAamp blood and tissue kit (catalog no. 29106; QIAGEN)
2. Area 2
 - a. Sarstedt 1.7-ml screw-top tubes
 - b. Aluminum foil
 - c. Perkin-Elmer reaction tube cap strips (8 and 12 strips)
 - d. Floaters
 - e. Capping instrument
 - f. -70°C freezer
 - g. Eppendorf microcentrifuge
 - h. Rainin Gilson P20, P200, and P1000 Pipetman
 - i. 20-, 200-, and 1,000- μ l plugged DNase-free aerosol-resistant pipette tips
 - j. Extended-length pipette tips (p200)
 - k. Spray/squirt bottles—bleach, ethanol
 - l. Refrigerator
 - m. -20°C freezer
 - n. 1.7-ml microcentrifuge flip-top tubes

- o. 2-ml microcentrifuge tubes
- p. Microtube racks
- q. Water bath
- r. Biosafety cabinet

3. Area 3

- a. Electrophoresis gel box, tray and combs, and power source
- b. Perkin-Elmer thermal cycler, model 9600
- c. 200-ml Erlenmeyer flasks
- d. Stir bars
- e. UV-protective face shield or goggles
- f. UV illuminator box
- g. Rainin Gilson P20, P200, and P1000 Pipetman
- h. 20-, 200-, and 1,000- μ l plugged DNase-free aerosol-resistant pipette tips
- i. Spray/squirt bottles—bleach, ethanol
- j. Refrigerator
- k. 1.7-ml microcentrifuge flip-top tubes
- l. Microtube rack
- m. Low-electroendosmosis (EEO) agarose (catalog no. A-6013; Sigma)
- n. NuSieve GTG agarose (catalog no. AB196; American Bioanalytical)
- o. Chemical fume hood
- p. QIAquick PCR purification kit protocol (catalog no. 28104; QIAGEN)
- q. Eppendorf microcentrifuge

B. Reagents

1. Deoxynucleoside triphosphates (dNTPs)
Stock dNTPs (Perkin-Elmer) dATP, dCTP, dGTP, and dTTP (10 mM each) and dUTP (100 mM; Pharmacia Biotech). Store at -20°C in area 1. Expiration: do not use past manufacturer's control date.

III. MATERIALS (continued)

2. Molecular-biology-grade water, diethyl pyrocarbonate treated (catalog no. 9920; Ambion), 500 ml. Expiration, 1 year.
3. Enzymes
 - a. AmpliTaq DNA polymerase (Perkin-Elmer), 250 U/tube, 5 U/ μ l; store at -20°C in area 1. Expiration: do not use beyond manufacturer's control date.
 - b. TaqStart antibody (Clontech), 1.1 $\mu\text{g}/\mu\text{l}$; provided with dilution buffer (50 mM KCl–10 mM Tris-HCl [pH 7.0]). Store at -20°C in area 1. Expiration, 1 year.
 - c. AmpErase (uracil *N*-glycosylase [UNG]) (Perkin-Elmer), 100 μl , 1 U/ μl . Store at -20°C in area 1. Expiration: do not use beyond manufacturer's control date.
 - d. Restriction enzyme *Apa*I (catalog no. 1145; New England Biolabs). Enzyme concentration is 10,000 U/ml. Enzyme should be stored at -20°C or lower in area 2. Enzyme is shipped with an aliquot of 10 \times NEBuffer 4 (see below) and 100 \times bovine serum albumin (BSA). Reaction conditions: 1 \times NEBuffer 4 supplemented with 100 μg of BSA per ml (1 \times). Enzyme and buffer expiration, 1 year.
 - 1 \times NEBuffer 4 contains 50 mM potassium acetate, 20 mM Tris acetate, 10 mM magnesium acetate, and 1 mM dithiothreitol, with a pH of 7.9 at 25°C .
 - e. QIAGEN protease
 - (1) QIAGEN protease should be stored at 4°C until resuspension. Expiration of powdered enzyme is 1 year.
 - (2) Add 7 ml of H_2O to the vial of protease provided by the manufacturer. Mix thoroughly and dispense into 200- μl aliquots; freeze at -20°C . Aliquots are single use. Expiration, 6 months. Store in area 1.
4. Buffers
 - a. 10 \times PCR buffer (Perkin-Elmer): 500 mM KCl, 100 mM Tris-HCl (pH 8.3), 15 mM MgCl_2 , 0.01% (wt/vol) gelatin. Expiration: do not use past manufacturer's control date. Store at -20°C in area 1.
 - b. TBE buffer, 10 \times stock solution; 10 \times TBE buffer, 1 liter (catalog no. V4251; Promega). 10 \times stock: 890 mM Tris acetate, 890 mM boric acid, 20 mM EDTA. Expiration of stock solution, 1 year. Do not use if the buffer contains a precipitate. Store at room temperature in area 3.
 - c. TE buffer, 100 \times stock solution (Tris-EDTA buffer, catalog no. T-9285; Sigma): 1.0 M Tris-HCl (pH 8.0), 0.1 M EDTA. Store at room temperature. Expiration, 1 year.
 - d. Agarose gel loading buffer
Mix the following components in a 50-ml conical tube: 20 g of sucrose and 125 mg of bromophenol blue. Bring up to 50 ml with deionized water passed through a 0.2- μm -pore-size filter. Store at room temperature in area 3. Expiration date of loading gel buffer, 1 year.
 - e. AW1 and AW2 buffers for QIAamp purification
Add 190 ml of 100% ethanol to the buffer as provided by QIA-GEN. Mix thoroughly, and store in 7- to 8-ml single-use aliquots at room temperature in area 1. Expiration, 1 year.
 - f. AL buffer for QIAamp purification
Mix reagent AL1 into buffer AL (reagent AL2); both are provided in the kit. Mix thoroughly by shaking. Aliquot into 1.5 ml into microcentrifuge tubes (single use), and store in the dark at room temperature in area 1. Expiration, 1 year.
 - g. Buffer PE for QIAquick protocol
Add 100% ethanol to the buffer PE that is provided by the manufacturer. The volume of ethanol to be added is provided on the bottle label. Store at room temperature. Expiration, 1 year.
5. Primers HSV-3 and HSV-4 (Gibco BRL)
 - a. Primers are received as lyophilized pellets. These are suspended in 50 μl of DNase- and RNase-free water in area 1; this is the stock solution. Expiration of stock solution, 1 year.
 - b. *Note*: Strict adherence to protocol is essential to avoid contamination of primer lot. Primers should be diluted in area 1 be-

III. MATERIALS (continued)

fore the technologist performs any tasks in area 2 or 3. *Never dilute primers after working in area 2 or 3.*

- c. Preparation of the primer stock solution should be done a day in advance of the next anticipated use of the primer pair to ensure that they are totally resuspended.
- d. Dilute an aliquot of the stock solution to 20 pmol/μl of working solution with the required amount of molecular-biology-grade H₂O. The amount of primer in each lot is variable, so different amounts of molecular-biology-grade H₂O will be required to dilute the stock solution to 20 pmol/μl. Do not make more primer working solution than is needed for the master mix described below (dilute primers are not stable). Stock solution should be stored at -20°C in area 1. Expiration, 6 months.

6. Preparation of reagents

- a. Master mix (for 560 reactions)
 - (1) Mix the following components in area 1 dead-air box:

10 × PCR buffer	5.6 ml
dNTPs		
dATP	1.12 ml
dGTP	1.12 ml
dTTP	1.12 ml
dUTP	0.224 ml
primer HSV-3	2.24 ml
primer HSV-4	2.24 ml
double-distilled H ₂ O	33.6 ml

- (2) Aliquot the mixture into sterile 2.0-ml Sarstedt screw top tubes. The amounts listed above allow for 30 aliquots of 562 μl (six reactions) and 42 aliquots of 735 μl (eight reactions). There may be a few microliters of mixture left; discard it. Label tubes with the following information: master mix, number of reactions. (six or eight), date of preparation, batch number, and initials of technologist preparing mixture. The tubes are stored at -20°C in area 1.
- (3) Prior to use, add TAQ (*see below*) and UNG (0.5 μl/reaction) to the master mix. To the six-reaction aliquot

add 3.0 μl of UNG and 19.5 μl of TAQ. To the eight-reaction aliquot add 4.0 μl of UNG and 25.5 μl of TAQ.

- (4) For each individual reaction the final concentrations of the master mix components are as follows.

<u>Component</u>	<u>Volume/ reaction (100 μl)</u>	<u>Final concentration</u>
10 × PCR buffer	10 μl	1 × (1.5 mM MgCl)
dNTPs		
dATP	2 μl	0.2 mM
dCTP	2 μl	0.2 mM
dGTP	2 μl	0.2 mM
dTTP	2 μl	0.2 mM
dUTP	0.4 μl	0.4 mM
Primer HSV-3	4 μl	0.4 μM
Primer HSV-4	4 μl	0.8 μM
UNG	0.5 μl	0.8 μM
TAQ	3 μl	0.5 U
double-distilled H ₂ O	60.1 μl	2.5 U
Specimen	10 μl added in area 2	

- (5) Master mix expiration, 6 months.

b. AmpliTaq/TaqStart working solution (TAQ)

- (1) Mix the following components in the area 1 dead-air box:

<u>Reagent</u>	<u>Volume/ reaction (100 μl)</u>	<u>Volume/ 580 reactions</u>
TaqStart	0.5 μl	0.290 ml
Dilution buffer	2.0 μl	1.160 ml
AmpliTaq	0.5 μl	0.290 ml

- (2) Make 580 reaction mixtures rather than 560 so there will be extra solution for aliquoting. Aliquot the mixture into sterile 2.0-ml Sarstedt screw-top tubes. The amounts given above allow for 30 aliquots of 19.5 μl (six reactions) and 42 aliquots of 25.5 μl (eight reactions). There may be a few microliters of mixture left; discard it. Label tubes with the following information: TAQ, number of reactions (six or eight), date of preparation, batch number, and initials of technologist

III. MATERIALS (continued)

- preparing mixture. The tubes are stored at -20°C in area 1. Expiration, 6 months.
- c. Preparation of TBE buffer, $1\times$ working solution
 - (1) Add 2 liters of $10\times$ TBE stock solution into the 20-liter carboy. Fill to the 20-liter mark with deionized water passed through a $0.2\text{-}\mu\text{m}$ -pore-size filter.
 - (2) Store at room temperature in area 3.
 - (3) Expiration date of TBE buffer, 12 months from date of preparation.
 - d. Preparation of TE buffer, $1\times$ working solution.
 - (1) Mix $100\ \mu\text{l}$ of $100\times$ TE solution with 9.9 ml of deionized water passed through a $0.2\text{-}\mu\text{m}$ -pore-size filter.
 - (2) Store at room temperature.
 - (3) Expiration, 6 months.
7. Decontamination solutions
- a. 10% Bleach. Add 25 ml of concentrated bleach with 225 ml of deionized water passed through a $0.4\text{-}\mu\text{m}$ -pore-size filter in a squirt bottle. A squirt bottle of 10% bleach should be made for each of the three work areas. Expiration, 1 week.
 - b. 70% Ethanol solutions. Mix 480 ml of 100% ethanol with 170 ml of deionized water passed through a $0.4\text{-}\mu\text{m}$ -pore-size filter in a spray bottle. A spray bottle of 70% ethanol should be made for each of the three work areas. Expiration, 1 week.
8. HSV positive control
- a. Stock solution: HSV type 1 (or type 2) from ATCC (type 1, ATCC 539-VR; type 2, ATCC 540-VR). Total volume = 1 ml; concentration, 10/50% tissue culture infective doses/ml. Aliquot ($10\ \mu\text{l}$) and freeze at -70°C . Expiration, 1 year. Aliquoting of positive control should not be done in area 2; do this in area 3.
 - b. HSV working solution. Each Monday take an aliquot of HSV stock and dilute to 10^{-2} with molecular-biology-grade water (Ambion). Add $3\ \mu\text{l}$ of stock positive control to $27\ \mu\text{l}$ of water (10^{-1}). Add $10\ \mu\text{l}$ of the 10^{-1} dilution to $90\ \mu\text{l}$ of water (10^{-2}). Store several aliquots of the 10^{-2} dilution at -70°C for use later in the week. Each day the assay is run, take an aliquot of the 10^{-2} positive control and dilute to 10^{-4} by adding $3\ \mu\text{l}$ to $297\ \mu\text{l}$ of water. These dilutions of the positive control should be performed in a section of the laboratory other than area 2. Use $3\ \mu\text{l}$ of the 10^{-4} dilution as the positive control in the HSV assay. Use the 10^{-2} dilutions for the week and then discard; discard the 10^{-4} dilutions after each use.
9. DNA molecular weight standard for agarose gel electrophoresis
Use Ready Load, 100-bp DNA ladder (catalog no. 10380-012); fibco BRL). The solution is premixed with loading dye. The concentration is $0.1\ \mu\text{g}/\mu\text{l}$. Add $5\ \mu\text{l}$ of the DNA ladder solution to the first lane (on the left) of all agarose gels. Expiration, 1 year. Store at 2 to 8°C in area 3.

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. One positive control (pooled ATCC 539-VR [serotype 1] and ATCC 540-VR [serotype 2]) is included in each run. The positive control used to validate the assay is different from the ATCC positive controls. Newly obtained HSV DNA specimens are evaluated by comparing the previous positive control with the new positive control in the same PCR. Relative signal intensities are compared by visually examining DNA-containing bands following agarose gel electrophoresis. The new positive control specimen must have a comparable band intensity by PCR prior to designation as a routine positive control.
- B. Multiple negative controls (at least three) are included in each run. One negative control (using H_2O) is prepared using the QIAGEN protocol.

IV. QUALITY CONTROL*(continued)*

- C. The primer pair used in this reaction is published and has been shown to amplify DNA of HSV types 1 and 2. The primers do not amplify cytomegalovirus, Epstein-Barr virus, or varicella-zoster virus DNA (1).
- D. The following steps have been taken to reduce the risk of contamination.
 - 1. Separate areas for assay setup, specimen preparation and amplification, and detection of amplified products
 - 2. Unidirectional work flow (*see* work flow notes)
 - 3. The use of dUTP and UNG to decrease the risk of carryover contamination
 - 4. Good laboratory technique and a laminar-flow hood during specimen preparation to avoid contamination between specimens
 - 5. After amplification, reaction tubes are opened in a biosafety or chemical fume hood in area 3.
- E. Each batch of master mix is tested as follows.
 - 1. Twenty reactions are performed using water as a template. This is to ensure that the reagents are not contaminated. If any of the reactions are positive, the master mix is rejected.
 - 2. One each of a previous positive and previous negative patient specimen is run with the new batch of master mix along with the positive control. Results must match those obtained with the previous batch or the master mix is rejected.
- F. Verify that all reagents and materials meet expiration date and QC parameters as per NCCLS document M22-A2 (3).

V. PROCEDURE**A. Master mix preparation (area 1)**

- 1. Remove required combination of six- and/or eight-reaction aliquots of master mix from the -20°C freezer. Allow to thaw.

Number of patient specimens	Master mix aliquots
1	6 reactions
2	6 reactions
3	8 reactions
4	8 reactions
5	12 reactions (2 × 6)
6	12 reactions (2 × 6)

- 2. Turn off UV light and wipe down dead-air box surface with 10% bleach and then 70% ethanol.
- 3. Assemble tray and tray/retainer set with corresponding number of 200 μl reaction tubes.
- 4. After master mix is thawed, remove TAQ aliquots and AmpErase (UNG) from the freezer. Pipette entire contents of TAQ aliquots (19.5 μl for six reactions and 25.5 μl for eight reactions) and prescribed amounts of UNG (0.5 μl per reaction, 3.0 μl for six reactions, and 4.0 μl for eight reactions) into master mix aliquots. If using more than one tube of master mix, add the TAQ, then combine aliquots of match mix, and finally add the UNG (0.5 μl per reaction). *Do not vortex enzymes.* Mix by inverting and then centrifuge briefly at low speed to bring solution out of cap.
- 5. Return UNG to the freezer.
- 6. Pipette 90 μl of the master mix-TAQ aliquots into each reaction tube.
- 7. Place tray in Ziploc baggie and set aside.
- 8. Wipe dead-air space surface with 10% bleach and then 70% ethanol. Before leaving area 1, turn UV light timer to 15 min.

V. PROCEDURE (*continued*)

9. Bring bagged tray and tray map to area 2.
10. Bring necessary QIAGEN reagents from area 1 (columns, microcentrifuge tubes, water, alcohol, AL and AW buffers, and protease) to area 2.

B. Specimen preparation and loading (area 2)

1. Place bagged reaction tray in 4°C refrigerator until ready to use.
2. Set up rack for specimen preparation (QIAamp)
3. Each patient sample requires two microcentrifuge tubes, one spin column, three spin collection tubes, and a 2-ml vial for storage.
4. Perform specimen preparation as follows.
 - a. Vortex CSF thoroughly.
 - b. Pipette 200 µl of CSF into microcentrifuge tube using extended-length pipette tips, put remaining CSF in labeled storage tube, and freeze.
 - c. Add 20 µl of QIAGEN protease and 200 µl of AL buffer, and vortex thoroughly.
 - d. Incubate at 56°C for 10 min in a water bath using a flotation rack.
 - e. Add 200 µl of 100% ethanol and vortex.
 - f. Transfer lysate to a QIAamp spin column which is already inserted into a 2-ml collection tube. Centrifuge for 1 min. Use the microcentrifuge at $6,000 \times g$ (8,000 rpm, setting 8). Place QIAamp spin column in a clean 2-ml collection tube.
 - g. Add 500 µl of AW1 buffer and centrifuge for 1 min. Use the microcentrifuge at $6,000 \times g$ (8,000 rpm, setting 8). Place QIAamp spin column in a clean 2-ml collection tube.
 - h. Add 500 µl of AW2 buffer and centrifuge for 1 min. Use the microcentrifuge at $6,000 \times g$ (8,000 rpm, setting 8). Then centrifuge in the microcentrifuge at full speed for 2 min. Place QIAamp spin column in a 1.7-ml microcentrifuge tube labeled with the patient's specimen number and date.
 - i. Elute DNA by pipetting 50 µl of distilled water (room temperature) onto the QIAamp spin column. Incubate at room temperature for 5 min.
 - j. Centrifuge spin column at $6,000 \times g$ for 1 min (8,000 rpm, setting 8).
 - k. Remove and discard spin column.
 - l. Cap and vortex specimen. Freeze specimen at -20°C , or continue with amplification.
5. Wipe down laminar-flow hood with 10% bleach and then 70% ethanol.
6. Remove tray from refrigerator and, using trap map as a guide, pipette 10 µl of prepared specimen into the test well.
7. Pipette 10 µl of molecular-biology-grade water (Ambion) into the appropriate negative and positive control wells.
8. Cap test wells. *Test wells should be capped before the positive control is added.*
9. Use the 10^{-4} dilution of positive control (see item III.B). Add 3 µl of the positive control DNA to the appropriate well. If performing PCR with a vitreal specimen, include an inhibition control (spiked specimen) by adding 3 µl of positive control to an additional aliquot of the vitreal specimen.
10. Cap the remaining wells.
11. Place tray into thermal cycler and run program 125.
 - Place tray in Perkin-Elmer 9600 thermal cycler. Press "STOP" until main menu appears—"9600" appears in upper right corner. Press "OPTION" until cursor is beneath "RUN"; "ENTER." Display should read "METHOD # #." Press "1-2-5"; "ENTER." Display should read "REACTION VOLUME 100 µl"; "ENTER." The thermal cycler runs for 2.4 h. See Table 12.2.3-2 for details of thermal cycler parameters for program 125.

Table 12.2.3–2 Thermal cycler protocol

HOLD × 1:	94°C	1 min
CYCLE × 40:	94°C	30 s
	60°C	30 s (decrease temperature 0.2°C per cycle)
	72°C	45 s
HOLD × 1:	4°C	Forever

V. PROCEDURE (*continued*)

12. Clean biosafety cabinet and pipettes with 10% bleach followed by 70% ethanol; turn on the UV light.
13. When program is in the final hold (program 8), remove the tray from the thermal cycler.
14. Print run record.
15. Bring tray and tray map into area 3.

C. Detection (area 3)

1. Fill out gel map.
2. Wipe down area 3 fume hood with 10% bleach and then 70% ethanol.
3. Wear gloves at all times when handling electrophoretic equipment, photographic equipment, and agarose gels.
4. Pour 2% agarose gel approximately 40 min before thermal cycler is finished.
 - a. Weigh out 2 g of low-EEO agarose and put into a 100-ml Erlenmeyer flask.
 - b. Add 50 ml of H₂O and 50 ml of 1× TBE buffer.
 - c. Add magnetic stir bar and stopper flask with Kimwipes.
 - d. Place on hot plate. Set heat and stir controls to 4.
 - e. Bring solution to a gentle boil.
 - f. While the agarose solution is heating, place tape at either end of gel tray to make a tight seal and insert two combs.
 - g. After agarose has come to a boil, add 2.5 µl of ethidium bromide (10 mg/ml; Bio-Rad) to agarose solution. Swirl to mix.

Caution: Ethidium bromide is a powerful mutagen and is moderately toxic. Gloves should be worn when working with solutions that contain this dye.
 - h. Pour agarose solution into tray and insert combs. Let stand to cool for 20 to 30 min.
 - i. Fill gel box with 300 ml of 1× TBE buffer and 300 ml of filtered deionized water.
 - j. Remove tape and combs and place gel tray in gel box; buffer solution should cover gel. Place the tray in the gel box with the holes farthest away from the positive charge (red).
5. Work with the amplified material in the chemical fume hood.
6. Remove cap strips from first patient row of tubes carefully to avoid any aerosolization. (Do this while caps are still warm and malleable.)
7. Add 10 µl of loading dye to each tube and pipette up and down to mix; use a new tip for each tube.
8. Pipette 35 µl of each sample (using a P200 Pipetman) into appropriate gel wells. Use a new pipette tip for each tube.
9. Cap first row of tubes when all reaction mixtures have been loaded onto the gel. Use a new strip of caps.
10. Uncap the next patient row of tubes and proceed in the same manner.
11. Each half of the gel (16 lanes) should have an aliquot of amplified positive control (usually the last well).

V. PROCEDURE (*continued*)

12. Add 5 μ l of DNA molecular weight standard to the first lane (on the left) in each row of the gel.
13. Place protective lid on gel box and connect leads. Let gel run for approximately 25 min at 150 to 160 V.
14. The remaining amplified material should be stored at 4°C.
15. Remove gel tray from gel box. Carefully slide gel from gel tray onto UV box (gels fragment very easily). Put on UV-protective face shield and then turn UV box on to high-intensity setting and photograph.
Caution: Use protective eyeglasses or face shield when viewing gels on UV box.
16. Photograph gel. Camera settings should be as follows: shutter speed, 2 (0.5 s); aperture, 11. Develop the photo for 30 to 60 s.
17. Discard gel in infectious-substance boxes. Empty and rinse gel box into the sink. Wipe down UV box with 10% bleach and then 70% alcohol. Wipe down fume hood with 10% bleach and then 70% ethanol.
18. Trim picture and tape to worksheet; label lanes on the gel photo.
19. Record in result area of the worksheet and have a supervisor or director review and sign.

D. Further evaluation of positive results (assay validation)

1. All patient specimens that are positive for HSV DNA are retested. If there is adequate volume of the specimen, a new aliquot should be prepared and tested in the repeat run.
2. The remaining volume of amplified product that was not loaded onto the agarose gel is to be used for a restriction enzyme digestion assay.
3. The positive patient sample and the positive control for the run are to be used in the restriction enzyme digestion assay.
4. Preparation of reaction mixture in area 2
 - a. Separate reaction tubes should be prepared for the positive patient specimen and the positive control.
 - b. Mix the following in a 1.7-ml microcentrifuge tube.
 - (1) 5 μ l of 10 \times NEBuffer 4
 - (2) 4 μ l of *Apa*I enzyme
 - (3) 0.5 μ l of 100 \times BSA
 - (4) 20 μ l of distilled H₂O (dH₂O)
 - c. Take the tubes to area 3 and refrigerate until ready to use.
5. The remaining volume of amplified material should be purified using the QIAquick PCR purification kit protocol (QIAGEN).
 - a. Purify the remaining reaction mixture for both the positive patient specimen and the positive control from the run.
 - b. Add 300 μ l of buffer PE to 60 μ l of amplified product and vortex.
 - c. Apply sample to a QIAquick column which has been inserted into a 2-ml collection tube and centrifuge for 30 to 60 s.
 - d. *All centrifugation steps are performed at full speed in an Eppendorf microcentrifuge.*
 - e. Discard flow through and place column into a new collection tube.
 - f. Add 0.75 ml of PE buffer to the column and centrifuge for 30 to 60 s.
 - g. Discard flowthrough, place column into a new collection tube, and centrifuge for an additional 1 min.
 - h. Place column in a clean microcentrifuge tube.
 - i. Elute DNA in 30 μ l of TE buffer (pH 8.0), add the TE buffer to the center of the column, let sit for 1 min, and then centrifuge for 1 min.
6. Add 23 μ l of purified PCR products to the reaction mixture; the total reaction volume will be 50 μ l. Do not discard the remaining 7 μ l of purified product.

V. PROCEDURE *(continued)*

7. Gently vortex the reaction tubes and incubate for 1 h at room temperature.
8. While the reaction mixture is incubating, prepare a 3% gel using the NuSieve GTG agarose as described above.
9. Add 250 μ l of buffer PE to 50 μ l of digested product and vortex.
10. Apply sample to a QIAquick column which has been inserted into a 2-ml collection tube and centrifuge for 30 to 60 s.
 - a. All centrifugation steps are performed at full speed in an Eppendorf microcentrifuge.
 - b. Discard flowthrough and place column into a new collection tube.
 - c. Add 0.75 ml of PE buffer to the column, let sit at room temperature for 1 min, and centrifuge for 30 to 60 s.
 - d. Discard flowthrough, place column into a new collection tube, and centrifuge for an additional 1 min.
 - e. Place column in a clean microcentrifuge tube.
 - f. Elute DNA in 30 μ l of TE buffer (pH 8.0), add the TE buffer to the center of the column, let sit for 1 min, and then centrifuge for 1 min.
11. The total volume for each tube should be 30 μ l. Add 4 μ l of loading dye and load onto the gel.
12. To the remaining 7 μ l of purified *undigested* PCR product add 10 μ l of water and 3 μ l of loading dye.
13. The following specimens should be loaded onto the agarose gel.
 - a. 5 μ l of molecular weight standard
 - b. 20 μ l of undigested positive control
 - c. 35 μ l of digested positive control
 - d. 20 μ l of undigested positive patient specimen
 - e. 35 μ l of digested positive patient specimen
14. Run gel (as described above) for 30 to 40 min. Cleavage of the HSV product by *ApaI* should yield bands of 190 and 100 bp.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. Report as positive or negative for HSV DNA types 1 and 2.
- B. Call results to physician of record or designee. Note on the worksheet the name of the person called, date, and time, and initial.
- C. Document all testing in hard copy or computerized work card.

VII. INTERPRETATION

- A. If any of negative control reactions is positive, the run is invalid and must be repeated.
- B. If there is not a 290-bp product amplified in the positive control reaction, the run is invalid and must be repeated.
- C. A clinical specimen is considered negative for HSV DNA if there is no 290-bp product amplified from the specimen. Report as "negative for HSV DNA types 1 and 2."
- D. A specimen is considered positive for HSV DNA if *all* of the following occur. In that case, report as "positive for HSV DNA types 1 and 2."
 1. There is a 290-bp product amplified from the specimen.
 2. The clinical presentation is consistent with either meningitis or encephalitis (e.g., fever, headache, photophobia, and lymphocytic pleocytosis in CSF for meningitis and fever, altered mental status, magnetic resonance imaging or computed tomography temporal lobe changes, CSF lymphocytic pleocytosis, and RBCs in CSF for encephalitis).

VII. INTERPRETATION (continued)

3. When the amplified product is digested with *ApaI*, the DNA fragments are 100 and 190 bp in size.
- E. If the clinical presentation is not consistent with either meningitis or encephalitis, repeat testing should be performed. If available, a second aliquot of the specimen should be processed and both the original and repeat specimen should be run together. If both specimens are not positive, the specimen should be reported as “negative for HSV DNA types 1 and 2.” If both specimens are positive, perform restriction digestion as outlined above.
- F. For vitreal specimens, if the specimen is negative for HSV DNA and the spiked control is positive, report as “negative for HSV DNA types 1 and 20.” If the specimen is negative and the inhibition control is negative, repeat testing. If similar results are obtained, report as “uninterpretable, specimen contains a substance that inhibits amplification.” If the specimen is positive report as “positive for HSV DNA types 1 and 2.”

VIII. LIMITATIONS OF TESTING

- A. A negative result for HSV DNA by PCR does not rule out the possibility that HSV DNA is present in the specimen at a concentration below the level of sensitivity of the assay. The assay is capable of detecting 0.7 viral particles/μl of CSF. This is equivalent to 3 viral particles in the reaction mixture.
- B. A positive result for HSV DNA by PCR may be the result of contamination rather than a true positive result. This protocol employs several steps to decrease the risk of contamination, including separate areas for assay setup, specimen preparation, and amplification and detection of amplified products; unidirectional work flow (*see work flow notes*); the use of dUTP and UNG to decrease the risk of carryover contamination; good laboratory technique and the use of a laminar-flow hood during specimen preparation to avoid contamination between specimens; and opening of reaction tubes under a fume hood in area 3 after amplification.

PART 10

Detection of *Mycoplasma pneumoniae* in Respiratory Specimens by PCR

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Mycoplasma pneumoniae is a common cause of lower respiratory tract infection. *M. pneumoniae* causes about 50% of cases of pneumonia in school-age children and between 2 and 4% of community-acquired pneumonia requiring hospitalization among adults. Because culture and serologic tests for diagnosis of *M. pneumoniae* infections may be unreliable and results may not be available in a timely fashion,

PCR-based assays for *M. pneumoniae* infection have been developed. PCR results can be made available in 1 day, and PCR has been shown to be approximately 85% sensitive and 98% specific for diagnosis of *M. pneumoniae* infection (1–4, 6–8). Testing can be performed on throat swab specimens, as well as sputum and bronchoalveolar lavage (BAL) specimens. The

target of *M. pneumoniae* amplification is a 144-bp fragment of genomic DNA (1). The primer pair is specific for *M. pneumoniae* and does not amplify DNA from other species of *Mycoplasma*, oral microbiota, or other respiratory pathogens. Detection is performed using a specific probe in an ELISA-type format (Table 12.2.3–3).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen collection

1. The appropriate specimens for *M. pneumoniae* PCR include throat swab, sputum, or BAL specimens.
2. The required specimen volumes are 500 µl for sputum and 1.5 ml for BAL specimens.
3. Dacron swabs should be used for collecting throat swab specimens. Materials in other types of swabs can be inhibitory to PCR.
4. The Dacron swab should be placed in viral transport medium and briskly mixed in the medium, and the shaft of the swab should be broken off, leaving the swab in the transport container.

B. Timing of specimen collection

There are no particular timing issues to consider in collecting these specimens; however, the specimen type and time of collection should be recorded.

C. Specimen transport

1. Specimens should be transported to the laboratory at room temperature.
2. Throat swab specimens must be transported in viral transport medium. Sputum and BAL specimens do not require transport medium and should be collected and transported in sterile containers.
3. Specimens should be stored in a refrigerator if they cannot be transported within a few hours.
4. Specimens should not be frozen before transport.
5. Once specimens are received in the laboratory they should be stored at 4°C until they are tested.
6. After testing is completed, store the extracted specimens at –70°C.
7. Store any remaining primary specimen from positive patients at –70°C.

Table 12.2.3–3 PCR primers and probe for detection of *Mycoplasma pneumoniae* in respiratory specimens

Primer or probe designation	Nucleotide sequence, 5'–3'	Product size (bp)
Primer MP5-1	GAA GCT TAT GGT ACA GGT TGG	144
Primer MP5-2	ATT ACC ATC CTT GTT GTA AGG	144
Probe MP5-4 ^a	CGT AAG CTA TCA GCT ACA TGG AGG	144

^a Label probe 5' end with biotin.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING (continued)

D. Specimen labeling and submission

The laboratory should determine a mechanism to ensure that the specimen type and time of collection are recorded.

E. Rejection criteria

1. Specimens other than throat swabs, sputum, or BAL fluid (e.g., nasal wash, lung tissue, or CSF) require director approval.
2. Reject throat swabs that are not submitted in transport medium.
3. Reject throat swabs made of material other than Dacron.
4. Reject specimens that arrive in leaky containers.
5. Request a repeat specimen, or obtain the information, when collection time or specimen type has not been provided.
6. If an improperly collected, transported, or handled specimen cannot be replaced, document in the final report that specimen quality may have been compromised.

III. MATERIALS

A. Special supplies and equipment

1. Area 1
 - a. Repeat pipettor with tips
 - b. Perkin-Elmer 9600 reaction tray and retainer sets
 - c. Perkin-Elmer 200- μ l reaction tubes
 - d. Ziploc baggies
 - e. Dead-air box
 - f. 2.0-ml Sarstedt screw-top tubes
 - g. Low-speed microcentrifuge
 - h. Rainin Gilson P20 and P200 Pipetman
 - i. 20- and 200- μ l plugged DNase-free aerosol-resistant pipette tips
 - j. Spray/squirt bottles—bleach, ethanol
 - k. Refrigerator
 - l. -20°C freezer
 - m. Microtube racks
 - n. 1.7-ml microcentrifuge flip-top tubes
 - o. 2-ml microcentrifuge tubes
 - p. Microtube racks
 - q. QIAamp blood and tissue kit (catalog no. 29106; QIAGEN)
 - r. Coats and gloves dedicated to area 1
2. Area 2
 - a. Sarstedt 1.7-ml screw-top tubes
 - b. Aluminum foil
 - c. Perkin-Elmer reaction tube cap strips (8 and 12 strips)
 - d. Floaters
 - e. Capping instrument
 - f. -70°C freezer
 - g. 50-ml conical tubes
 - h. Eppendorf microcentrifuge
 - i. Rainin Gilson P20, P200, and P1000 Pipetman
 - j. 20-, 200-, and 1,000- μ l plugged DNase-free aerosol-resistant pipette tips
 - k. Spray/squirt bottles—bleach, ethanol
 - l. Refrigerator
3. Area 3
 - a. Electrophoresis gel box, tray and combs, and power source
 - b. Perkin-Elmer thermal cycler, model 9600
 - c. 200-ml Erlenmeyer flasks
 - d. Stir bars
 - e. UV-protective face shield or goggles
 - f. UV illuminator box
 - g. Camera
 - h. Rainin Gilson P20, P200, and P1000 Pipetman
 - i. Automated multichannel pipette
 - j. 20-, 200-, and 1,000- μ l plugged DNase-free aerosol-resistant pipette tips
 - k. Spray/squirt bottles—bleach, ethanol
 - l. Refrigerator

III. MATERIALS (*continued*)

- m. 1.7-ml microcentrifuge flip-top tubes
- n. Microtube rack
- o. Disposable reagent reservoirs
- p. Low-electroendosmosis agarose (catalog no. A-6013; Sigma)
- q. Loading dye
- r. Chemical fume hood
- s. 37°C incubator
- t. Microwell automated plate washer
- u. Microwell automated plate reader
- v. Detection reagents (GEN-ETI-K DEIA #PS0001, DNA EIA kit; DiaSorin)
- w. Deionized water
- x. Coats and gloves dedicated to area 3

B. Reagents

1. Deoxynucleoside triphosphates (dNTPS)
Stock dNTPs (Perkin-Elmer) dATP, dCTP, dGTP, and dTTP (10 mM each) and dUTP (100 mM; Pharmacia Biotech). Store at -20°C in area 1. Expiration per manufacturer's control date.
2. Molecular-biology-grade water, diethyl pyrocarbonate (DEPC) treated (catalog no. 9920; Ambion), 500 ml. Expiration, 1 year.
3. Deionized ultrafiltered water (Fisher W2-20), 20 liters. Expiration, 1 year.
4. Enzymes
 - a. AmpliTaq DNA polymerase (Perkin-Elmer), 250 U/tube; 5 U/ μl ; 50 μl . Store at -20°C in area 1. Expiration per manufacturer's control date.
 - b. AmpErase—uracil *N*-glycosylase (UNG) (Perkin-Elmer), 100 μl ; 1 U/ μl . Store at -20°C in area 1. Expiration per manufacturer's control date.
 - c. QIAGEN protease
 - (1) QIAGEN protease should be stored at 4°C until re-suspended. Expiration of powdered enzyme is 1 year.
 - (2) Add 7 ml of H_2O to the vial of protease provided by the manufacturer. Mix thoroughly and dispense into 200- μl aliquots; freeze at -20°C . Aliquots are single use. Expiration, 6 months. Store in area 1.

5. Buffers

- a. $10\times$ PCR buffer II (Perkin-Elmer)—500 mM KCl, 100 mM Tris-HCl (pH 8.3), 0.01% (wt/vol) gelatin. Expiration per manufacturer's control date. Store at -20°C in area 1.
- b. TBE buffer, $10\times$ stock solution, $10\times$ TBE buffer, 1 liter (catalog no. V4251; Promega).
 - (1) $10\times$ stock—890 mM Tris acetate, 890 mM boric acid, 20 mM EDTA
 - (2) Expiration of stock solution, 1 year
 - (3) Do not use if the buffer contains a precipitant.
 - (4) Store at room temperature in area 3.
- c. Detection washer buffer
 - (1) $25\times$; 40-ml volume. Add 40 ml of $25\times$ wash buffer to 960 ml of deionized water (or 20 ml to 480 ml of water, or 10 ml to 240 ml of water, depending on the number of detection reactions).
 - (2) Store at room temperature in area 3; use the buffer the day it is prepared.
- d. Agarose gel loading dye
 - (1) Mix the following components in a 50-ml conical tube: 20 g of sucrose and 125 mg of bromophenol blue. Bring up to 50 ml with deionized water passed through a 0.2- μm -pore-size filter.
 - (2) Store at room temperature in area 3.
 - (3) Expiration of gel loading dye, 6 months.
- e. AW buffer for QIAamp purification
 - (1) Add 190 ml of 100% ethanol to the buffer as provided by QIAGEN.
 - (2) Mix thoroughly; store in 7- to 8-ml single-use aliquots at room temperature in area 1.
 - (3) Expiration, 1 year.
- f. AL buffer for QIAamp purification
 - (1) Mix reagent AL1 into AL buffer (reagent AL2); both are provided in the kit.
 - (2) Mix thoroughly by shaking. Aliquot 1.5 ml into

III. MATERIALS (continued)

- microcentrifuge tubes (single use); store in the dark at room temperature in area 1. Expiration, 1 year.
- g.** TE buffer, 100× stock solution (Tris-EDTA buffer, catalog no. T-9285; Sigma)
- (1) 1.0 M Tris-HCl (pH 8.0), 0.1 M EDTA
 - (2) Store at room temperature.
 - (3) Expiration, 1 year.
 - (4) Mix 1 ml of 100% TE buffer with 99 ml of water (final concentration: 10 mM Tris-HCl [pH 8.0], 1 mM EDTA). Mix and store at room temperature in area 1.
- 6.** Oligonucleotides
- a.** *M. pneumoniae* primers: MP5-1 and MP5-2 (Gibco BRL)
- (1) Primers are received as lyophilized pellets. Suspend these in 50 µl of DNase- and RNase-free water in area 1; this is the stock solution. Expiration of stock solution, 1 year.
 - (2) *Note:* Strict adherence to protocol is essential to avoid contamination of primer lot. Primers should be diluted in area 1 before the technologist performs any tasks in area 2 or 3. *Never dilute primers after working in area 2 or 3.*
 - (3) Preparation of the probe stock solution should be done a day in advance of the next anticipated use of the primer pair to ensure that they are totally resuspended.
- b.** Human DNA control primers (DQA primers): DQA-1 and DQA-2 (Gibco BRL)
- (1) Human DNA control to evaluate specimen quality for throat swab specimen only
 - (2) Primer sequences (214-bp product)
 - (a) DQA-1: 5'-GTG CTG CAG GTG TAA ACT TGT ACC AG-3'
 - (b) DQA-2: 5'-CAC GGA TCC GGT AGC AGC GGT AGA GTT G-3'
 - (3) Primers are received as lyophilized pellets. Suspend these in 50 µl of DNase- and RNase-free water in area 1; this is the stock solution. Expiration of stock solution, 1 year.
 - (4) *Note:* Strict adherence to protocol is essential to avoid contamination of primer lot. Primers should be diluted in area 1 before the technologist performs any tasks in area 2 or 3. *Never dilute primers after working in area 2 or 3.*
 - (5) Preparation of the primer stock solution should be done a day in advance of the next anticipated use of the primer pair to ensure that they are totally resuspended.
 - (6) Dilute an aliquot of the stock solution to 20 pmol/µl of working solution with required amount of double-distilled H₂O (ddH₂O). The amount of primer in each lot is variable, so different amounts of ddH₂O will be required to dilute the stock solution to 20 pmol/µl. Do not make more primer working solution than is needed for the master mix described below (dilute primers are not stable). Stock solution should be stored at -20°C in area 1. Expiration, 6 months.
- 7.** MgCl₂ solution for PCR (25 mM solution; Perkin-Elmer). Store at -20°C in area 1. Expiration per manufacturer's control date. The MgCl₂ stock solution is included when the TAQ polymerase is ordered.
- 8.** Preparation of reagents
- a.** *M. pneumoniae* master mix
- (1) Mix the following components in area 1 dead-air box (800 reactions):
- | | |
|--------------------------|----------------|
| 10× PCR buffer II |4.0 ml |
| MgCl ₂ (25 M) |4.8 ml |
| dNTPs | |
| dATP |800 µl |
| dCTP |800 µl |
| dGTP |800 µl |
| dTTP |800 µl |
| dUTP |160 µl |
| primer MP5-1 |1.0 ml |
| primer MP5-2 |1.0 ml |
| ddH ₂ O | 21.24 ml |

III. MATERIALS (continued)

- (2) Aliquot the mixture into sterile flip-top microcentrifuge tubes. The amounts given above allow for 28 aliquots of 293 µl (6.5 reactions) and 70 aliquots of 383 µl (8.5 reactions)
- (3) There may be a few microliters of mixture left; discard it. Label tubes with the following information: master mix, number of reactions (six or eight), date of preparation, batch number, and initials of technologist preparing mixture. Store the tubes at -20°C in area 1.
- (4) Prior to use, add TAQ (0.25 µl/reaction) and UNG (0.5 µl/reaction) to the master mix. To the 6-reaction aliquot add 3.0 µl of UNG and 1.5 µl of TAQ. To the 8-reaction aliquot add 4.0 µl of UNG and 2.0 µl of TAQ.
- (5) For each individual reaction the final concentrations of the master mix components are as follows.

Component	Volume/ reaction (50 µl)	Final concentration
10× PCR buffer	5 µl	1×
MgCl ₂ (25 mM)	6 µl	3 mM
dNTPs	1 µl (A, C, G, T)	0.2 mM each
dUTP	0.2 µl	0.4 mM
Primer MP5-1	1.25 µl	0.5 µM
Primer MP5-2	1.25 µl	0.5 µM
UNG	0.5 µl	0.5 U
TAQ	0.25 µl	1.25 U
ddH ₂ O	26.55 µl	
Specimen	5 µl added in area 2	

- (6) Master mix expiration, 6 months.
- b. DQA Master mix**
- (1) Mix the following components in area 1 dead-air box (120 reactions).

10× PCR buffer II	600 µl
MgCl ₂ (25 mM)	720 µl
dNTPs	
dATP	120 µl
dCTP	120 µl
dGTP	120 µl
dTTP	120 µl
dUTP	24 µl
primer DQA-1	60 µl
primer DQA-2	60 µl
ddH ₂ O	3.366 ml

- (2) Aliquot the mixture into sterile flip-top microcentrifuge tubes. The amounts given above allow for 15 aliquots of 203 µl (4.5 reactions) and 7 aliquots of 293 µl (6.5 reactions).
- (3) There may be a few microliters of mixture left; discard it. Label tubes with the following information: master mix, number of reactions (four or six), date of preparation, batch number, and initials of technologist preparing mixture. The tubes are stored at -20°C in area 1.
- (4) Prior to use, add TAQ (0.25 µl/reaction) and UNG (0.5 µl/reaction) to the master mix. To the four-reaction aliquot add 2.0 µl of UNG and 1.0 µl of TAQ. To the six-reaction aliquot add 3.0 µl of UNG and 1.5 µl of TAQ.
- (5) For each individual reaction the final concentrations of the master mix components are as follows:

Component	Volume/ reaction (50 µl)	Final concentration
10× PCR buffer II	5 µl	1X
MgCl ₂ (25 mM)	6 µl	3 mM
dNTPs	1 µl (A, C, G, T)	0.2 mM each
dUTP	0.2 µl	0.4 mM
Primer DQA-1	0.5 µl	0.2 µM
Primer DQA-2	0.5 µl	0.2 µM
UNG	0.5 µl	0.5 U
TAQ	0.25 µl	1.25 U
ddH ₂ O	28.5 µl	
Specimen	5 µl added in area 2	

III. MATERIALS (*continued*)

- (6) Master mix expiration, 6 months
- c. Preparation of TBE buffer 10× working solution
 - (1) Add 2 liters of 10× TBE stock solution into the 20-liter carboy. Fill to the 20-liter mark with deionized water passed through a 0.2- μ m-pore-size filter.
 - (2) Store at room temperature in area 3.
 - (3) Expiration date of TBE buffer, 12 months from date of preparation.
9. Decontamination solutions
 - a. 10% Bleach. Add 25 ml of concentrated bleach with 225 ml of deionized water passed through a 0.4- μ m-pore-size filter in a squirt bottle. A squirt bottle of 10% bleach should be made for each of the three work areas. Expiration, 1 week.
 - b. 70% Ethanol solutions. Mix 480 ml of 100% ethanol with 170 ml of deionized water passed through a 0.4- μ m-pore-size filter in a spray bottle. A spray bottle of 70% ethanol should be made for each of the three work areas. Expiration, 1 week.
10. Positive controls
 - a. *M. pneumoniae* positive control
Stock solution. Obtain *M. pneumoniae* from ATCC (ATCC29085), and resuspend the lyophilized material in 1 ml of PPLO broth. Store 5- μ l aliquots in screw-top microcentrifuge tubes at -70°C . Expiration, 1 year.
 - b. DQA positive control
 - (1) Human placental DNA (catalog no. D4642; 5 U; 20 U/mg; Sigma)
 - (2) Stock solution. Resuspend the 5 U (250 μ g) of DNA in 250 μ l of TE buffer (10 mM Tris-HCl [pH 8.0], 1 mM EDTA). Concentration of stock solution is 1 μ g/ μ l. Store 5- μ l aliquots in screw-top microcentrifuge tubes at -70°C . Expiration, 1 year.
 - (3) Working solution. Make a 1:1,000 dilution of the stock solution and store at -70°C . Concentration of working solution is 1 ng/ μ l. Expiration, 1 year.
 - (4) Use 3 μ l as positive control for the DQA assay.
11. DNA molecular weight standard for agarose gel electrophoresis
Use Ready Load (100-bp DNA ladder, catalog no. 10380-012; Gibco BRL). The solution is premixed with loading dye. Concentration is 0.1 μ g/ μ l. Add 5 μ l of the DNA ladder solution to the first lane (on the left) of all agarose gels. Expiration, 1 year.
12. Preparation of microwell plates coated with *M. pneumoniae* MP5-4 probe
 - a. Preparation of microwell plates is done in area 1. Prepare one or two full (96-well) plates.
 - b. Dilute probe to a final concentration of 50 pg/ μ l.
 - c. Using a multichannel pipettor, pipette 100 μ l of diluted probe into each microwell. Cover plate, place in a Ziploc bag, and incubate overnight at 4°C .
 - d. The following day pick up concentrated wash buffer from cold room. *Do not take wash buffer from area 3.*
 - e. Prepare 1× wash solution, 480 ml of Fisher water (must be Fisher water), and 20 ml of 25× wash buffer. This will wash two plates. If washing one plate, make one-half the volume.
 - f. In area 1, aspirate probe from the microwells, add 300 μ l of 1× wash solution, soak for 30 s, and aspirate contents of each well. Repeat this process four more times (total of five washes). After rinsing, turn strips over and gently tap on blotting paper.
 - g. Store strips at 4°C in area 3. Expiration date, 1 month.

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. One positive control is included in each run. *M. pneumoniae* DNA is used as the template (see item III.b) for the positive control reaction.
- B. Multiple negative controls (at least three) are included in each run. One negative control (using phosphate-buffered saline [PBS]) is prepared using the QIAGEN protocol.
- C. Inhibition controls are performed on each clinical specimen, except BAL specimens. An aliquot of specimen is “spiked” with positive control DNA. This spiked control must be positive to ensure that there were no inhibiting substances in the specimen.
- D. To evaluate the quality of the specimen, a human DNA control is performed on throat swab specimens. If no human DNA is detected, a disclaimer is included in the report of the result.
- E. The primer pair used in this reaction is published and has been shown to amplify *M. pneumoniae* DNA. The primers do not amplify other species of *Mycoplasma*, organisms in the oral microbiota, or other organisms causing upper respiratory tract infection or pneumonia (1).
- F. The following steps have been taken to reduce the risk of contamination.
 1. Separate areas for assay setup, specimen preparation and amplification, and detection of amplified products
 2. Unidirectional work flow
 3. The use of dUTP and UNG to decrease the risk of carryover contamination
 4. Good laboratory technique and a laminar-flow hood during specimen preparation to avoid contamination between specimens
 5. After amplification reaction, tubes are opened in a chemical fume hood in area 3.
 6. Periodic wipe tests of all three laboratory areas
- G. Each batch of master mix is tested as follows.
 1. Twenty reactions are performed using water as a template. This is to ensure that the reagents are not contaminated. If any of the reactions are positive, the master mix is rejected.
 2. The *M. pneumoniae* positive control, a previous positive patient specimen, and a previous negative patient specimen are tested with the new master mix. This is to ensure that the sensitivity of the assay is acceptable. Results must match those obtained with the previous batch of master mix, or the new batch of master mix is rejected.
- H. Detection plates are evaluated by running a previous positive and previous negative specimen and six negative controls (water). Patient results must match results obtained on the previous run and negative controls must be negative, or the plate is rejected.
- I. Verify that all reagents and materials meet expiration date and QC parameters as per NCCLS document M22-A2 (5).

V. PROCEDURE

A. Master mix preparation (area 1)

1. Remove required combination of six- and/or eight-reaction aliquots of *M. pneumoniae* master mix from -20°C freezer. Allow to thaw.

Number of patient specimens	Master mix aliquots
1	6 reactions
2	8 reactions
3	12 reactions (6 + 6)
4	14 reactions (6 + 8)

V. PROCEDURE (continued)

2. Remove the required number of reaction aliquots of DQA master mix from the -20°C freezer. Allow to thaw.
3. Turn off UV light and wipe down dead-air box surface with 10% bleach and then 70% ethanol.
4. Assemble tray and tray retainer set with corresponding number of 200- μl reaction tubes.
5. After master mix is thawed, remove TAQ and AmpErase (UNG) from the freezer. Pipette appropriate amount of TAQ and UNG into the master mix (0.5 μl of UNG per reaction, 0.25 μl of TAQ per reaction; *see* below). If using more than one tube of master mix (i.e., four patients require six- and eight-reaction aliquots), combine aliquots of master mix before adding TAQ and UNG.
 - ☑ *Do not vortex enzymes.* Mix by inverting and then centrifuge briefly at low speed to bring solution out of cap.

Master mix	TAQ	UNG
<i>M. pneumoniae</i> —6	1.5 μl	3 μl
<i>M. pneumoniae</i> —8	2.0 μl	4 μl
DQA—4	1.0 μl	2 μl
DQA—6	1.5 μl	3 μl

6. Return TAQ and UNG to the freezer.
 7. Pipette 45 μl of the master mix-TAQ aliquots into each reaction tube.
 8. Place tray in Ziploc baggie and set aside.
 9. Wipe dead-air space surface with 10% bleach and then 70% ethanol. Before leaving area 1 turn UV light timer to 15 min.
 10. Bring bagged tray and tray map to area 2.
 11. Bring necessary QIAGEN reagents from area 1 (columns, microcentrifuge tubes, water, alcohol, AL and AW buffers, and protease) to area 2.
- B. Specimen preparation and loading (area 2)**
1. Place bagged reaction in tray in 4°C refrigerator until ready to use.
 2. Set up rack for specimen preparation (QIAamp).
 3. Each patient sample requires two microcentrifuge tubes, one spin column, and three spin collection tubes.
 4. Perform specimen preparation as follows.
 - a. For throat swab specimens, vortex the swab in the transport medium, express fluid from the swab, and discard. Transfer 1.5 ml to a microcentrifuge tube and centrifuge for 15 min at $23,000 \times g$. Resuspend the pellet in 200 μl of PBS.
 - b. For BAL specimens, place 1 to 2 ml of specimen in a microcentrifuge tube and centrifuge for 15 min at $23,000 \times g$. Resuspend the pellet in 200 μl of PBS.
 - c. Pipette 200 μl of sputum, concentrated throat swab specimen, or concentrated BAL specimen into microcentrifuge tube using extended-length pipette tips; put remaining specimen in the refrigerator.
 - d. Add 25 μl of QIAGEN protease and 200 μl of AL buffer; vortex thoroughly.
 - e. Incubate at 70°C for 30 min (may incubate for up to 3 to 4 h) in a water bath using a flotation rack. Sample should not be viscous; reincubate for 10 to 20 min if needed.
 - f. Add 210 μl of 100% ethanol and vortex.
 - g. Transfer lysate to a QIAamp spin column which is already inserted into a 2-ml collection tube. Centrifuge for 1 min. Use the microcentrifuge at $6,000 \times g$ (8,000 rpm, setting 8). Place QIAamp spin column in a clean 2-ml collection tube.

V. PROCEDURE (*continued*)

- h.** Add 500 μ l of buffer AW and centrifuge for 1 min.
 - (1) Use the microcentrifuge at $6,000 \times g$ (8,000 rpm).
 - (2) Place QIAamp spin column in a clean 2-ml collection tube.
- i.** Add 500 μ l of AW buffer and centrifuge for 1 min.
 - (1) Use the microcentrifuge at $6,000 \times g$ (8,000 rpm). Then centrifuge in microcentrifuge at full speed for 2 min.
 - (2) Place QIAamp spin column in a 1.7-ml microcentrifuge tube labeled with the patient's specimen number and date.
- j.** Elute DNA by pipetting 200 μ l of distilled water prewarmed to 70°C onto the QIAamp spin column. Incubate at 70°C for 5 min in a water bath.
- k.** Centrifuge spin column at $6,000 \times g$ for 1 min (8,000 rpm, setting 8).
- l.** Remove and discard spin column. Specimen may be frozen at -20°C , or continue with protocol.
- m.** Cap and vortex specimen; put on blue boiling caps.
- n.** Boil specimens for 10 min.
- 5.** Wipe down laminar-flow hood with 10% bleach and then 70% ethanol.
- 6.** Remove tray from refrigerator; using worksheet as a guide, pipette 5 μ l of prepared specimen into the test well, the inhibition control well, and the DQA well if needed.
- 7.** Pipette 5 μ l of distilled water or QIAGEN processed water into the appropriate negative control wells.
- 8.** Cap test wells. *Test wells should be capped before the positive control is brought into the biosafety cabinet.*
- 9.** Dilute positive control for use as follows.
 - a.** For *M. pneumoniae*, dilute a 5- μ l aliquot of stock solution 1:10 (add 45 μ l of distilled H₂O (dH₂O) to the tube and mix well). Use 2 μ l of *Mycoplasma* DNA as positive control.
 - b.** For DQA, use 3 μ l of the working solution (1 ng/ μ l) as positive control.
- 10.** Pipette 3 μ l of *M. pneumoniae* positive control into each inhibition control tube ("spiked") and the positive control well. Pipette 3 μ l of DQA control into the positive control well.
- 11.** Cap the remaining wells.
- 12.** Place tray into thermal cycler and run program 126 (Perkin-Elmer 9600).
Thermal cycler parameters:
HOLD 1: 20°C for 10 min
HOLD 2: 94°C for 10 min
35 cycles: 94°C for 30 s, 55°C for 30 s, and 72°C for 30 s
HOLD 3: 95°C for 15 min
- 13.** Clean biosafety cabinet and pipettes with 10% bleach followed by 70% ethanol; turn on the UV light.
- 14.** After program is finished, *immediately* immerse tubes *completely* in ice. This will denature the DNA. The tubes must be at 95°C and placed directly in ice. The DQA tubes do not need to be placed in ice.
- 15.** Print run record.
- 16.** Bring tray and tray map into area 3.

C. Detection (area 3)

- 1.** Agarose gel detection for DQA reactions
 - a.** Fill out gel map.
 - b.** Wipe down area 3 fume hood with 10% bleach and then 70% ethanol.
 - c.** Wear gloves at all times when handling electrophoretic equipment, photographic equipment, and agarose gels.
 - d.** Pour 2% agarose gel approximately 40 min before thermal cycler is finished.

V. PROCEDURE (continued)

- (1) Weigh out 2 g of low-EEO agarose and put into a 100-ml Erlenmeyer flask.
 - (2) Add 50 ml of H₂O and 50 ml of TBE buffer.
 - (3) Add magnetic stir bar and stopper flask with Kimwipes.
 - (4) Place on hot plate. Set heat and stir controls to 4.
 - (5) Bring solution to a gentle boil.
 - (6) While the agarose solution is heating, place tape at either end of gel tray to make a tight seal and insert two combs.
 - (7) After agarose has come to a boil, add 2.5 µl of ethidium bromide (10 mg/ml; Bio-Rad) to agarose solution. Swirl to mix.
 - (8) **Caution:** *Ethidium bromide is a powerful mutagen and is moderately toxic. Gloves should be worn when working with solutions that contain this dye.*
 - (9) Pour agarose solution into tray and insert combs. Let stand to cool for 20 to 30 min.
 - (10) Fill gel box with 300 ml of 1 × TBE and 300 µl of dH₂O.
 - (11) Remove tape and combs and place gel tray in gel box; buffer solution should cover gel. Place the tray in the gel box with the holes farthest away from the positive charge (red).
 - e. Work with the amplified material in the chemical fume hood.
 - f. Remove cap strips from DQA tubes carefully to avoid any aerosolization. (Do this while caps are still warm and malleable.)
 - g. Add 5 µl of loading dye to each DQA tube, and pipette up and down to mix; use a new tip for each tube.
 - h. Pipette 35 µl of each sample (using a P200 pipette) into appropriate gel wells. Use a new pipette tip for each tube.
 - i. Add 5 µl of DNA molecular weight standard to the first lane (on the left) in each row of the gel.
 - j. Place protective lid on gel box, and connect leads. Let gel run for approximately 25 min at 150 to 160 V.
 - k. The remaining amplified material should be stored at 4°C.
 - l. Remove gel tray from gel box. Carefully slide gel from gel tray onto UV box (gels fragment very easily). Put on UV-protective face shield and then turn UV box on to *high* intensity setting and photograph.
Caution: *Use protective eyeglasses or face shield when viewing gels on UV box.*
 - m. Photograph gel. Camera settings: shutter speed, 2 (0.5 s); aperture, 5.6. Develop the photo for 30 to 60 s.
 - n. Discard gel in infectious-substance boxes. Empty and rinse gel box into the sink. Wipe down UV box with water. Wipe down fume hood with 10% bleach and then 70% ethanol.
 - o. Trim picture and tape to worksheet; label lanes on the gel.
 - p. Record in result area of the worksheet and have a supervisor or director review and sign.
2. Probe detection of *M. pneumoniae* reactions
 - a. Bring detection reagents, including microwell strips, to room temperature.
 - b. Add 100 µl of hybridization buffer to each microwell; use plugged pipette tips.
 - c. Add 20 µl of denatured amplified sample to the appropriate microwell. Seal the micotiter wells, and mix by tapping the plate gently.
 - d. Incubate for 1 h ± 5 min at 50°C (± 1°C).
 - e. Just before end of the incubation, prepare working anti-double-stranded DNA (anti-dsDNA) antibody solution. Make a 1:50 dilution of the anti-dsDNA antibody solution using the anti-dsDNA diluent.

V. PROCEDURE (continued)

Number of strips	Anti-dsDNA (μl)	Anti-dsDNA diluent (μl)
1	20	980
2	40	1,960
3	60	2,940
4	80	3,920

- f. Prepare 500 ml of wash buffer; add 20 ml to 480 ml of Fisher water (must be Fisher water). Store unused buffer for 1 week at 4°C. After refrigeration, warm buffer at 37°C to resuspend any crystals. Wash plate five times in an automated plate washer (program 9) (add 350 μl of wash buffer, soak for 30 s, and aspirate).
- g. Add 100 μl of diluted anti-dsDNA antibody to each well. Cover and incubate for 30 \pm 2 min at room temperature.
- h. Wash plate as described in step V.C.2.f.
- i. Prepare working enzyme tracer solution. Make a 1:50 dilution of the tracer with tracer diluent.

Number of strips	Enzyme tracer (μl)	Tracer diluent (μl)
1	20	980
2	40	1,960
3	60	2,940
4	80	3,920

- j. Pipette 100 μl of diluted enzyme tracer into each well. Cover and incubate for 30 \pm 2 min at room temperature.
- k. Prepare the working chromagen-substrate solution before the end of the incubation period.
- (1) Add equal volumes of chromagen and substrate

Number of strips	Chromagen (ml)	Substrate (ml)
1	0.5	0.5
2	1.0	1.0
3	1.5	1.5
4	2.0	2.0

- (2) Store chromagen-substrate in the dark until ready to use.
- l. Wash plate as described in step V.C.2.f.
- m. Pipette 100 μl of chromagen-substrate into each well. Cover and incubate for 30 \pm 2 min at room temperature in the dark.
- n. Pipette 100 μl of blocking reagent into each well.
- o. Measure optical density at 450 nm (OD_{450}) just after adding the blocking reagent.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. Report results as positive, low positive, or negative for *M. pneumoniae* DNA.
- B. Call positive results to requesting area. Note on the worksheet the name of the person called, date, and time, and initial.
- C. Document all testing in hard copy or computerized work card.

VII. INTERPRETATION**A. *M. pneumoniae* PCR**

1. The cutoff for a positive result is an OD₄₅₀ of ≥ 1.0 .
2. An OD₄₅₀ between 0.5 and 1.0 is reported as a low positive.
3. An OD₄₅₀ of <0.5 is negative.
4. The cutoff was determined by calculating the mean and standard deviation (SD) of the OD values of 116 negative patients. The cutoff is set at the mean + 10 SDs.
5. If any of the negative control reactions are positive (OD > cutoff), the run is invalid and must be repeated.
6. If the *M. pneumoniae* positive control reaction does not have an OD above 1.0, the run is invalid and must be repeated.
7. A clinical specimen is considered negative for *M. pneumoniae* DNA if the OD value of the specimen is below the cutoff and if the spiked control has an OD value greater than the cutoff value. For BAL specimens there is no inhibition control.
8. If the clinical specimen is negative for *M. pneumoniae* DNA (OD < cutoff) and the spike control is also negative, the test is invalid and testing of the specimen must be repeated. If similar results are obtained on repeat testing, the test should be reported as “uninterpretable; specimen contains a substance that inhibits amplification.”
9. If the patient result is low positive or positive and the spike is negative, the specimen should be retested and the result discussed with the supervisor, senior technologist, or director before reporting.

B. DQA PCR

1. If the negative control reaction is positive, the run is invalid and must be repeated.
2. If there is not a 214-bp product amplified in the positive control reaction, the run is invalid and must be repeated.
3. If the clinical specimen does not contain a 214-bp band, the result should include following disclaimer: “Interpret with caution; no human DNA detected.”

VIII. LIMITATIONS OF TESTING

- A. A negative result for *M. pneumoniae* DNA by PCR does not rule out the possibility that *M. pneumoniae* DNA is present in the specimen at a concentration below the level of sensitivity of the assay. The assay is capable of detecting 200 CFU of *M. pneumoniae* per ml of specimen. It is also possible that there is inhibition of the PCR which is not detected by this protocol.
- B. A positive result for *M. pneumoniae* DNA by PCR may be the result of contamination rather than a true positive result. This protocol employs several steps to decrease the risk of contamination, including separate areas for assay setup, specimen preparation, and amplification and detection of amplified products; unidirectional work flow; the use of dUTP and UNG to decrease the risk of carryover contamination; good laboratory technique and the use of a laminar-flow hood during specimen preparation to avoid contamination between specimens; opening of reaction tubes under a fume hood in area 3 after amplification; and periodic wipe tests of work areas.
- C. The presence of *M. pneumoniae* DNA in the lower respiratory tract may not always correlate with clinical disease. The DNA may be present from a previous (resolved) upper respiratory tract infection unrelated to the current illness.

PART 11

Detection of *Bordetella pertussis* by PCR

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

When clinical and epidemiologic criteria are used to evaluate patients during outbreaks of pertussis, both direct fluorescent-antibody (DFA) and culture methods are found to be deficient at establishing a laboratory diagnosis. Both methods are affected by a number of factors: patient age, antimicrobial agent use, stage of disease that specimens were obtained, vaccination status, specimen type collected, and specimen transport conditions. Since PCR detects *Bordetella pertussis* DNA and not viable organisms, the sensitivity can be as low as <1 cell, making this the preferred method for many laboratories (1, 2, 5, 9, 16, 18). A number of excellent studies have prospectively compared the performance of DFA testing, culture, and PCR, and the sensitivity, specificity, positive predictive value, and rapid turnaround time of PCR have been shown to be outstanding (3, 4, 6, 8, 10, 13, 14, 15). Unfortunately, no test for *B. pertussis* is pres-

ently cleared by the Food and Drug Administration; thus, laboratories must each design, develop, and validate the procedure they use for pertussis PCR.

A wide variety of different regions of *B. pertussis* DNA have been successfully used as targets, and an even wider variety of methods have been used to detect the product produced by amplifying the various targets (refer to Supplemental Reading). To date, comparisons between the different PCR targets and then the different methods to detect those targets have yet to be published. As a result of these issues, the sensitivity, specificity, accuracy, and QC of *B. pertussis* PCR procedures may vary widely among different laboratories. Despite these problems, PCR is a rapid, sensitive, and specific technique that remains positive far longer than culture, provides positive results for previously treated or vaccinated patients, and is the only method that can provide positive

results in the late stages of disease. The diagnosis of pertussis lends itself nicely to PCR because there is no prolonged carrier state and most laboratories do not perform antimicrobial susceptibility testing, so an isolate is not required. The procedure described here is based on the procedure published by E. M. Glare et al. which targets a repeated insertion sequence (IS481), which results in a highly sensitive assay (5). It is one of many methods which have been adapted for use in diagnostic laboratories. The method described to detect target product uses ethidium bromide staining, following agarose gel electrophoresis.

■ **NOTE:** Laboratories performing PCR must have a legal contract and your hospital must obtain a testing license from Roche Molecular Systems, Inc., due to patent ownership. Failure to do so has resulted in lawsuits and fines.

II. SPECIMEN COLLECTION

- A. Nasal wash or nasal aspirate specimens are the specimens of choice, and they should be refrigerated if tested the same day they are taken or frozen for longer time delays.
- ☑ **NOTE:** Positive results have been reported using PCR with specimens collected as late as 60 days after onset of symptoms, but generally 40 days is a practical cutoff.
- B. Do not use standard nasopharyngeal swabs for PCR since the alginate component, the aluminum shaft, and transport medium inhibit PCR-based assays (17).
- C. If swabs must be used, observe the following steps.
1. Use Dacron.
 2. To avoid additional DNA extraction, keep swabs dry and do not place in transport.
 3. Freeze upon receipt in the laboratory. Refer to procedure 3.11.6 for further details.
- ☑ **NOTE:** Nasopharyngeal aspiration and washing yield sufficient material for numerous diagnostic procedures. Aspirate specimens are easily divided and saved, are suitable for all testing methods (PCR, culture, and DFA testing), and can be frozen for long periods of time (2 years at -70°C).

III. MATERIALS

- A. **Phase 1 (specimen digestion)**
1. Alcohol wipes
 2. 10% Bleach solution
 3. 70% Ethyl alcohol
 4. 20- μl aliquot of proteinase K
 5. 50- μl aliquot of 1 M Tris buffer, pH 7.6
 6. Sterile (DNase-free) water
 7. 50 μl of positive control
 8. Pipettes: P2, P20, and P200
 9. Pipette tips: 1 to 20 μl (with filter inserts) and 50 to 100 μl
 10. Sterile Falcon tube
 11. Sterile 1.5-ml microcentrifuge tubes
 12. Microcentrifuge cap opener(s)
 13. Microcentrifuge tube rack(s)
 14. Felt tip pen with fine tip
 15. Latex gloves
 16. Boiling float
 17. Boiling water bath
 18. Microcentrifuge
 19. Timer
 20. Hood for containment of DNA aerosol
- ☑ **NOTE:** There are many choices in how DNA can be extracted from clinical specimens. Some homogenize the specimen, treat with mucolytic agents, centrifuge to obtain a pellet, resuspend the pellet, and then boil to lyse the bacterial cells and release DNA (7). Amplification can then be performed directly or following DNA purification using a method such as the QIAamp extraction kit (QIAGEN Inc.). DNA purification adds cost but ensures that inhibitors are not present in the sample. Laboratories choosing to boil and not further purify the DNA must include an internal control with each specimen to detect inhibition.
- B. **Phase 2 (preparation of PCR master mix and addition of nucleic acid)**
1. GeneAmp PCR core reagent kit (Perkin-Elmer)
 2. AmpliTaq polymerase (extra vial; Perkin-Elmer, Applied Biosystems, or Invitrogen Life Technologies)
 3. Primers (sequence 5' to 3')
 - a. First primer (BCCH 01), 5'-GAT TCA ATA GGT TGT ATG CAT GGT T-3'
 - b. Second primer (BCCH 99), 5'-AAT TGC TGG ACC ATT TCG AGT CGA CG-3'
 4. Magnesium chloride
 5. Digested specimens, positive and negative (no DNA) controls
 6. Pipettes: P2, P20, and P200
 7. Pipette tips: 1 to 20 μl and 50 to 100 μl
 8. 0.5-ml GeneAmp reaction tubes, for each specimen and controls (Perkin-Elmer)
 9. Sterile distilled water
 10. Mineral oil
 11. Latex gloves
 12. Racks for 1.5- and 0.5-ml microcentrifuge tubes

III. MATERIALS (continued)

13. Discard beaker containing 10% bleach

■ **NOTE:** Because they are not commercially available, laboratories must purchase primers from oligonucleotide synthesis laboratories. Biochemistry and microbiology departments at many universities are now specializing in primer synthesis and offer this service for purchase.

C. Phase 3 (amplification of target DNA)

1. Specimens
2. Thermal cycler (480 or 9600; Applied Biosystems or Perkin-Elmer)
3. Mineral oil
4. Tissue paper or wipes
5. Cotton-tipped swabs

D. Phase 4 (agarose gel electrophoresis and ethidium bromide staining)

1. Tris-acetic acid-EDTA buffer
2. Agarose, DNA pure
3. Pipette (P20) and tips
4. Plastic wrap
5. Spatula

6. 125-ml flask
7. Vinyl and latex gloves
8. Mini-Electrophoresis unit and power supply
9. Hot plate
10. 0.5-ml microcentrifuge tubes
11. 0.5-ml microcentrifuge rack
12. DNA ladder, 50 to 2,000 bp
13. Loading buffer, 6×
14. Ethidium bromide
15. Transilluminator
16. Camera (DS-34 Polaroid)
17. Film, 667 B/W Polaroid 3000 ASA

■ **NOTE:** Ethidium bromide is toxic and is a powerful mutagen. Always wear gloves when working with the dye. Deactivate solutions and decontaminate after use; do not discard down the drain. Consult your region's recommendations for proper disposal. Alternately, ethidium bromide can be added to the gel to minimize the hazard.

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

A. Include positive and negative controls with each run to monitor for contamination and inhibition.

1. Negative controls consist of water and no DNA.
2. Positive controls can be prepared using one of two possible methods.
 - a. Subculture a strain of proven *B. pertussis* to two charcoal plates without cephalixin.
 - (1) After 72 h of incubation, scrape the growth from the plates using sterile swabs and emulsify in 10 ml of sterile phosphate-buffered saline.
 - (2) Prepare dilutions of the inoculum from 10^{-1} to 10^{-4} , and then place 100 μ l of each dilution on each of two charcoal plates.
 - (3) Spread the inoculum over the entire surface of each plate and freeze the original 10-ml suspension.
 - (4) After 5 to 7 days of incubation, average the colony counts from each dilution. The dilution yielding approximately 250 CFU is the working dilution.
 - (5) Thaw and vortex the original 10-ml suspension.
 - (6) Redilute to 3 ml of the working dilution and aliquot in 50- μ l volumes in sterile 0.5-ml microcentrifuge tubes.
 - (7) Store at -70°C . Test positive control before using.
 - b. Purified *B. pertussis* DNA can be purchased.
 - (1) ABI (Advanced Biotechnologies Incorporated), River Park II, 9108 Guilford Rd., Columbia, MD 21046. Phone: (301) 470-3220. Fax: (301) 497-9773. Website: <http://www.abionline.com>.
 - (2) Catalog no. 08-748-100, *Bordetella pertussis* ATCC 9340
 - (3) Follow manufacturer's instructions for preparation.

IV. QUALITY CONTROL

(continued)

- B. Ideally, include a positive control containing a high copy number of the target of interest and a low positive control in each run. Select the low positive control by running dilutions of the working dilution and calculating the limits of detection for the assay.
- C. To eliminate inhibition of amplification when performing PCR using clinical specimens, purify the DNA prior to amplification using the QIAamp extraction kit (QIAGEN Inc.) or by including a 1:5 and a 1:25 dilution of the DNA preparation from each specimen.
 - **NOTE:** This would result in three microcentrifuge tubes for each sample (two diluted and one undiluted). Diluting original samples may reduce the sensitivity of the assay since target nucleic acid is also being diluted.
- D. Test any change in reagents (primer, master mix, etc.) or equipment prior to using them with clinical samples to ensure that results are not affected.

V. PROCEDURE

■ **NOTE:** This procedure is divided into four phases: specimen digestion (to release the nucleic acid from the cells), preparation of PCR master mix and addition of nucleic acid from the specimen, amplification of the target DNA, and detection of the amplified DNA product using agarose gel electrophoresis.

A. Phase 1

1. Remove specimens from freezer, assign numbers, and wipe the entire biosafety hood interior with 10% bleach followed by 70% alcohol. Start boiling water bath.
2. Wearing latex gloves, place enough 1.5-ml microcentrifuge tubes for all specimens and controls into the hood. Wipe pipettes with alcohol and place in hood; then number the caps of microcentrifuge tubes.
3. Place 1 μ l of 1 M Tris-HCl buffer followed by 1 μ l of proteinase K into each microcentrifuge tube.
4. Using separate pipette tips, place 50 μ l of each specimen, 50 μ l of positive control, and 50 μ l of sterile distilled water (negative control) into separate microcentrifuge tubes. Cap each tube before proceeding to the next.
5. Incubate for 60 min at 35°C in heating block; while incubating microcentrifuge tubes, remove core reagent kit from freezer and place in hood.
6. Place the incubated microcentrifuge tubes in the boiling float and place tubes on the boiling water bath. Boil for 20 min to inactivate proteinase K.
7. Remove tubes and float from water, place tubes in microcentrifuge, pulse spin, and place tubes in hood.

B. Phase 2

1. Label GeneAmp reaction tubes with the specimen numbers, then the positive control, and then the negative control. Keep the tubes in this order through the duration of the procedure. Place the corresponding microcentrifuge tube in front of each GeneAmp tube in the rack.
2. Pipette master mix constituents into a sterile Falcon tube in the following order, changing pipette tips between each reagent, and then mix well.

<u>Reagent</u>	<u>Volume</u>
Sterile distilled water	48 μ l
10 \times PCR buffer II	10 μ l
dATP	2 μ l
dCTP	2 μ l
dGTP	2 μ l
dTTP	2 μ l
Primer 1	0.75 μ l
Primer 2	0.75 μ l
AmpliTaq polymerase	0.5 μ l
25 mM MgCl ₂	12 μ l

V. PROCEDURE (*continued*)

■ **NOTE:** Refreeze any remaining primer, refreeze kit components, and freeze remaining master mix at -70°C for future use.

3. Pipette 68 μl of master mix into each GeneAmp tube, and then return to the first tube.
4. Pipette 12 μl of MgCl_2 into the first tube, and then immediately add 20 μl of the specimen or control and eject pipette tip into the discard bleach beaker.
5. Add 2 drops of mineral oil (overlay) *without* allowing the dropper to touch the sides of the tube. Promptly cap the tube and proceed to the next tube following steps V.B.3 through 5. Immediately proceed to phase 3.

C. Phase 3

1. Program the thermal cycler to run the following cycles in sequence.
 - a. Time delay at 94°C for 4.5 min
 - b. Thirty-three denaturing, annealing, and extending cycles, as follows: denaturation at 94°C for 1 min, annealing at 57°C for 1 min, and extension at 72°C for 1 min.
 - c. Time delay at 72°C for 5 min
 - d. Hold at 4°C until the thermal cycler is turned off and tubes are removed. If cycling overnight, samples will be held stable until you are ready to remove the tubes.
2. Add 1 drop of mineral oil to each thermal cycler well that will be used. Avoid using wells around the perimeter if possible.
3. Firmly place each reaction tube in a well of the cycler and set the program to run.
4. When finished, remove tubes, wiping off the oil using tissue paper or wipes.
5. Turn off cycler; then, using a cotton-tipped swab, remove residual oil in the used wells.
6. Immediately proceed to phase 4 or store tubes at -70°C until prepared to proceed.

D. Phase 4

1. Mix each amplified sample and the molecular weight ladder with sample buffer.
2. Prepare 2% agarose gel.
3. Load gel with samples. Always place the molecular weight ladder in well 1 (far left side), followed by the samples, positive control(s), and lastly the negative control.
4. Electrophorese for 1 h at 80 V.
5. Visualize DNA by UV fluorescence after ethidium bromide staining.
6. Photograph each minigel using the equipment listed in item III above or other methods at your disposal to produce a permanent record of the gel (required by regulatory agencies).

POSTANALYTICAL CONSIDERATIONS**VI. INTERPRETATION OF RESULTS**

- A. Positive specimens are those exhibiting a 188-bp band when compared with known positive control and molecular weight ladder.
- B. Negative specimens are those which do not exhibit a 188-bp band when compared with known positive control and molecular weight ladder.
- C. Clinical specimens cannot be interpreted unless positive and negative controls respond appropriately.

VII. REPORTING RESULTS

- A. Report positive results as “Positive for *Bordetella pertussis* by PCR. This test is performed pursuant to a license agreement with Roche Molecular Systems, Inc.”
 - B. Report positive results to the physician(s) ordering the test and to the public health department.
 - C. Report negative results as “Negative for *Bordetella pertussis* by PCR. This test is performed pursuant to a license agreement with Roche Molecular Systems, Inc.”
 - D. Add the following statement: “This test was developed and its performance characteristics determined by (laboratory name). It has not been cleared or approved by the Food and Drug Administration.”
- **NOTE:** Duplicate and/or repeat specimens should not be accepted. Sensitivity of molecular methods does not increase with repeated testing. Positive results have been reported using PCR with specimens collected as late as 60 days after onset of symptoms (K. L. McGowan and M. L. Leet, unpublished data).

VIII. LIMITATIONS OF THE PROCEDURE

- A. Performance of PCR assays requires strict adherence to the College of American Pathologists (CAP) Molecular Standards (March 2003) concerning specimen handling, preparation of procedure manuals, required physical facilities, etc.
- B. At this time, use of PCR for diagnosis of pertussis is too labor-intensive and complex to be performed routinely in most laboratories.
- C. Unknown samples for evaluating pertussis PCR competency are not available from commercial sources such as the CAP. On a twice-a-year basis, laboratories performing PCR should exchange frozen specimens with other hospital or public health laboratories that are known to competently perform the assay. These records should be maintained for CAP, Centers for Medicare and Medicaid Services, and hospital inspections.
- D. PCR should not be used for test of cure since the method does not necessarily detect viable organisms and nucleic acid can remain on mucous membranes for extended periods of time following treatment.
- E. Recent publications have reported that *Bordetella holmesii* can be detected by PCR assays that target IS481 of *B. pertussis* (11, 12). This would result in false positives. Since *B. holmesii* has been cultured from patients with cough, this would appear to compromise assays that target IS481; however, *B. holmesii* has largely been isolated from blood cultures from immunocompromised patients, and its incidence in respiratory specimens from various regions of the United States has yet to be determined. Laboratories can easily screen for *B. holmesii* by culturing each clinical specimen on a small Mueller-Hinton agar plate incubated aerobically at 35°C for a total of 48 to 72 h. *B. holmesii* produces a soluble brown pigment that is easily visualized. A known positive strain of *B. holmesii* should be used for comparison.

12.3.1

Introduction

Bacteria and fungi can be identified by using nucleic acid hybridization techniques. Nucleic acid probes can be used to confirm the identification of culture isolates that have been tested by presumptive identification methods. Alternatively, probes can be used as the primary method for identifying isolated organisms. Culture identification by probe hybridization is not dependent on the ability to detect minute

quantities of nucleic acid, and thus sensitivity is not a limiting factor in this application of molecular technology. The advantage of probe-based identification is greatest for slow-growing organisms like the mycobacteria or for organisms for which convenient commercial identification systems are not available. Although the specificity of the available commercial probes is high and they facilitate rapid

identification of a number of pathogens (Table 12.1–4), misidentifications do occur and serve to emphasize the need for caution in using any single characteristic in identification of a species. It should also be emphasized that at this point identification by probe hybridization is more expensive than conventional techniques for many organisms.

12.3.2

Identification of Bacteria and Fungi by Using Nucleic Acid Probes

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Bacteria and fungi can be identified by using nucleic acid probes. Nucleic acid probes can be used to confirm the identification of isolates that have been tested by presumptive identification methods. Alternatively, probes can be used as the primary method for identifying isolated organisms. The AccuProbe system (Gen-Probe, Inc., San Diego, Calif.) is currently the only DNA probe system available commercially. DNA probes are available

for the organisms listed in Table 12.1–4. The sample preparation procedure for mycobacterial and fungal probes differs from that for bacterial probes and is described in procedure 12.3.3.

■ **NOTE:** Sample preparation methods are identical for mycobacteria and fungi.

The AccuProbe system is based on nucleic hybridization of a DNA probe (oligomer) that is complementary to the rRNA of the target organism. The probes are la-

beled with an acridinium ester. The organism is treated to release the rRNA and then incubated with the labeled single-stranded DNA probe. If the rRNA and DNA probes are complementary, a stable DNA-RNA hybrid forms. A hydrolyzing reagent is added to selectively remove unbound DNA probe. The chemiluminescence of the DNA-RNA hybrids is quantitated in relative light units (RLU) with a luminometer.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Test growth from appropriate solid media with morphology suggestive of the organism in question. Samples may be tested as soon as growth is visible, but they should be less than 48 h old. If a single colony is to be tested, it should be at least 1 mm in diameter. Alternatively, several (three or four) smaller colonies can be tested. Do not use confluent growth.

III. MATERIALS

A. Reagents

1. Identification reagent kit (provided)
 - a. Reagent 1 (lysis reagent)
 - b. Reagent 2 (hybridization buffer)
 - c. Reagent 3 (selection reagent)
2. Detection reagent kit (provided)
 - a. Detection reagent 1
 - b. Detection reagent 2
3. Organism-specific probe kit (provided)

B. Materials required but not provided

1. 1- μ l plastic sterile inoculating loops, applicator sticks

2. Reference strains for controls

3. Incubator or water bath (35 to 37°C; for gram-positive bacteria)
4. Water bath or heating block (60°C)
5. Micropipettes (50 and 300 μ l)
6. Repipettors (50 and 300 μ l)
7. Vortex mixer
8. Leader 1 luminometer or AccuLDR luminometer (Gen-Probe)

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that all reagents and materials meet expiration date and QC parameters per NCCLS document M22-A2 (1).
- B. Include in each run appropriate reference strains representing a positive and negative control for each organism being tested.
- C. Negative and positive control strains should yield the following values.

	<u>AccuLDR (RLU)</u>	<u>Leader (RLU)</u>
Negative control	<600	<20,000
Positive control	>1,500	>50,000

V. PROCEDURE

A. Equipment preparation

1. Adjust the incubator or water bath to 35 to 37°C if testing gram-positive bacteria.
2. Adjust the water bath or heating block to 60 ± 1°C.
3. Prepare the luminometer for operation. Make sure there are sufficient volumes of detection reagents 1 and 2.

B. Sample preparation

1. Label the probe reagent tubes. Remove and retain the caps.
2. Pipette 50 µl of reagent 1 (lysis reagent) into each probe reagent tube.
3. Transfer one or several colonies from solid medium into probe reagent tubes. Avoid taking any of the solid medium with the cells. Twirl the loop or stick in reagent 1 to remove the cells, and mix thoroughly.
4. For gram-positive organisms, recap the probe reagent tubes and incubate them at 35 to 37°C for 5 min. Remove the tubes from the water or dry bath, and then remove and retain the caps.

C. Hybridization

1. Pipette 50 µl of reagent 2 (hybridization buffer) into each probe reagent tube.
2. Recap the tubes, and mix the contents by shaking or vortexing.
3. Incubate for 15 min at 60°C in a water bath or heating block.

D. Selection

1. Remove the probe reagent tubes from the water or dry bath. Remove and retain the caps. Pipette 300 µl of reagent 3 (selection reagent) into each tube. Recap the tubes, and vortex them to mix the contents completely.
2. Incubate the probe reagent tubes for 5 min at 60°C.
3. Remove the tubes from the water or dry bath, and leave them at room temperature for at least 5 min. Remove and discard the caps. Read results in the luminometer within 30 min (within 1 h for *Streptococcus pneumoniae*) after removing the tubes from the water bath or heating block.

E. Detection

1. Select the appropriate protocol from the menu of the luminometer software.
2. Using a damp tissue or paper towel, wipe each tube to ensure that no residue is present on the outside of the tube, and insert the tube into the luminometer according to the instrument instructions.
3. When the analysis is complete, remove the tube from the luminometer. The sample cannot be read again.

F. Procedure notes

1. A precipitate may form in the hybridization buffer. Warming and mixing the solution at 35 to 60°C will dissolve the precipitate.
2. The hybridization and selection reactions are temperature dependent. Therefore, it is imperative that the incubator, water bath, or heating block be

V. PROCEDURE *(continued)*

- maintained within the specified temperature. The entire liquid reaction volume in the probe reagent tube must be exposed to the required temperature.
3. With gram-positive bacteria, the hybridization reaction should be started within 30 min of adding cells and reagent 1 to the probe reagent tubes.
 4. The hybridization and selection reactions are time dependent. Hybridize for at least 20 min. Incubate the probe reaction tubes during the selection step for at least 5 min but no more than 6 min.
 5. It is critical to have a homogenous mixture during the selection (vortex) step, specifically after the addition of reagent 3.
 6. Troubleshooting
 - a. Elevated negative control values of more than 20,000 RLU in the Leader 1 luminometer or more than 600 photometric light units (PLU) in the AccuLDR luminometer (formerly PAL) can occur. If they do, streak a portion of the growth onto the appropriate agar medium and incubate it to check for multiple colony types.
 - b. Low positive control values (less than 50,000 RLU in the Leader 1 or less than 1,500 PLU in the AccuLDR) can be caused by insufficient cell numbers, by testing mixed or aged cultures, or, for gram-positive organisms, by leaving cells exposed to the lysis reagent for more than 30 min before hybridization reagents are added.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. Report results as genus and species as indicated.
- B. Document all testing in hard copy or computerized work card.

VII. INTERPRETATION

- A. The results of the AccuProbe culture identification test are based on the following cutoff values. Samples producing signals higher than or equal to the cutoff values are considered positive. Samples with signals lower than these values are considered negative. Results from samples in the indeterminate range must be retested.

	<u>AccuLDR (RLU)</u>	<u>Leader (RLU)</u>
Cutoff value	1,500	50,000
Repeat range	1,200–1,499	40,000–49,000

- B. Performance characteristics
 1. Sensitivity, 100%
 2. Specificity, 100%
 3. Percent agreement with reference identification, 100%

12.3.3

DNA Probes for the Identification of Mycobacteria

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

A commercially manufactured system, the AccuProbe culture confirmation test, is available for identification of isolates of several species of mycobacteria. The system is based on the use of DNA probes that are complementary to species-specific rRNA. The mycobacterial cells are lysed by sonication, heat killed, and exposed to DNA that has been labeled with a chemi-

luminescent tag. The labeled DNA probe combines with the organism's rRNA to form a stable DNA-RNA hybrid. A selection reagent "kills" the signal on all unbound DNA. Chemiluminescence produced by DNA-RNA hybrids is measured in a luminometer.

Probes for the identification of *Mycobacterium tuberculosis* complex, *Myco-*

bacterium avium, *Mycobacterium intracellulare*, *Mycobacterium gordonae*, *M. avium-M. intracellulare* complex, and *Mycobacterium kansasii* are available. Nucleic acid probes provide the most rapid identification of mycobacteria of any identification systems.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Any actively growing culture less than 1 month old recovered on any solid or broth medium such as Middlebrook 7H9, 7H10, 7H11, or 7H11 selective or Lowenstein-Jensen medium can be used.

III. MATERIALS

A. Reagents supplied by manufacturer (Table 12.3.3-1)

☑ Indicate the expiration date on the label and in the work record or on the manufacturer's label.

B. Supplies (required but not supplied)

1. Micropipettes (100 μ l)
2. Micropipettor (300 μ l)
3. Repipettor (300 μ l)
4. Repipettor syringes
5. Plastic sterile inoculating loops (1 μ l)

C. Equipment (required but not supplied)

1. Luminometer (Leader 1, Leader 250, or PAL)
2. Vortex mixer
3. Water or dry bath, 90°C (\pm 5°C)
4. Water or dry bath, 60°C (\pm 1°C)
5. Water bath sonicator

Table 12.3.3–1 Reagents for AccuProbe culture confirmation

Reagent ^a	Description	Storage temp (°C)
Lysing tubes	Lyophilized glass beads and buffer	23–25
Probe reagent	Tubed lyophilized species-specific DNA (in foil pouches) ^b	4
Reagent 1	Specimen diluent	23–25
Reagent 2	Probe diluent	23–25
Reagent 3	Selection reagent	23–25
Detection I	H ₂ O ₂ in nitric acid solution containing 1 N NaOH	23–25
Detection II	H ₂ O ₂ in nitric acid solution containing 1 N NaOH	23–25
Ultrasonic enhancer	Detergent-like solution to increase sonication power	23–25

^a All reagents are stable for approximately 1 year from date of manufacture.

^b After pouch is opened, stable for 2 months.

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Verify that all reagents and materials meet expiration date and QC parameters per NCCLS document M22-A2 (1).
- B. Frequency and tolerance of controls
 1. Run a positive and negative control with each batch of organisms tested.
 2. If controls are not within limits, check age of culture (should be less than 1 month old), level of water in sonicator, quality of sonicator (by observing waving water patterns while sonicator is on; water should “dance”), and temperature of hybridization; if necessary, run a tritium standard.
- C. Control organisms (Table 12.3.3–2)

V. PROCEDURE

- A. Degas the water for 15 min. Turn on 95°C water bath (or heat block) and 60°C water bath (or heat block).
- B. Add 100 µl of reagent 1 (specimen diluent) and 100 µl of reagent 2 (probe diluent) (Table 12.3.3–1) to each lysing tube.
- C. Working in a biological safety cabinet, transfer a loopful (1 µl) of test organism into the lysing tube. Twirl the loop against the side of the tube to remove the entire inoculum.

Table 12.3.3–2 Control organisms for AccuProbe mycobacterial culture confirmation tests

Probe to be tested	Control	
	Positive	Negative
<i>M. avium</i>	<i>M. avium</i> ATCC 25291	<i>M. intracellulare</i> ATCC 13950
<i>M. intracellulare</i>	<i>M. intracellulare</i> ATCC 13950	<i>M. avium</i> ATCC 25291
<i>M. tuberculosis</i> complex	<i>M. tuberculosis</i> ATCC 25177	<i>M. avium</i> ATCC 25291
<i>M. gordonae</i>	<i>M. gordonae</i> ATCC 14470	<i>M. scrofulaceum</i> ATCC 19073
<i>M. avium</i> complex	<i>M. intracellulare</i> ATCC 13950	<i>M. gordonae</i> ATCC 14470
<i>M. kansasii</i>	<i>M. kansasii</i> ATCC 12478	<i>M. tuberculosis</i> ATCC 25177

V. PROCEDURE (*continued*)

- D. Place the lysing tubes in the sonicator. Ensure that the water level is high enough to cover the contents of the tube. Do not allow the tubes to touch the sides of the sonicator. Sonicate at room temperature for 15 min.
- E. Place the lysing tubes in the 95°C water bath (or heat block) for 15 min.
- F. Allow the tubes to cool at room temperature for 5 min.
- G. Pipette 100 µl of the killed lysate into the probe reaction tube.
- H. Incubate the tubes for 15 min at 60°C in the water bath (or heat block).
- I. Pipette 300 µl of reagent 3 (selection reagent) (Table 12.3.3–1) into each tube. Recap and vortex the tubes, and immediately place them back into the 60°C water bath (or heat block). Incubate for 5 min for *M. avium* complex and *M. gordonae*, 8 min for *M. kansasii*, and 10 min for *M. tuberculosis* complex.
- J. Prepare the luminometer for operation by completing a wash cycle. Wipe each tube with a damp tissue before inserting it into the luminometer. Read each tube and controls. The luminometer records relative light units (RLU).
- K. Procedure notes
 1. It is important to maintain the 60°C ($\pm 1^\circ\text{C}$) dry bath, because annealing of the DNA-RNA hybrid is temperature sensitive.
 2. The water level of the sonicator should be high enough to cover the hybridization buffer, beads, and organisms.
 3. Other sources of error include failure to vortex after addition of the organism-buffer mixture to the probe tube and after addition of reagent 3, which inactivates the acridinium ester not bound to rRNA.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

- A. Report results as genus and species as indicated.
- B. Document all testing in hard copy or computerized work card.

VII. INTERPRETATION

- A. A positive result is >30,000 RLU.
- B. Signals below 30,000 RLU are considered negative.
- C. Repeat any test with a result between 20,000 and 29,999 RLU.

VIII. LIMITATIONS OF THE PROCEDURE

- A. This method cannot be used directly on fresh clinical specimens. It is for culture identification only.
- B. A small number of biochemically determined *M. avium* complex isolates will not produce a positive result with the *M. avium* complex probe. The taxonomic status of these strains is currently uncertain.
- C. The *M. tuberculosis* complex culture confirmation test does not differentiate among *M. tuberculosis*, *Mycobacterium bovis*, *M. bovis* BCG, *Mycobacterium africanum*, and *Mycobacterium microti*. Additional tests such as niacin and nitrate reductase are required to differentiate *M. tuberculosis* from other members of the group (*see* section 4).
- D. The *M. avium* complex culture confirmation test does not differentiate between *M. avium* and *M. intracellulare*.
- E. The sample preparation for the identification of fungal pathogens *Histoplasma capsulatum*, *Blastomyces dermatitidis*, and *Coccidioides immitis* is identical to that of the mycobacteria. These organisms may be identified using the appropriate Gen-Probe kits and reagents.

12.4.1

Introduction

The ability to identify specific strains within a species of pathogen is an important aid in the rational development of effective measures to prevent and control nosocomial infections. The efforts of both microbiologists and hospital epidemiologists are facilitated greatly by the availability of the newer molecular epidemiologic typing techniques. The variety of molecular epidemiologic tools available at present is considerable, and based on current experience the methods that appear to be the most practical and useful for both

large- and small-scale epidemiologic studies are the DNA-based methods such as pulsed-field gel electrophoresis (Table 12.1–5). Although these methods clearly have limitations, they generally are a significant improvement over the more conventional typing methods, many of which are too cumbersome, insensitive, and time-consuming to be of practical value for epidemiologic evaluations. It is important to understand that no single technique is universally applicable and that the choice for a particular application is re-

lated to the species studied, the scope of the question posed, and the convenience of the technique. The techniques of molecular epidemiology are useful in answering real clinical and infection control questions and are not limited to research uses. Examples include distinguishing between relapse and reinfection in an individual patient and in tracking the spread of an individual strain of a bacterium or fungus within the hospital environment (1–3).

12.4.2

Plasmid Fingerprinting of Gram-Negative Organisms

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Plasmids are extrachromosomal circles of DNA that are present in many but not all species of bacteria. Many organisms, particularly those that are resistant to multiple antimicrobial agents, may harbor two or more plasmids. The presence of similarly sized plasmids in a series of isolates collected as part of an epidemiological investigation can be used in conjunction with other typing schemes to indicate the presence of an epidemic strain in a hospital or community. However, two or more isolates of the same species that are devoid

of plasmid DNA cannot be assumed to be the same strain. Isolates of the same species each showing a single plasmid of similar molecular size should be investigated further by cleaving the plasmid DNA with restriction endonucleases to confirm the similarity of the plasmids.

Plasmid fingerprinting techniques focus on the recovery of the supercoiled, covalently closed, circular form of the molecule. Lysis of the cell wall with detergent at high pH allows denaturation of chromosomal DNA without irreparable harm

to plasmid DNA. Precipitation of plasmid DNA with high concentrations of NaCl and isopropanol results in preparations relatively free of chromosomal DNA. Although plasmids normally have a molecular size ranging from 1 to 100 kb, some *Pseudomonas* plasmids may be as large as 400 kb. It is important to run molecular size standards consisting of supercoiled plasmids and not restriction endonuclease fragments for accurate determinations of plasmid size.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Most enteric gram-negative bacilli and *Pseudomonas* species grown on a nonselective agar medium for 18 to 24 h will yield plasmid DNA with this procedure.

III. MATERIALS

☑ **NOTE:** Autoclave all centrifuge tubes and pipette tips before use to destroy any nucleases that may be present.

- A. Sterile microcentrifuge tubes (1.5 ml) with caps
- B. Pipettor, variable volume (0 to 20 μ l)
- C. Pipettor, variable volume (20 to 200 μ l)
- D. Sterile pipette tips
- E. Disposable 5-ml pipettes
- F. Microcentrifuge (maximum speed, 12,000 \times g)

- G. Wet ice in bucket
- H. Vacuum line with trap
- I. TE buffer (50:10), pH 8.0 (50 mM Tris, 10 mM EDTA)
- J. Lysis buffer, pH 12.4 (stable for 1 month): Trizma base-Na, EDTA-sodium dodecyl sulfate (SDS)-NaOH
- K. 2 M Tris, pH 7.0 (stable for 6 months)
- L. 5 M NaCl (indefinite stability)
- M. 100% Ethanol
- N. Stop mix (running dye) (stable for 1 year): bromophenol blue-SDS-Ficoll type 400

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. Verify that all materials and reagents meet expiration date and QC parameters per NCCLS document M22-A2 (1).
- B. A standard strain containing well-characterized plasmids should be lysed in parallel with each plasmid screen to ensure the quality of the lysis buffer. *Escherichia coli* V517, which contains eight plasmids, is a good QC strain and also serves as an excellent source of molecular size standards (it is available from the ATCC [ATCC 37514]). Supercoiled standards also can be purchased from several commercial sources.

V. PROCEDURE

- A. Pipette 40 μ l of TE buffer (50:10) into a 1.5-ml microcentrifuge tube.
- B. Suspend one-fourth loopful (0.01-ml inoculating loop) of bacteria taken from an 18- to 24-h growth on a nonselective agar plate in the buffer.
- C. Add 0.6 ml of lysis buffer, and mix by inverting the tube 20 times. Do not vortex.
- D. Incubate at 37°C in a water bath for 20 min.
- E. Add 30 μ l of 2 M Tris (pH 7.0), and invert the tube 10 times to mix.
- F. Add 160 μ l of 5 M NaCl, and invert the tube 10 times.
- G. Place tubes on wet ice for at least 20 min. Incubation may continue for up to 1 h.
- H. Centrifuge tubes at 12,000 $\times g$ in a microcentrifuge for 5 min. Pour supernatant into a fresh (sterile) 1.5-ml centrifuge tube.
- I. Add 0.55 ml of cold absolute isopropanol (store at -20°C), and mix by inverting the tube.
- J. Freeze at -20°C for at least 20 min. Tubes can be left in the freezer overnight.
- K. Remove tubes from freezer, thaw at room temperature, and centrifuge at 12,000 $\times g$ for 3 min. Discard supernatant, and cautiously remove remaining alcohol with a Pasteur pipette connected to a vacuum line. Do *not* remove pellet at bottom of tube. Place inverted tubes on a paper towel for 30 min. Make sure that all alcohol is removed.
- L. Suspend DNA in 30 μ l of TE buffer (10:1). Add 6 μ l of stop mix. Allow at least 1 h for DNA to suspend.
- M. Electrophorese 15- μ l samples through a 0.7% agarose gel at 200 V/h.
- N. Stain gel in ethidium bromide (0.2 $\mu\text{g}/\text{ml}$ of water).
 NOTE: Wear gloves when handling ethidium bromide.
- O. Photograph gel with orange filter and mid-range UV transilluminator.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

The manner in which the results of plasmid fingerprinting investigations are reported depends on three factors: why the tests were ordered, who ordered them, and the expertise and comfort level of the microbiologist performing the test. Physicians and many infection control practitioners who request such tests will need to be given both the results and an interpretation of the results. The following guidelines are suggested.

- A. Provide a duplicate picture of the gel for the record. If you are not comfortable releasing a copy of the gel, you probably are not comfortable with the results, and the procedure should be deemed inconclusive. Some isolates of *Pseudomonas* spp. are difficult to lyse, and a report of “inconclusive” is better than a guess.

VI. REPORTING RESULTS

(continued)

- B.** Include in your report the sizes of the plasmids, if possible, and a comment such as “Plasmid patterns of isolates A, B, and C suggest that they are the same strain” or “Plasmid patterns suggest the presence of three unrelated isolates.”
- C.** Report a series of isolates that each have a single plasmid, all of approximately the same size, with a caution that further studies may be warranted. Whether further studies are done depends on the strength of the other data collected as part of the epidemiologic investigation. For example, if the isolates were collected within a short time from patients on the same ward with a common health care practitioner and if the antibiograms for all of the isolates are identical and have an unusual resistance pattern, this is strong supporting evidence of strain identity, and further information is probably not required. The strength of the data should be reflected in the report. If, on the other hand, the isolates were collected from patients on different wards, have antibiograms showing nothing but susceptibility, were collected over the course of 2 months, and do not have a substantial epidemiologic link, additional typing data should be sought, and the report should indicate that this is being done.
- D.** Results generated for infection control investigations do not necessarily have to be entered on a patient’s chart. Provide a copy of the gel to the infection control practitioner, and discuss the results in the context of what is known about the outbreak.

VII. INTERPRETATION

Some chromosomal DNA fragments will be present in plasmid preparations and will be seen on agarose gels, indicating that the bacteria have lysed. The chromosomal DNA band, which tends to be diffuse, will migrate to the 12- to 15-kb area of the gel. Plasmids produce sharp, well-delineated bands on agarose gels. Plasmids >15 kb in size will migrate more slowly than the chromosomal band, while smaller plasmids will migrate more quickly than the chromosomal band. Isolates with multiple plasmids producing identical or very similar plasmid migration profiles after electrophoresis are likely to represent multiple isolates of the same strain. Plasmids placed in the outside lanes of a gel may migrate slightly more slowly (smile effect). This problem can be reduced by running stop mix in the two outside lanes of the gel. Two isolates determined to be devoid of plasmids cannot be assumed to be the same strain on this basis. If several isolates each contain only a single plasmid, all similar in size, other typing procedures or restriction enzyme analysis of the plasmids should be performed. Typing of isolates should be done only within a defined epidemiologic situation or to assess the relatedness of isolates from a single patient.

- A.** Organisms such as *Stenotrophomonas maltophilia*, *Serratia marcescens*, and some species of *Acinetobacter*, all of which are frequently involved in outbreaks of nosocomial infections, are often devoid of plasmid DNA. The presence of a chromosomal DNA band in the absence of plasmid DNA indicates that the technique is working and that the isolates did undergo lysis. In this situation, alternative typing methods must be used.
- B.** The presence of a large bright band in the pocket of the gel without indications of DNA elsewhere in the gel suggests that the isolates did not lyse well and that the DNA has not migrated out of the pocket of the gel. In this situation, the pH of the lysis buffer should be checked.

VIII. LIMITATIONS OF TESTING

- A.** Not all organisms have plasmid DNA. Large plasmids tend to cluster in the upper portions of the gel, and it is difficult to distinguish the sizes of plasmids that are >100 kb. Exercise caution when determining the relatedness of large plasmids. Because plasmids of identical size can be totally unrelated to one another, always exercise caution when isolates with a single plasmid each are encountered.
- B.** Whereas plasmid profiling is a relatively simple and rapid means of assessing organism relatedness, and remains quite useful especially in the context of antimicrobial resistance studies, it has been largely replaced as an epidemiologic typing method by chromosomal DNA-based typing methods.

12.4.3

Plasmid Fingerprinting of Staphylococci

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Plasmid analysis is based on the fact that different bacterial strains often carry different types or numbers of plasmids. This is a useful epidemiologic tool for investigations of strain relatedness. Approx-

mately 80 to 90% of the clinical isolates of staphylococci carry one or more plasmids. Plasmid DNA is isolated from the bacterial cells, digested with a restriction endonuclease, and electrophoresed

through agarose. Different plasmids display different patterns of fragment sizes. For initial analysis, the restriction endonucleases *EcoRI* and *HindIII* are recommended.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Most staphylococci grown on a nonselective agar medium for 18 to 24 h will yield plasmid DNA with this procedure.

III. MATERIALS

A. Stocks and purchased chemicals

Indicate the expiration date on the label and in the work record or on the manufacturer's label. All materials are stable for 2 years at room temperature unless otherwise noted. Stock solutions that must be autoclaved or filter sterilized are noted.

1. 1 M Tris, pH 8.0 (autoclave)
2. 1 M Tris, pH 7.0 (autoclave)
3. Sodium dodecyl sulfate (SDS), 20% (filter sterilize)
4. 0.5 M EDTA, pH 8.0 (autoclave)
5. 4 M NaCl (autoclave)
6. 2 N NaOH
7. Sucrose (50%) (filter sterilize)
8. Ethanol (95%)
9. Agarose
10. Mueller-Hinton broth (MHB) for coagulase-negative staphylococci
11. TSB for *Staphylococcus aureus*
12. Restriction endonucleases *EcoRI* and *HindIII* and buffers (New England BioLabs, Inc., Beverly, Mass.)
13. Molecular size standards (New England BioLabs, Inc.); use *EcoRI* or *HindIII* digests of bacteriophage lambda

14. 3 M sodium acetate (autoclave)
15. Lysozyme stock (1 mg/ml [Applied Microbiology, New York, N.Y.])
16. Lysozyme stock (20 mg/ml)
17. RNase A stock solution (10 mg/ml [New England BioLabs, Inc.])
18. RNase dilution buffer (New England BioLabs, Inc.): 1 M Tris (pH 8.0), 1 M Tris (pH 7.0), 4 M NaCl
19. Dye mixture: 20 mM EDTA, 50% glycerol, 0.1% bromophenol blue, 1% xylene cyanol
20. 10× TBE buffer: Tris base, boric acid, Na₂EDTA

B. Working solutions

Indicate the expiration date on the label and in the work record or on the manufacturer's label. Working solutions are made from stock solutions and are stable for 1 year at room temperature.

1. TES-SDS: 100 mM Tris, 70 mM EDTA, 50 mM NaCl, and 1.5% SDS
2. TES-sucrose: 100 mM Tris, 70 mM EDTA, 50 mM NaCl, and 5% sucrose

III. MATERIALS (*continued*)

3. 0.375 M EDTA, pH 8.0
4. TE buffer (10:0.1): 10 mM Tris and 0.1 mM EDTA
5. 0.4% SDS–0.4 N NaOH
6. RNase A working solution. Dilute RNase A stock solution 1:100 in 10 mM Tris (pH 7.5)–15 mM NaCl. Boil in water bath for 15 min. Cool gradually to room temperature. Aliquot, and store at -20°C .
7. Loading dye, 1:1 mixture. Mix the dye and 1% SDS in a 1:1 ratio.
8. Loading dye, 1:1:4 mixture. Mix 1 part dye mixture, 1 part 1% SDS, and 4 parts distilled water.
9. DNA wash solution: 10 mM Tris, 100 mM EDTA, 75 mM sodium acetate

C. Supplies and equipment

1. Power supply
2. Gel box for electrophoresis
3. Microcentrifuge
4. Microcentrifuge tube (1.5 ml) (supplier not critical)
5. Shaking water bath or shaking platform in incubator
6. Vacuum line or vacuum unit (for aspiration of liquids)
7. Transilluminator (mid-range UV)
8. Camera unit (e.g., Polaroid MP-4 or handheld Polaroid-type Fodyne FCR-10)

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. Verify that all materials and reagents meet expiration date and QC parameters per NCCLS document M22-A2 (1).
- B. A staphylococcal strain of known plasmid content should be run in parallel with each screening procedure. *S. aureus* SM818-73 and coagulase-negative strain SM734-41 are available from one of the authors (M. A. Pfaller) of this procedure as controls.

V. PROCEDURE**A. DNA preparation**

1. Using three to five well-isolated colonies, inoculate one tube of growth medium for each test and control strain to be screened. For *S. aureus*, use 10 ml of TSB; for coagulase-negative staphylococci, use 20 ml of MHB divided into two 10-ml cultures (for convenience in processing).
2. Incubate with shaking at 37°C for 16 to 24 h.
3. Centrifuge broth for 15 min at $7,000 \times g$, and remove supernatant by aspiration.
4. Suspend cells in 1 ml of sterile saline, and transfer them to a sterile 1.5 ml microcentrifuge tube (supplier not critical).
5. Centrifuge at top speed ($12,000 \times g$) for 15 s. Carefully aspirate supernatant.
6. Suspend cells in 100 μl of TES-sucrose. For *S. aureus*, add 50 μl of dilute lysostaphin. Make dilute lysostaphin by mixing 5 μl of lysostaphin stock with 45 μl of TES-sucrose. For coagulase-negative staphylococci, add 15 μl of lysostaphin stock and 50 μl of lysozyme stock. Mix well.
7. Incubate tubes in water bath at 37°C for 20 min for *S. aureus* and 60 min for coagulase-negative staphylococci.
8. Add 50 μl of 0.375 M EDTA (pH 8.0) to each tube. Mix by inverting the tube 10 to 15 times. Solution may become very viscous.
9. Incubate on ice for 15 min.
10. Add 100 μl of TES-SDS (SDS must be in solution with no precipitate). Mix by inverting the tube 10 to 15 times.
11. Place on ice for at least 30 min. Hold for additional time if necessary.
12. Centrifuge at $12,000 \times g$ for 15 min. Use of a refrigerated microcentrifuge or a centrifuge located in a cold room is optimal but not mandatory. Centrifugation at room temperature will also work.

V. PROCEDURE (*continued*)

13. Remove 300 μ l of supernatant, and place it in a new microcentrifuge tube. Avoid the pellet and any viscous material. If less than 300 μ l is available, make up difference with TES-sucrose. Discard pellet in appropriate bio-safety container.
14. Add 150 μ l of 0.4% SDS–0.4 N NaOH. Mix by inverting the tube 10 times. Quickly place on ice for 5 min.
15. Add 150 μ l of 3 M sodium acetate (pH 5.4), and invert the tube 10 times. Return to ice quickly, and incubate for 60 min or longer.
16. Centrifuge at $12,000 \times g$ for 15 min. Remove supernatant to a fresh tube. Avoid white pellet. Discard pellet in appropriate biosafety container.
17. Add 1 ml of 95% cold ethanol to supernatant. Mix by inverting the tube 20 times, until contents are well mixed. This can be stored overnight at -20°C .
18. Centrifuge at $12,000 \times g$ for 30 min. (Shorter centrifugation times will reduce yield.) Remove supernatant by aspiration with drawn-glass pipette, taking care to save the pellet (may be difficult to see).
19. Suspend pellet in 500 μ l of DNA wash solution. Incubate at 37°C for 20 min. Vortex gently (low setting) at 10 min and again at 20 min.
20. Centrifuge at $12,000 \times g$ for 10 min.
21. Transfer supernatant to a new microcentrifuge tube containing 1 ml of cold 95% ethanol. Mix by inverting the tube 20 times. This mixture can be stored overnight at -20°C .
22. Centrifuge at $12,000 \times g$ for 30 min and remove supernatant, taking care to save the pellet. Centrifuge an additional 5 min, and aspirate remaining ethanol.
23. Dry under vacuum for 30 min. This is sufficient time for 20 to 30 tubes.
24. Remove 3 μ l of plasmid preparation, and combine it with 10 μ l of the 1:1:4 dye mixture. Electrophorese through an agarose gel to screen for whole-plasmid DNA. Electrophoresis times will vary depending on the size of the gel and the apparatus used. Alternatively, the samples can be stored at -20°C . DNA is stable in a -20°C non-frost-free freezer (defrosting cycle is hard on DNA samples) for approximately 6 months.

B. Restriction analysis of plasmid DNA

1. Place 3 μ l of the plasmid preparation in each of two fresh tubes for restriction enzyme digestion (one with *EcoRI*, the other with *HindIII*), and store the remainder at -20°C .
2. To the 3- μ l DNA sample add the following: 4.5 μ l of sterile water; 1.0 μ l of $10\times$ restriction buffer, per manufacturer; 1.0 μ l of RNase A working solution; and 0.5 μ l of restriction enzyme (*EcoRI* or *HindIII*).
3. Centrifuge at $12,000 \times g$ for 15 s. Place in 37°C water bath for 2 h. Add 3 μ l of the 1:1 mixture of SDS and dye.
4. Prepare 0.7% agarose gel by using $1\times$ TBE buffer. Load the entire 13- μ l sample into a well of the gel. Use a *HindIII* or *EcoRI* digest of phage lambda loaded onto a separate well as molecular size standards for restriction digests.
5. Electrophorese for 4 h at 100 V or for 1.5 h at 130 V (slower is better). The dark blue dye should move >3 cm. Photograph using a mid-range (260 nm) transilluminator and orange filter (Kodak 22A Wrattan or equivalent).

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

A report of the results of plasmid analysis, detailing which isolates are related or distinct, should be issued to the service that generated the request for typing (*see* legend to Fig. 12.4.3–1 for an example). Photographs of the results may accompany the report at the discretion of the laboratory.

VII. INTERPRETATION

One of the most difficult aspects of interpreting plasmid patterns is determining whether there was adequate lysis of the cells during the protocol to provide DNA for analysis. In preparations with no detectable plasmid DNA, small amounts of chromosomal DNA must be present for the preparation to be considered adequate for analysis. If no chromosomal DNA is present (it usually appears as a faint smear in the molecular size range of 12 to 15 kb) and no plasmid DNA is detectable, repeat the procedure.

Two or more isolates are presumed to be the same strain if all of the bands in both the *Hind*III and *Eco*RI restriction digests are identical. If multiple bands do not match between isolates, they are presumed to represent different strains.

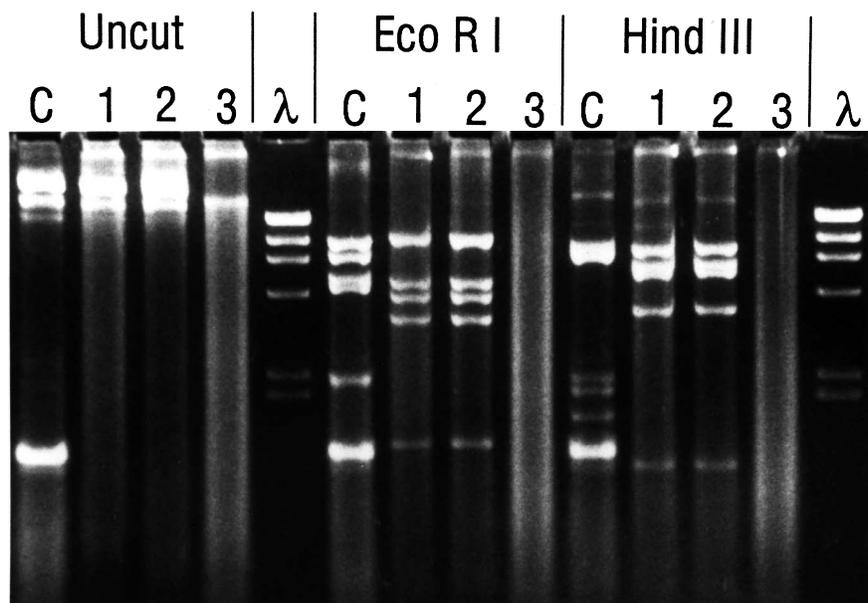

Figure 12.4.3–1 *S. aureus* plasmid DNA preparations. Uncut, undigested plasmid DNA; *Eco*RI, DNA digested with *Eco*RI; *Hind*III, plasmid DNA digested with *Hind*III. Lanes: C, control strain SM818-73; 1, 2, and 3, isolates collected from a single patient. Isolate 3 does not have detectable plasmid DNA. The report for this group of isolates stated, “Based on restriction endonuclease analysis of plasmid DNA, these strains were grouped as follows: isolates 1 and 2 are identical to each other; isolate 3 is not related to isolates 1 and 2.”

12.4.4

Method for Ribotyping by Using a Chemiluminescent Probe

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Ribotyping was first described in 1986 by Grimont and Grimont (1), and since that time it has emerged as one of the most powerful tools of molecular epidemiology. Ribotyping involves the use of Southern blot analysis to detect polymorphisms in the chromosomal regions containing the rRNA genes. Classic ribotyping uses labeled probes containing *Escherichia coli* 16S and 23S rRNA sequences. Both the nature of the probe and

the mode of labeling, however, may vary. Ribotyping has three main advantages: (i) the genes coding for rRNA are highly conserved, allowing for the use of a single probe to subtype all eubacteria; (ii) because most bacteria contain multiple rRNA genes, a reasonable number of bands are obtained after probing; and (iii) all strains have rRNA genes. The availability of chemiluminescent labeling techniques and the recent development of an

automated ribotyping system (3, 5, 6) make ribotyping more feasible for the investigation of nosocomial outbreaks by the clinical laboratory.

■ **NOTE:** This procedure has been adapted from that of Gustafsson (2) and Stull and LiPuma (8). The method described is optimized for *Staphylococcus aureus* but can also be used for ribotyping other gram-positive and gram-negative bacteria (1–3, 5–8).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Most organisms grown on a nonselective agar medium for 18 to 24 h will yield chromosomal DNA for this procedure.

III. MATERIALS

A. Reagents

■ **NOTE:** Unless otherwise stated, all reagents are available from Sigma Chemical Co., St. Louis, Mo.

1. Lysostaphin (500 U/ml)
2. 10% Bleach
3. Denhardt's solution
4. Chondroitin sulfate A
5. Bromophenol blue
6. Proteinase K (20 mg/ml)
7. RNasin RNase inhibitor
8. High-pressure liquid chromatography (HPLC) water
9. Enhanced chemiluminescence (ECL) kit (Amersham, Arlington Heights, Ill.)
10. 16S and 23S rRNA from *E. coli* MRE600
11. Restriction endonucleases (individualized for each organism; available from New England BioLabs Inc., Beverly, Mass.)

12. BHI broth or other appropriate liquid medium
13. TES buffer: 0.01 M Tris (pH 8), 0.1 M NaCl, 0.001 M EDTA
14. 50× TAE buffer: 242.2 g of Tris base, 57.15 ml of 17.5 M glacial acetic acid, 100 ml of 0.5 M EDTA, water to make up 1 liter (pH 8.5)
15. Denaturation solution: 1.5 M NaCl, 0.5 M NaOH
16. Depurination solution: 250 mM HCl
17. Neutralization solution: 1 M Tris-HCl (pH 8.0), 1.5 M NaCl
18. Phenol
19. Chloroform
20. Isoamyl alcohol

III. MATERIALS (continued)

21. Prehybridization buffer: 25 mM KH_2PO_4 (pH 7.4), $5\times$ SSC ($1\times$ SSC is 0.15 M NaCl plus 0.015 M sodium citrate), $5\times$ Denhardt's solution, 50 μg of salmon sperm DNA per ml, 6 M urea, diethyl pyrocarbonate (DEPC)-treated water
 22. Hybridization buffer: 6 M urea, 1.1% sodium dodecyl sulfate (SDS), $0.5\times$ SSC, DEPC-treated water
 23. Secondary wash buffer: $2\times$ SSC, DEPC-treated water
 24. Electrophoresis loading buffer: 27 ml of glycerol, 3 ml of $10\times$ TAE buffer, 0.1% (wt/vol) SDS, 10 ml of 0.5 M EDTA (pH 8.0), 10 mg of bromophenol blue, water to make up 100 ml
 25. Glutaraldehyde
 26. Agarose
 27. Ethidium bromide
 28. 5 M NaCl
 29. 70 and 100% ethanol
- B. Supplies**
1. Cellophane (any brand)
 2. Nitrocellulose membrane
 3. Gel blot paper
 4. Nylon mesh
 5. X-ray film
 6. Scissors
 7. Forceps
 8. Eppendorf tubes (1.5 ml)
- C. Equipment**
1. Agarose gel electrophoresis apparatus
 2. Power supply
 3. UV transilluminator and photodocumentation setup
 4. Autoradiograph cassettes and intensifying screens
 5. Vacuum desiccator
 6. Vacuum oven
 7. Microcentrifuge
 8. Block heater (60°C)

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. Verify that all materials and reagents meet expiration date and QC parameters per NCCLS document M22-A2 (4).
- B. A standard control strain of the same species, if available, should be prepared along with the test strains.
- C. The use of molecular typing tests to identify related strains is most effective if a group of appropriate epidemiologically unrelated control organisms can be prepared and compared with the isolates in question. Appropriate control strains include the following.
 1. Identical species isolated in the same unit on different dates
 2. Identical species isolated on the same date in different units

V. PROCEDURE**A. DNA preparation**

1. Methods for extraction of genomic DNA from *S. aureus* are outlined below.
2. Inoculate one colony into 4 ml of broth, and incubate overnight at 35°C.
3. Pipette 1 ml of the sample into each of three 1.5-ml Eppendorf tubes, and centrifuge for 5 min at $14,000\times g$ in a microcentrifuge.
4. Wash pellet once with TES buffer, vortex, and pellet for 5 min at $14,000\times g$. Discard supernatant into 10% bleach. Suspend pellet in 200 μl of TES buffer by vortexing.
5. Add 10 μl of lysostaphin to the cell suspension, vortex, and incubate at 37°C for 30 min.
6. Add 20 μl of SDS and 1.2 μl of proteinase K, and incubate in a 60°C block heater for 1 to 2 h.
7. Extract genomic DNA with two phenol-chloroform-isoamyl alcohol (25:24:1) extractions (230 μl) followed by one chloroform-isoamyl alcohol extraction (230 μl).
8. Precipitate the DNA by adding 1/25 volume of 5 M NaCl and 2.5 volumes of cold 100% ethanol to the aqueous layer of the final extraction. Mix by inverting the tube four or five times. Store at -20°C for 30 min.

V. PROCEDURE (*continued*)

9. Centrifuge at $14,000 \times g$ for 10 min, wash the pellet with 70% ethanol, and centrifuge again ($14,000 \times g$ for 10 min).
10. Dry the pellet in a vacuum oven at 60°C. Resuspend it in 20 μ l of HPLC-grade water. After resuspension, consolidate all three samples from the same isolate.

B. DNA restriction

1. Restriction enzymes must be individualized for each organism. The enzymes *Xba*I, *Hind*III, *Kpn*I, and *Eco*RI have been used successfully to identify strains of *S. aureus*.
2. Using a UV spectrophotometer, determine the A_{260} and A_{280} of the extracted DNA. Calculate the A_{260}/A_{280} ratio to determine the purity of the DNA sample. This ratio should be 1:8 or greater. If it is less than 1:8, the DNA should be reextracted and precipitated.
3. Determine the amount of DNA present by using the A_{260} .
4. Dilute 4 μ g of test and control DNA to a total volume of 18 μ l. Add 2 μ l of $10\times$ restriction buffer. Add 2 to 10 U of restriction enzyme, mix, and digest as recommended by the manufacturer.
5. Prepare a 1% agarose gel in $1\times$ TAE buffer. Electrophoretically separate the restricted DNA in TAE buffer for 4 h at 100 V.
6. Stain the gel with ethidium bromide, and visualize the restriction products by using a UV-light box.
7. Depurinate, denature, and neutralize the gel by soaking with gentle shaking in depurination and denaturation buffer for 15 min each and neutralization buffer for 30 min. Rinse the gel with distilled water twice between each buffer. Transfer the DNA to a nitrocellulose membrane by Southern blotting overnight.
8. Soak the nitrocellulose membrane (blot) in $6\times$ SSC for 5 min. Allow it to air dry. Sandwich it between sheets of fresh Whatman 3MM paper, and bake it at 80°C under vacuum for 2 h.

C. Labeling of probe

■ **NOTE:** The ECL kit is designed to label DNA. To label RNA used as a probe in this typing method, the following protocol should be followed in place of the kit instructions.

1. Dilute 1 μ l of 16S–23S rRNA from *E. coli* MRE600 (4 μ g/ml) with 399 μ l of kit water in a 1.5-ml microcentrifuge tube (final concentration, 10 ng/ μ l).
2. Boil the mixture for 2 min in a water bath, and then snap-cool it in an ice-water bath for 5 min. Centrifuge briefly to settle contents to bottom.
3. Add 400 μ l of DNA-labeling reagent and mix gently. Add 400 μ l of glutaraldehyde solution and mix gently.
4. Incubate at 37°C for 10 min. Add 30 U of RNasin RNase inhibitor, mix well, and immediately place on ice.
5. Store the labeled probe in 50% glycerol in a 1.5-ml microcentrifuge tube at -20°C (equal volumes of probe and glycerol).

D. Hybridization

■ **NOTE:** The hybridization buffer supplied in the ECL kit must not be used. All solutions must be prepared with DEPC-treated water.

1. Roll the blot into a nylon mesh with the DNA surface facing inward. Place it in a hybridization tube. Prehybridize the blots at 40°C in prehybridization buffer (0.125 ml per cm^2 of nylon mesh) in a hybridization oven.
2. After 3 h, discard the prehybridization buffer and replace it with hybridization buffer. Add 20 ng of probe per ml of hybridization buffer. Do not pipette the probe directly onto the blot.
3. Hybridize for 5 h at 40°C.
4. Wash the blot twice in primary wash buffer for 20 min each at 40°C.

V. PROCEDURE (*continued*)

5. Remove the blot from the tube and place it in a clean container. Wash it twice in secondary wash buffer for 5 min at room temperature with gentle agitation.

E. Detection

1. Prepare a tray containing the following items: scissors, forceps, blotting paper, detection reagents 1 and 2 (at 4°C and separate until use), washed blot in secondary wash buffer, cassette and X-ray film, cellophane, and timer.
2. Working as quickly as possible in a darkroom, with the lights on, remove the blot from the wash buffer with forceps. Drain off excess reagents. Place the blot on the tray. Mix equal amounts (~10 ml) of each detection reagent, and pour the mixture onto the blot. Incubate for exactly 1 min.
3. Drain off excess reagents, and lay the blot on a piece of blot paper for 10 s to absorb excess moisture. Cover the blot with cellophane and place it in the cassette with the DNA side up. Smooth out all air bubbles.
4. Turn off the lights. Place the film in the cassette (clip off a corner to mark the orientation). Obtain a 1-min exposure.

F. Procedure notes

1. The sensitivity of chemiluminescent ribotyping is directly related to the amount of DNA analyzed in each reaction. Underloaded lanes will require longer exposure times. Luminescence persists for 3 to 7 h.
2. Labeled probe has been used successfully for up to 3 months when stored at -20°C in 50% glycerol.
3. Molecular size standards can also be labeled with the ECL kit to provide convenient determination of molecular weights.
4. The chemiluminescent ribotyping procedure has been completely automated. The instrumentation and ribotyping kits are available commercially from Qualicon, Wilmington, Del.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

A report of the results of ribotyping that details which isolates are indistinguishable (clonal), similar (subtypes), or different should be issued to the service that generated the request for typing.

VII. INTERPRETATION

- A. Figure 12.4.4-1 shows examples of ribotype patterns of *S. aureus*.
 - B. Strains with indistinguishable ribotype patterns are considered to be clonal.
 - C. Strains with one or two band shifts are also considered to be clonally related subtypes.
 - D. Strains that differ by more than three bands are considered independent strains.
- **NOTE:** Isolates with indistinguishable or highly related ribotype patterns (one to three band differences) may require further analysis by pulsed-field gel electrophoresis or some other highly discriminative technique for optimum strain delineation.

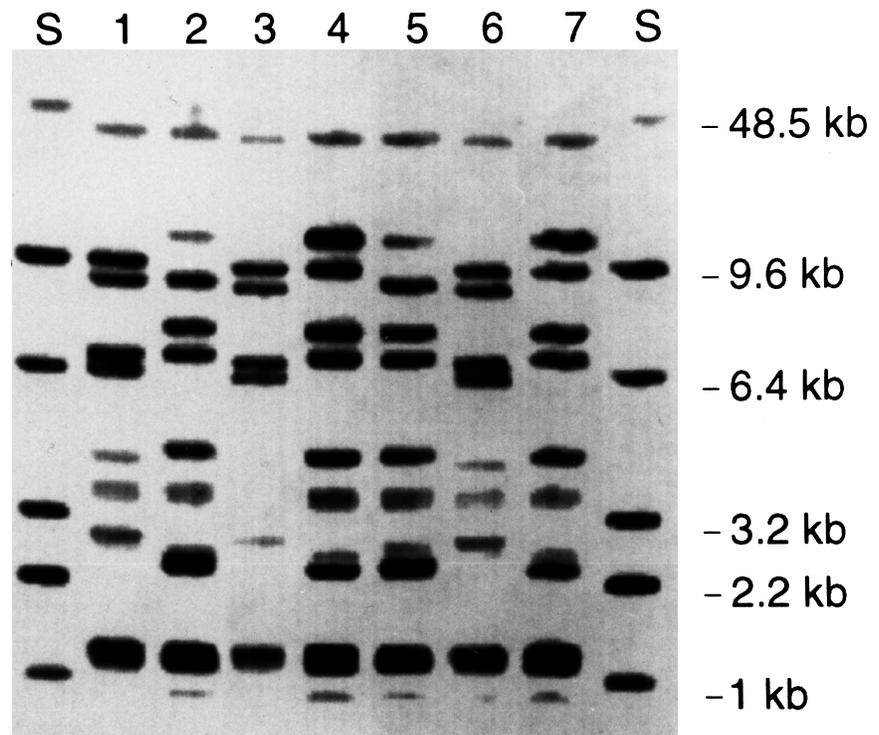

Figure 12.4.4-1 Ribotype profiles of *S. aureus* isolates. Lanes: S, molecular size standards; 1 and 6, ribotype A; 2 and 5, ribotype B; 3, ribotype C; 4 and 7, ribotype D. Figure from **H. D. Isenberg (ed.)**. 1998. *Essential Procedures for Clinical Microbiology*. ASM Press, Washington, D.C.

12.4.5

Chromosomal Restriction Fragment Analysis by Pulsed-Field Gel Electrophoresis: Application to Molecular Epidemiology

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Chromosomal restriction fragment analysis is based on the fact that chromosomes are not static and can undergo both rearrangements and point mutations. Changes in nucleotide sequence are reflected in the restriction endonuclease patterns of chromosomal DNA when the fragments are separated on agarose gels. Physical characterization of bacterial and fungal DNA at the genomic level has been limited by (i) the difficulty in obtaining suitable fragments of chromosomal DNA because of the shearing of large DNA molecules in

solution and (ii) the inability of conventional (constant-field) agarose gel electrophoresis to resolve DNA molecules in an appropriate size range (40 to 4,000 kbp). These constraints have been overcome by the development of techniques for (i) preparing unit length chromosomal DNA by the in situ lysis of organisms embedded in agarose and subsequent digestion of the DNA directly in the agarose with restriction enzymes that have infrequent recognition sites and (ii) resolving the resulting large DNA fragments in agarose gels by

alternation of electric fields by a technique known as pulsed-field gel electrophoresis (PFGE). Thus, total genomic DNA can be resolved into a limited number of restriction fragments with distinct electrophoretic mobilities. PFGE has been shown to be highly effective in molecular epidemiologic studies of bacterial and yeast isolates.

■ **NOTE:** This procedure addresses the use of PFGE for typing bacterial isolates and has been adapted from Maslow et al. (1) and Pfaller et al. (3).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Most organisms grown on a nonselective agar or broth medium for 18 to 24 h will yield chromosomal DNA for the procedure.

III. MATERIALS

A. Reagents

■ **NOTE:** Unless otherwise stated, all reagents are available from Sigma Chemical Co., St. Louis, Mo.

1. InCert agarose (low melting temperature) (FMC BioProducts, Rockland, Maine)
2. SeaKem agarose (high melting temperature) (FMC BioProducts)
3. Ethidium bromide
4. Restriction endonucleases (individualized for each organism; available from New England BioLabs, Beverly, Mass.)
5. 10× restriction buffers as provided by manufacturer (New England BioLabs)
6. Molecular size standards, 48.5-kbp lambda ladder molecular size standards (New England BioLabs)
7. Brij 58 (polyoxyethylene 20 cetyl ether)

8. Sodium deoxycholate
9. Sodium lauroyl sarcosine
10. RNase A (molecular biology grade)
11. Lysostaphin
12. Lysozyme
13. Proteinase K
14. PIV buffer: 10 mM Tris (pH 7.6), 1 M NaCl (total volume, 500 ml; autoclave, and store at 4°C)
15. Lysis buffer: 6 mM Tris (pH 7.6), 1 M NaCl, 100 mM EDTA (pH 7.6), 0.5% Brij 58, 0.2% sodium deoxycholate, 0.5% sodium lauroyl sarcosine (total volume, 100 ml; filter sterilize, and store at 4°C)
16. Lysis solution: 20 µg of RNase per ml, 1 mg of lysozyme per ml, 5 U of lysostaphin per ml (add enzymes to lysis buffer just before use)

III. MATERIALS (*continued*)

17. ES buffer: 0.5 M EDTA (pH 8.0), 10% sodium lauroyl sarcosine (total volume, 500 ml; filter sterilize and store at room temperature)
18. ESP solution: 100 µg of proteinase K per ml of ES buffer (total volume, 100 ml; store at 4°C) (20× proteinase stock solution: 100 mg of proteinase K in 50 ml of ES buffer; incubate at 50°C for 1 h and store at 4°C [this solution is highly stable])
19. 1× TE buffer: 10 mM Tris (pH 7.6), 0.1 mM EDTA (pH 7.6) (total volume, 500 ml; autoclave, and store at room temperature)
20. Lysostaphin buffer: 50 mM Tris (pH 7.6), 0.15 M NaCl (total volume, 50 ml; autoclave, and store at room temperature)
21. 10× TBE buffer: Tris base, boric acid, Na₂EDTA

B. Supplies

1. Snap-top tubes (15 ml)
2. Snap-top tubes (5 ml)
3. Round-bottom tubes, screw cap (15 ml)

4. Six-well tissue culture plate
5. Insert mold
6. Glass tray (20 by 30 cm), metal tray (15 by 25 cm)

C. Equipment

1. Orbital shaker
 2. Incubators at a variety of temperatures (25, 37, and 50°C)
 3. Vacuum line for aspiration of liquids
 4. Camera unit for photodocumentation
 5. Transilluminator, mid-range UV
 6. Test tube roller
 7. Heating platform
 8. Pulse-field gel box, pump, gel molds, cooling water bath, power supply, pulse wave switches
- **NOTE:** Electrophoresis conditions specified in this procedure require the CHEF-DRII system from Bio-Rad with their MiniChiller. However, other forms of PFGE apparatus may be used.

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. A standard control strain of the same species, if available, should be prepared along with every preparation as a control for the DNA isolation procedures.
- B. The use of molecular typing tests to identify related strains is most effective if a group of appropriate epidemiologically unrelated control organisms can be prepared and compared to the isolates in question. Appropriate control strains would be as follows
 1. Identical species isolated in the same unit on different dates
 2. Identical species isolated on the same date in different units
- C. The many points to be checked are as follows.
 1. All lanes should have electrophoresed more or less straight.
 2. The restriction digests should be complete. A complete digest will have few if any dim bands located above or between bright bands in the same lane. Bright and dim are relative terms and apply only within the context of the same region of one lane. An incomplete (or partial) digest will have one or more dim bands located above or between bright bands in the same lane.
 3. The DNA in all lanes should have digested and have visible bands. Usually, all strains of the same species will have about the same number of bands with the same size distribution for any given restriction enzyme and running conditions.
 4. If any of the above conditions are not met, then some or all of the samples must be retested. Sometimes the plugs do not digest, and the failed samples need to be prepared again.
- D. DNA size standards
 1. *Staphylococcus aureus* ATCC 8325 digested with *Sma*I
 2. The chromosomes of *Saccharomyces cerevisiae* (Bio-Rad Laboratories, Richmond, Calif.)
 3. Lambda ladder (48.5 kbp)

IV. QUALITY CONTROL (continued)

- E. Verify that all materials and reagents meet expiration date and QC parameters per NCCLS document M22-A2 (2).

V. PROCEDURE

A. Sample preparation

1. For each strain, inoculate a single colony into 0.5 ml of broth (TSB).
2. Grow for 2 h or until turbid.
3. Streak out onto an agar plate, and incubate overnight (ON).
4. Pick a single colony, inoculate 5 ml of broth, and incubate ON.
5. Prepare the plugs on day 1.
 - a. Mix InCert agarose (1.3% [wt/vol]) in PIV buffer in a 15-ml tube. Prepare 1 ml per strain (plus 1 ml extra), vortex, and place into a beaker of boiling water to dissolve. Revortex prior to aliquoting.
 - b. For each strain, label one 15-ml snap-top tube, one 5-ml snap-top tube, and one 15-ml round-bottom tube.
 - c. For each strain, label one plug mold. Then tape the bottom of the plug molds, place them in a metal tray, put this tray in a glass tray filled with ice, and place it in the refrigerator for at least 30 min.
 - d. Put 5 ml of cold PIV buffer into each 15-ml snap-top tube and place on ice.
 - e. Carefully dispense 1 ml of dissolved agarose into each 5-ml snap-top tube, and keep the tubes in a 50°C heat block.
 - f. Dispense 1.5 ml of the ON culture into each 15-ml snap-top tube with cold PIV buffer.
 - g. Centrifuge the 15-ml snap-top tubes at $1,100 \times g$ for 15 min at 4°C.
 - h. Decant the PIV buffer from the cell pellet, suspend the cells thoroughly in 1.5 ml of cold PIV buffer, and place on ice.
 - i. Add 1 ml of cells in PIV buffer to the 5-ml snap-top tube with 1 ml of molten InCert agarose, and vortex the tube lightly.
 - j. Working quickly, dispense 105 μ l of the mixture into each well of the plug molds.
 - **NOTE:** The final concentration of organisms is $\sim 10^9$ CFU/ml. Since 1 CFU contains $\sim 10^{-14}$ g of DNA, each plug has ~ 1 μ g of DNA.
 - k. Keep the molds in the tray on ice, and place at 4°C for 30 min to solidify.
6. Lyse the plugs on days 2, 3, and 4.
 - a. Make fresh lysis solution by adding RNase and lysozyme (for gram-negative bacteria) or lysostaphin and lysozyme (for gram-positive bacteria) to stock lysis buffer.
 - (1) RNase stock solution: dissolve RNase at 10 mg/ml in sterile water, heat in boiling water for 20 to 30 min, dispense 100 μ l per microcentrifuge tube, and store at -20°C .
 - (2) Lysozyme stock solution: dissolve 0.5 g of lysozyme in 10 ml of sterile water (final concentration, 50 mg/ml), dispense 200 μ l per microcentrifuge tube, and store at -20°C .
 - (3) Lysostaphin stock solution: dissolve 5,000 U of lysostaphin in 10 ml of lysostaphin buffer, dispense 200 μ l per microcentrifuge tube, and store at -20°C .
 - b. Dispense 4 ml of lysis solution into each labeled 15-ml round-bottom tube.
 - c. For each strain, push out the 12 plugs into the tube with lysis solution.
 - d. Incubate ON at 37°C with gentle shaking.
 - e. Chill the tubes on ice for at least 15 min to harden the plugs.
 - f. Carefully aspirate the lysis solution.

V. PROCEDURE (*continued*)

- g. Dispense 4 ml of ESP solution into each tube, and incubate ON at 50°C, shaking gently.
- h. Chill the tubes. Change to fresh ESP solution, and again incubate ON at 50°C.
- i. The plugs can now be used directly for restriction enzyme digestion as outlined below or can be placed in fresh ESP solution and stored at 4°C (stable for up to 2 years).

B. Restriction enzyme digestion

- ☑ Perform steps V.B.1 and 2 on day 1 of restriction enzyme digestion.
 - 1. Turn on a water bath at the temperature appropriate for the restriction enzyme.
 - 2. Wash the plugs in 10 ml of 1 × TE buffer at 37°C on a roller. Four washes are required, at least two of which should be a minimum of 2 h; the others should be at least 1 h. For convenience, one of the washes can continue ON.
- ☑ Perform steps V.B.3 through 6 on day 2 of restriction enzyme digestion.
 - 3. Complete the TE buffer washes, if necessary.
 - 4. For each plug, prepare a labeled microcentrifuge tube containing 10× restriction enzyme buffer and bovine serum albumin (final concentration, 100 µg/ml); add water to a final volume of 250 µl.
 - 5. Add a washed plug to the tube.
 - 6. Add restriction enzyme (2 to 10 U, per manufacturer), mix gently, and incubate ON at the appropriate temperature. See Table 12.4.5–1 for restriction endonucleases appropriate for some species.
- ☑ Perform steps V.B.7 through 11 on day 3.
 - 7. Chill the tubes before handling the inserts.
 - 8. Pour out a plug into a labeled well of a six-well tissue culture plate. Save the plate.
 - 9. Add 1 ml of ES buffer to a microcentrifuge tube and put the plugs into the tube.
 - 10. Incubate the tube at 50°C for 2 h.
 - 11. Pour out the plug into the same tissue culture plate well as above (step V.B.8). Add 300 µl of ESP solution to each tube. Replace the plug into the tube and store at 4°C.

C. Gel preparation, loading, and electrophoresis

- 1. Make the gel with SeaKem high-melting-temperature agarose (1% [wt/vol]) dissolved in 0.5× TBE buffer. Wash the gel ON in 0.5× TBE buffer.
- 2. By using a glass coverslip or surgical blade, cut a slice ~1 mm thick off the end of the plug, and load it into a well of the gel.
- 3. Fill all the wells with agarose, and place the gel in a PFGE box with 0.5× TBE buffer.
- 4. Run the gel in accordance with the manufacturer's recommendations for the equipment being used. See Table 12.4.5–2 for CHEF-DRII running conditions.
- 5. Store the remainder of the plug in ESP solution at 4°C in a microcentrifuge tube.

D. Gel visualization

- 1. Stain the gel for 30 min with ethidium bromide solution (0.5 µg/ml in water).
- 2. Rinse the gel with deionized water, and destain in water for at least 2 h.
- 3. Photograph under UV illumination.

Table 12.4.5-1 Suggested enzymes and running conditions for some species

Organism(s)	Enzyme	Fragment size range (kb) ^a	Running conditions ^b
<i>Acinetobacter</i> spp.	<i>Sma</i> I	50–250	C
<i>Citrobacter</i> spp.	<i>Spe</i> I	50–300	B/C
<i>Escherichia coli</i>	<i>Spe</i> I	50–300	B/C
	<i>Xba</i> I	50–400	B
<i>Enterobacter</i> spp.	<i>Spe</i> I	50–500	B
	<i>Not</i> I	100–700	A
<i>Enterococcus</i> spp.	<i>Sma</i> I	<50–250	C
<i>Klebsiella</i> spp.	<i>Spe</i> I	50–400	B
<i>Legionella pneumophila</i>	<i>Sfi</i> I	100–500	B
	<i>Asc</i> I	100–600	A
<i>Moraxella catarrhalis</i>	<i>Bgl</i> III	<50–100	C
	<i>Pme</i> I	50–250	C
<i>Neisseria meningitidis</i>	<i>Spe</i> I	50–250	C
	<i>Sfi</i> I	100–350	B/C
<i>Providencia</i> spp.	<i>Sfi</i> I	50–450	B
<i>Pseudomonas</i> spp.	<i>Spe</i> I	50–500	A
	<i>Dra</i> I	50–300	B/C
	<i>Xba</i> I	50–250	C
<i>Serratia</i> spp.	<i>Spe</i> I	50–450	B
	<i>Dra</i> I	<50–100	C
<i>Staphylococcus</i> spp.	<i>Sma</i> I	50–400	B
	<i>Eag</i> I	50–400	B
<i>Stenotrophomonas</i> spp.	<i>Xba</i> I	50–500	B
	<i>Spe</i> I	50–400	B
<i>Candida</i> spp.	<i>Sfi</i> I	300–800	A
	<i>Bss</i> III	100–600	A
	<i>Eag</i> I	50–500	A
	Karyotype (uncut)	500–2,000	D

^a Size range includes the majority of fragments created after digestion with the corresponding enzyme. Some species will have several fragments under 48.5 kbp; however, it is difficult to analyze them when the 48.5-kbp lambda ladder molecular size standard is used. In order to analyze those fragments, use *Hind* III-cut lambda as a molecular size standard and/or a lower switch time, such as 5 to 15 s.

^b See Table 12.4.5-2.

Table 12.4.5-2 Examples of running conditions^a

Running condition	Agarose concn (%)	Switch time(s)		Time (h)	Run (V/cm)	Range of band sizes best separated (kb)	Largest band resolved (kb)
		Initial	Final				
A	1.0	10.0	90	24	6.0	100–650	776.0
B	1.0	5.0	60	23	6.0	50–500	630.5
C	1.0	5.0	30	23	6.0	<50–350	436.5
D	0.7	120	280	48	4.5	500–2,000	2,000

^a All electrophoretic conditions are at 13°C.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

A report of the results of PFGE typing that details which isolates are indistinguishable (clonal), similar (subtypes), or different should be issued to the service that generated the request for typing.

VII. INTERPRETATION

- A. Examples of chromosomal-DNA patterns of *S. aureus* and *Stenotrophomonas maltophilia* are shown in Fig. 12.4.5-1 and 12.4.5-2.
- B. Strains with identical PFGE patterns are considered to be clonal.
- C. Strains with one to three band shifts consistent with a single genetic event (e.g., a point mutation resulting in the loss or gain of a restriction site, an insertion, a deletion, or a chromosomal inversion) are also considered to be clonally related subtypes (Fig. 12.4.5-2).
- D. Strains that differ at four or more bands are considered independent strains, although strains with multiple similarities may have a common ancestry.

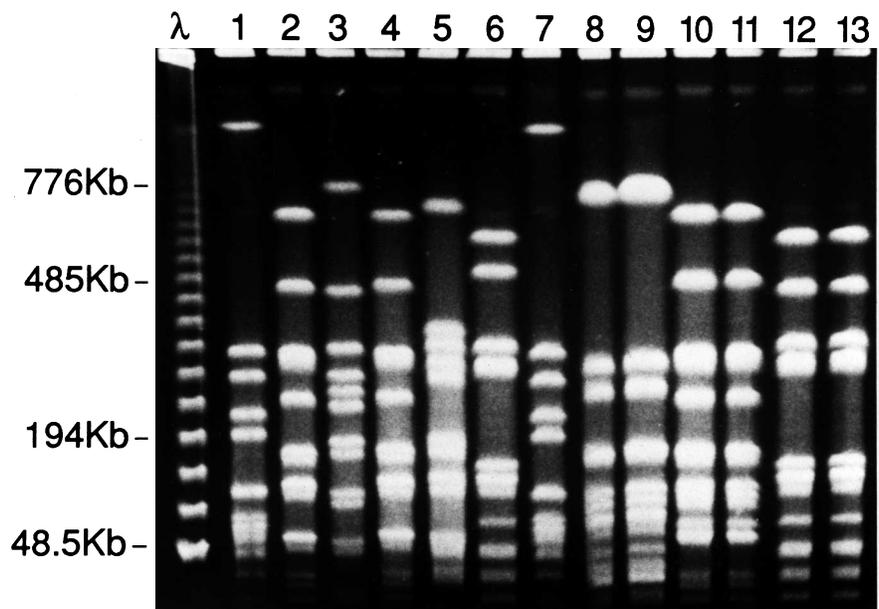

Figure 12.4.5-1 Restriction fragment length polymorphism of *S. aureus* chromosomal DNA digested with *Sma*I. Switch time ramped from 10 to 90 s (running condition A [Table 12.4.5-2]). Lanes 1 through 7 show different patterns. Lanes 8 and 9, 10 and 11, and 12 and 13 represent three pairs of indistinguishable patterns. This photo was kindly provided by Andreas Widmer.

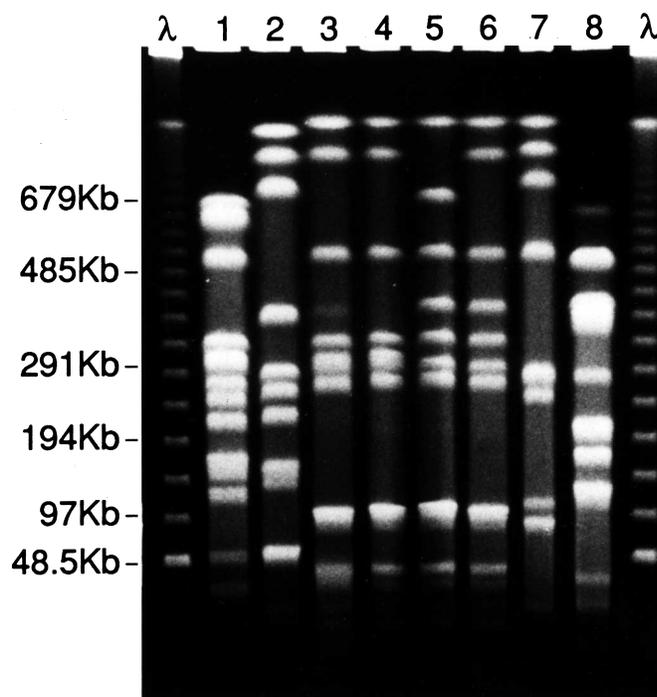

Figure 12.4.5–2 Restriction fragment length polymorphism of *S. maltophilia* chromosomal DNA digested with *SpeI* (running condition A [Table 12.4.5–2]). Lanes 3 and 4 show identical patterns, while the patterns in lanes 5 and 6 are similar but not identical and represent subtypes of a single strain.

12.4.6

Characterization of Pathogenic Microorganisms by Genomic Fingerprinting with Arbitrarily Primed PCR

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Genomic fingerprinting by arbitrarily primed PCR (AP-PCR) is a method for sampling homologous sequences of related pathogens in such a way that small sequence differences are observed. Primers are chosen arbitrarily and annealed (hybridized) to the genome at low stringency (low temperature and high salt con-

centration). Subsequent PCR results in the amplification of sequences bounded by these low-stringency annealing events. The products are then arrayed by electrophoresis to yield "fingerprints" which differ depending on the relatedness of the genomic templates. The more closely related

two genomic templates are, the more similar the resultant fingerprints will be. For very closely related but distinct templates, additional arbitrary primers can be used until a distinction is revealed.

■ **NOTE:** This procedure is adapted from Welsh and McClelland (2).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Most organisms grown on a nonselective agar or broth medium for 18 to 24 h will yield chromosomal DNA for this procedure.

III. MATERIALS

A. Reagents

■ **NOTE:** Unless otherwise stated, all reagents are available from Sigma Chemical Co., St. Louis, Mo.

1. TE buffer: 10 mM Tris (pH 8.0), 1 mM EDTA
2. PK solution: 1 mg of proteinase K per ml, 0.2 M EDTA, 1% *N*-lauroyl sarcosine, 0.1 M Tris (pH 8.0)
3. 10× *Taq* (Mg) buffer: 100 mM Tris (pH 8.3), 500 mM KCl, 40 mM MgCl₂
4. AP-PCR master: 500 μl of 10× *Taq* (Mg) buffer, 20 μl of 200 μM oligonucleotide primer, 200 μl of deoxyribonucleoside triphosphates (dNTP) (a 5 mM concentration of each dNTP), 3,730 μl of water, 25 μl of AmpliTaq (5 U/ml) (total volume, 4,500 μl) (New England BioLabs, Beverly, Mass.).

5. Oligonucleotide primers. The MB universal sequencing and reverse sequencing primers work well, but almost any primer ranging from 10 to 50 nucleotides in length will work (New England BioLabs).

6. Formamide dye: 10 ml of 98% deionized formamide, 10 mg of xylene cyanol, 10 mg of bromophenol blue, 200 μl of 0.5 M EDTA (pH 8.0)

7. Agarose (FMC BioProducts)

8. Ethidium bromide (10 mg/ml)

B. Equipment

1. Power supply
2. Electrophoresis chamber
3. UV transilluminator and photodocumentation equipment
4. 96-well thermal cycler with disposable tubes and racks
5. Multichannel Pipetman

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. A standard control strain of the same species, if available, should be prepared along with the test strains as a control for the DNA isolation and amplification procedures.
- B. The use of molecular typing tests to identify related strains is most effective if a group of appropriate epidemiologically unrelated control organisms can be prepared and compared to the isolates in question. Appropriate control strains are as follows.
 - 1. Identical species isolated in the same unit on different dates
 - 2. Identical species isolated on the same date in different units
- C. Verify that all materials and reagents meet expiration date and QC parameters per NCCLS document M22-A2 (1).

V. PROCEDURE**A. Specimen**

Use a fresh colony of the organism to be typed grown on suitable agar medium.

B. DNA sample preparation

- 1. Grow a 1- to 5-ml culture to late log phase or saturation in a 10-ml culture tube.
- 2. Pellet cells by low-speed centrifugation ($3,000 \times g$ for 10 min).
- 3. Suspend the cells in 5 ml of TE buffer, and repellet them.
- 4. Resuspend the cells in 0.2 ml of TE buffer and add 0.2 ml of PK solution.
- 5. Incubate the mixture at 50°C for 1 h to overnight, until the solution is clear.
- 6. Add 3 ml of TE buffer, and transfer 0.4 ml to a 1.5-ml centrifuge tube. Add 0.4 ml of phenol, vortex, and centrifuge briefly to separate the phases. Recover and save the aqueous phase. Add 0.4 ml of chloroform, vortex, and centrifuge briefly to separate phases. Recover and save the aqueous phase.
- 7. Add 1/10 volume of 3 M sodium acetate and 2 volumes of ethanol. Chill the mixture at -20°C . Pellet the DNA by centrifugation in a microcentrifuge.
- 8. Dry the pellet in a vacuum oven at 60°C, and dissolve the DNA in 100 μl of TE buffer.
- 9. Check the concentration of DNA by running several twofold serial dilutions on a 1% agarose gel and comparing the ethidium bromide fluorescence of the DNA with a molecular mass standard (New England BioLabs).

C. Genomic fingerprinting

NOTE: In order to select the optimum range of DNA concentrations to be used for fingerprinting, an initial experiment with multiple dilutions of the template DNA should be performed. Once the optimum range of DNA concentrations has been determined, as few as two dilutions of each DNA can be used.

- 1. Array the purified DNAs in a “master” 96-well microtiter tray at about 10 ng/ μl in each well.
- 2. Using a multichannel pipette, perform a series of four fivefold dilutions on a representative subset of DNAs in additional 96-well dishes. The final desired DNA concentration for bacteria in the AP-PCR experiment is generally about 1 ng/ μl , but this can vary depending on the DNA quality. For this reason, it is usually wise to perform the initial amplification on more than one dilution at a time.
- 3. In the 96-well array, combine 45 μl of AP-PCR mixture with 5 μl of DNA dilution stocks of 10, 2, 0.4, 0.08, and 0.016 ng/ μl from step V.C.2.
- 4. Perform the amplification as follows: two cycles of 5 min at 94°C for template denaturation, 5 min at 40°C for primer annealing, and 5 min at 72°C for primer extension, followed by 40 cycles of 1 min at 94°C for template

V. PROCEDURE (continued)

denaturation, 1 min at 40°C for primer annealing, and 2 min at 72°C for primer extension.

5. Separate the amplification products by electrophoresis in 1.5% agarose at 100 V for 4 h. Stain the gel with ethidium bromide (0.5 µg/ml in water) and visualize under UV light.
6. After this initial experiment, choose two dilutions that give the most robust and informative fingerprints and use them for all subsequent experiments, allowing 48 strains to be examined at one time.

D. Procedure notes

1. In AP-PCR even slight variations in the pH or ionic strength of the buffers used, the temperature of the reaction, or the source of the DNA polymerase may result in wide variations in the intensities of the individual amplicons.
2. The reproducibility and discriminatory power of each primer and amplification protocol must be validated by analyzing sets of isolates that have been previously well defined by epidemiologic data and/or independent typing studies.
3. The most reliable epidemiologic results are obtained when a set of isolates is tested in a single amplification reaction and analyzed on a single electrophoretic gel.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

A report of the results of AP-PCR typing that details which isolates are indistinguishable (clonal), similar (subtypes), or different should be issued to the service that generated the request for typing.

VII. INTERPRETATION

- A. Standard guidelines for interpretation of AP-PCR are not yet available, and the interpretation of fingerprinting results obtained with this technique is empirical.
- B. Under conditions where variability of amplicon sizes can be demonstrated among epidemiologically unrelated isolates, those showing either no differences or changes only in band intensity can be considered epidemiologically related.
- C. AP-PCR patterns with three or more fragment (amplicon) differences may be considered to represent different strains.
- D. AP-PCR patterns differing by one or two bands remain difficult to interpret but may be considered to represent isolates which are subtypes of one another and possibly epidemiologically related.

12.4.7

Genotyping of Hepatitis C Virus by INNO-LiPA HCV II

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The INNO-LiPA HCV II is a line probe assay, for in vitro use, for the genotyping of hepatitis C virus (HCV) in human serum and plasma. This test allows the genotyping of the six major HCV types and their most common subtypes. The assay is based on variations found in the 5' untranslated regions (5' UR) of the different HCV genotypes. Type-specific probes are tailed with a poly(T) tail by terminal deoxynucleotidyl transferase and attached to nitrocellulose membranes.

Biotin-labeled amplified products are reversibly hybridized to the probes on the

strips. The biotin group is incorporated by employing a 5'-biotinylated primer during amplification. The labeled product obtained from the 5' UR will hybridize only to a probe (or line) that gives a perfect sequence match, allowing stringent discrimination at the subtype level.

After hybridization, streptavidin labeled with alkaline phosphatase is added and bound to any biotinylated hybrid previously formed. Incubation with BCIP-NBT (bromochloroindolylphosphate-nitroblue tetrazolium) chromogen results in

a purple-brown precipitate. A line will occur only when there is a perfect match between the probe and the biotinylated PCR products.

Mutations occurring within the quasi-species pool of sequences from one isolate do not affect the outcome of the genotype.

Because of the sensitivity of the PCR method, it is necessary to limit the potential for contamination by performing each step of the process in a separate area of the laboratory and to dedicate equipment to each of the areas.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

A. Specimen

Amplicons from either the Roche HCV AmpliCor (qualitative) or Roche HCV Monitor (quantitative) assay may be used.

B. Specimen storage and handling

Amplicons must be stored at 2 to 8°C after amplification and must be used within 7 days of amplification.

III. MATERIALS

A. Reagent preparation

1. The hybridization solution and the stringent wash solution should be prewarmed at 50°C. Make sure that all crystals are dissolved.
2. Dilute concentrated rinse solution 1:5 in type I water. Prepare 8.5 ml of diluted solution per strip.
3. Dilute the concentrated conjugate 1:100 with conjugate diluent. Prepare 2 ml per strip plus 2 ml excess. Perform dilution during stringent-wash step.
4. Dilute the concentrated substrate 1:100 in substrate buffer. Prepare 2

ml per strip plus 2 ml excess. Perform dilution during conjugate incubation.

B. Area 3

1. INNO-LiPA HCV II genotyping kit (Innogenetics)
2. Incubation trays (Innogenetics)
3. Water bath, shaking, adjustable to 50 ± 0.5°C
4. Calibrated thermometer
5. Aspiration apparatus
6. Type I water
7. Sterile aerosol barrier pipette tips
8. Plastic tweezers
9. Graduated cylinders

III. MATERIALS (*continued*)

10. Adjustable volume pipette
11. Pipetaide
12. Sterile glass pipettes
13. Timer
14. Vortex mixer
15. Dedicated lab coat
16. Powder-free gloves

C. Reagent storage

1. Kit should be stored isolated from any source of contaminating DNA.
2. Store kit at 2 to 8°C. Do not freeze.
3. Bring all kit components to room temperature before use and return to the refrigerator immediately after use.
4. The vial containing denaturation solution should be closed immediately after use; prolonged exposure of this solution to air leads to a rapid deterioration of the denaturing strength.
5. Conjugate and substrate solutions are stable for 24 h at room temperature when stored in the dark.

D. Warnings and precautions

1. Conjugate, conjugate diluent, substrate buffer, and rinse solution contain sodium azide. These solutions are harmful when ingested. Thoroughly flush drains with water after disposal of solutions containing sodium azides.
2. BCIP-NBT substrate contains dimethylformamide and may harm the fetus. This solution is harmful when inhaled or ingested or when skin contact occurs, and it is irritating to the eyes. BCIP-NBT solution should be removed by the health protection office as chemical hazardous waste.
3. Denaturing solution contains sodium hydroxide and is irritating to the eyes and skin.

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL**

- A. It is required to include one negative control each time a test is performed. Use the negative control amplicon from the Roche amplification of the same genotyping specimen run. The negative control should show no apparent signal for any of the lines on the strip, except for the conjugate control line.
- B. A positive control should be included with each run to help evaluate the reproducibility of the genotyping runs. Use one of the positive control amplicons from the Roche amplification of the same genotyping specimen run.
- C. The uppermost line on the strip is the marker line. This allows correct orientation of the strip.
- D. The second line controls the addition of reactive conjugate and substrate solution during the detection procedure. This line should always be positive and should have approximately the same intensity on each strip in the same test run.
- E. Color intensities between lines on a strip may differ from one line to the other.

V. PROCEDURE**A. Hybridization**

1. Check that the temperature of the water bath is $50 \pm 0.5^\circ\text{C}$. Keep the lid closed at all times.
2. Fill out an HCV genotyping worksheet. Record lot number and expiration date of kit used. Record date of amplicon amplification and whether it was a qualitative or quantitative run.
3. Prewarm the hybridization solution in the water bath. Mix before use and ensure that all crystals are dissolved.
4. Using a Kimwipe wetted in type II water, wipe the surface of the tray to decrease static electricity.
5. Using tweezers, remove the required number of strips from the tube and with a pencil label each strip with a sequential number above the black strip. Place strips individually into the bottom of a trough on the tray.

V. PROCEDURE (*continued*)

6. Pipette 20 µl of denatured amplicon into the upper corner of the trough corresponding to each control and patient.
7. Mix the prewarmed hybridization solution. Using the Pipetaide and sterile glass pipette, add 2 ml of hybridization solution to each trough with a strip. Be careful not to touch the tip of the pipette to the trough. Gently mix. Be careful not to splash reagents from one trough to another.
8. Ensure that each strip is completely submerged.
9. Place the tray in the metal tray in the $50 \pm 0.5^\circ\text{C}$ water bath. Close the lid and start the bath shaking. Incubate for 60 min.
10. Prewarm the stringent wash solution at $50 \pm 0.5^\circ\text{C}$ during hybridization.

B. Stringent wash

1. Remove the tray from the water bath.
2. Hold the tray at an angle and aspirate the liquid from each trough with a pipette.
3. Add 2 ml of prewarmed stringent wash solution into each trough.
4. Rinse by rocking the tray for 10 to 20 s at room temperature (20 to 25°C).
5. Aspirate the solution from each trough as in step V.B.2.
6. Repeat the washing step in step V.B.3.
7. Incubate each strip in 2 ml of prewarmed stringent wash solution in the shaking water bath at $50 \pm 0.5^\circ\text{C}$ for 30 min.
Be sure to check temperature in water bath before incubation.
8. Dilute the concentrated rinse solution and conjugate during the stringent wash. See Tables 12.4.7–1 and 12.4.7–2 for volume preparation.

Table 12.4.7–1 Rinse solution preparation

No. of strips	Vol (ml) of:		Total vol (ml)
	Type I water	RS concentrate	
1	6.8	1.7	8.5
2	13.6	3.4	17
3	20.4	5.1	25.5
4	27.2	6.8	34
5	34	8.5	42.5
6	40.8	10.2	51
7	47.6	11.9	59.5
8	54.4	13.6	68
9	61.2	15.33	76.5
10	68	17	85

Table 12.4.7–2 Conjugate and substrate preparation

No. of strips	Vol of:		Total vol (ml)
	SB buffer or conjugate diluent (ml)	Substrate or conjugate (µl)	
1	3.96	40	4
2	5.94	60	6
3	7.92	80	8
4	9.9	100	10
5	11.88	120	12
6	13.86	140	14
7	15.84	160	16
8	17.82	180	18
9	19.8	200	20
10	21.78	220	22

V. PROCEDURE (*continued*)**C. Color development**

All subsequent incubations are carried out at 20 to 25°C on the dry half of the shaking water bath. Ensure that the strips move back and forth in the trough for homogenous staining.

1. Remove the tray from the water bath.
2. Hold the tray at an angle and aspirate the liquid from each trough with a pipette.
3. Add 2 ml of dilute rinse solution into each trough.
4. Rinse by rocking the tray for 1 min at room temperature (20 to 25°C).
5. Aspirate the solution from each trough as in step V.B.2.
6. Repeat the washing step in steps V.B.3 to 5.
7. Add 2 ml of the diluted conjugate to each trough and incubate for 30 min while agitating the tray on the shaker. Cover shaker with lid covered in foil.
8. Dilute the substrate for ~10 min prior to the end of the conjugate incubation.
9. Wash each strip as in steps V.B.2 to 6 above.
10. Add 2 ml of substrate buffer to each trough and repeat steps V.B.4 and 5 above.
11. Add 2 ml of the prepared substrate solution to each trough and incubate at room temperature for 30 min while agitating the tray in the shaker. Cover the shaker with the lid covered in aluminum foil.
12. Stop the color development by washing the strips twice in 2 ml of type I water while agitating the tray for at least 3 min. Discard waste in formamide waste bottle.
13. Using tweezers, remove the strips from the troughs and place on absorbent paper. Place strips on HCV genotyping worksheet in proper order, with the uppermost line on the strip placed over the marking strip on the worksheet, and tape into place.
14. Allow the strips to dry completely before reading the results. Store developed strips in the dark.

D. Procedure notes

1. Incubation temperature of $50 \pm 0.5^\circ\text{C}$ during hybridization and stringent wash is critical.
2. Always close the lid of the water bath during incubation to avoid false positives. Covering the troughs with microplate sealers may cause cross-contamination.
3. The amplitude of motion generated by the shaker is critical. The amplitude should be as high as possible without spilling (setting 5).
4. Adjust the level of the water in the bath between one-third and one-half of the height of the trough.
5. Aspirate the liquid from the trough with a pipette attached to a vacuum aspirator. Hold the tray at an angle to allow all liquid to flow to one end of the trough.
6. Do not allow strips to dry between the washing steps.
7. Do not damage the surfaces of the strips when aspirating. Aspirate the liquid at the top of the strip above the marker line.
8. Make sure the entire strip is washed by immersion in the solution.
9. Do not touch strips with bare hands; use clean tweezers that are dedicated to this procedure.
10. Make sure test strips are placed in the tray with their coated membrane side up (marked side).
11. Throughout the test, the strips should remain in the same trough.

V. PROCEDURE (*continued*)

12. All hybridization and stringent-wash steps should be performed using the rotating shaker. The shaking of the solution over the strips is important in achieving maximum sensitivity.
13. Developed strips should be stored in the dark at room temperature.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

A report of the results of HCV genotyping that specifies the genotype of the infecting virus should be issued to the service that generated the request for typing.

VII. INTERPRETATION

- A. The second line on the strip is the control for the addition of reactive conjugate and substrate solution during the detection procedure. This line should always be positive and should have the same intensity on each strip in the same run.
- B. If this strip is not positive or there is unequal intensity on the strips, fill out a Quality Control Failure/Problem form and notify the lead scientist.
- C. The assay result of each negative control should be no apparent signal for any of the lines on the strip, except for the conjugate control line.
- D. If any lines appear positive except for the conjugate control line, fill out a Quality Control Failure/Problem form and notify the lead scientist.
- E. The assay result of each positive control should be consistent with the genotype of the control used. The strip pattern should be consistent between runs of the same control lot.
- F. Collect all line numbers which are positive on the INNO-LiPA HCV II strip and deduce the genotype by using the interpretation chart.

12.5.1

Introduction

Antimicrobial agent resistance is an increasing problem worldwide, particularly among critically ill hospitalized patients. For this reason, there is a renewed interest in monitoring the development and spread of antimicrobial agent resistance and a recognition of the need for effective interventions to limit the spread of resistance to prolong the therapeutic life of the available antimicrobial agents. Unfortunately, conventional methods to perform antimicrobial agent susceptibility testing may be too slow and insensitive in detecting an-

timicrobial agent resistance to be of much use clinically. The techniques of molecular biology have been used to characterize resistance at the DNA level and may provide rapid, sensitive, and specific information to the clinician for use in therapeutic decision making (1–4). Genetic material that confers antimicrobial agent resistance may be carried on the bacterial chromosome or on transposons or plasmids and has been detected by probe hybridization or by DNA amplification with PCR (Table 12.1–6). Molecular detection

of resistance has potential value for decisions directly related to patient care and is useful for calibration of conventional susceptibility tests and for precise definition of the mechanisms of resistance to selected antimicrobial agents. Molecular techniques have been used to detect genes encoding several different mechanisms of resistance against antimicrobial agents, e.g., β -lactam agents, aminoglycosides, macrolides, and fluoroquinolones, after isolation of a clinical isolate (Table 12.1–6).

12.5.2

Detection of Enterococcal Vancomycin Resistance by Multiplex PCR

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The emergence of vancomycin resistance among enterococci is considered one of the major antimicrobial resistance threats worldwide. The expression of vancomycin resistance involves the complex interaction of several genes, but classification of resistance is based on the altered ligase (an enzyme involved in the D-alanine branch of peptidoglycan synthesis) which is central to the production of cell wall precursors with decreased affinity for vancomycin (Table 12.5.2-1). Currently, the ligase designations include VanA (*vanA*), VanB (*vanB*), and VanC1 to -3 (*vanC-1*, *vanC-2*, *vanC-3*). All five Van types may be encountered clinically, but resistance encoded by *vanA* or *vanB* presents the greatest infection control and therapeutic threat because it is genetically transferable, results in high-level vancomycin resistance (MICs, ≥ 32 $\mu\text{g/ml}$), and occurs in the two most common enterococcal species (*Enterococcus faecalis* and *Enterococcus faecium*), both of which are frequently resistant to multiple agents, including penicillins and aminoglycosides. Although presumptive identification of the mechanism of vancomycin resistance may be inferred on the basis of phenotypic criteria, the only definitive method for establishing the mechanism of resistance is detection of the ligase gene(s). PCR provides an ideal molecular tool for definitively establishing the mechanism of vancomycin resistance in clinical isolates of enterococci. In the present protocol, a PCR procedure that uses primers internal to each of the known *van* genes is described. This method may be used to arbitrate equivocal susceptibility results obtained by phenotypic methods, to characterize "outbreak" strains, and to evaluate the accuracy of various phenotypic susceptibility testing methods.

NOTE: This procedure is adapted from that of Free and Sahn (2).

Work flow in the laboratory must proceed in a unidirectional manner, beginning in the reagent preparation area and moving to the specimen preparation area and then to the amplification and detection area. Pre-amplification activities must begin with reagent preparation and proceed to specimen preparation. Reagent preparation activities and specimen preparation activities must be performed in separate, segregated areas. Supplies and equipment must be dedicated to each activity and not used for other activities or moved between areas. Lab coats and gloves must be worn in each area and must be changed before leaving that area. Equipment and supplies used for reagent preparation must not be used for specimen preparation activities or for pipetting or processing amplified DNA or other sources of target DNA. Amplification and detection supplies and equipment must be confined to the amplification and detection area at all times.

Table 12.5.2-1 PCR primers for detection of *vanA*, *vanB*, *vanC-1*, and *vanC-2* in enterococci

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Test growth of *Enterococcus* spp. for which the vancomycin MIC is elevated (≥ 8.0 $\mu\text{g/ml}$) or which show growth on an agar screen plate from appropriate solid medium. Select two to four well-isolated colonies from pure culture. The optimal colony age is 18 to 48 h; substantially older colonies have been used successfully.

III. MATERIALS

☑ **NOTE:** Unless otherwise stated, all materials are available from Sigma Chemical Co., St. Louis, Mo.

A. Reagents

1. Agarose (type 1-A, low electroendosmosis)
2. Autoclaved Tris-borate-EDTA (TBE) buffer (pH 8.3 to 8.5)
3. 6 \times Gel electrophoresis loading buffer (0.25% bromophenol blue, 0.25% xylene cyanol, and 30% glycerol in H₂O)
4. Sterile distilled H₂O
5. Ethidium bromide (0.5 $\mu\text{g/ml}$ of H₂O)
6. Autoclaved light mineral oil
7. PCR master mix
 - a. 10 \times PCR buffer (100 mM Tris-HCl [pH 9], 500 mM KCl, 1% Triton X-100 [Promega, Madison, Wis.])
 - b. 10 mM concentration of each deoxyribonucleoside triphosphate

c. 25 μM concentration of each primer (primer designations, primer sequences, and amplicon sizes given in Table 12.5.2-1)

d. 25 mM MgCl₂

e. 5,000 U of *Taq* (Promega) per ml

8. Size marker, ϕ X174 phage DNA *Hae*III digest (Promega), diluted 1:40 with 6 \times electrophoresis buffer

B. Supplies

1. Sterile 0.5-ml snap-cap PCR thermal reactor tubes
2. Sterile, plugged micropipette tips (10, 200, and 1,000 μl)
3. Sterile bacteriologic transfer needles or sterile toothpicks

C. Equipment

1. Vortex mixer
2. Thermal cycler
3. Electrophoresis gel box
4. Electrophoresis power supply
5. UV transilluminator and photodocumentation equipment

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Positive controls
 1. *vanA*, *E. faecium* 228
 2. *vanB*, *E. faecalis* V583 or *E. faecalis* ATCC 51299
 3. *vanC-1*, *E. gallinarum* AIB 39
 4. *vanC-2*, *E. casseliflavus* ATCC 25788
- B. Negative control, *E. faecalis* ATCC 29212
- C. Run appropriate positive and negative controls with each test procedure.
- D. Verify that all materials and reagents meet expiration date and QC parameters per NCCLS document M22-A2 (3).

V. PROCEDURE

A. Preparation of PCR master mix for *vanA* and *vanB* detection (prepare in area 1: reagent preparation area)

1. Volumes based on 99- μl reaction mixture.

☑ **NOTE:** Overestimating the final required volume by one or two reactions allows for volume loss and pipetting errors and is recommended.
2. Using sterile technique add the following volumes of each reaction component to each PCR thermal reactor tube.
 - a. 52.5 μl of distilled H₂O
 - b. 10 μl of 10 \times PCR buffer

V. PROCEDURE (*continued*)

- c. 2 μ l of each of the following
 - (1) Deoxynucleoside triphosphate stock (10 mM) (total volume, 8 μ l)
 - (2) *vanA-1* primer stock (25 μ M)
 - (3) *vanA-2* primer stock (25 μ M)
 - (4) *vanB-1* primer stock (25 μ M)
 - (5) *vanB-2* primer stock (25 μ M)
 - d. 20 μ l of 25 mM MgCl₂ stock
 - e. 0.5 μ l of 5,000-U/ml *Taq* stock
- **NOTE:** If the *vanC-1* and *vanC-2* genes are of interest, their respective primers would replace those of *vanA* and *vanB* at the same volume and concentration.
3. Use the vortex mixer to gently but thoroughly mix the contents.
 4. Transfer 99 μ l of mixture to each reaction tube.
- B. Sample preparation: preparation of DNA template (prepare in area 2: specimen preparation area)**
1. Use a sterile toothpick or inoculating needle to select two to four well-isolated colonies from pure culture (18 to 48 h old).
 2. Emulsify colonies in PCR mixture.
 3. Using aseptic technique, gently overlay each tube with 75 μ l of sterile mineral oil (not necessary if self-sealing PCR tubes are used).
- C. PCR amplification (area 3: amplification and detection area)**
- **NOTE:** Have the thermocycler on so that cycling can begin as soon as the tubes are ready. Amplify the target region of *van* genes in a programmed thermocycler as follows.
1. 1.3-min hot start at 95°C (bacterial lysis and release of target DNA)
 2. 30 cycles of 94°C for 1 min, 56°C for 1 min, and 72°C for 1 min, with a final extension at 72°C for 1 min
- **NOTE:** If not able to perform detection of PCR product soon after completion of this cycle, program the machine to hold at 4°C or place reaction mixture in a refrigerator or freezer until needed for electrophoretic analysis.
- D. Electrophoretic detection of PCR products (area 3: amplification and detection area)**
1. Prepare a 1.5% agarose gel in 1 \times TBE buffer.
 2. Remove 8.3 μ l of reaction mixture from below the mineral oil layer, combine with 1.7 μ l of 6 \times loading buffer, and mix by pipetting.
 3. Prepare size marker by adding 0.5 μ l of marker to 7.5 μ l of H₂O and 2 μ l of 6 \times loading buffer.
 4. Apply a total of 10 μ l of sample to each well, and perform electrophoresis (70 V for 50 min) in 1 \times TBE buffer containing ethidium bromide (0.5 μ g/ml).
 5. Visualize the gel under UV light and photograph with Polaroid type 667 film.
- **NOTE:** The gel may be destained in H₂O (approximately 30 min) to optimize visualization of results.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

Report the results of the PCR procedure detailing the specific vancomycin resistance genotype detected. If negative, report "vancomycin resistance genes *vanA*, *-B*, and *-C* not detected."

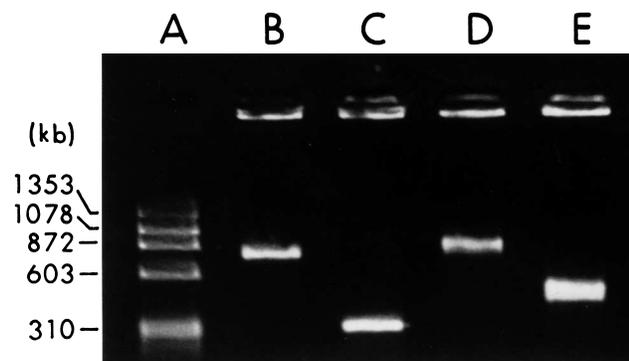

Figure 12.5.2–1 Agarose gel electrophoresis pattern of *van* PCR products. Lanes: A, size marker ϕ X174 phage DNA *Hae*III digest; B, *vanA* product (783 bp); C, *vanB* product (297 bp); D, *vanC-1* product (822 bp); E, *vanC-2* product (439 bp). PCR products for *vanA* and *vanB* resulted from the reaction described above; *vanC-1* and *vanC-2* products were obtained with single primer sets per reaction mixture. Figure from Free and Sahn (2).

VII. INTERPRETATION

- A. Amplification of a 783- or 297-bp product indicates the presence of *vanA* or *vanB*, respectively (Fig. 12.5.2–1). Either result establishes the presence of acquired and transferable vancomycin resistance and confirms the need to initiate appropriate infection control and patient management measures.
- B. If no PCR product is observed with a strain that appeared nonsusceptible by a phenotype-based method and if appropriate results are obtained with control strains (*see below*), the isolate probably contains a *vanC* gene. This can be confirmed by using the *vanC-1* and *vanC-2* primers, which yield 822 and 439-bp amplification products, respectively (Fig. 12.5.2–1).

12.5.3

Detection of Methicillin Resistance in Staphylococci by PCR

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The primary mechanism of resistance to methicillin and related compounds (oxacillin, nafcillin) in both *Staphylococcus aureus* and coagulase-negative staphylococci is the production of a unique penicillin binding protein, termed PBP2a or PBP2', that has a low affinity for β -lactam antibiotics. The gene encoding PBP2a, known as *mecA*, has been cloned and sequenced. The phenotypic expression of *mecA* is often heterogeneous and difficult to detect in many antimicrobial susceptibility testing systems. An alternative method for identifying methicillin-resistant strains of staphylococci is to detect the *mecA* gene, which is absent in susceptible strains. Detection of *mecA* in staphylococci has been accomplished by both PCR

and DNA probe methods. In the present protocol, a PCR procedure that uses oligonucleotide primers to amplify a 533-bp region of *mecA* is described. This method is applicable to both *S. aureus* and coagulase-negative staphylococci and may be used to rapidly identify methicillin-resistant strains for clinical purposes and to aid in the development of phenotypic methods that can more accurately predict methicillin resistance.

Work flow in the laboratory must proceed in a unidirectional manner, beginning in the reagent preparation area and moving to the specimen preparation area and then to the amplification and detection area. Pre-amplification activities must begin with reagent preparation and proceed to

specimen preparation. Reagent preparation activities and specimen preparation activities must be performed in separate, segregated areas. Supplies and equipment must be dedicated to each activity and not used for other activities or moved between areas. Lab coats and gloves must be worn in each area and must be changed before leaving that area. Equipment and supplies used for reagent preparation must not be used for specimen preparation activities or for pipetting or processing amplified DNA or other sources of target DNA. Amplification and detection supplies and equipment must be confined to the amplification and detection area at all times.

■ **NOTE:** This procedure is adapted from that of Murakami and Minamide (1).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Test growth of *S. aureus* or coagulase-negative staphylococci from Mueller-Hinton agar. Select several colonies from pure culture. The optimal colony age is 18 to 24 h.

III. MATERIALS

■ **NOTE:** Unless otherwise specified, all materials are available from Sigma Chemical Co., St. Louis, Mo.

A. Reagents

1. Agarose, standard low M_r (Bio-Rad Laboratories, Richmond, Calif.)
2. Autoclaved Tris buffer (TE) (10 mM Tris-HCl [pH 8.0], 1 mM EDTA)
3. Electrophoresis loading buffer (0.25% bromophenol blue, 0.25% xylene cyanol, and 30% glycerol in $1 \times$ TBE [Tris-borate-EDTA] buffer).
4. Sterile distilled H₂O
5. Ethidium bromide (0.5 μ g/ml of H₂O)
6. Autoclaved light mineral oil
7. PCR master mix (GeneAmp PCR reagent kit; Perkin-Elmer Corp., Norwalk, Conn.)
 - a. PCR buffer (50 mM KCl, 10 mM Tris-HCl [pH 8.3])
 - b. MgCl₂ (1.5 mM)
 - c. 0.01% Gelatin
 - d. Deoxyribonucleoside triphosphates (200 mM each)
 - e. AmpliTaq DNA polymerase (0.025 per μ l)

III. MATERIALS (continued)

- f. Primers RSM-2647 and RSM-2648 (each at 0.25 μ M [final concentration]) (primer sequences given in Table 12.5.3-1)
 - g. Size marker, ϕ X174 phage DNA *Hae*III digest (Nippon Gene, Toyama, Japan); add 1 volume of electrophoresis loading buffer to 5 volumes of the digest to give a DNA concentration of 40 ng/ μ l.
 - 8. Achromopeptidase solution: 20,000 U of purified achromopeptidase (Wako BioProducts, Richmond, Va.) per ml of TE
- B. Supplies**
1. Sterile 0.5-ml snap cap PCR thermal reactor tubes
 2. Sterile, plugged micropipette tips (10, 200, and 1,000 μ l)
 3. Sterile bacteriologic transfer needles or sterile toothpicks
 4. 0.5 McFarland turbidity standard
 5. Microcentrifuge tubes (1.5 ml)
 6. Glass test tubes (12 by 75 mm)
- C. Equipment**
1. Vortex mixer
 2. Thermal cycler
 3. Electrophoresis gel box
 4. Electrophoresis power supply
 5. Microcentrifuge
 6. Heating block (55 and 100°C)
 7. UV transilluminator and photo-documentation equipment

ANALYTICAL CONSIDERATIONS

IV. QUALITY CONTROL

- A. Positive control, *S. aureus* ATCC 43300
- B. Negative control, *S. aureus* ATCC 25923
- C. Run positive and negative controls with each test procedure.
- D. Verify that all materials and reagents meet expiration date and QC parameters per NCCLS document M22-A2 (2).

V. PROCEDURE

- A. Area 2: preparation of template DNA**
1. Use a sterile toothpick or inoculating needle to select several well-isolated colonies from pure culture.
 2. Emulsify the bacteria in 1 ml of TE by vigorous vortexing to give a turbidity equal to a 0.5 McFarland standard (approximately 1.5×10^8 CFU/ml). Make sure that the bacteria are dispersed well in the TE.
 - **NOTE:** Too dense a bacterial suspension may give a false-negative result.
 3. Transfer 100 μ l of the bacterial suspension to a 1.5-ml microcentrifuge tube containing 2 μ l of achromopeptidase solution. Vortex and place the tube in a 55°C heating block for 30 min.
 4. Add 2.5 μ l of 4% sodium dodecyl sulfate (SDS; Polysciences Inc., Warrington, Pa.) to the digest.
 - **NOTE:** Some brands of SDS inhibit PCR. Vortex and place tube in the 100°C heating block for 5 min. Centrifuge at $10,000 \times g$ for 5 min, and use 5 μ l of the bacterial lysate for PCR.
- B. Area 3: PCR amplification**
1. Transfer 95 μ l of PCR master mix to a 0.5-ml microcentrifuge tube. Add 5 μ l of template DNA to the master mix and mix well by vortexing.
 2. Add 2 or 3 drops (about 100 μ l) of mineral oil to the reaction mixture to prevent evaporation.

Table 12.5.3-1 PCR primers for detection of *mecA* in staphylococci

Function	Name	Nucleotide sequence, 5'-3'
Primer	RSM-2647	AAA ATC GAT GGT AAA GGT TGG C
Primer	RSM-2648	AGT TCT GCA GTA CCG GAT TTG C

V. PROCEDURE (*continued*)

3. Add a drop of mineral oil to the tube holder of the thermal cycler for efficient heat transmission, and place the tube in the tube holder.
4. Amplify a target region of *mecA* for 40 cycles in a programmed thermal cycler as follows: denaturation at 94°C for 30 s, annealing at 55°C for 30 s, and extension at 72°C for 1 min, with a final extension at 72°C for 5 min.

C. Area 3: electrophoretic detection of the 533-bp PCR product

1. Prepare a 2% agarose minigel in 1× TBE buffer for electrophoresis.
2. Mix 10 µl of PCR product with 2 µl of loading buffer in a 1.5-ml microcentrifuge tube. Vortex. Apply 6 µl of the sample or size marker to each well, and perform electrophoresis in 1× TBE buffer (100 V for 20 to 30 min). Also apply positive and negative controls to each gel.
3. Stain the gel by gentle shaking in ethidium bromide solution until the 310-bp size marker is visible.
4. Visualize the gel under UV light and photograph with Polaroid type 667 film.

POSTANALYTICAL CONSIDERATIONS**VI. REPORTING RESULTS**

Report the results of the PCR procedure detailing the presence or absence of the *mecA* gene. Specify resistance to methicillin and all other β-lactam agents if *mecA* positive and susceptibility to methicillin, oxacillin, and nafcillin if *mecA* negative.

VII. INTERPRETATION

- A. Amplification of a 533-bp region of *mecA* indicates that the strain tested is methicillin resistant.
- B. A few *mecA*-positive strains appear phenotypically susceptible to β-lactam antibiotics because of their inability to express PBP2'. Since these strains have the potential to become truly resistant, they should be regarded as cryptically methicillin-resistant strains.
- C. Use of bacterial suspension of too high a density for preparation of template DNA may lead to false-negative results. A bacterial suspension of as few as 2×10^5 CFU/ml for preparation of template DNA is enough to detect *mecA*.
- D. Methicillin-resistant strains of coagulase-negative staphylococci can also be detected by this method. Species in which *mecA* has been detected using this procedure include *S. epidermidis*, *S. haemolyticus*, *S. sciuri*, *S. saprophyticus*, *S. hominis*, *S. capitis*, and *S. caprae*.

Introduction

Clinical microbiologists have long been comfortable with the analytical contributions they make to laboratory diagnosis. However, the total testing process for the microbiologist additionally includes preanalytical and postanalytical issues about which a technologist may feel less secure. Clearly, one major area of contribution unique to the clinical microbiologist is the critical data expertly provided to the infection control team of the institution. A sound infection control program of any health care institution is dependent on its relationship with the microbiology laboratory from which most of their critical data come. While accuracy and timeliness of critical microbiology diagnostic reports contribute to positive patient outcomes, the nature of skilled interpretive judgment on the part of trained technologists marks the clinical microbiologist as a uniquely qualified contributor to the data that drive infection control decisions.

Every infection control team must include a member of the microbiology lab-

oratory staff who should be given the opportunity to actively and equally participate as a critical member of that team. The microbiologist will have the knowledge that can link patient care and diagnosis within the institution to community health care issues that impact public health. This linkage, coupled with the expertise of the infection control professional and the attending physicians, provides the strength required to oversee and implement strategies that promote patient safety and health care quality.

This section addresses many issues that may be considered “extra work” for the laboratory and too time-consuming to focus enough expertise to accomplish the requests and needs of the submitter. It is true that relatively few institution-associated infections can be attributed to a microbial challenge originating from the environment. However, the potential contribution of the environment, including water, indwelling medical devices, surfaces, or air, cannot be discounted, particularly in light

of increasing numbers of patients suffering from immunosuppression. We have long known that many factors contribute to infection in humans, including the virulence of the etiologic agent, inoculum size, route of infection, and host factors, among others. In addition, in today’s health care environment, more hospitalized patients are sicker than in previous years, and these patient populations require more sophisticated medical manipulation and intervention. Therefore, what may be normal body microbiota or normal environmental organisms can have a negative impact on patient outcome.

The astute microbiologist will be prepared to address these issues with both infection control professionals and attending physicians. Understanding the microbiology of healthy individuals, of hospitalized patients, of special patient populations, and of the environment offers the infection control team a strategic view from which sound strategies for patient safety can arise.

13.2

Laboratory Support for Infection Control: Optimization by Policy and Procedure

The discipline of infection control had its formal beginnings in the 1970s and was refined in the 1980s. This discipline will continue to evolve, becoming part of the health care providers' overall program of continuous quality improvement. Superimposed on the evolution of infection control programs has been the rapid evolution of the health care field, introducing new modalities of care that are prone to high rates of nosocomial infection. Fewer patients are hospitalized, but in general, those that are hospitalized are sicker than similar populations in previous years. The numbers of indwelling lines, implanted devices, and complex procedures have greatly increased, as have the numbers of patients compromised by cancer chemotherapy regimens or transplant immunosuppressive therapy. Transfusion practices have evolved to include a variety of processed subsets of blood, and transplantation now includes many solid organs, bone, bone marrow, corneas, and various connective tissues. In addition, special patient populations such as the elderly, neonates, women, or ethnic minorities are being evaluated for their special health care needs that might require unique services. The microbiology laboratory is increasingly being asked to perform cultures that support the needs of these new programs. The involvement of the laboratory must be optimized by appropriate policies and procedures and the appointment of the chief microbiologist to the Infection Control Committee. With early patient release and with multiple hospitals often served by the same microbiology core laboratory, it is imperative that the laboratory develop methods and communication tools to assist in serving the patients' infection control needs. The Institute of Medicine in 2000 addressed the issue of patient safety, and although it did not specifically focus

on health care-associated infections, these are clearly critical areas for improvement and monitoring.

The microbiologist has a complex interface with the infection control team. Routine microbiology laboratory data are employed as one of the major sources of information to suggest incipient problems with health care-associated infections, and laboratorians' expertise must be employed to assist in the investigation of such infections. Adding to the complexity is the problem of pseudoinfections which result from contamination of cultures or culture specimens rather than from patients; such contamination may be introduced in the laboratory during specimen management or by the manufacturer of the collection and transport devices. If found in multiple cultures, such non-patient-related contamination events are termed "pseudoepidemics" and may plague the laboratory facility that does not institute immediate investigation and intervention strategies. The laboratory should play a pivotal role in the investigation of all apparent pseudoepidemics. The initial evaluation effort should focus on the possible contribution of laboratory processing or specimen manipulation in introducing the microorganism. The detection or elimination of the laboratory as a source of the contaminant is usually simple, so it is best to make the laboratory evaluation first. Is there a laboratory diluent or procedure common to all the specimens from which the organism has been grown? In some cases the laboratory is easily eliminated as a source of the contamination, for example, when growth appears in blood culture bottles that have not been sampled after receipt in the laboratory. Once the laboratory is eliminated as the source of the contaminant, the infection control team needs to devise a strategy and put in place a track-

ing system so that immediate investigation of all new positive culture events can be undertaken. Immediate investigation facilitates the process because it is easier to determine who collected the specimen, and how it was collected, if inquiries are made while responsible parties are still on the service and memories are not dulled by the intervention of time. The lot number and type of the antiseptics and/or devices used in the collection can be traced to the opened box in the room where the procedure was performed, and the team can quarantine all supplies of the same lot number pending cultural or epidemiologic resolution of the problem. A brief description of the problem, rationale for the undertaking, the designated responsible persons, and the plan of action should be prepared and distributed to all members of the investigational team, with a copy to the administration's representative on the Infection Control Committee. Most pseudoepidemics are similar enough that a standard type of form can be adapted for use among all of them. Use of a form minimizes the loss of data when investigators make informal notes and subsequently lose them. A sample investigation plan and associated form are supplied in Appendix 13.2-1. Such a formal plan and report form help to optimize the process and clarify the responsibilities. The document can be easily adapted for inclusion in minutes and reports.

The laboratory staff may occasionally be asked to perform inappropriate surveillance cultures that cannot be justified by current practice and that should not be done because the resulting information may be misleading and result in an inappropriate or irrational response. Sometimes well-meaning individuals will ask the laboratory to investigate presumed infectious incidents by culturing food or

pharmaceuticals. Culture protocols for most *clinical* laboratories are insufficient to accommodate the standard methods that these investigations require. Thus, these clinical laboratories should refer such products for culture to public health, commercial reference, or Food and Drug Administration laboratories that have the appropriate methodology in place to produce the results that may be required, should legal proceedings ensue. The microbiology laboratory must limit the scope of its cultural investigations in environmental microbiology and epidemiology to those that are endorsed by the Infection Control Committee.

The laboratory may inadvertently become an innocent victim of inappropriate environmental-culture requests. Specimens may be sent to the laboratory for culture as though they were intended for diagnosis of an infection, when they are really intended to document sterility of a reagent, device, or organ or fluid for administration, implantation, or transplantation. Sterility documentation requires a culture protocol, temperature(s) of incubation, and interpretation different from those that are applicable to diagnostic cultures. Thus, laboratories should institute policies regarding sterility testing and perform such tests only if the laboratory has the proper procedures in place. Moreover,

the laboratory should protect itself against inadvertent application of its diagnostic culture test result as though it were a result of a sterility test culture protocol. This type of communication should be accomplished by publishing in the laboratory handbook, and perhaps on all result reports, that the culture result was for diagnosis and cannot be utilized as a documentation of sterility. This is important because it is not always possible for the laboratorian to screen all specimens, reagents, or devices in advance regarding the intent of the culture.

The culture of specimens is just one of many ways in which the laboratory supports the infection control team. The antimicrobial agent susceptibility surveillance results should be published in a timely manner and subjected to careful evaluation for detection of emerging resistance trends. A new emphasis on early detection of emergence of resistance in certain nursing units or from specific body sites suggests that body site-specific antibiograms may be helpful for the intensive care units so that emergence of resistance is not masked by the large denominator of susceptible organisms isolated from outpatient clinics and units in which patients' stays are of short duration. In order to facilitate the interactions in infection control, the chief of microbiology should

serve on the Infection Control Committee and provide advice regarding appropriate cultural investigation of all epidemics and pseudoepidemics. Often, the ordering of cultures is a reflex reaction to a perceived problem when a little "shoe leather" epidemiology would solve the problem more rapidly and with fewer funds. Quarantining suspect goods during the investigation of the epidemiology of a problem, pending the determination that cultures must be done, is often superior to reflexively culturing these goods. While the goods are in quarantine, the necessity to culture can be assessed and the appropriate culture technology can be devised. Routine surveillance cultures and ad hoc investigative cultures are often the most overused or misused tests that a laboratory is asked to perform. Their overuse should be controlled by requiring authorization and oversight by officials of the infection control team. Institution of such a requirement is best accomplished by the adoption of a policy for control of such cultures. If adapted hospital wide, the policy will ensure that excessive, inappropriately designed cultural investigations are not launched. Control of excessive or misapplied cultures will allow the resources of the laboratory to be applied where they are needed most.

APPENDIX 13.2-1

Sample Investigation Plan for Infection Control

Cluster of *Burkholderia cepacia* in sputum and urine specimens—strategy for infection control investigation

I. FINDING

There has occurred a cluster of cultures positive for *Burkholderia cepacia* among urine and respiratory specimens that were submitted for patients from various nursing care units. The laboratory does not treat these two types of specimens similarly; thus, it is unlikely that this organism is being introduced into the specimens after their arrival in the laboratory. Thus, a formal investigation of the other potential sources of the organism is recommended as follows.

II. DISCUSSION

Documentation of similar problems from literature

A. Pseudoinfections due to *B. cepacia*

A literature review reveals that contaminated disinfectants and antiseptics (povidone iodine and benzalkonium chloride) have been responsible for pseudoepidemics due to this organism. Other sources have included a contaminated anesthetic solution and a blood gas analyzer. Focus of this investigation should include all water-based, non-sterile fluids to which the patient is exposed.

B. True infections due to *B. cepacia*

1. Cystic fibrosis literature reveals many infections in this patient population, but these would not be applicable to this case.
2. Literature search reveals little documentation of hospital epidemics of true infections due to this organism.

APPENDIX 13.2–1 (continued)

III. CONCLUSION

Given the resistant nature of this organism and its potential infectivity, an ongoing investigation should be initiated.

IV. RECOMMENDATIONS/ACTIONS

A. Laboratory responsibility

1. The laboratory will save all isolates of *B. cepacia* for future investigation from the standpoint of molecular epidemiology.
2. When new isolates are identified, the laboratory will immediately notify the nurse epidemiologist who is responsible for the unit in which the new isolates have occurred.

B. Nurse epidemiologist responsibility

The nurse epidemiologist who is in charge of the unit in which the isolate has occurred will initiate an immediate investigation to identify the possible source(s) of the organism, focusing on candidate sources that are most likely with this organism.

1. Specimen collection

Identify the individual who collected the specimen and determine what antiseptic was utilized in the collection process. If povidone iodine, identify the type (swab stick versus gauze pad versus vial) used and remove from the nursing unit all the lots of the implicated agent. If a collection kit that contains an antiseptic was used, remove samples of the kits. Record the lot number of the implicated kits on the form for investigation (below). Quarantine the implicated materials for possible further testing. This intervention must be done without delay in order to increase the likelihood that the supply on the nursing unit will be similar to that which was there on the day of collection.

2. Patient Chart Review

Conduct a chart review for possible means of colonization of the implicated patient site, focusing on the patient's recent (past 2 weeks) history. Since the organism is usually associated with water, the investigation should focus on moist or fluid environments but should not be overly restrictive. For example, a contaminated blood gas analyzer in an intensive care unit has been implicated as a source of a pseudoepidemic with this organism. Communicate the results of the investigation immediately to the Director of Clinical Microbiology to devise a strategy to investigate any implicated therapy or environmental source.

3. Notify the attending infectious disease faculty so that they might initiate a clinical consult.

4. Submit a monthly report of the ongoing investigation, summarizing the data from the investigation on the form below. Detail the chart review results on supplemental sheets with a listing of implicated environmental sources or therapies and providing written documentation relative to the action taken regarding any implicated sources.

C. Infectious disease responsibility

1. Consult on individual cases to ensure that therapy is adequate if infection is present.
2. Provide input on changes in recommendations/actions and follow-up throughout the course of the investigation.

V. FOLLOW-UP

Pending results of ongoing investigation, for example, if an implicated source is documented culturally, the source will be removed or cleaned and the monitoring will continue until the organism is no longer a problem.

APPENDIX 13.2–1 (continued)

Pseudoepidemic Investigation Report Form

Monthly report cover sheet, nurse epidemiologist _____

A. Cumulative culture results

Specimen type	Patient	Hosp ID #	Ward	Culture accession #	Date specimen collected

B. Specimen collection review

Ward	Antiseptic or other implicated source	Manufacturer	Lot #	Culture result, if indicated

C. Chart review—summary

List common nursing units, health care providers, procedures, devices, and therapies among the colonized or infected patients.

13.3

Policies for Environmental Sampling and Culturing for Infection Control

I. PRINCIPLE

Sampling of the environment should be performed only to answer a specific question, whether to support a defined hypothesis or to confirm an association generated by an epidemiologic investigation. Culturing for infection control purposes should be systematic, consistent, and part of a written infection control plan that is reviewed at least yearly and is specific to each facility. Arbitrary sampling risks generation of irrelevant or uninterpretable information. Worse, such information may be frankly misleading. In each case, in-

appropriate culturing can result in wasted effort and resources and may even cause harm to patients or personnel. For example, if arbitrary culturing identifies an irrelevant source of an organism, the epidemiologically important source may go undetected, leading to further unnecessary exposures.

Wasted resources may include laboratory time and supplies, infection control service time and effort, unnecessary treatment interventions or cleaning, building materials and worker time, and clinical

and administrative efforts. In addition to time and resources, meaningless results may lead to unwarranted fear and concern among workers and patients.

When indicated, environmental sampling may strengthen the results of an epidemiologic investigation. In addition to this confirmatory role, environmental cultures may have utility in measuring the impact of an intervention, e.g., confirming that a contaminated water source identified by an outbreak investigation has been adequately cleaned.

II. GUIDANCE FOR ENVIRONMENTAL SAMPLING

When considering whether to collect or process environmental cultures, the following criteria should be met.

- A. The decision to obtain environmental cultures should be based on epidemiologic evidence indicating an association between the environment and patient or personnel health.
- B. The decision to obtain environmental cultures must be supported by the infection control service, the hospital epidemiologist, and the microbiology laboratory director.
- C. Materials or surfaces to be cultured should be selected based on an epidemiologic association.
- D. Culture results should have a direct impact on an intended plan of action. If results will not affect the plan, cultures should not be performed.

III. CONTRAINDICATIONS TO ENVIRONMENTAL SAMPLING

Environmental culturing should never be performed merely to satisfy curiosity. Neither should environmental cultures precede an epidemiologic assessment of an outbreak (4). Though it may seem prudent to collect samples early for fear that they may not be available later, a prompt epidemiologic assessment is preferable and remains the best way to select the best specimens and avoid processing unnecessary, possibly misleading, samples.

IV. GUIDANCE FOR INFECTION CONTROL CULTURES**A. Surveillance cultures**

Surveillance cultures are performed prospectively, in contrast to retrospective evaluations of a patient's illness or an outbreak. Surveillance cultures may be of use when describing the local microbial ecology of a facility and the burden of a pathogen therein. However, organisms, sites, and populations for surveillance cultures must be chosen carefully to allow meaningful interpretation of data. Protocols for surveillance cultures should be designed with the infection control service, the hospital epidemiologist, and the clinical laboratory director. Surveillance protocols should ensure that culture methodology and intensity, population studied, and method of interpretation are all consistent and yield data that will have a meaningful impact on health care practices at the facility. If used, protocols should be instituted for predesignated time periods and reevaluated at least annually to decide whether further surveillance is warranted. Data should be analyzed and shared with appropriate clinical staff members.

B. Occupational health and employee cultures

Reasons for obtaining diagnostic studies of health care workers include confirmation of an epidemiologic link to an outbreak and evaluation of the infectious status of a worker recovering from a known, transmissible infectious disease, e.g., tuberculosis or influenza (1). States may differ regarding which infections require such testing. Local regulations should be consulted.

Routine screening cultures of employees are not useful and may yield confusing or harmful results. When an epidemiologic association has been demonstrated between an outbreak or cluster of infections and a particular worker, a confirmatory culture demonstrating the presence of related organisms may be helpful. The decision to perform such testing should be made with the infection control service, the hospital epidemiologist, and the clinical laboratory director, with attention to appropriate protection of worker confidentiality.

C. Testing of outbreak sources: pharmaceuticals and food and blood products

Clinical laboratories may receive requests to culture materials associated with outbreaks, e.g., food, pharmaceuticals, or other products that are suspected to be the source of an outbreak. Laboratories that do not routinely perform such testing should store specimens appropriately and refer them to the state or other reference laboratory for evaluation. Foods are stored at 4°C (5), and pharmaceuticals are stored according to manufacturers' instructions. Blood, transplant materials, and other biological products may be tested according to standardized protocols. Sources of protocols include the American Association of Blood Banks, the National Organ Procurement and Transplantation Network, the United Network for Organ Sharing, the American Association of Tissue Banks, and the Eye Bank Association of America.

D. Nonhuman and research materials

Animal specimens and research materials such as cell cultures should not be accepted for routine evaluations in a clinical microbiology laboratory. Appropriate media, methods, and safety precautions are necessary to perform effective cultures and to prevent transmission of animal pathogens to laboratory personnel (2). Research materials that may contain radioisotopes or hazardous chemical agents may pose additional risks. Requests to evaluate such materials should be assessed on a case-by-case basis, including careful discussion with the investigators and the clinical laboratory director.

V. SPECIAL CONSIDERATIONS

A. Medical progress continually generates new populations at increased risk of infectious diseases. Such fragile populations warrant special vigilance, effective surveillance, and appropriate infection control (3). Environmental sampling, however, should still meet the basic criteria outlined above.

V. SPECIAL CONSIDERATIONS

(continued)

- B. There are many organisms in the environment that are of interest and can have an effect on health. Arbitrary examination of the environment as a potential reservoir of such organisms may be a part of a research protocol, e.g., to describe microbial ecology. However, this is distinct from surveillance, infection control, or clinical care.
- C. Construction at or near a health care facility has been shown to be an independent risk factor for fungal infections in certain patient groups (6). Responses to construction activity should include protective measures such as controlling airflow to prevent movement of dust and particles from the construction site to patient care areas, prohibiting shared elevators and passages between construction personnel and high-risk patients, and ensuring that appropriate surveillance practices are in place to promptly alert care providers to unusual clusters of illness. Arbitrary environmental cultures are not useful.
- D. Concerns about water and air quality at health care facilities may lead to requests for environmental culturing. Sampling should be driven by clinical need and by specific features of individual facilities, e.g., water sources, climate, etc. The decision to perform environmental cultures should be made after careful consideration by the clinical laboratory director, the infection control service, and the hospital epidemiologist. Procedural and interpretive expertise is critical to the correct application of environmental microbiology. Facilities that do not routinely perform such testing should consider the services of a reference laboratory specializing in environmental microbiology.
- E. When an investigation reveals an epidemiologic association between a suspected environmental source and clinical infections, health care providers may request environmental cultures, e.g., of surfaces or equipment, to assess the effectiveness of cleaning measures. Such culturing should be performed only after the microbiology laboratory director, the infection control service, and the hospital epidemiologist have agreed upon the details of the process. These details include a statement of what specific organism is to be identified and how the culture results are going to be interpreted, i.e., what the exact parameters for defining adequate or inadequate cleaning will be.

The diversification of health care settings (e.g., home health care, nursing homes, assisted living, or outpatient dialysis centers) presents new challenges for the clinical microbiologist, hospital epidemiologist, and infection control professional as they work together to detect and investigate disease trends and outbreaks. A valuable tool in epidemiologic investigations is strain typing. This procedure is a quick guide that offers a simplified list of typing techniques of potential utility to clinical microbiologists. Readers seeking in-depth descriptions or detailed protocols should refer to References and Supplemental Reading.

Strain typing may be used (i) to recognize or confirm an outbreak, (ii) to confirm the source of transmission of an organism, (iii) to detect recurrent versus new infections in a patient, and (iv) to measure the impact of intervention strategies or prevention programs or to monitor trends in a microbial population, e.g., increasing proportions of a resistant strain of *Staphylococcus aureus* in a dialysis center (4).

Strain typing techniques are used to compare isolates of the same species to determine whether they share features, e.g., DNA macrorestriction patterns, nucleic acid sequences, or phenotypic traits that would suggest that they share a common origin. A strain, for purposes of this discussion, is represented by a group of isolates that have a common ancestor, and are indistinguishable from one another, but when analyzed by an effective typing method can be distinguished from other isolates of the same species. Organisms causing outbreaks can be related by strain type and by epidemiologic associations (7). Occasionally, an outbreak may include multiple strains.

Typing systems should be selected based on their utility for use with the target organism, discriminatory power, reproducibility, and ease of interpretation and use. The method chosen should be based on a feature of the target organism that is relatively stable and has adequate diversity within the species. Serotyping, for example, is based on antigenic surface de-

terminants and is useful for typing organisms including *Salmonella*, *Shigella*, *Legionella pneumophila*, and *Haemophilus influenzae*. There are over 2,000 antisera available for *Salmonella* typing (3). In contrast, serotyping is not useful for *S. aureus* because the organism does not possess adequate antigenic heterogeneity, i.e., epidemiologically unrelated organisms are likely to share a serotype (8). The discriminatory power of a typing method refers to its ability to differentiate among unrelated strains. A typing system should give consistent, reproducible results for the same isolate when tested on multiple occasions and be consistent for isolates over time, since epidemiologic investigations may be conducted over several months or even years (8). Typing methods vary greatly in their species-specific utility, complexity, interpretation, and rapidity (Table 13.5–1).

Typing methodologies are broadly divided into phenotypic (expressed) and genotypic (chromosomal and plasmid DNA, or RNA) categories.

I. PHENOTYPIC

Observe standard precautions.

A. Biotyping

Biotyping was one of the first methods used to investigate hospital outbreaks. The biotype is a profile generated from a battery of biochemical reactions used to identify an organism. Since isolates that vary by one or more reactions are not recognized as related, biotyping, for epidemiologic purposes, is not very discriminating (2, 4).

B. Antimicrobial susceptibility testing (AST)

AST may identify a new or changing antimicrobial susceptibility pattern that can be the first signal of an outbreak or a clinically significant trend. The information is readily available and inexpensive and may be useful in certain situations. The utility of AST for epidemiologic typing, however, is limited by changes in the microbial ecology of health care settings, e.g., the increasing rates of endemic methicillin-resistant *S. aureus* in hospitals. Susceptibility of organisms in an environment can change relatively quickly in response to the

Table 13.5–1 Typing systems for common outbreak isolates^a

Organism(s)	Primary method	Time (days) to result	Other methods used
<i>S. aureus</i>	PFGE	3	AP-PCR, plasmid profiling, Rep-PCR
Coagulase-negative staphylococci	PFGE	3	Plasmid profiling
Enterococci	PFGE	3	AP-PCR
<i>Streptococcus pneumoniae</i>	PFGE	3	Serotyping
<i>Listeria monocytogenes</i>	PFGE	3

<i>Salmonella</i> , <i>Shigella</i>	Serotyping	1	PFGE
<i>Pseudomonas aeruginosa</i>	PFGE	3	
<i>C. difficile</i>	Rep-PCR, AP-PCR	1	PFGE
<i>Mycobacterium tuberculosis</i>	IS6110 RFLP	1	Rep-PCR
Other mycobacteria	PFGE	3	

^a Compilation of data from references 1, 4, 6, and 8. AP-PCR, arbitrarily primed PCR.

I. PHENOTYPIC (continued)

selective pressure of antimicrobial use and can affect the utility of AST for epidemiologic typing (2).

C. Serotyping

Serotyping is based on antigenic determinants of bacterial cell components such as outer membranes, flagella, or capsules. Serotyping is used for *Salmonella*, *Shigella*, *Klebsiella*, *Streptococcus pneumoniae*, and other organisms but is not very discriminating for many other organisms.

D. Polyacrylamide gel electrophoresis

PAGE detects differences in cellular proteins by molecular size. Proteins are separated electrophoretically into visible bands within an acrylamide gel matrix. The protein bands can be visualized by staining or, rarely, detected radioactively (1).

E. Immunoblotting

Immunoblotting (Western blotting) is performed as a way to extract more information from PAGE. Following electrophoretic separation, proteins are transferred to a nitrocellulose membrane that is then exposed to specific antibodies, a labeled antiserum, and a detection substrate for visualization (1).

F. Bacteriophage typing

Bacteriophage typing identifies strains by their patterns of susceptibility to a specific set of phages (viruses that infect bacterial cells and cause lysis). This technique has been used primarily for *S. aureus*, however, DNA techniques have become the preferred method for *S. aureus* in the United States (2).

G. Multilocus enzyme electrophoresis (MLEE)

MLEE uses electrophoretic separation to distinguish among variants of neutral proteins, e.g., metabolic enzymes, of the organism. Variations are analyzed using mathematic algorithms (4).

II. GENOTYPIC

Observe standard precautions.

A. Plasmid profile analysis (PPA)

PPA (also known as plasmid fingerprinting) is one of the oldest genotypic methods of typing for epidemiologic support. Testing can be performed on many species, provides results in one day, is useful for high-volume testing, and is fairly inexpensive. PPA also is useful when serotyping of rough-phenotype colonies is not possible (5). However, plasmids can be acquired or deleted. For organisms that have few or no plasmids, this technique cannot be used. Plasmids are collected from the organism and assessed using restriction endonuclease digestion to yield enzyme-specific arrays of fragment sizes. This typing method has utility for assessing staphylococci, *Klebsiella*, *Enterobacter*, and *Serratia* (4, 8).

B. Restriction endonuclease analysis (REA)

Chromosomal REA uses restriction endonucleases that cut frequently to yield enzyme-specific fragments of the entire chromosome. This results in hundreds of bands. The variable presence of plasmid DNA, which is not reliably eliminated in this process, can affect the resulting patterns. This method has been used successfully for *Clostridium difficile* (7).

C. Southern blotting

Southern blotting utilizes the polymorphic nature of the locations of restriction enzyme target sequences in chromosomal DNA. Digested fragments are separated by gel electrophoresis, transferred to nitrocellulose or nylon membranes, and treated with radioactive, colorimetric, or chemiluminescently labeled DNA probes that bind to homologous chromosomal fragments. This method is more time-consuming and laborious than other methods available for routine epidemiologic typing (8).

D. Ribotyping

Ribotyping is an adaptation of the Southern blot-restriction fragment length polymorphism (RFLP) method. Probes from the 16S and 23S rRNA genes of *Escherichia coli* are used, reducing the complexity of patterns seen with simple restriction digestion while retaining enough variability to allow discrimination of strains. This method has been used for epidemiologic studies of pathogens including *E. coli* and *S. aureus* (7, 8).

E. Pulsed-field gel electrophoresis (PFGE)

PFGE was developed in 1984 by Schwartz and Cantor, originally for eukaryotic cells, and adapted for use in bacteria (6). Organisms are embedded in agarose, wherein cells are lysed and chromosomal DNA is released and digested with restriction enzymes. The DNA fragments are separated by electrophoresis through the agarose matrix using a pulsed current, oriented diagonally, allowing separation of very large DNA fragments. This method is highly reproducible and discriminatory (4).

F. PCR-based locus-specific restriction fragment length polymorphism (RFLP) typing

PCR-based locus-specific RFLP typing amplifies a gene locus using specific primers and then analyzes the product by electrophoresis. PCR is based on the amplification of a minute quantity of DNA by repetitive replication cycles. Heat-stable polymerase enzymes are used, and incubation in heating devices with automated temperature controls (thermocyclers) allows repetitive association and dissociation between a DNA target sequence and a selected set of replication primers. The amplified DNA sequence is cut by restriction endonuclease digestion, and fragments are separated electrophoretically in an agarose or polyacrylamide gel and visualized by staining with ethidium bromide (4). PCR can detect DNA from organisms that might not be retrievable by conventional culture methods, including nonviable organisms. However, PCR techniques are extremely susceptible to contamination and cross-contamination, since any amount

II. GENOTYPIC (continued)

of contaminating DNA can be amplified and result in the appearance of spurious bands on gel electrophoresis.

G. Randomly amplified polymorphic DNA (RAPD) analysis

RAPD analysis is performed using an arbitrary sequence for the primer. A short primer that hybridizes at random chromosomal sites results in amplification of an array of sequences of various lengths. The resultant sequences are analyzed by gel electrophoresis (5).

H. Repetitive element (Rep)-PCR

Rep-PCR amplifies repetitive sequences in bacterial genomes, which result in strain-specific patterns. Enterobacterial repetitive intergenic consensus (ERIC) is another set of elements that are used for typing. ERIC patterns are not as complex as Rep patterns. When used in conjunction, both Rep and ERIC amplifications enhance the discriminatory ability of PCR. Rep-PCR can be automated and data from multiple outbreaks can be compared (5).

I. Cleavase fragment length polymorphism (CFLP)

CFLP uses a thermostable endonuclease, cleavase 1, which recognizes and cuts DNA at the sites of secondary structures formed only at higher temperatures (5).

J. Amplified fragment length polymorphism (AFLP)

AFLP amplifies DNA fragments created by restriction enzyme digestion. The most common procedure uses two enzymes to make fragments with differing end sequences. The cut DNA fragments are linked to fragments containing the sequence for binding the PCR primer. PCR is performed, amplified fragments are separated electrophoretically, and the patterns are examined using radioactive or fluorescent labels or ethidium bromide staining (5).

K. Nucleic acid sequencing

Nucleic acid sequencing can be performed on amplified sequences of DNA or RNA. Sequencing reactions incorporating labeled nucleotides are examined by gel electrophoresis. The sequence is read using differential fluorescent labeling of nucleotides. Resulting data can be stored on computers for sequence comparison. This method is the “gold standard” for viral typing (5). For other organisms, however, identical sequences may not predict identical phenotype or behavior.

III. RESEARCH VERSUS CLINICAL TOOLS

This brief overview of strain typing methods demonstrates the wide range of techniques available. The list is not exhaustive, and even among those methods included, many are too costly or are unavailable for clinical use, or they generate results that are not useful for purposes of epidemiology. Nucleic acid amplification technology has resulted in powerful methods that raise the possibility of identifying and characterizing organisms directly from clinical specimens, instead of awaiting pure cultures. These methods now allow identification of organisms that we remain unable to culture, e.g., hepatitis C virus and the organism causing Whipple’s disease, *Tropheryma whipplei* (4). New organisms are now being classified using 16S rRNA sequencing.

Techniques currently felt to be clinically useful, adaptable, and readily available for strain typing to support epidemiologic investigations are compared below (Table 13.5–2).

Table 13.5–2 Comparison of strain typing methods^a

IV. RELATIVE COST

Strain typing costs are determined by the same parameters as other laboratory tests. Instrumentation costs vary greatly; for RFLP, RAPD analysis, and CFLP, equipment costs range from \$8,000 to \$12,000; PFGE equipment costs range from \$10,000 to \$20,000; and AFLP and DNA sequencing equipment costs range between \$45,000 and \$130,000. The relative cost per test has been estimated at \$11 for RAPD analysis, \$14 for RFLP, \$20 for AFLP, \$22 for PFGE, \$40 for CFLP, and \$40 for DNA sequencing (5).

SUPPLEMENTAL READING

Persing, D. H., T. F. Smith, F. C. Tenover, and T. J. White (ed.). 1993. *Diagnostic Molecular Microbiology: Principles and Applications*. American Society for Microbiology, Washington, D.C.

I. PRINCIPLE

A. Ecology and transmission

1. *Legionella* spp. are ubiquitous in the aquatic environment. They are commonly found in a variety of natural and manufactured water sources, including drinking water systems, cooling towers, evaporative condensers, hot-water heaters, and respiratory therapy equipment.
2. The epidemiologic reservoir for nosocomial infections caused by *Legionella* spp. has been shown to be hospital water distribution systems, especially those for hot water. These organisms have been shown to be part of the microbiota that normally populates these systems (11).
3. Acquisition of legionellosis occurs primarily after inhalation of aero-

sols containing *Legionella* organisms (2). It has not been possible to document the environmental source of all *Legionella* infections of humans, particularly when sporadic cases occur, making "common-source" investigation irrelevant.

4. Certain people are more susceptible to *Legionella* infections than others. The more susceptible include the elderly, those with a history of smoking, those with underlying diseases such as reduced immune response, and surgical patients (8).

B. Source confirmation and isolation criteria

1. Recovery of *Legionella* spp. from an environmental source does not constitute proof that this is the source of the infecting agent. *Le-*

gionellae are frequently isolated from water sources unrelated to human disease (2).

2. Four criteria must be considered when investigating the source of a *Legionella* outbreak.
 - a. Association between exposure and a potential source
 - b. Identification of the mechanism of aerosol production
 - c. Clear documentation of *Legionella* etiology
 - d. Isolation of the same *Legionella* species from patients and implicated environmental source. In settings where a species of *Legionella* is ubiquitous, subtyping may be necessary for adequate association of the disease with an environmental source.

II. REAGENTS, MEDIA, AND SUPPLIES

A. Collection containers and swabs

1. Widemouthed glass or plastic bottles; for example, Nalgene polypropylene 4- and 32-oz. (1 oz. = 29.573 ml) bottles (*see* Appendix 13.6-1 for addresses of suppliers)
2. Sterile cotton or polyester applicator; for example, S/P sterile Dacron-tipped applicator

B. Filters and filter assemblies

1. 0.2- μ m-pore-size polycarbonate membrane filters (Nuclepore)
2. Plastic filter funnel, 47 mm; for example, Gelman 47-mm magnetic plastic filter funnel
3. Filter funnel holder; for example, Gelman three-port filter funnel manifold
4. Stainless steel forceps; for example, Nalgene stainless steel filter forceps

C. Media

1. The most widely used medium is an ACES (*N*-2-acetamido-2-aminoethanesulfonic acid)-buffered (pH 6.9) charcoal yeast extract agar supplemented with cysteine, ferric pyrophosphate, and, optimally, α -ketoglutarate (BCYE $_{\alpha}$) (*see* Appendix 13.6-2 for formulation).
2. For environmental sites, selective media may also be necessary to prevent overgrowth of non-*Legionella* organisms. The two most commonly used selective media are GPVA medium (BCYE $_{\alpha}$ supplemented with glycine, polymyxin B, vancomycin, and anisomycin) and DGVP (BCYE $_{\alpha}$ supplemented with dyes, glycine, vancomycin, and polymyxin B) (*see* Appendix 13.6-2 for formulation).

II. REAGENTS, MEDIA, AND SUPPLIES (continued)

3. Other *Legionella* selective media have been described and are also satisfactory. However, different manufacturers may have slight variations in antibiotic supplement formulations.

D. Reagents

1. Acid treatment reagent, pH 2.0
Acid treatment of water is used to isolate *Legionella* spp. by suppressing the growth of other organisms not able to withstand exposure to acid (pH 2.0) (see Appendix 13.6–2).
2. Membrane-filtered reagents
Membrane filtration of all direct-fluorescence antibody reagents is recommended to eliminate *Legionella* spp. or cross-reacting organisms that have been found in these reagents and that cause false-positive direct-fluorescence assay reactions. Steam (or other) sterilization techniques are inadequate because they render organisms nonviable but do not remove them from the reagents, where they can be visually detected (see Appendix 13.6–2).
 - a. Filter-sterilized phosphate-buffered saline, pH 7.6
 - b. Filter-sterilized deionized or distilled water
3. Chlorine neutralizer for water collection container: sodium thiosulfate (Sigma Chemical Co.)
4. Buffered-glycerol mounting fluid, pH 9.0 (see Appendix 13.6–2).
5. *Legionella* direct-fluorescence assay polyclonal reagent (commercially available); for example,

SciMedx polyvalent polyclonal direct-fluorescence assay conjugate for *Legionella pneumophila*, serogroups 1 to 6.

E. Microscope and supplies

1. Fluorescence microscope with a filter system for fluorescein isothiocyanate detection and filters that produce a maximum excitation wavelength of 490 nm and a mean emission wavelength of 520 nm; for example (other microscopes and assemblies may give comparable results), Leitz Dialux 20 fluorescence microscope with HBO-100 mercury incident light source, Leitz I cube filter system (2 × KP490 and 1-mm GG455 primary filter, TK 510 dichroic beam-splitting mirror, and K515 secondary filter), 10× to 40× dry objective, 63× to 100× oil objective, and 6.3× to 10× eyepiece
2. Stereoscopic microscope; for example (other microscopes and assemblies may give comparable results), Reichert-Jung Series 40 Student stereoscopic microscope with either 15× fixed or 10× to 20× Magni-Changer magnification with 10× wide-field eyepiece
3. Illuminator (for oblique lighting); for example, Reichert-Jung Stereostar/200M Starlite illuminator with fixed, prefocused condenser
4. Fluorescence microscope slides
Slide has two etched 10-mm circles and is frosted on one side of one end; for example, S/P fluorescent slide

PREANALYTICAL CONSIDERATIONS

III. SPECIMENS

Observe standard precautions.

A. Site and sample selection

1. Select sampling sites based on epidemiologic data suggesting an association between patients and potential sources of water.
2. Sources of water that have been shown to contain *Legionella* spp. (2) are listed below as a guide for selecting samples.
 - a. General potable-water system of hospital
 - (1) Hot-water heater (water and sediment)
 - (2) Holding tank
 - b. Potable-water final-distribution outlets (patient contact areas)
 - (1) Shower outlet
 - (2) Hot- and cold-water faucets
 - (3) Hemodialysis water (incoming)

III. SPECIMENS (*continued*)

- c. Equipment
 - (1) Respiratory therapy
 - (2) Humidifiers
 - (3) Ice maker and ice
 - (4) Whirlpools (water and sediment)

B. Sample collection

The two primary types of samples that should be collected in a potable-water system are a swab and a 1-liter water sample at each site. Larger volumes of water (1 to 10 liters) may be needed for detection of legionellae in water having very low counts. Swabs are collected to address the issue of localization of the organisms in the distal termini of the water distribution system, from various points within plumbing systems, or from surfaces of spas or cooling towers. If necessary, hot-water storage tank samples can be collected as outlined below.

1. Swab samples

- a. After removal of showerheads or aerators, insert sterile swabs into shower and sink outlets and rotate them against the interior surface to dislodge residue (approximately four times while moving swab upwards into the opening).
- b. Plate swabs directly onto BCYE_α and BCYE_α selective media by streaking them down the middle of the agar surface and cross-streaking with a fresh sterile swab or loop (*see* Appendix 13.6–2 for medium formulations).
- c. In order to keep swabs moist in case further processing is necessary, place swabs in a small volume of original water taken at the same time. Store refrigerated.

2. Water samples

- a. After the swab sample has been taken, collect a 1-liter sample in an appropriate sterile water collection bottle. Use aseptic technique.
- b. Sample containers should be sterile, preferably widemouthed, and either plastic or glass. If water is chlorinated, include sodium thiosulfate in the sterile container as a chlorine neutralizer. Add 0.83 ml of 0.1 N sodium thiosulfate solution to each liter sample container prior to sterilization. This concentration of sodium thiosulfate will neutralize approximately 5 mg of free chlorine per liter (1).
- c. Transport samples to the laboratory in insulated containers to protect samples from extremes in temperature.
- d. If samples cannot be processed the same day they are collected, refrigerate them at 4°C to minimize decline of *Legionella* spp. and to minimize overgrowth of competing microbiota in sample. Process samples in the laboratory as soon as possible, preferably within 48 h of collection.

3. Hot-water storage tanks

- a. Immediately collect the first 10 to 50 ml of the water into a suitable sterile container. This sample reflects the stagnant water in the supply pipe.
- b. Allow the water to flush for approximately 30 s, and then collect another 10 to 50 ml in a suitable sterile container. This water reflects the tank.
- c. Process both samples with direct-plating technique (*see* item V.B).

ANALYTICAL CONSIDERATIONS**IV. QUALITY CONTROL AND QUALITY ASSURANCE****A. Commercially prepared, ready-to-use media**

The NCCLS subcommittee on medium QC recommends that media not be retested by the user as long as the media are obtained from commercial sources that employ the QC criteria listed in the NCCLS standard for commercially prepared microbiological culture media (10).

IV. QUALITY CONTROL AND QUALITY ASSURANCE

(continued)

B. Media prepared in-house

Each batch of media must be tested for pH and the ability to support the growth of legionellae (6, 10).

1. Measure pH.
 - a. The pH of the medium is critical. It must be 6.9 ± 0.05 .
 - b. To check solid media, use a surface electrode (if available), or emulsify the agar from one plate in distilled water and measure the pH of the emulsion.
 - c. If given lots of ingredients do not conform to the acceptable pH range, adjust the pH of the completed liquid medium by adding sterile 1 N HCl or 1 N KOH.
2. Check for support of *Legionella* growth.
 - a. Prepare a standardized inoculum by emulsifying actively growing (in logarithmic stage) *L. pneumophila* in sterile distilled or deionized water to a turbidity equivalent of a 0.5 McFarland standard. The NCCLS subcommittee on medium QC recommends using *L. pneumophila* ATCC 33152 and *Legionella bozemanii* ATCC 33217 (10).
 - b. Dilute the cell suspension 1:100 in sterile phosphate-buffered saline, and inoculate each test plate with a 10- μ l calibrated loop of the diluted suspension to provide 10^3 to 10^4 CFU per plate. Streak the plates for isolated colonies, and incubate at 35°C in a humidified atmosphere (>50%). If this does not provide isolated colonies on the media, use a 10-fold-lighter inoculum (10).
 - c. Examine the media daily. On agar plates, growth should be present in the heavily inoculated area after 1 day. Isolated colonies should be macroscopically visible in 2 to 3 days. If cells in standard inoculum have been refrigerated or frozen, growth will be slower.
3. Selective capability of selective medium

Since the NCCLS subcommittee on medium QC has not listed an ATCC organism with which to test the inhibitory capacity of *Legionella*-selective media and since there is no current literature on this subject, a standard procedure cannot be recommended (10). If possible, selective media should be checked using an environmental water sample known to contain legionellae and other bacteria.

4. Sterility check

Incubate one uninoculated plate to check for sterility.

C. QC of reagents

Fluorescent-antibody reagent

1. Each day the test is performed, use a positive and a negative control to verify that the staining agent is reactive and that all reagents are *Legionella* free.
2. Process a positive control smear separately from sample smears to avoid possible carryover.

D. QA

Report all isolates of *Legionella* to the Infection Control Committee for review of QA.

V. SAMPLE PREPARATION

A. Concentration by filtration (potable water)

Samples such as potable ("drinking") water have very low bacterial counts and usually require concentration by filtration for successful recovery of *Legionella* (Fig. 13.6-1).

1. Filter samples through sterile 47-mm filter funnel assemblies containing 0.2- μ m-pore-size filters. Capillary pore membranes are preferred (i.e., Nuclepore polycarbonate) because of their uniform, smooth-bore pores.

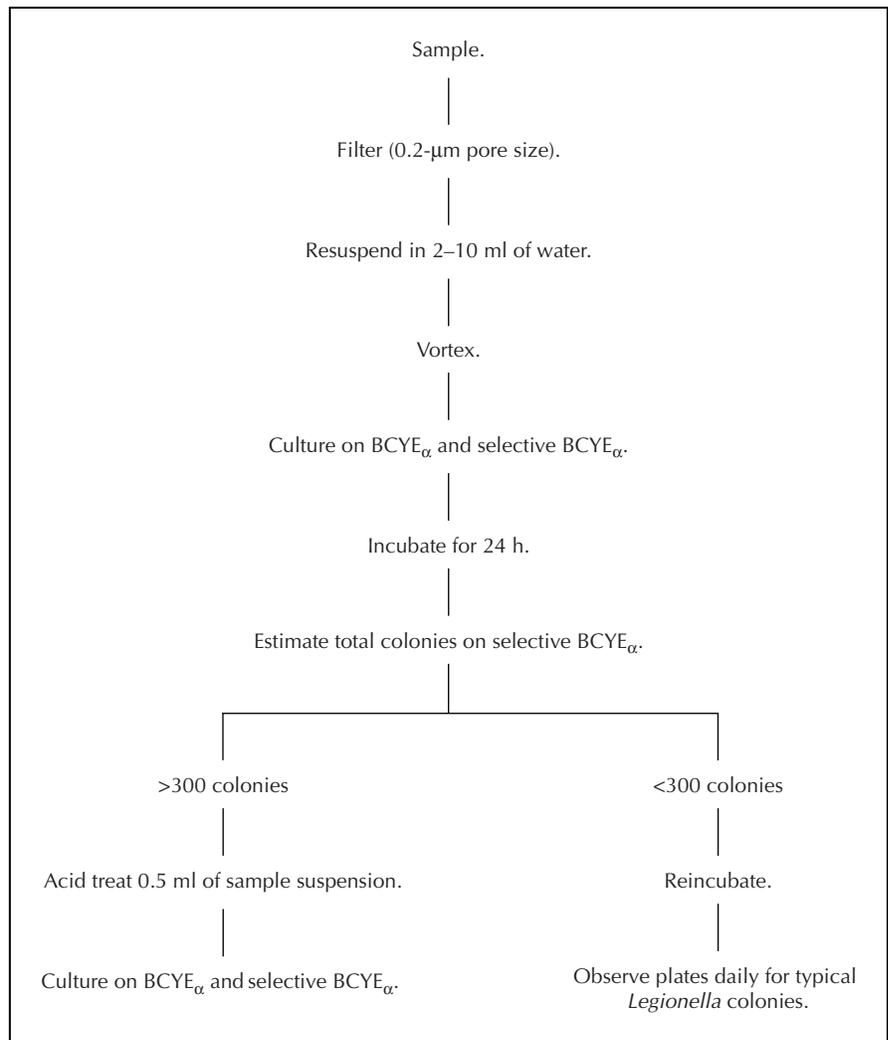

Figure 13.6–1 Flowchart for concentration by filtration.

V. SAMPLE PREPARATION (continued)

2. Immediately remove the filter with sterile forceps, and place it soiled side down or folded to the outside in a 50-ml sterile centrifuge tube or similar-size vessel containing 2 to 10 ml of original sample (record volume). The smaller amount of original sample will yield a lower detection limit.
3. If more than one filter is required to concentrate a sample, combine all filters into one tube.

B. Direct plating (nonpotable water and sediment)

Samples other than drinking water, such as nonsterile humidifier water, need not be concentrated (Fig. 13.6–2). Place a 10-ml sample in a 50-ml centrifuge tube and process directly.

C. Sample dispersion for both concentration and direct-plating samples

Tighten caps on sample centrifuge tubes. Vortex for 30 s to disperse organisms from filter or break up aggregates in water (3, 6).

D. Acid treatment for concentration by filtration (6)

1. Samples that are found to have high concentrations of bacteria after plating will require acid (pH 2.0) treatment to improve recovery of *Legionella* spp.

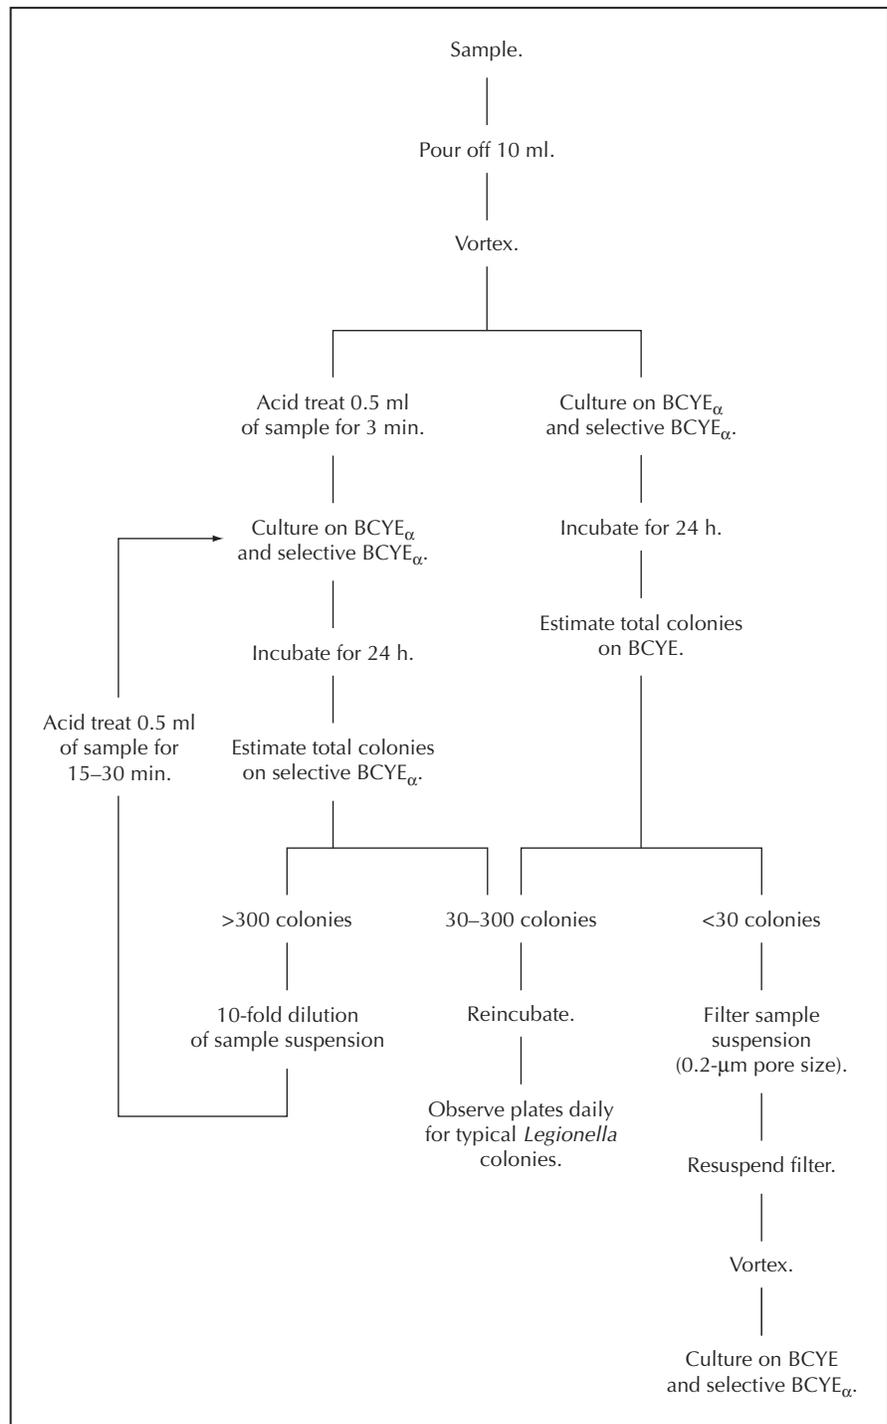

Figure 13.6–2 Flowchart for direct plating.

V. SAMPLE PREPARATION (continued)

2. Place 0.5 ml of the vortexed suspension into a sterile screw-cap tube (13 by 100 mm) containing 0.5 ml of acid treatment reagent, and mix. (The final pH of the mixture should be approximately 2.2.)
3. Let the acidified suspension stand for 3 min at room temperature. Acid treatment can be extended to 15 to 30 min if plates are overgrown after the initial 3-min treatment period (12).

VI. SPECIMEN PLATING**A. Concentration-by-filtration samples**

Plate specimens without acid treatment.

B. Direct-plating specimens

Plate both acid-treated and untreated suspensions.

C. Procedure

1. Inoculate 0.1 ml of suspension onto duplicate plates of BCYE_α and selective BCYE_α, such as GPVA or DGPV. A BAP may also be utilized for each sample to indicate the presence of organisms with colony morphologies similar to those of legionellae. If species other than *L. pneumophila* are expected, include duplicate BCYE_α plates that contain 1.0% albumin (ABCYE_α). *Legionella micdadei* and *L. bozemanii* have shown a preference for this medium (9).
2. Spread inoculum with a sterile glass (or disposable plastic) rod.

D. Storage of sample suspensions

Store sample suspensions at 4°C in case further dilutions, concentrations, or acid treatment is necessary.

VII. INCUBATION

Incubate all plates at 35°C in a humidified atmosphere (>50%) for up to 10 days.

■ **NOTE:** A candle jar or humidified CO₂ incubator (2 to 5% CO₂) is acceptable.

VIII. CULTURE EVALUATION**A. Total-bacterial-count examination**

After 24 h of incubation, examine plates to determine the adequacy of processing for each sample set. Ideally, there should be a plate with 30 to 300 colonies (Fig. 13.6–1 and 13.6–2).

1. Original direct-plating samples

- a. If the total count of non-*Legionella* organisms in an acid-treated sample exceeds 300 colonies on BCYE_α selective medium, make a further 10-fold dilution of the refrigerated sample suspension. Repeat acid treatment (for 15 to 30 min) and plating (*see* item V.D above).
- b. If the total count in a non-acid-treated sample is fewer than 30 colonies on BCYE_α agar, concentrate the original sample water as previously described (*see* item V.A above).

2. Original concentration-by-filtration sample

- a. If the total count in a sample exceeds 300 colonies on BCYE_α selective medium, treat the refrigerated sample suspension with acid as previously described for direct-plating samples (*see* item V.D above).
- b. If the total count in a sample is fewer than 300 colonies on BCYE_α agar, reincubate plates.

B. Examination of cultures for legionellae

1. After the initial 24 h of incubation, examine all cultures daily with the aid of a dissecting microscope for the appearance of gray-white bacterial colonies that have a “ground-glass” appearance.
2. Using a bacteriological needle, aseptically pick each suspect colony onto BCYE agar and a BCYE_α agar plate prepared without L-cysteine. If BCYE_α agar without L-cysteine is not available, a BAP can be used with the following precaution: some *Legionella* strains adapt to grow on blood agar in the absence of L-cysteine but require cysteine when first isolated (5).
3. Streak the inoculated portion of each plate with a sterile loop to provide areas of heavy growth, and incubate for up to 48 h. One plate can be divided, and several suspect colonies can be evaluated for growth requirements.

VIII. CULTURE EVALUATION (continued)

C. Presumptive identification of *Legionella* (Fig. 13.6–3)

1. Colony characteristics
 - a. Macroscopic: slow-growing (3 to 5 days) colonies on BCYE_α agar that are gray-white, glistening, convex, 1 to 4 mm in diameter, round with entire edges; absence of growth on BCYE_α without cysteine or on sheep blood agar; early in growth, show a pink or blue-green iridescence; older colonies become creamy white and often lose their iridescence.
 - b. Magnified with dissecting microscope with high oblique illumination: speckled opalescence resembling cut or ground glass.
 - c. Tenacity: colonies stringy, difficult to pick off, do not streak uniformly on subculture.
 - d. Colony fluorescence
Place the BCYE_α agar plate with suspect *Legionella* colonies under long-wave (366-nm) UV light. The colonies of some species (Fig. 13.6–3) autofluoresce a brilliant blue-white or bright red.
 ■ **NOTE:** *L. pneumophila*, the most commonly isolated *Legionella* sp., does not autofluoresce.
2. Gram stain reaction
 - a. Gram stain suspected *Legionella* colonies, preferably with carbol fuchsin instead of safranin counterstain, because safranin produces very faintly pink cells.
 - b. *Legionella* cells are small, gram-negative bacilli, 0.5 μm wide by 1 to 2 μm long. Depending on their physiologic state, some cells may be pleomorphic, with lengths up to 20 μm.

IX. CONFIRMATORY IDENTIFICATION OF LEGIONELLAE

Confirm presumptive *Legionella* spp. by immunofluorescence or nucleic acid analysis. When these confirmatory techniques are not available in the laboratory, proceed with the biochemical tests listed in Fig. 13.6–3 for presumptive identification, and send subcultures of the presumptive legionellae to a reference public health laboratory for further identification and subtyping. Because there are many subtypes in some species, especially *L. pneumophila*, subtyping of patient and environmental isolates may be necessary to confirm the source of the outbreak (2).

Immunofluorescence procedure

A. Direct water testing: smear preparation

When there is strong epidemiological evidence of a waterborne outbreak of legionellosis but water culture results are negative, an immunofluorescence procedure can be performed on the water to detect viable, nonculturable *Legionella* organisms, as reported in the literature (7). See Supplemental Reading for general references on immunofluorescence. Since there are specific problems associated with these techniques in the detection of *Legionella* spp., a specific step-by-step procedure is given here.

Caution: General directions are given here, but more-specific instructions are given by the manufacturers of the reagents chosen.

1. Using sample suspension selected from those in item V above, fill the two 10-mm circles on a two-well fluorescence microscope slide.
 - a. If concentration of original material is necessary, centrifuge 100 ml at $3,500 \times g$ for 30 min at room temperature.
 - b. Reconstitute the sediment with 1 to 2 ml of filter-sterilized deionized or distilled water or phosphate-buffered saline (pH 7.6).
2. Air dry sample smears.
3. Gently heat fix by rapidly passing the slide through a flame.

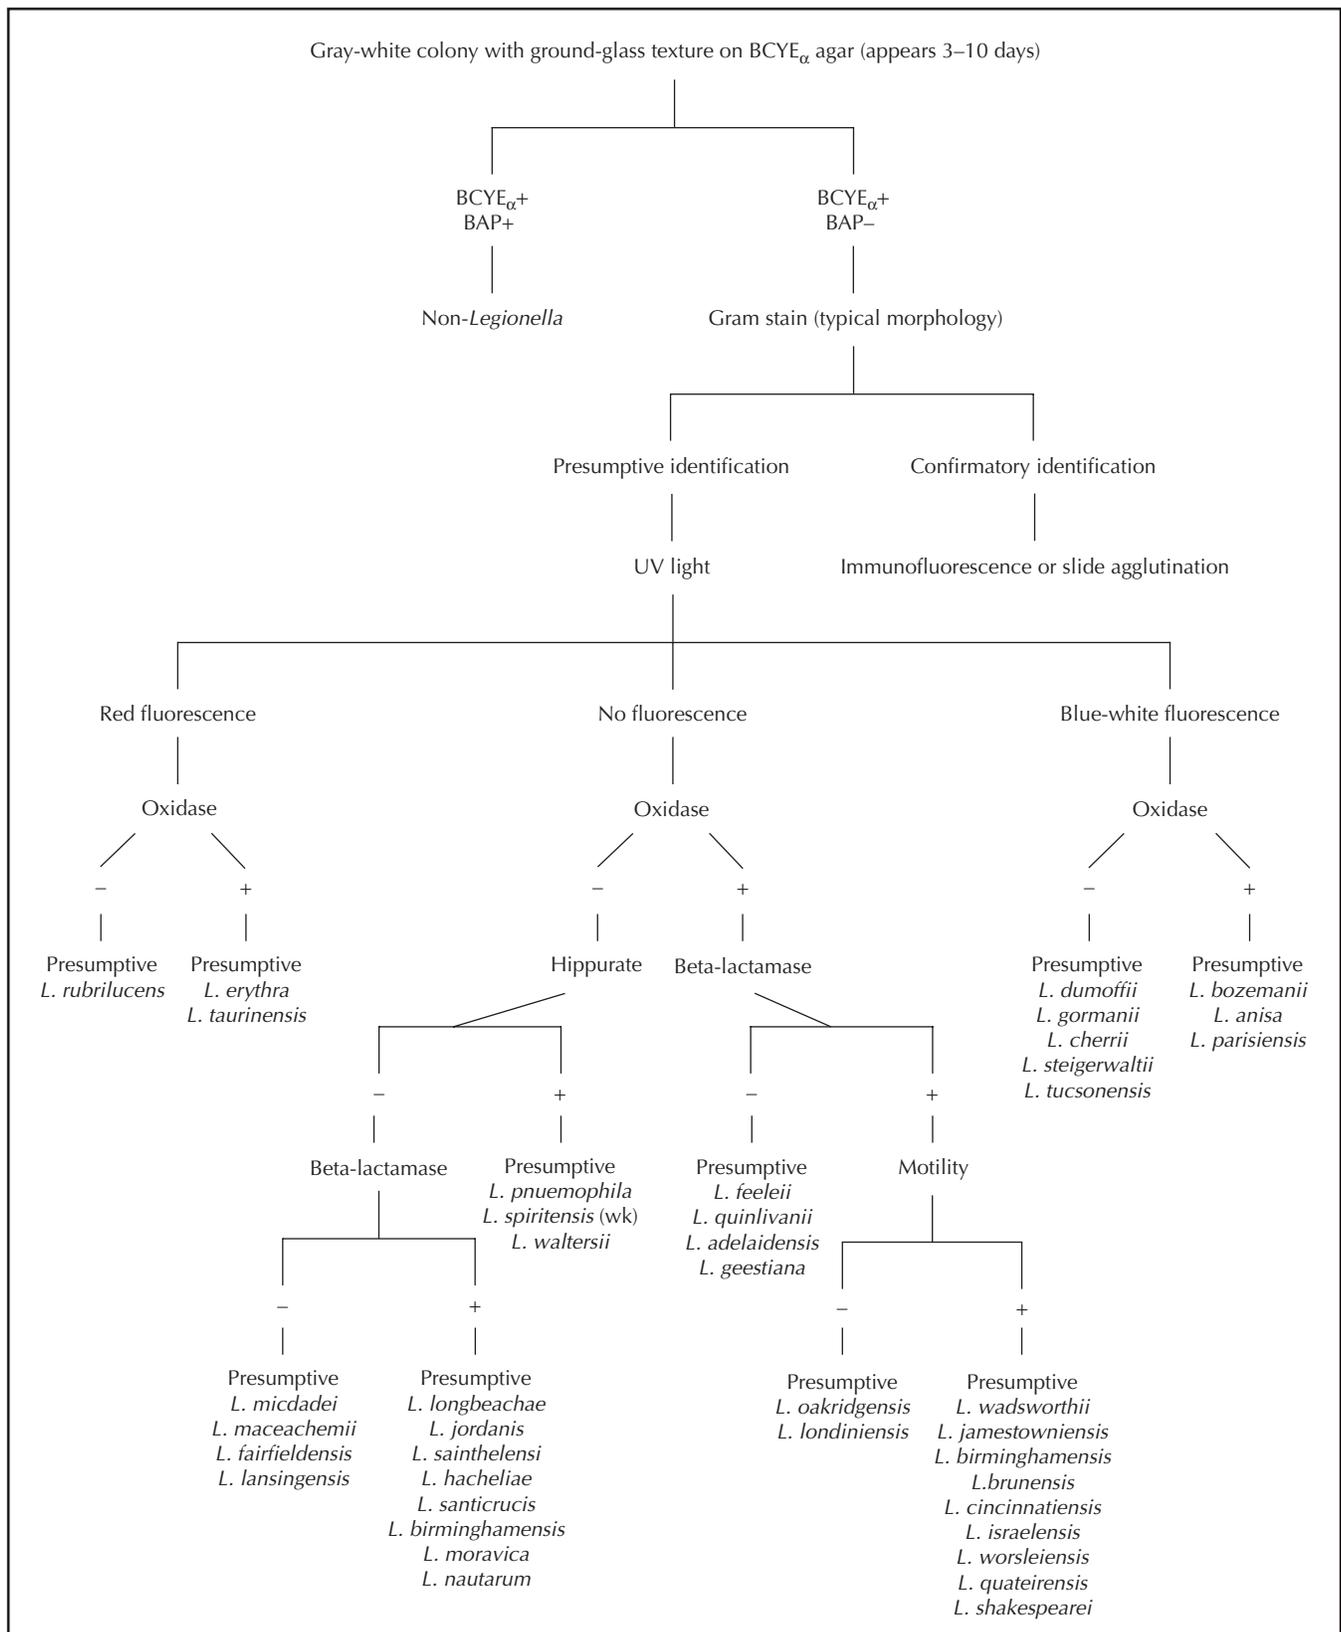

Figure 13.6–3 Flowchart for identification of the family Legionellaceae. wk, weak.

IX. CONFIRMATORY IDENTIFICATION OF LEGIONELLAE (*continued*)

4. Treat slide with filter-sterilized 1% formalin for 10 min.
5. Rinse with filter-sterilized phosphate-buffered saline (pH 7.6).

B. Culture confirmation: smear preparation

1. Using aseptic technique, remove a distinct colony of suspect *Legionella* from the culture plate, and suspend it in a test tube containing 0.5 to 1 ml of filter-sterilized 1% formalin in saline to the turbidity of a McFarland no. 0.5 standard. Avoid suspensions above a no. 0.5 McFarland standard, because fluorescence may be quenched by a prozone effect (too many organisms).
2. Using a Pasteur pipette, apply 1 or 2 drops of the suspension to a well on the slide, and then remove with the same Pasteur pipette. A thin film will remain on the well.
3. Air dry the smears.
4. Heat fix by rapidly passing the slide through a flame.

C. Fluorescence staining procedure

1. Apply enough *Legionella* fluorescent-antibody reagent to cover the specimen. It is best to use a polyclonal conjugate, because failures of some monoclonal reagents with environmental *Legionella* spp. have been reported (13).
2. Follow instructions on incubation time, temperature, and rinse given by the manufacturer, making sure all rinse water is filter sterilized (0.2- μ m-pore-size filter).
3. Air dry slides.
4. Add 2 or 3 drops of mounting medium to slide. Apply coverslip.

D. Examination of stained slides

1. Observe slides with a fluorescence microscope with a filter system for fluorescein isothiocyanate detection.
2. Use a 10 \times to 40 \times objective to screen slides for fluorescent rods.
3. Use a 63 \times to 100 \times oil objective to confirm cellular morphology.
4. Typical *Legionella* fluorescent-antibody morphology: short coccobacillary rods (direct water samples) or long filamentous rods (culture samples) showing bright (3 to 4+) apple-green cell wall fluorescence with darker centers.
5. Organisms that stain with $\leq 2+$ fluorescence intensity or that do not show typical *Legionella* morphology are reported as fluorescent-antibody negative.

E. Follow-up tests

If organisms of appropriate morphology are stained by a polyvalent conjugate, stain additional smears with serogroup- or species-specific reagents (whichever is appropriate) to further identify *Legionella* organisms (4). An organism that gives positive fluorescent-antibody results with only one serogroup-specific conjugate can be reported as belonging to that serogroup.

POSTANALYTICAL CONSIDERATIONS**X. REPORTING RESULTS****A. Qualitative**

1. Negative results should be reported as "*Legionella* species not found."
2. Positive results should be reported as "presumptive" or "confirmed" (whichever is appropriate). Give the *Legionella* species and serogroup (if known) and method performed; for example, *Legionella pneumophila* serogroup 1 found (confirmed by direct-fluorescence antibody and culture).

B. Quantitative

1. Swab sample: report as CFU per swab; for example, *Legionella pneumophila* found: 20 CFU per swab.
2. Water sample: report as CFU per milliliter or CFU per 100 ml; for example, if 1,000 ml of sample was filtered, the filter was placed in 2 ml of original

X. REPORTING RESULTS

(continued)

sample, and 0.1 ml was plated on two BCYE_α plates, the detection limit would be <1 CFU per 100 ml or <0.01 CFU/ml.

- a. Negative results would be reported as “*Legionella* species not found: <detection limit” (i.e., <0.01 CFU/ml or <1 CFU/100 ml with the example above).
- b. Positive results should be reported as the *Legionella* species and serogroup, method performed, and quantitation (number of colonies on each plate multiplied by detection limit); for example, *Legionella pneumophila* serogroup 1 found: 100 CFU/100 ml or 1 CFU/ml (confirmed by direct-fluorescence antibody and culture).

APPENDIX 13.6-2

Reagents and Media

A. Reagent formulations

1. Acid treatment reagent, pH 2.0 (0.2 M KCl or HCl) (1)
 - a. Solution A: 0.2 M KCl (14.9 g of KCl per liter of deionized or distilled water)
 - b. Solution B: 0.2 M HCl (16.7 ml of 10 N HCl per liter of deionized or distilled water)
 - c.

0.2 M HCl 3.9 ml
0.2 M KCl 25.0 ml

Mix these solutions, and measure pH (should be approximately pH 2). Dispense into screw-cap tubes in 1.0-ml volumes, and sterilize by autoclaving.

2. Filter-sterilized phosphate-buffered saline, pH 7.6 (0.01 M buffer, 0.85% NaCl)
 - a. Concentrated stock solution

Na₂HPO₄ 12.36 g
NaH₂PO₄·H₂O 1.80 g
NaCl 85.00 g
deionized or distilled water to make
final volume of 1,000 ml

- b. Working solution

concentrated stock solution 100 ml
deionized distilled water to make final
volume of 1,000 ml

Filter sterilize working solution through 0.22- μ m-pore-size filter, place in sterile container, and store in refrigerator.

3. Filter-sterilized deionized or distilled water
Filter sterilize distilled or deionized water through 0.22- μ m-pore-size filter, place in sterile container, and store in refrigerator.
4. Filter-sterilized formalin, 1%

formalin (commercial formaldehyde) 1 ml
filter-sterilized laboratory pure water 99 ml

5. Buffered-glycerol mounting fluid, pH 9.0

glycerol, reagent grade 90 ml
0.2 M Na₂HPO₄ 10 ml

6. McFarland nephelometer density standard no. 0.5 (3)
Add 0.5 ml of 0.048 M BaCl₂ (1.175% [wt/vol] BaCl₂·2H₂O) to 99.5 ml of 0.18 M (0.36 N) H₂SO₄ (1% [vol/vol]). Distribute 4 to 6 ml into screw-cap tubes of the same size as those used in growing or diluting the broth culture inoculum. Tightly seal these tubes to prevent any evaporation, label them, and store them in the dark at room temperature. Vigorously agitate this standard on a mechanical vortex mixer just before use.

APPENDIX 13.6–2 (continued)

B. Media

Individual ingredients listed below can be purchased from medium manufacturers or from Sigma Chemical Co.

1. BCYE_α base (1)

activated charcoal (Norit SG)	2.0 g
yeast extract	10.0 g
ACES buffer	10.0 g
ferric pyrophosphate, soluble	0.25 g
L-cysteine HCl·H ₂ O	0.4 g
agar	17.0 g
potassium α-ketoglutarate	1.0 g
deionized or distilled water	1.0 liter

Dissolve yeast extract, agar, charcoal, and α-ketoglutarate in approximately 850 ml of water, and boil. Dissolve 10 g of ACES buffer in 100 ml of warm water, adjust the pH to 6.9 ± 0.05 with 1 N KOH, and mix. Autoclave for 15 min at 121°C. Cool to 50°C in a water bath. Dissolve 0.4 g of cysteine and 0.25 g of ferric pyrophosphate in 10 ml of water each, and filter sterilize separately (0.22-μm-pore-size filter). After base has cooled to 50°C, add the filtered cysteine and ferric pyrophosphate, in that order. Adjust the pH to 6.9 at room temperature with sterile 1 N KOH, and bring to a final volume of 1.0 liter with distilled water. Swirl the medium to maintain the charcoal in suspension between pouring plates (15 by 100 mm) of 20 ml each.

Appropriately label batch with name of medium, date prepared, pH, lot number, and technician initials. Expiration date is 2 months if the medium is stored bagged and at 4°C.

2. GPVA medium (1)

glycine	0.3%
polymyxin B	100 U/ml
vancomycin	5 μg/ml
anisomycin	80 μg/ml

To cooled BCYE base with glycine (50°C), add filter-sterilized antibiotics (0.22-μm-pore-size filter), and mix. Adjust pH to 6.9 + 0.05 with sterile 1 N KOH, and bring to a final volume of 1.0 liter with distilled water. Swirl the medium to maintain the charcoal in suspension between pouring plates (15 by 100 mm) of 20 ml each. Appropriately label batch with name of medium, date, prepared, pH, lot number, and technician initials. Expiration date is 1 month if the medium is stored bagged and at 4°C.

3. DGVP medium (4)

glycine	0.3%
dyes:	
bromocresol purple	10 μg/ml
bromothymol blue	10 μg/ml
vancomycin	1.0 μg/ml
polymyxin B	50 μg/ml

To cooled BCYE_α base with glycine (50°C), add filter-sterilized antibiotics and dyes (0.22-μm-pore-size filter), and mix. Prepare 1% concentration of dyes by dissolving in 0.1 N KOH. Add 1 ml of respective dye per liter of medium. Adjust pH to 6.9 ± 0.05 with sterile 1 N KOH, and bring to a final volume of 1.0 liter with distilled water. Swirl the medium to maintain the charcoal in suspension between pouring plates (15 by 100 mm) of 20 ml each. Appropriately label batch with name of medium, date, prepared, pH, lot number, and technician initials. Expiration date is 1 month if the medium is stored bagged and at 4°C.

4. ABCYE_α medium (2)

To BCYE_α base described above, add 10 g of bovine serum albumin (fraction V) per liter.

APPENDIX 13.6–2 (continued)

I. PRINCIPLE

Patients undergoing hemodialysis are at risk for the development of endotoxin-mediated pyrogenic reactions, gram-negative bacteremia with sepsis, and chronic inflammatory response syndrome. These events may be related to excessive levels of gram-negative bacillary contamination of the water and dialysate used for

hemodialysis applications. This cause-and-effect relationship has led to the establishment of microbiological guidelines pertaining to the allowable levels of contamination in both the dialysate bath and dialysis water. These recommendations include frequency of monitoring and a list

of methods considered acceptable for the performance of quantitative testing. Endotoxin testing is discussed in the appendixes at the end of this procedure because it is not routinely done in the clinical setting and is performed usually by renal reference laboratories.

PREANALYTICAL CONSIDERATIONS

II. TEST FREQUENCY AND TIMING

A. Routine (no contamination or infection problem indicated)

Collect samples for monitoring purposes at least monthly.

B. Repeat

Collect repeat cultures when bacterial counts exceed the allowable level. If culture growth exceeds permissible standards, reculture the water system and dialysis machines weekly until acceptable results are obtained.

C. Ad hoc

Collect samples when clinical indications suggest pyrogenic reaction and/or septicemic complications following a specific request by the clinician and/or the infection control practitioner.

D. Timing

Samples should always be collected before sanitization/disinfection of the water treatment system and dialysis machines. If the system has just been disinfected (e.g., formaldehyde, hydrogen peroxide, chlorine, peracetic acid), flush the system completely before collecting samples. Drain and flush storage tanks and distribution system until disinfectant residual is no longer detected before collecting samples. Culture water and dialysis fluid weekly for new systems until an established pattern has been determined. For established systems, culture monthly unless a greater frequency is dictated by historical data at a given institution.

III. SPECIMENS

Collection

A. Dialysis water

1. Sample at a point immediately past the water treatment system (e.g., reverse-osmosis unit, deionization units, etc.).

III. SPECIMENS (*continued*)

2. If storage tanks are employed, sample as water exits the storage tank.
3. Sample just before the water enters the dialysis machine or central proportioner.
4. If the unit reprocesses hemodialyzers for reuse on the same patient, sample the water that is used to rinse the dialyzers and prepare the dialyzer disinfectant.

B. Dialysate

1. Following dialysis, collect dialysis fluid from the effluent dialysate port on the dialyzer.
2. With some newer dialysis machines, dialysate flow stops when the effluent line is disconnected from the port. In these instances the machines are equipped with dialysate sampling ports that can be accessed using a syringe.

C. Volume

Collect a minimum of 50 ml from each sampling point into sterile endotoxin-free containers. Most commercially available sterile plastic centrifuge tubes are actually endotoxin free.

IV. SUPPLIES FOR HETEROTROPHIC PLATE COUNT

- A. TSA (soybean casein digest agar in 100-mm-diameter plates); other acceptable media include standard methods agar and plate count agar. Blood agar and CHOC are not appropriate for this testing.
- B. 95% Ethanol
- C. Glass rod spreader (bent in the shape of a hockey stick) or commercially available sterile spreaders
- D. 35°C incubator
- E. Sterile 1-ml and 100- and 10- μ l pipettes

ANALYTICAL CONSIDERATIONS**V. PROCEDURE**

Observe standard precautions.

- A. Mix water samples by swirling or vortexing the sample container. Plate the following volumes onto the center of agar plates: 0.1 and 1 ml. For dialysate samples, add a third plate and inoculate with 10 μ l of sample. Spread inocula with a cool alcohol-flamed glass rod spreader or a sterile, plastic disposable spreader.
- B. Incubate plates in ambient air at 35°C for 48 h.
- C. Calculate the total colony count as follows: colony count \times volume of sample plated. Use plates with colony counts between 30 and 300.
- D. Identification of organisms is not required but can be done using standard procedures (in some cases identification may be difficult). Retain a plate containing representative colonies for 1 week in case bacteriologic follow-up is necessary.
- E. Report total CFU per milliliter.
- F. *Note:* Membrane filtration is the recommended method for testing hemodialysis fluids (1, 3). Commercially produced samplers (2) are also available for testing within the facilities but should not be used in the laboratory as an alternative to either membrane filtration or the spread plate method.

POSTANALYTICAL CONSIDERATIONS**VI. INTERPRETATION****A. Dialysate**

Favero and coworkers (5) and Dawids and Vejlsgaard (4) showed that the attack rate for pyrogenic reactions among patients undergoing renal dialysis was directly related to the number of organisms in the patients' dialysate bath. These studies provided the basis for the guideline of $< 2,000$ CFU/ml for dialysate. These dialysate standards will be lowered over the next 5 years.

VI. INTERPRETATION

(continued)

B. Water used for hemodialysis applications

The standard for bacteria in water was set to $1 \log_{01}$ less than that of the dialysate bath (<200 CFU/ml). However, this would allow for microbial amplification in the final dialysate bath without exceeding the Association for the Advancement of Medical Instrumentation (AAMI) standards (3). In the new standards for hemodialysis there will be an action limit of 50 CFU/ml, which means that the facility should consider some intervention.

C. Note: All water used for hemodialysis applications (i.e., preparing concentrates and dialysates, reprocessing dialyzers) must also be tested for the presence of endotoxin. In addition, there will most likely be an endotoxin requirement for the dialysate bath as well.

VII. CULTURE REPORTING

Report colony count per milliliter. When colony counts exceed 200 CFU/ml (water) and 2,000 CFU/ml (dialysate), call the medical director of the dialysis unit and the infection control practitioner immediately. For colony counts exceeding 50 CFU/ml in water, notify the technical staff responsible for maintaining the water treatment system.

VIII. QUALITY CONTROL AND QUALITY ASSURANCE

Report the results of all tests to the Infection Control Committee and to the nurse manager of the dialysis unit responsible for QA oversight.

APPENDIX 13.7-1

Bacterial Endotoxin Test (*Limulus* Amebocyte Lysate)

I. PRINCIPLE

Endotoxins are lipopolysaccharide (LPS) components of the gram-negative bacterial outer membrane. The toxic component of LPS resides in the lipid portion, lipid A. The polysaccharide subunit contributes to the toxicity of the molecule by promoting its water solubility. In humans, endotoxin may cause fever and leukopenia or, in more severe cases, shock. The threshold pyrogenic response is 5 endotoxin units (EU)/kg of body weight/h (intravenous administration). Endotoxin in hemodialysis fluids may contribute to a phenomenon now described as the chronic inflammatory response syndrome.

The use of *Limulus* amebocyte lysate for the detection of endotoxin evolved from the observation that gram-negative bacterial infections of the horseshoe crab, *Limulus polyphemus*, resulted in fatal intravascular coagulation. This is now known to be due to an enzyme reaction catalyzed by endotoxin. This phenomenon has led to the development of a series of tests that can be used for the detection of endotoxin in materials (e.g., devices, drugs, biologicals) used for human therapy.

Several test formats are commercially available, from a simple tube gel clot test to kinetic detection methods (e.g., colorimetric and turbidimetric assays).

PREANALYTICAL CONSIDERATIONS

II. SPECIMEN

A. Any liquid may be tested for endotoxin activity. Some compounds or solutions, because they may contain metals or surfactants or have high ionic strength or osmolarity, may give false-positive or false-negative results, produce enhancement, or inhibit the reactions. Testing methods and interpretation of results should be carefully reviewed. Some clinical laboratories may prefer to contract a commercial laboratory for this testing.

B. The pH of the sample should be 6.0 to 7.5.

C. Collect samples as in specimen for the culture of water and dialysate as described in item III of this procedure. If glass containers are used they should be made endotoxin free by baking in an oven at 180°C for 4 h.

D. Samples can be stored at 2 to 8°C for 24 h. For longer storage or shipping to a reference laboratory, samples can be frozen at -20°C.

III. REAGENTS AND SUPPLIES

Several commercial sources can supply endotoxin reagents and standards, testing systems, and test kits. Some of the leading U.S. vendors are listed below. This list is intended for informational purposes only and may not include every vendor or manufacturer selling these products in the United States.

A. Associates of Cape Cod, Falmouth, Mass. (endotoxin standards, gel clot reagents, multitest and single-tube tests, colorimetric and turbidimetric assays, contract testing services), <http://www.acciusa.com/>

B. Bio-Whittaker, Walkersville, Md. (endotoxin standards, gel clot reagents, turbidimetric reagents), http://www.cambrex.com/operating_companies/biowhittaker/

C. Charles River Laboratories, Charleston, S.C. (endotoxin standards, traditional gel clot reagents, colorimetric and turbidimetric assays, contract testing services), <http://www.criver.com/products/endotoxin/index.html>

D. DiaPharm, West Chester, Ohio (chromogenic *Limulus* amebocyte lysate [LAL] assay), <http://www.diapharma.com/>

ANALYTICAL CONSIDERATIONS

IV. PROCEDURE

Follow the manufacturer's instructions in the package labeling or package insert for the test kit or in the procedure manual for the LAL kinetic assay systems.

V. QUALITY CONTROL

A. The test sample must be run in parallel with dilutions of the endotoxin standard that bracket the endpoint sensitivity of the kit.

Observe standard precautions.

APPENDIX 13.7-1 (continued)

- B. The endotoxin control standard end point can be 0.001 to 5 EU/ml depending on whether a kinetic qualitative assay (e.g., turbidimetric, colorimetric) or a semiquantitative assay (gel clot, colorimetric) is used. If the control endpoint is less than the required standard sensitivity of the kit, notify the supervisor or director for instructions on how to restart.
- C. The sample inhibition control (sample plus an endotoxin spike containing two to four times the sensitivity of the LAL reagent) must be positive for each sample or the test is invalid.

POSTANALYTICAL CONSIDERATIONS

VI. REPORTING RESULTS

- A. If the test result of the sample is negative, report each negative sample as below the detectable limit of the test utilized. This will depend on the sensitivity of the reagents used, e.g., <0.03 EU/ml, <0.06 EU/ml, etc.
- B. Reporting of positive results will vary depending on whether one is using a quantitative kinetic assay, gel clot assay, or single-tube test. For the kinetic assays, results will be reported as EU per milliliter; for the gel clot test the EU per milliliter of the last tube to clot and the breakpoint will be reported. The first tube not to gel result would be the range between these two points. For single-tube tests the result would be reported as greater than or equal to the sensitivity of the single-tube test, e.g., ≥ 0.06 EU/ml, ≥ 0.125 EU/ml.

VII. LIMITATIONS

- A. The LAL reaction is enzyme mediated and has an optimal pH and specified salt and divalent-cation requirements. Occasionally, test samples may have to have pH adjusted or diluted to bring samples into optimal test conditions. Negative results with samples that inhibit the LAL test do not necessarily mean that endotoxin is not present in the sample.
- B. In some instances reactions may be enhanced. In these instances the sample may contain other contaminants, i.e., β -glucans such as cellulosic material (i.e., cupraammonium rayon, cellulose, cellulose acetate, or cellulose di- or triacetate), which may react with the LAL reagents. These materials are LAL-reactive materials and do not necessarily indicate the presence or absence of endotoxin.
- C. A standard for each product undergoing endotoxin testing must be established. In guidelines for water requirements for dialysis set forth in *American National Standard: Hemodialysis Systems* (1), the standard states that dialysis water must contain a colony count of ≤ 200 CFU/ml and a bacterial lipopolysaccharide activity less than 2 EU/ml with an action limit of 1 EU/ml measured by the LAL assay. This requirement is currently recommended only for hemodialysis facilities that reprocess hemodialyzers (2). However, the CDC recommends that both be measured since there are times when colony counts can be low and endotoxin activity high and the reverse can also be true (3-5). Current draft standards and CDC guidelines in development will address these issues further (Appendix 13.7-2).

APPENDIX 13.7–2

Maximum contaminant standards for hemodialysis

Fluid	Current AAMI standard		Draft AAMI RD52	
	CFU/ml	EU/ml	CFU/ml	EU/ml
Water to prepare dialysate	200 standard; action limit of 50 CFU/ml	2; action limit of 1	NA ^a	NA
Water for reprocessing hemodialyzers	200 standard; action limit of 50 CFU/ml	2; action limit of 1	NA	NA
Dialysate bath	2,000	No standard	200	2

^a NA, not applicable.

Draft standards in development that will impact hemodialysis

Association for the Advancement of Medical Instrumentation. 2002. *Recommended Practice Dialysate for Hemodialysis*. AAMI RD52 (in committee). Association for the Advancement of Medical Instrumentation, Arlington, Va.

Centers for Disease Control and Prevention and Healthcare Infection Control Practices Advisory Committee (HICPAC). 2003. Guidelines for environmental infection control in health-care facilities. *Morb. Mortal. Wkly. Rep.* **52**(RR-10): 1–48.

I. PRINCIPLE

A. Patient population

Patients with end-stage renal disease (ESRD) can receive transplants or be treated by either hemodialysis or peritoneal dialysis. In 1998, of the 346,453 patients in the United States with ESRD, 29% had a functioning graft, 61% were being treated by maintenance hemodialysis, and 7.3% were being treated by some form of peritoneal dialysis (16). The predominant types of peritoneal dialysis performed in the United States are continuous ambulatory peritoneal dialysis (CAPD) and continuous cycling peritoneal dialysis (CCPD).

B. Method

Dialysis fluid is infused into the peritoneum through a permanent catheter (Tenckhoff, Ash, Swan Neck, Toronto Western Hospital). This treatment can be done at home, which allows more freedom and flexibility. In ambulatory peritoneal dialysis (APD), there is 2 liters of dialysis fluid in the peritoneal

cavity all the time, so the blood is being cleaned constantly. The fluid is changed regularly throughout the day.

There are two kinds of APD: CAPD and CCPD.

In CAPD, the dialysis fluid is exchanged four times a day. An exchange is done by draining the old fluid and refilling the peritoneal cavity with fresh fluid. This takes about 45 min. The exchanges are spaced throughout the day.

In CCPD, the patient is attached to an automatic cyclor machine during the night and exchanges are done during sleep. In the morning, when the patient is coming off the machine, about 2 liters of dialysis fluid is left in the peritoneal cavity for the day. In the evening, this fluid is drained out when the patient is reconnected to the automatic cyclor for the night.

Intermittent peritoneal dialysis (IPD) is done on an inpatient basis. Most people need about 36 to 44 h of

IPD weekly, so it means spending 2 or 3 days away from home every week. In IPD, the dialysis fluid is left in the peritoneal cavity for a short period of time and then is drained out. One complete cycle is called an exchange, and an IPD exchange takes about 1 h to complete.

C. Precautions

All bag manipulations are performed using aseptic techniques to reduce the danger of external contamination.

D. Outcome

Even with aseptic techniques infections are not uncommon, and incidence rates vary from center to center. Approximately one episode of peritonitis in 24 patient-treatment months has been observed. Some centers have even reported one episode in 60 patient-treatment months (7). See Appendix 13.8-1 for further discussion.

PREANALYTICAL CONSIDERATIONS

II. SPECIMEN

A. Collection and transport

1. Safety precautions

Enclose dialysate bag in a larger plastic bag. Place this bag into a disposable plastic or other leakproof container and transport it to the laboratory.

2. Obtain the first cloudy effluent for culture (greatest probability of obtaining a positive culture). Patients who receive automated peritoneal dialysis (e.g., CCPD) may have effluent that appears clear; if this is the case, a second exchange is performed with a dwell time of at least 1 h and the appearance of the fluid is reevaluated.

Approximately 6% of adults with culture-positive peritonitis have effluent that is clear and experience abdominal pain (3, 6-8).

II. SPECIMEN (continued)

3. Conditions

- a. Deliver to the laboratory immediately, transport at room temperature.
- b. If delivery will take more than 1 h after collection, refrigerate but do not freeze.

B. Processing

1. Mix contents of the bag by inverting the bag 10 to 20 times.
2. Disinfect the entry port with povidone-iodine (allow to air dry), and withdraw 100 ml of fluid and place in sterile 50-ml screw-cap centrifuge tubes.
3. Perform a cell count with differential. If there are >50 WBCs/mm³, culture may be indicated (9). An elevated dialysate WBC count, >100 WBC/mm³, of which at least 50% are PMNs, is supportive of a diagnosis of microbially induced peritonitis (6–8). Cell count and differential may be performed by hematology or another appropriate laboratory if the microbiology laboratory is not equipped to do it.
4. Centrifuge samples for 15 min at $3,000 \times g$ and carefully decant the supernatant from each tube.
5. Perform Gram stain from the sediment.
6. Vortex and suspend the sediment with 5 ml of sterile saline.
7. Use resuspended sediment from step II.B.6 above to inoculate media (*see* item IV.B below).

III. MATERIALS

Media, supplies, and instruments are those commonly utilized in the laboratory and are employed selectively, as dictated by the choice of culture protocol. In general, the following may be employed: blood agar plate, CHOC plate, EMB or Mac-

Conkey agar, inhibitory mold agar plate, BHI agar with blood or Sabouraud's dextrose agar, and blood culture media (e.g., BacT/Alert FAN blood bottle, Septi-Chek, or BACTEC bottle).

ANALYTICAL CONSIDERATIONS

IV. PROCEDURE

Observe standard precautions.

A. Microscopic examination

1. Gram stain
 - a. Concentrate specimen by centrifugation as described above.
 - b. Prepare a Gram-stained smear, and review microscopically.
 - c. If organisms are detected by microscopic examination, report these immediately.
 - d. A Gram stain is positive in 9 to 40% of peritonitis episodes, and when positive, it is predictive of culture results in approximately 85% of the cases (7). Even though the Gram stain is positive in less than 50% of the cases, it is still clinically useful in promoting early therapy.

2. Acid-fast smear

The clinical utility of acid-fast stains is extremely limited. Leukocyte differential and acid-fast smears often fail to aid in the diagnosis of peritonitis associated with *Mycobacterium* spp. Tuberculous peritonitis is a rare complication of peritoneal dialysis (7, 18). Nontuberculous mycobacteria (*Mycobacterium fortuitum*, *Mycobacterium kansasii*, *Mycobacterium goodii*) have been associated with peritonitis. Clinically, these organisms should be considered as etiologic agents in cases of sterile peritonitis.

B. Culture

1. Bacteria

- a. Inoculate aerobic culture plates and broth (blood culture bottles) with concentrated specimen. Using a Pasteur pipette, aspirate the sediment and place 1 drop on bacteriological culture plates (blood agar, CHOC, EMB,

IV. PROCEDURE (*continued*)

or MacConkey agar). Place 5 ml of sample into a blood culture bottle. Incubate plates in 5% CO₂ at 35°C for 48 h and the blood culture system (lysis centrifugation, BACTEC, BacT/Alert, Septi-Chek) for 5 to 7 days (1, 2, 5, 10, 12–15, 17, 19–22).

b. Anaerobic bacteria in CAPD, CCPD, or IPD peritonitis are rare. Anaerobic bacteria are associated with severe peritonitis, and it may be useful to include them in a workup. The International Society for Peritoneal Dialysis considers culturing for anaerobes an optional procedure (7).

(1) Inoculate nonselective anaerobic culture media (*see* section 4 of this handbook), and incubate them at 35°C under an anaerobic atmosphere for 7 days.

(2) A broth should be incubated for an additional week for delayed appearance of slowly growing anaerobes.

2. Mycobacteria and fungi

Cultures can be performed either in parallel or in tandem.

a. Parallel cultures

(1) Concentrated dialysate is inoculated onto both mycobacterial and fungal media on the same day.

(2) This is indicated if acid-fast smear, calcofluor white stain, or KOH preparation is positive.

b. Tandem cultures

(1) Concentrated dialysate is reserved in the refrigerator for 5 days.

(2) If the bacterial cultures are negative and the patient is not responding to therapy, fungal and mycobacterial cultures are set up. The extended incubation period will allow for increased yield of bacteria or rapidly growing yeasts and mycobacteria. This will reduce the need for supplemental cultures for acid-fast bacteria or fungi.

V. LIMITATIONS OF THE PROCEDURE**A. Supplemental biopsy**

Biopsy may be indicated when bacterial cultures are negative and tuberculous peritonitis is suspected.

B. Other supplemental methods

Limulus amebocyte lysate and other tests for the detection of infectious agents may not be sufficiently sensitive or specific to be of value unless employed rigidly for specific therapeutic protocols (4, 11).

POSTANALYTICAL CONSIDERATIONS

VI. INTERPRETATION**A. Contamination**

Patient skin microorganisms (*Staphylococcus aureus* and other *Staphylococcus* species) are the predominant cause of peritonitis associated with ambulatory and automated dialysis. Dialysis-associated peritonitis is characterized by low levels of these organisms; thus, the primary difficulty in interpretation of culture results lies in distinguishing exogenous contaminants from those actively producing infection. Here are some simple caveats.

1. Consider the following positive.

a. One or more colonies or colony types, regardless of the identity of the organism, that grow on streak lines or in inoculated areas

b. One or more colonies or colony types that grow in the inoculum or on streaked lines that differ in appearance from those that grow outside of the streaked lines or inoculum

VI. INTERPRETATION*(continued)*

2. Consider the following contaminants.

- a. Colonies found exclusively outside both the inoculum and streak lines
- b. Colonies of the same appearance that grow on streak lines as those outside the streak lines or inoculum

B. Quantitation

Low numbers of organisms are considered potentially significant, but confounding organisms are frequently isolated from patients without peritonitis. Use clinical judgment.

C. Clinical correlation

1. Cell count

- a. Normal peritoneal fluid (6-h dwell time for CAPD)
 - (1) Contains 50 to 100 WBCs/mm³, mostly mononuclear
 - (2) Visibly clear
- b. Peritoneal dialysis fluid
 - (1) Contains >100 WBCs/mm³
 - (2) Visibly cloudy

2. Differential

- a. Bacterial peritonitis: PMNs predominate (>50%) (6–8)
- b. Mycobacterial peritonitis
 - (1) Neutrophils are sometimes associated with mycobacterial peritonitis (18).
 - (2) Mononuclear cells are often associated with mycobacterial peritonitis (7, 18).
- c. Allergic peritonitis: eosinophils comprise up to 10% of the WBC count (7, 8).

3. Signs and symptoms

- a. Patients with cloudy fluid and/or abdominal pain and/or fever (>4-h dwell time, CAPD)
- b. Patients with cloudy fluid and/or abdominal pain, and/or fever at any point in the automated peritoneal dialysis treatment cycle (CCPD). In equivocal cases, i.e., abdominal pain and/or fever and clear dialysate, add a second exchange with a dwell time of at least 2 h (7).

4. Clinical response

For patients who fail to demonstrate clinical improvement in 48 to 96 h, a reevaluation is essential. Specifically, cell counts, Gram stain, and cultures should be repeated with the aid of antimicrobial removal devices. Among clinical concerns in patients with persistent symptoms is the presence of intra-abdominal or gynecological pathology requiring surgical intervention, or the presence of mycobacteria, fungi, or other fastidious organisms (6–8).

VII. QUALITY ASSURANCE**A. QC**

1. Routine QC of media and reagents as described elsewhere in this handbook
2. Parallel culture of sterile saline or distilled water used to resuspend the cells in step II.B.6

B. QA

Report all positive cultures both to Infection Control and to the referring dialysis unit. Upon establishing that there is an increased infection rate, a repetitive microorganism, or an apparent pseudoinfection, Infection Control and the dialysis facility should initiate an investigation and consider the institution of appropriate intervention or monitoring strategies.

APPENDIX 13.8-1

CAPD and Infections Associated with Automated Peritoneal Dialysis

A. CAPD-associated infections

1. Types

- a. Infection of the catheter exit site or subcutaneous tunnel
- b. Infection of the peritoneum
- c. Infection of the catheter exit site or subcutaneous tunnel is often a precursor to infection of the peritoneum.

2. Etiologic agents

Although bacteria predominate, fungal and mycobacterial infections are reported and are probably more common than the data suggest.

3. Origin

- a. Common skin microorganisms: access via catheter lumen or periluminal space
- b. Intestinal organisms, transmural access
- c. Hematogenous seeding (streptococci and *M. tuberculosis*)
- d. Vaginal, ascending (yeasts)
- e. Environmental (e.g., tap water, *Mycobacterium chelonae*, *Methylobacterium mesophilicum*, *Stenotrophomonas maltophilia*, and other pseudomonads)

B. Culture negativity

Even with all the advancements made in culture techniques, 20% of all cases of peritonitis (cloudy dialysate, abdominal pain, etc.) are culture negative. There are several plausible explanations for this.

1. Dilution

Large volumes of dialysate may lower the concentration of bacteria to below detection limits of the culture method used.

2. Inhibitory substances

Organisms may be present but have their growth inhibited. While not all the antibacterial factors are known, suppression by the sequestration in phagocytic cells and the presence of antimicrobial agents in the fluid are the most documented sources of false-negative cultures.

3. Exacting growth requirements

False-negative cultures may also be caused by a lack of suitable growth requirements for the spectrum of etiologic agents.

4. Avoidance

To minimize the number of false-negative cultures, the laboratory should provide for the following.

- a. Concentration of microorganisms
- b. Dilution or removal of antimicrobial agents
- c. Lysis of host cells to release intracellular microorganisms
- d. Parallel or tandem cultures for bacteria, fungi, and mycobacteria

C. Optimal culture protocol

While there is a plethora of different methods for culturing peritoneal dialysis fluid (1–3, 6–11, 13), with no one method proven to be better than the others, a consensus within the renal community has been reached (5, 12). However, a clearly inferior method is simply culturing a small volume of unconcentrated dialysis fluid. Many methods described in the literature have called for a variety of techniques, including lysis-centrifugation, sonication, antimicrobial removal methods, large-volume culture, etc. (1–4, 6–11, 13). The consensus in the community is known as “Consensus Guidelines for the Treatment of Peritonitis in Pediatric Patients Receiving Peritoneal Dialysis” (12) and the “Adult Peritoneal Dialysis-Related Peritonitis Treatment Recommendations” (5).

1. Send the whole bag to the laboratory.
2. Send a sample to hematology for an unspun leukocyte count and cell differential. The cell differential could be performed by cytofuging 200 μ l of effluent dialysis fluid (1:10 to 1:100 dilution in physiologic saline for WBC counts of $>1,000$) at $8,000 \times g$ for 7 min and evaluating using Pap smear staining.
3. Concentrate 50 to 100 ml of effluent for Gram stain and culture.
4. Culture should include broth enrichment (blood culture system, i.e., BACTEC or BacT/Alert).

I. PRINCIPLE

Air is the medium that transports fungi from sources such as soil, construction disturbances, or moldy hospital environments (7, 14, 16). Although breathing airborne fungi is common and for most individuals results in no effects on health, hospitalized patients with extreme immune suppression are susceptible to infections with those airborne fungi that can grow at body temperatures (11).

Generally, patients are maintained in controlled environments during periods of severe immune suppression. Environmental controls for protected environments include increased air changes, positive-pressure rooms, and highly filtered air (1, 9, 15, 19, 20). When it is determined that such individuals have experienced a nosocomial infection due to opportunistic airborne filamentous fungi, an investigation

is required to determine whether the controlled environment failed or whether there were other breaks in prescribed procedure, e.g., transport of an unmasked patient outside the controlled environment. Failing to detect the latter, the institution may elect to undertake air sampling to determine whether the controlled environment is working effectively.

Air sampling should not be initiated lightly, since the conduct and interpretation of air cultures for fungi are relatively complex. Ubiquitous in all environments, *fungi in controlled environments must be quantitated and their numbers compared with those in the ambient air in contiguous uncontrolled environments*. These results will provide a basis for determining the efficacy of the suspect controlled environment. Although environmental sampling

of hospital air for fungi is not recommended on a routine basis, there are a number of instances in which sampling may be judged necessary: (i) when nosocomial infections are due to common environmental airborne fungi (10, 14, 16), (ii) during outdoor or indoor construction in close proximity to susceptible patients, (iii) prior to initial occupancy of special controlled environments, and (iv) when procedures necessary for the cleanest air quality are being established and maintained. In general, microbiologic testing should be limited to environments associated with immunocompromised patients in transplant protocols. Laminar-flow rooms for other hospital applications (surgical suites, pharmacy, etc.) are tested with a particle counter and anemometer.

PREANALYTICAL CONSIDERATIONS

II. SPECIMEN

A. Sample site selection

Comparison samples are essential in order to determine the effectiveness of filtration and provide a rank order concentration of fungi. For example, the level of fungi in a protected environment might be compared with the levels outdoors and in adjacent areas of the hospital that are not controlled environments (5, 9). Where multiple nosocomial infections have occurred, the rooms of those affected might also be compared with the rooms of those unaffected. Sample site selection must be tailored to the goals of the undertaking; understanding the items that follow will help in the design of the sampling strategy.

B. Sample volume

The volume of air sampled is based on the expected number of fungi in the environment in question and determined by the air volume per unit time of the sampler. The sample volume must be of sufficient size to provide quantitative information at the lower limits of detection when the air is relatively clean and at the higher limits of detection when the air is relatively dirty.

Temperature of incubation of cultures is often adjusted to meet the objectives of the study (see below) and will affect the quantitation. During the growing

Table 13.9–1 Air samplers for quantitation of viable fungal spores^a

Sampler type	Principle	Rate (liters/min)	Comment(s)
Sieve impactor ^b	Impaction on agar plate	28	Low volume precludes short-term collections that might relate to specific activities; effective for high concentrations of spores.
Slit impactor ^c	Impaction on rotating agar plate	30–700	High volume allows short-term collections that might relate spore aerosols to specific activities; effective for low concentrations of spores; quantification may be compromised at high levels of spores.
Centrifugal impactor ^d	Impaction on plastic strips containing agar media	40	Calibration difficult, thus limited to relative determinations
Impingers (glass)	Impingement into liquids	12.5	Low-volume sampling rates and tendency to disrupt clumps limits application to nonclinical sampling.
Filters (cassette)	Filtration of air through 0.2- μ m-pore-size filters	1–2 or 140–1,400	Not practical for viable microbes
Settling plates	Gravity		Most significant spores are too small and buoyant to settle. Lack of quantification severely limits utility.

II. SPECIMEN (continued)

season, when crops, lawns, and gardens are not covered with snow or ice, outdoor air is generally found to contain approximately 1,000 CFU/m³ (upper limits as high as 100,000 CFU/m³) when cultures are incubated at room temperature and only 1 to 200 CFU/m³ when cultures are incubated at 37°C.

For indoor areas with minimum filtration, fungal levels are generally about one-third the level detected outside (2). Areas subjected to high-efficiency filtration can be expected to have <1/10 the number of fungi found in adjacent indoor areas. If filters are properly installed and maintained (15), filtration systems remove the majority of fungi, and thus it is necessary to collect high-volume samples (>1 m³; i.e., 35.3 ft³) (21). However, when there is snow or ice cover outdoors for extended periods, outdoor levels of fungi may be drastically reduced.

C. Air sampling device

Basic information regarding the types of samplers available and their relative advantages and disadvantages is provided in Table 13.9–1. Many air samplers were devised to sample particles rather than fungi. Thus, they are relatively ineffective for sampling air for fungi. Low-volume samplers operating at 1 ft³/min or less require sampling times of 35 min or more to ensure adequate air sample volume. The extended employee involvement and the attendant noise

II. SPECIMEN *(continued)*

of sampling may make these samplers relatively useless. More-specific information on the various air sampling devices is provided in Appendix 13.9–1.

Settling plates have often been utilized in the past, but they provide data of little relevance. Since airborne particles settle at different rates (6) and since the smallest fungal particles are often the pathogens of greatest concern, these pathogenic agents may be missed. For example, *Aspergillus fumigatus* spores are 2 to 3.5 μm in diameter, and their aerodynamic buoyance is enhanced by the presence of surface echinulations. Thus, only volumetric methods of sampling provide reliable data.

D. Surface sampling

Subsequent sampling of suspect surfaces may be useful if relatively large numbers of similar organisms are found during air sampling. Such sampling may serve to link an obvious source such as a moldy sink, cabinet, or air duct to a problem with airborne fungi (12, 18, 19). Simply swabbing the suspect area and plating the swab onto media are generally sufficient for such follow-up analysis.

III. MEDIA

Use inhibitory mold agar with chloramphenicol (one plate per sample). (Other suitable selective media, particularly those that promote differentiation of the fungi to produce distinguishing identification characteristics, may be substituted.) Consult section 8 of this handbook for specific guidance on identification of fungi. Although more fungi may be recovered on other media such as rose bengal agar (8), extensive subculturing may be necessary to facilitate identification.

ANALYTICAL CONSIDERATIONS

IV. SPECIMEN PROCESSING

Observe standard precautions.

A. Initial processing

With most air sampling devices, the media are inoculated in association with the operation of the sampler. Specific instructions for the use of the device should be followed.

B. Incubation temperature

1. Room temperature

The selection of the temperature of incubation is determined by the goals of the project. Room temperature incubation is selected to establish rank order differences among the areas sampled. The cleanest environment rank order should be established by using room temperature incubation. This will allow for a determination of filtration efficiencies in various controlled environments in question but will not generally allow for identification of the fungi suspected as pathogens.

2. Incubation at 37°C

Incubation at the more elevated temperature will provide a selective environment for the isolation of airborne fungi that tend to be opportunistic pathogens, e.g., *Aspergillus* species (4). In quantitative comparisons, fungi that grow at room temperature are generally 10-fold more numerous than those that grow at 37°C. Inhibiting growth of the nonpathogenic fungi by incubation at the higher temperature will facilitate the detection and identification of the most likely pathogens.

V. QUALITY CONTROL

Periodically calibrate air-sampling equipment for accurate quantitative measure (17). Generally, a flowmeter or critical orifice may be employed to calibrate the volume of air sampled. Calibration of pumps is also a necessity for reliable data interpretation. Individuals seeking calibration advice should contact the manufacturer of the sampling device or consult with an industrial hygienist with experience in the use of the sampling device.

VI. IDENTIFICATION OF FUNGI

It is imperative that these cultures be handled in a biosafety hood.

When tests have been conducted with room temperature incubations for the purpose of determining rank orders of fungal colony counts, it is sufficient to quantitate the colonies without identifying the species of fungi present. When the source of a specific fungal infection is sought and incubation is performed at 37°C, colonies exhibiting appropriate gross morphology should be subjected to microscopic examination and subcultured for further identification only if required to fulfill the intent of the investigation. Species identification methods are covered in section 8 of this handbook.

POSTANALYTICAL CONSIDERATIONS

VII. CALCULATIONS**A. Conversion factors**

1. $1 \text{ ft}^3 = 28.4 \text{ liters}$
2. $1 \text{ m}^3 = 35.3 \text{ ft}^3$
3. $1 \text{ ft}^3/\text{min} = 0.0283 \text{ m}^3/\text{min}$

B. Performing calculations

Divide the number of colonies of the total sample by the volume of air sampled to determine the CFU per cubic meter. Where calibration indicates the necessity, adjust air sample volumes by the appropriate factor.

VIII. DATA INTERPRETATION

The ubiquity of fungi in the environment dictates that low levels of fungi not be considered a cause for alarm; thus, methods that detect fungi without quantification will be of no use. Moreover, methods, such as settling plates, that are insufficiently sensitive to detect fungal pathogens provide no useful information.

Rank ordering of fungal levels within the controlled environmental areas, in adjacent uncontrolled areas, and outdoors may allow for a determination to be made relative to a malfunction of filtration devices, interruptions in the positive pressure, leaks to the outdoors, or point sources of fungal spores. Such interpretation must be made in the local environment of concern and must incorporate a knowledge of the effect of snow cover and temperature of incubation. Generally, protected environments with high-efficiency filtration should exhibit levels of fungi approximately a full order of magnitude lower than the levels detected in the adjacent outdoor environment, but this differential level cannot be expected during long periods of snow cover.

When test samples have been incubated at 37°C to specifically detect and identify a fungal pathogen, its presence may help implicate an environmental source, but its absence does not rule out the temporary presence of such a source during the actual period of patient exposure. If only one colony of a pathogen is recovered, repeat sampling is indicated. Multiple-hit pathogens on culture plates are of greater concern than the single isolation of a “random” airborne pathogenic particle. Repeat sampling is indicated if multiple colonies of a pathogen are recovered from air sampling in highly filtered areas. In areas that provide a protective environment (99.97% efficient filtration for 0.3- μm particles, >12 air exchanges/h, and a pressure differential of 0.01 in. water gauge [2.5 Pa.] outflow of air), the total pathogen

VIII. DATA INTERPRETATION (continued)

(*A. fumigatus*, *Aspergillus flavus*, *Aspergillus terreus*, *Fusarium* spp., or other potentially opportunistic fungus) level should be maintained at <0.1 CFU/m³ (22). If total pathogen levels exceed 1.0 CFU/m³ on several occasions, the air systems or procedural practice in the patient areas requires intensive evaluation.

When gross colony counts rather than fungal pathogens are determined for the most highly filtered areas, fungal levels should not exceed 15 CFU/m³ for cultures incubated at room temperature or 2 CFU/m³ for cultures incubated at 37°C. The homogeneous occurrence of an organism suggests a point source from an indoor area (12), and such problems generally arise from situations that include uncontrolled humidity or water leakage. Removal efficiencies of filtration were established for fungi that grow at 37°C (13), and there may one day be sufficient data to conduct rank order studies at this temperature.

Because of the delay in results from microbiological sampling, real-time quantitative analysis is useful for assurance that the filters are properly installed, especially during initial preoccupancy testing and epidemiological outbreak investigation. The particle counter (either optical or condensation based) is useful for filter evaluations and for assurance of proper installation of the filter. The condensation particle counter will assess small leaks which may be due to tears in the filter media. This would not be possible with the air sampling apparatus for viable fungal particles, but it must be remembered that the particle counter should be used only as an indicator of a problem. These devices provide rank order analysis to determine if the area with the highest filtration has the lowest particle counts. This is useful because if such testing is conducted before microbiological testing during the commissioning of new protective areas, problem solving can be accomplished before expensive microbiology testing takes place. The assurance of pressurization for the protected rooms and room air exchange confirmation are essential before testing for viable or nonviable airborne particles (21).

APPENDIX 13.9–1

Features of Mechanical Volumetric Sampling Devices

A. Sieve impactors

1. General description

Sieve impactors are efficient air particle collectors (2, 5, 6) and are commercially available (see Table 13.9–1). The Andersen device is the most commonly used volumetric sampler. This sampling device uses inertial impaction on the agar surface to collect viable particles. Each stage of the sampler has 200 or 400 holes through which the particles travel, and the holes get smaller as the stage number descends. This provides the basis for the differentiation of various particle sizes. The sieve impactors differentiate respirable (<5- μ m-diameter) viable particles from nonrespirable (>5- μ m-diameter) particles when at least two stages of the sampler are used. If the sampler sieve impactor has six stages, the particles above stage 3 are considered nonrespirable, while the particles above stage 6 are respirable. Because of the design and aerodynamic nature of airborne particles, stage 3 removes particles that are >5 μ m in diameter, allowing the smaller remaining particles to become impacted on stage 6. Because of a statistical correction formula, this sampler allows reasonable accuracy in sampling of areas with high concentrations of airborne fungi. The correction is applied whenever >19 colonies are counted on the sample plate. Because of the reimpaction potential of incoming viable particles, a table for conversion is available (1).

2. Disadvantages

The sampler generally operates at 1.0 ft³/min. In a relatively clean environment, the sample time for determining 1.0 CFU of pathogens per m³ would have to be extended to >35 min in order to collect 35.3 ft³ (or 1 m³) of air. Sieve impactors generally employ a vacuum pump and are a noise nuisance in an occupied patient room. For long sampling times, patient room vacuum may be replaced by employing an airflow that restricts the critical orifice interfaced to the air sampler.

B. Slit impactor

1. General properties

The slit impactor is an efficient particle collector that utilizes inertial force to impact viable particles onto the surface of the agar. These devices do not differentiate particle

APPENDIX 13.9–1 (continued)

sizes (7). They have a rotating disk on which a standard-sized plate (150 by 15 mm) of agar medium is placed. The rotation of the plate under the stationary slit allows for production of appropriate time-concentration relationships. Slit impactors have preset sample volume rates ranging from 30 to 700 liters/min; thus, variation of sample time will allow for quantitation. Since the sample volume ranges as high as 25 ft³/min, these collectors take only minutes. Thus, they may be used to distinguish changes in concentration over brief periods, and such changes might be referable to local activities that induce them.

2. Disadvantage

Accuracy is limited where there are high concentrations of fungal spores.

C. Centrifugal sampler

1. General properties

The centrifugal impactor utilizes the same principles as other impactors. A strip containing wells of agar medium is placed around the sampling head. The compact portable nature of this device and its quiet operation make it ideal for inconspicuous operation (3).

2. Disadvantages

Calibration is done at the factory, and quantitation of air volume is thus not possible except at the factory. Thus, only relative comparisons of fungal contamination between different areas can be made.

Working with a welled strip of media makes identification difficult and requires extra subculturing.

D. Filtration

This method is primarily used for evaluation of airborne minerals and respirable dust (4). Because of their smallness and low-volume sample rate (~1 liter/min), filter cassettes are not practical for sampling viable microbes.

E. Impingement

Because of their low-volume sampling rates and tendency to disrupt viable particle clumps, the application of these devices is limited to areas where high concentrations are suspected, e.g., turkey barns.

F. Rotorods

This device employs impaction on a sticky glass surface that is rotated in ambient outdoor air. Rotorods are not practical for low-level indoor sampling. Generally employed for air analysis of spores and pollen in allergy studies (7), the device measures numbers of nonviable particles.

Microbiological Assay of Environmental and Medical-Device Surfaces

I. PRINCIPLES

A. Recommendations against routine assays (“monitoring”)

Although a number of textbooks in the 1970s recommended routine environmental monitoring in a variety of settings, the vast majority of these practices have proven expensive and of little value (2, 5, 8, 9, 16, 17, 20). Routine monitoring is defined in this context as those procedures that are random and undirected and that differ from those targeted for defined purposes (5). This procedure is not intended in any way to discourage sampling and assay of environmental or medical-device surfaces for which specimen collection, culture, and data interpretation are conducted in accordance with defined protocols. The only routine environmental microbiological assay regimen generally recommended today is for QA purposes: (i) monitoring of sterilization processes by using bacterial spores (biological indicators), (ii) monthly cultures of water and dialysate fluids in the hemodialysis unit (*see* procedure 13.7), and (iii) periodic

monitoring of dental-unit water supplies or filtered rinsing water in automated endoscope reprocessors (note that there are no current established standards for the situations listed in item iii, but such monitoring is often done in settings where water quality is a major concern). All other environmental microbiological assays should be performed only in response to epidemiologic investigations suggesting that environmental or medical-device surfaces may be microbial reservoirs or sources of health care-associated disease transmission. Also, the monitoring must be in conformance with relevant policy of the institution (*see* procedures 13.2 and 13.3). Microbiological assays may also be helpful in testing the effectiveness of new or modified cleaning and/or disinfecting procedures. Selection of appropriate sampling and culturing techniques is critical if results are to be meaningful. A number of methods for sampling various types of surfaces and devices have been described. Because of the

lack of standard guidelines or protocols as well as the complexity and variety of surfaces and medical devices, the microbiologist will necessarily select the appropriate methodology by reviewing the current literature and using scientific judgment and common sense. Moreover, no assays of environmental or medical-device surfaces should be done unless criteria regarding possible results of the cultures and a corresponding corrective action plan have been established (14, 17, 20).

B. Monitoring plan

No environmental monitoring should be conducted without prior approval of the Infection Control Committee (or, at a minimum, a designated person who has consulted with a qualified microbiologist) and the existence of a carefully formulated and detailed plan of action (14). Items to consider when developing such a plan are summarized in Table 13.10–1. In addition to an objective, a summary of the current literature, and a bibliography, the written plan should include clear descriptions

Table 13.10–1 Considerations before undertaking environmental surface sampling

Background information from the literature and present activities (i.e., preliminary results from an epidemiologic investigation)
Location and accessibility of surfaces to be sampled
Method of sample collection and the appropriate equipment for this task
Number of replicate samples needed
Number and type of control or comparison samples needed
Parameters of the sample assay method and whether the sampling will be qualitative, quantitative, or both
An estimate of the maximum allowable microbial numbers and types on surface(s) sampled (refer to the Spaulding classification for devices and surfaces [23] summarized in item V)
Some anticipation of a preliminary corrective action plan

of (i) location(s) and methods of sample collection, including possible problems with physical access for adequate sampling; (ii) frequency of sample collection (related to time and/or clinical indications); (iii) sample assay method(s), including whether the as-

says will be quantitative or qualitative; (iv) sample volumes to be assayed; (v) media (selective or nonselective), diluents, rinse fluids, and neutralizers as appropriate; (vi) incubation times and conditions and allowable time lapse between sample collection and assay;

(vii) a listing of other physical or chemical factors pertinent to a particular setting that may affect culture results; and (viii) an estimate of the maximum allowable microbial numbers and types on the surface(s) sampled.

PREANALYTICAL CONSIDERATIONS

II. MEDIA, REAGENTS, AND EQUIPMENT

A. Media

Virtually all media (preprepared, dehydrated, or individual components), reagents, and equipment appropriate for environmental microbiological culturing are available from a variety of commercial suppliers of media and equipment serving the clinical microbiology laboratory community.

1. Media appropriate for quantitative determinations of microorganisms
 - a. Nutrient-rich, nonselective agar media (e.g., TSA or BHI agar plates with or without 5% sheep or rabbit blood supplement for enhanced recovery of fastidious pathogens)
 - b. Nutrient-rich, nonselective broth media (as above) with or without supplements (as above) for saturation of absorbent pads placed beneath membrane filters
 - c. Selective agar or broth media (as above) for culture of specific groups of microorganisms (e.g., MAC or Cetrimide or Sabouraud agar or broth)
 - d. Addition of disinfectant neutralizers to culture media may be appropriate (*see* item III.B.1.b below).
2. Media appropriate for qualitative determinations for specific groups of microorganisms
 - a. Nonselective broth media, as necessary, for initial enrichment of low levels of microorganisms recovered from surfaces
 - b. Selective broth media (e.g., Cetrimide or MAC) to detect the presence of specific groups of microorganisms
3. Media appropriate for culturing environmental microorganisms that are expected to be physically damaged or "stressed" (e.g., such as those microorganisms recovered from finished treated or raw water ["naturally occurring" water microorganisms])

- a. Avoid using high-nutrient-content media (e.g., blood agar, TSA) in these situations, as these media may actually inhibit the growth of damaged organisms (1).

- b. Media with reduced nutrient content (e.g., R2A agar, diluted peptone) to recover microorganisms from environments with minimal nutrient concentrations (1)

B. Reagents

Special reagents necessary for environmental and medical-device sampling are minimal and consist primarily of rinse or dilution fluids (e.g., nonbacteriostatic saline [0.85% wt/vol, sodium chloride]) or various buffer solutions (with or without specific neutralizers of disinfectants), preprepared or custom-made (11).

C. Equipment

Equipment necessary for the vast majority of environmental or medical-device sampling is available in most well-equipped clinical microbiology laboratories and includes a variety of glass- or plasticware (e.g., petri plates, beakers, flasks, screw-cap tubes and bottles, pipettes), incubators, an ultrasonic bath, vortex mixers, membrane filter holder assemblies, a vacuum source with a vacuum flask and "traps" to protect the vacuum source, a biological safety cabinet, and so forth. For membrane filter assays, a variety of prepackaged sterile filter holders, filters, and sample tubes as well as culture plates and media are available from a number of commercial sources. Sterile gloves are appropriate for use during aseptic sampling techniques. Tweezers, forceps, scissors, or other devices for manipulating sampling materials should be single-use disposables or sterilized, preferably by steam autoclaving, prior to use. Some means for spot decontamination of tweezers, scissors, etc., should also be available

II. MEDIA, REAGENTS, AND EQUIPMENT *(continued)*

(e.g., ceramic oven devices used for inoculating loop “flaming”). In the past, natural gas Bunsen burners or propane torches were commonly available in laboratories. Open-flame burners, however, may not be allowed in

modern laboratory facilities for safety reasons. Additionally, use of such burners in biological safety cabinets may interfere with the proper airflow in the cabinet.

ANALYTICAL CONSIDERATIONS

III. COLLECTION AND ASSAY OF SPECIMENS

☑ **NOTE:** Observe proper aseptic procedures.

A. General

Collect microbiological samples by using a sterile swab, sponge, or “wipe” cloth subsequently eluted in a rinse fluid (commonly termed swab-rinse, sponge-rinse, or wipe-rinse method, respectively), by directly eluting an item with rinse fluid (rinse method), or by pressing an agar medium surface directly on a surface to be sampled (i.e., replicate organism direct agar contact [RODAC] method). A summary of surface sampling methods is shown in Table 13.10–2. Whichever

Table 13.10–2 Comparison of surface sampling methods^a

Method	Location for use	Assay technique	Procedure notes	Points of interpretation	Availability of standards	References
Sample-rinse Moistened swab-rinse	Nonabsorbent surfaces, corners, crevices, devices, instruments	Dilutions; qualitative or quantitative assays	Assay multiple measured areas or devices with separate swabs	Report results per measured area or, if assaying an object, per the entire sample site	Yes for food industry; no for health care	10–12, 18
Moistened sponge-rinse	Large areas, housekeeping surfaces (e.g., floors, walls)	Dilutions; qualitative or quantitative assays	Vigorously rub a sterile sponge over the surface	Report results per measured area	Yes for food industry; no for health care	10–12, 18
Moistened wipe-rinse	Large areas, housekeeping surfaces (e.g., countertops)	Dilutions; qualitative or quantitative assays	Use a sterile wipe	Report results per measured area	Yes for food industry; no for health care	10–12, 18
Direct immersion	Small items capable of being immersed	Dilutions; qualitative or quantitative assays	Use membrane filtration if rinse volume is large and anticipated microbiological concentration is low.	Report results per item	No	
Containment	Interior surfaces of containers, tubes, bottles, etc.	Dilutions; qualitative or quantitative assays	Use membrane filtration if rinse volume is large	Evaluate both the type(s) and numbers of microorganisms	Yes for food/industrial applications for containers prior to fill	
RODAC	Previously cleaned and sanitized flat, nonabsorbent surfaces; not suitable for irregular surfaces	Direct assay	Overgrowth occurs if used on heavily contaminated surfaces. Use neutralizers in the agar if surface disinfectant residuals are present.	Provides direct, quantitative results; minimum of 15 plates per average hospital room	No	11, 13

^a See also Appendix 13.10–1.

III. COLLECTION AND ASSAY OF SPECIMENS (continued)

technique is chosen, observe proper aseptic procedure throughout the sampling and assay processes.

B. Rinse fluid

1. Choice of fluid

- a. Surfaces without residual disinfectant or other toxic substances
 - (1) Sterile nonbacteriostatic saline (0.85% [wt/vol] sodium chloride) or a buffer solution
 - (2) General multipurpose broth medium (e.g., TSB or BHI broth) supplemented with 0.5% beef extract (3, 16)

- b. Surfaces with residual disinfectant or other toxic substances

Many environmental or instrument surfaces have residues of disinfectants (e.g., phenolics, hypochlorites, iodophors, quaternary ammonium compounds, hydrogen peroxide, formaldehyde, glutaraldehyde) that may require incorporation of specific neutralizers into the rinse medium, particularly when the rinse medium itself serves as a culture medium for enrichment in qualitative assays. Use of specific neutralizers in rinse or recovery media is often necessary to eliminate toxic carryover in the assay that may reduce the numbers of microorganisms and give an erroneous result (Table 13.10–3). More comprehensive discussions of the use of disinfectant neutralizers have been published elsewhere (12, 21). Commercially available recovery media having a spectrum of neutralizing agents (e.g., Dey-Engley medium) (11), nonspecific neutralization of disinfectants by incorporation of protein supplements in rinse media (e.g., 0.5% beef extract), or double-strength broth media (e.g., 2× TSB or BHI broth) may be advocated when the exact nature of residual chemicals is not known. A combination of 0.07% lecithin and 0.5% polysorbate (Tween) 80 is often recommended as a routine supplement to rinse or recovery media (Table 13.10–3) (3, 17). Unfortunately, specific neutralizers themselves may be toxic to certain groups of microorganisms. For example, sodium thiosulfate will inhibit the growth of some streptococci (21), and Dey-Engley medium may prevent the growth of certain mycobacteria (6). An effective approach to the problem of residual disinfectant or other toxic substances on surfaces being sampled is to employ the membrane filter assay method with extensive postfiltration rinsing along with adequate controls to ensure that rinsing is effective.

2. Culture methods for rinse fluids (1, 3, 11)

- a. Quantitative culture, agar spread plate method
 - (1) Make serial 10-fold dilutions of the rinse fluid in tubes of sterile medium.
 - (2) Pipette 0.1 ml of each dilution (e.g., undiluted, 1:10, 1:100) onto a standard agar plate surface.

Table 13.10–3 Neutralizers of common disinfectant chemicals^{a,b}

Disinfectant(s)	Neutralizer
Glutaraldehyde	Glycine
Formaldehyde	Glycine
Phenolics	Polysorbate (Tween) 80
Quaternary ammonium compounds	Lecithin + polysorbate (Tween) 80 ^c
Chlorine	Sodium thiosulfate
Iodine	Sodium thiosulfate
Hydrogen peroxide	Catalase

^a Reference 21.

^b Used in lieu of or in combination with membrane filtration assay methods.

^c Often recommended as a routine supplement for rinse or recovery media (3, 17). Lethen broths and agars are commercial alternatives.

III. COLLECTION AND ASSAY OF SPECIMENS *(continued)*

- (3) Use a separate, sterile, bent spreader (“hockey stick”) to distribute the inoculum on each plate surface.
 - (4) Dry the plates in a biological safety cabinet to prevent extraneous contamination, and invert them for incubation.
 - (5) Incubate plates under conditions and for periods of time sufficient to recover implicated microbial populations.
 - (6) Examine plates with a well-lighted binocular dissecting microscope or a back-lighted magnified colony-counting device to discern small colonies.
 - (7) Count colonies on plates having between 30 and 300 colonies.
 - (8) Report the numbers of microorganisms per unit or unit area sampled (taking into account the dilution and volume of diluent assayed).
- b. Quantitative culture, membrane filter method**
- (1) Make dilutions of rinse fluid as explained in item III.B.2.a(1) above.
 - (2) Filter portions (1 ml, or more if desired) of each dilution through a membrane filter (0.45- or 0.22- μm pore size, 47-mm diameter [filters with gridded surfaces facilitate colony counting]).
 - (3) Rinse filters thoroughly by suctioning additional sterile rinse medium (with or without specific or nonspecific chemical neutralizers, as dictated by the sampling regimen) through them.
 - (4) Using sterile forceps, place filters sample side up on petri plates containing the agar medium of choice (avoid trapping air between the filter and the agar surface) or on sterile absorbent pads saturated with the appropriate broth medium.
 - (5) Incubate filters appropriately, and use a well-lighted dissecting microscope to count colonies on filters having between 20 and 200 colonies.
 - (6) Report the numbers of microorganisms as explained in item III.B.2.a.(8) above.
- c. Quantitative culture, pour plate method**
- Quantitative culture using the pour plate method is precise and relatively simple but may be cumbersome and time-consuming in a clinical microbiological laboratory. Up to 2 to 3 ml of sample or diluted sample fluid may be placed in an empty petri plate and then mixed with molten agar medium (brought to 44 to 46°C; a thermostatically controlled water bath is required). After solidification, plates are inverted and incubated as usual. Subsurface colonies are discrete and obviate problems of spreading and colony coalescence. Subsurface growth, however, may be slower than on the agar surface, colony morphologies are atypical (e.g., “flying saucer” shaped), and retrieval of colony material for subculture may be difficult. Details of this culture method are given elsewhere (1).
- d. Qualitative culture (to detect low numbers of selected groups of microorganisms in heterogeneous microbial populations [3])**
- (1) Use an appropriate broth nutrient medium rather than 0.85% sodium chloride or buffer as a rinse fluid for sample collection.
 - (2) Transfer 0.5 ml of the rinse fluid onto the surface of an appropriate agar medium (e.g., MAC for selective culture of coliforms or Cetrimide agar for culture of *Pseudomonas* spp.).
 - (3) Tilt the plate to distribute the inoculum over the agar surface, dry agar surface in a biological safety cabinet, and invert plate for incubation.
 - (4) Incubate the broth rinse fluid at an appropriate recovery temperature.
 - (5) Subculture rinse fluid as in item III.B.2.d.(2) above at intervals of 4 and 24 h.

III. COLLECTION AND ASSAY OF SPECIMENS (continued)

- (6) If rinse fluid appears turbid after 4 or 24 h of incubation, streak a loopful of fluid on separate plates of the selected subculture medium.
- (7) After appropriate incubation, examine subculture plates with a well-lighted dissecting microscope to detect small colonies.

C. Swab-rinse sampling method (3, 4, 7, 10–12, 16, 17)

■ **NOTE:** It must be acknowledged that the recommended agitation methods and durations for elution of microorganisms from sample collection devices (e.g., swabs, sponges, cloths) will result in much less than 100% recovery (15). Once an agitation method and its duration are chosen, however, their application should be consistent among specimens.

1. Sampling large, flat, nonabsorbent surfaces

- a. Cut a square hole of specified size (e.g., 2 by 2 in.) in a piece of heavy paper (e.g., craft or butcher paper) as a sampling template, and make one for each sample to be taken.
 - b. Wrap templates, and sterilize them in an autoclave.
 - c. Use sterile swabs of nonabsorbent cotton or polyester fiber (approximately 0.5 by 2 cm on a 12- to 15-cm applicator stick).
 - d. Moisten the swab in a test tube containing 4 to 5 ml of sterile rinse medium by first immersing the swab head in rinse medium and then wringing out excess fluid by pressing and rotating the swab on the inside surface of the tube above the fluid.
 - e. Place template on selected area, using a separate template for each sampling site.
 - f. Slowly rotate the moistened swab on the surface while pulling the swab toward you in close parallel streaks within the template opening to effect a shearing action between the surface and the swab.
 - g. Repeat the swab motion with the same swab in streaks at right angles to the first streaks.
 - h. Place the swab head in a tube of rinse fluid of known volume (e.g., 10 ml) by cutting the plastic applicator stick with sterile scissors or by using the inside lip of the tube to break a wooden applicator stick below the portion that was handled.
 - i. Cap the tube, and then shake end to end 50 times, or process for 30 s on a vortex mixer at high speed.
 - j. Assay the rinse fluid, and report results as explained in item III.B.2 above.
- ##### 2. Sampling irregular or recessed surfaces (e.g., tubes, containers, or external or internal surfaces of medical devices)
- a. Develop a plan for sampling each surface or device to ensure consistency from sample to sample for comparison purposes (e.g., 10 cm upward from the distal tip of the flexible fiber-optic endoscope insertion tube's outer surface, or swab rotated 10 times in the suction valve seat).
 - b. Collect swab specimens, and elute as explained in steps III.C.1.h and i above;
 - c. Assay rinse fluid, and report results as explained in item III.B.2 above.

D. Sponge-rinse (11) and wipe-rinse (18) sampling methods

1. The sponge-rinse and wipe-rinse methods are useful for sampling relatively large environmental surfaces (e.g., in food-handling areas during an outbreak of *Salmonella* infections).
2. Sterilize individually packaged squares (e.g., 5 by 5 cm) of cellulose sponge or disposable nonwoven fabric (rayon) wiping cloths (approximately 15 by 25 cm) by autoclaving (sponges and wipes must *not* be the types preloaded with cleaning or disinfecting agents).
3. Use sterile crucible tongs or sterile latex gloves to handle sponges or wipes.

III. COLLECTION AND ASSAY OF SPECIMENS *(continued)*

4. Moisten the sterile sampling materials with approximately 10 ml of rinse fluid (nonbacteriostatic saline, buffer, or nutrient medium with or without disinfectant neutralizers as discussed above).
 5. Vigorously rub each designated area (up to several square meters) in a consistent manner.
 6. Place the sponge or wipe into a sterile, sealable plastic bag or mason-type jar with a liquid-tight lid.
 7. Add 50 to 100 ml of sterile rinse fluid to the bag or jar.
 8. Massage the plastic bag or shake the jar vigorously for a least 1 min to elute the microorganisms.
 9. Assay the rinse fluid, and report results as explained in item III.B.2 above.
- E. Rinse sampling method (direct immersion)**
1. The rinse sampling method using direct immersion is one of the most efficient methods for recovering surface microorganisms from items small enough to be placed into a culture tube or flask and thoroughly exposed to a rinse solution.
 2. Using sterile forceps or gloves, place the item to be sampled into a container of sterile rinse fluid of known volume.
 3. Shake the container vigorously for 1 min (use a plastic or unbreakable container if breakage of glass is possible), or use an ultrasonic cleaning bath to facilitate removal of microorganisms from occluded surfaces (19).
 4. Assay rinse fluid, and report results as explained in item III.B.2 above.
- F. Rinse sampling method (Containment)**
1. The rinse sampling method using containment is used for sampling bottles or containers (e.g., nebulizer reservoirs) or respiratory therapy tubing.
 2. Place a suitable volume of rinse fluid (e.g., 10 to 50 ml) in the bottle or tubing, and seal appropriately with sterile lids or rubber stoppers.
 3. Vigorously shake sealed item end to end approximately 50 times.
 4. If necessary, decant the sample fluid into a sterile collection vessel.
 5. Assay rinse fluid, and report results as explained in item III.B.2 above.
- G. RODAC sampling-culture method (11)**
1. The RODAC technique is very convenient and less cumbersome than other methods (e.g., item III.C.1 above) for estimating the sanitary quality of flat, smooth surfaces (e.g., floors, tabletops). Reserve this sampling method for surfaces that have been recently cleaned and sanitized, since heavily contaminated surfaces may result in rapid overgrowth of the plates.
 2. Purchase special sterile plastic plates that when filled with 16.5 ml of agar medium will form a convex agar meniscus. (RODAC plates are commercially available empty or prefilled with a selected number of media; other similar plates may hold less medium. Follow manufacturers' directions accordingly.)
 3. Fill empty plates with a general culture medium (e.g., TSA with or without added disinfectant neutralizers) for total counts or with a selective medium (e.g., MAC) for detecting specific groups of microorganisms.
 4. Use a minimum of 15 plates for an average hospital room, with sampling sites chosen randomly to prevent biasing of results.
 5. Press a plate firmly, without circular or linear movement, against a dry surface.
 6. Count colonies after 48 h of incubation at the selected temperature.

IV. CULTURE WORKUP**A. Selection of colonies**

At least two colonies representative of each morphological type present on culture plates should be picked for subsequent identification and further characterization.

B. Characterization of isolates

If the sampling has been done in response to an epidemiologic investigation of a disease outbreak, identification of isolates to the species level is mandatory, and characterization beyond the species level should be seriously considered (17). Methods for identification of microorganisms are given in other sections of this handbook.

POSTANALYTICAL CONSIDERATIONS

V. INTERPRETATION (9)

When interpreting sampling results for environmental and medical-device surfaces, it is important to keep the general principles of the Spaulding classification in mind (23).

A. Critical medical instruments

Critical medical instruments (e.g., surgical instruments) break the blood barrier or penetrate to normally sterile areas of the body and carry a high degree of infection risk if contaminated at the time of use. The generally acceptable microbiological standard for these items is the absence of all viable microbial forms, including bacterial spores (i.e., no microbial growth should be observed when an instrument previously subjected to a validated sterilization cycle is sampled).

B. Semicritical medical instruments

Semicritical instruments (e.g., flexible fiber-optic endoscopes, laryngoscope blades) generally come into contact only with mucous membranes during use and have a moderate degree of infection risk if they are contaminated at the time of use. The minimum acceptable microbiological standard for this class of instruments is the absence of all microorganisms except an occasional bacterial sporeformer not recognized as an overt pathogen (e.g., certain species of the genus *Bacillus* or *Clostridium*).

C. Noncritical medical instruments

Noncritical medical instruments (e.g., blood pressure cuffs, stethoscopes) come into contact only with intact skin during use and carry a low risk of disease transmission if contaminated. The basic criterion for safety is visible cleanliness, and a generally acceptable microbiological standard for this category is the absence of recognized pathogens.

D. (Noncritical) environmental surfaces (9)

Assuming at least minimal levels of hygiene and aseptic technique, environmental surfaces (e.g., the outer surfaces and controls of medical devices such as X-ray or hemodialysis machines, housekeeping surfaces [floors, walls, tabletops, etc.]) do not usually come into direct contact with the patient, and if they do, it is usually with intact skin. These surfaces pose the least risk of disease transmission, but this risk may be categorized into two levels. The first level would comprise those surfaces that are touched frequently during patient care ("high-touch" surfaces, such as adjustment knobs or handles on hemodialysis machines, instrument carts, X-ray machines, dental units, or even bed rails). If highly contaminated, these surfaces could play a role in secondary cross-contamination via hands of health care workers or contact with medical instruments. The lowest level of risk would be represented by housekeeping surfaces (e.g., floors, walls, tabletops, window sills). The basic criterion for safety at both levels would be visible cleanliness and the absence of recognized pathogens (5,

V. INTERPRETATION (9)

(continued)

9, 22, 23). In all cases, the growth of microorganisms in a particular assay may represent accidental contamination during collection or assay, and proper controls and caveats need to be provided for these considerations.

VI. ACKNOWLEDGMENTS

The authors thank Donald Vesley, School of Public Health, University of Minnesota, Minneapolis, and George Mills (retired), Center for Devices and Radiological Health, U.S. Food and Drug Administration, Rockville, Md., for their review and thoughtful comments.

APPENDIX 13.10–1

Sampling of Complex Medical Instruments

Although sampling of smooth, easily accessible environmental surfaces is rather straightforward, efficient sampling of certain medical instruments (or individual components of the instruments) may be hindered by the functional design, materials, construction, expense, and fragility of the devices. For example, the suction, air, water, elevator, or CO₂ channels and other complex or occluded components of flexible fiber-optic and video gastrointestinal endoscopes (2, 3), their accessories (e.g., biopsy forceps, snares) (1), and support equipment (e.g., water supplies, automated endoscope reprocessors) (7) generally present several major and sometimes unique dilemmas in obtaining adequate, pertinent microbiological samples. Description of exact methods for microbiological assay of various physically complex medical devices such as these is far beyond the scope of this procedure, but the following considerations and suggestions are among the minimal criteria for an adequate, meaningful assay of these and similar medical devices.

Prior to sampling protocol formulation, determine the exact configuration of the device as well as access routes to pertinent areas by thorough examination of the instruction manual and, possibly, consultation with the manufacturer. Knowledge of the exact methods and materials routinely used in the between-patient reprocessing of the instrument as well as the length of time between processing and microbiological assay will be essential to choosing appropriate sampling or assay methods and also to accurate interpretation of results.

The use of a sterile swab or brush or even ultrasonic energy where possible to dislodge residual material in or on the device should be considered in the sampling protocol. For instance, a swab-rinse technique is appropriate for sampling the exterior surfaces of the flexible endoscope, the distal opening of the suction-biopsy channel port, or the valve seats in any of the ports. Swab samples from these last two locations, however, may not be appropriate for quantitative assay and may not be representative of the microbial flora of the interior of the channels. A more adequate sample could be obtained in the following manner (i.e., a “flush/brush/flush” technique) from the interior surface of the suction-biopsy channel segment from the biopsy valve to the distal tip of the instrument (2, 4). (*Note*: There are three accessible segments in the suction-biopsy channel system: from the biopsy valve to the distal tip, from the suction valve [in the viewing head of the instrument] distally to the juncture with the biopsy port, and from the suction valve proximally through the umbilical cord to the power light suction source.) Introduce a portion (e.g., 5 ml) of sterile rinse fluid (e.g., buffer solution, buffer solution with neutralizers, or TSB supplemented with lecithin and polysorbate [Tween] 80) into the biopsy valve port, and let it flow downward through the channel. Collect rinse fluid exiting the distal tip in a sterile container. Using aseptic technique and sterile gloves, insert a sterile (disposable [preferable] or autoclaved reusable) cleaning brush into the biopsy port, and brush through the entire length of the channel several (e.g., three or four) times. Rinse the brush tip in sterile rinse fluid each time it exits the distal tip with measured portions of sterile rinse fluid, and finally, rinse the channel with another portion of sterile rinse fluid. If the brush is disposable, sterile scissors may be used to cut the brush off into the collection vessel. The collected fluids and brush tip should then be thoroughly vortexed or exposed to ultrasonic energy to disrupt particulate material and break up clumped microorganisms, thereby ensuring the most accurate determination of CFU per milliliter. Since most of these devices are routinely very difficult to clean, a second brushing and rinsing with a fresh sterile brush in the sampling regimen to ensure a representative sample may be considered if particulate material is seen exiting the lumen during the final flush. Unfortunately, it is not possible to pass a brush through other channels (air, water, CO₂) of the vast majority of flexible gastrointestinal endoscopes, so a simple rinse procedure is all that is possible in these instances. In the latter instances where brushing of the channel lumens is impossible, it must be considered during data interpretation that simple flushing is the least efficient method of sampling. With a simple flush-through technique, a number of fluid dynamic factors inherent to sampling intact lumens of any diameter (e.g., velocity,

APPENDIX 13.10–1 (continued)

viscosity, density, surface tension of the eluent) severely limit turbulent flow and shear forces necessary to overcome the adhesion forces of tightly bound patient material and microbial biofilms. Stated differently, a positive quantitative result in this instance most likely does not reflect the entire microbial content of the lumen. Likewise, a negative culture certainly does not indicate that the intact lumen is either “clean” or “sterile” (2).

Small items in the endoscopic set (e.g., valves, biopsy forceps) can be sampled by using an immersion rinse technique (*see* item III.E above), preferably augmented by ultrasonic energy to ensure adequate release and suspension of microorganisms (8). The long, springlike shaft of unsheathed biopsy forceps or other similar accessories can be coiled under the surface of rinse fluid in a flask before the flask is exposed to ultrasonic energy. This will also aid in separating the spring coils and release of material trapped inside the spring. Accessories such as this having plastic sheaths and no access ports (most are single-use disposables) cannot be accurately assayed quantitatively or qualitatively unless they are physically destroyed by aseptic cutting into small segments to ensure penetration of elution fluid and ultrasonic energy (or culture broth) into the lumen spaces.

Similar considerations and strategies for sampling and culturing are appropriate for other physically complex medical devices (e.g., hemodialysis machines, dental instruments, respiratory therapy equipment). Whatever the source, the rinse fluid sample should be assayed immediately if possible or as soon as practical to ensure minimal effects of possible residual disinfectant or other toxic chemicals. For quantitative determinations, a membrane filter assay (*see* above) followed by flushing of each filter with additional portions of sterile rinse fluid is recommended.

Note on using certain clinical assay methods in environmental sampling protocols

Most methods for bacteriological assays of specimens in clinical laboratories are those designed primarily for human source material. For example, it is common to use a rapid and inexpensive semiquantitative method to detect low-level bacteriuria (urine with $<10^5$ CFU/ml). Platinum loops calibrated to deliver fluid volumes of approximately 1/100 or 1/1,000 ml are used to streak plates of blood, MAC, EMB, or other agars (5). When done in a consistent and specific manner, the technique appears to provide sufficient speed, economy, sensitivity, and precision for diagnostic purposes when human source specimens having a microbial load between 10^3 and 10^5 CFU/ml are assayed (6). However, it is clearly inappropriate when a clinical technique such as this is applied in an environmental microbiology research setting where patients are being exposed to potentially contaminated rinse fluids during diagnostic or surgical procedures (9). The “standard” clinical method in this instance does not employ the appropriate media or incubation time and temperature for optimal recovery of waterborne microorganisms, nor does it have the necessary sensitivity, precision, or replicate size to accurately detect microbial populations of less than 10^3 to 10^4 CFU/ml. Accordingly, the “loop-streak” method is clearly an inappropriate technique for the vast majority of all environmental microbiological assays and especially inappropriate for invocation of the term “sterile.” Readers are therefore cautioned to adopt a critical, multidisciplinary approach whenever adapting any standard clinical laboratory specimen collection and assay method to environmental microbiology settings.

I. PRINCIPLE

Surveillance cultures from immunocompromised patients provide a service that can directly impact patient care and outcome in this patient population, but a rational, planned approach must be considered in order to optimize resources and interpretive impact. While some studies suggest that surveillance cultures may be of value, other studies suggest that routine surveillance may not be helpful. Differing conclusions from these studies may be due to insufficient data or inconclusive definitions of test conditions rather than from opposing data for similar populations. Selective surveillance, depending on occurrences at a particular time, can be useful in predicting anticipated difficulties in immunocompromised individuals. Surveillance could be part of studies to define the natural history of colonization by microorganisms and infections during pretreatment and after treatment of the immunosuppressed patient.

Several studies in the 1980s suggested that surveillance cultures of urine, stool, or respiratory specimens from this popula-

tion could be accurate predictors of subsequent systemic infection due to gram-negative organisms (5) and yeasts (13, 15) in neutropenic patients. However, other studies have questioned the value of surveillance cultures in predicting bacterial and fungal infections either in transplant recipients (4, 14) or in patients likely to develop chemotherapy-induced mucositis (14). Selective surveillance appears to be most helpful in identifying antimicrobial-resistant organisms, particularly with the increase in infections with gram-positive bacteria (1, 7). Routine stool surveillance cultures for vancomycin-resistant enterococci (VRE) have now been suggested for patients at risk for infection with those organisms (10, 11). When stool colonization is identified, those patients could be isolated to prevent nosocomial spread of the organism. Methicillin-resistant *Staphylococcus aureus* (MRSA) colonization of the anterior nares was found to be a significant predictor of MRSA infection in liver transplant recipients (3).

Surveillance cultures can also be an important part of impact studies. For example, rectal cultures routinely collected from liver and kidney transplant recipients helped document that VRE colonization can persist for months to years (12); cultures of stool provided evidence that antimicrobial chemotherapy targeted to intestinal anaerobic bacteria in marrow transplant recipients reduced the severity of acute graft-versus-host disease (2); and surveillance cultures were useful in confirming the efficiency of suppression of body microbiota by antimicrobial agents (4) and that yeast colonization after bone marrow transplantation was a frequent event in spite of double prophylaxis with oral amphotericin B and fluconazole (9), that cultures can be helpful in predicting who will be at risk for development of mucositis (6), and that mucous membranes might be sources of strains of coagulase-negative staphylococci causing bacteremia (8).

PREANALYTICAL CONSIDERATIONS

II. SPECIMENS

Observe standard precautions.

A. General surveillance culture for bacteria and yeasts

A combination of sites should be selected and decided upon in coordination with the medical staff utilizing the culture results. Samples may include specimens of urine and stool and specimens from oropharyngeal, vaginal, and central catheter line sites. All swab specimens are collected using the techniques for obtaining these specimens for routine culture. Swabs should be submitted in transport media that is routinely used for other routine swab cultures.

B. Selective bowel culture

A rectal swab or stool specimen is collected and submitted as for routine culture.

II. SPECIMENS (continued)

C. Selective surveillance cultures

Samples for selective surveillance cultures are collected from specific sites for VRE and MRSA; usually rectal and oropharyngeal swabs are obtained. Other sites may be selected depending on the current protocol(s). Samples are collected and transported the same as for general surveillance cultures.

III. SCHEDULE OF SPECIMEN SUBMISSION

The schedule of submission is dependent on the coordination of the medical staff and infection control and laboratory personnel. Some examples are at admission; before and after, e.g., bowel decontamination, total body radiation, and resolution of neutropenia; and during or after isolation.

IV. MEDIA

A. General surveillance culture for bacteria and yeasts

BAP, CHOC, MAC, colistin-nalidixic acid agar, BHI, BHI supplemented agar, anaerobic blood agar, or equivalent alternative media are used.

B. Selective bowel culture

Media can be tailored to select for organisms appropriate for the specific bowel decontamination regimen or to select organisms resistant to specific antimicrobial regimens, for example, Mueller-Hinton agar (MHA) with blood and vancomycin and cefepime.

Always inoculate a nonselective medium, such as BAP, along with the selective media.

C. Selective surveillance cultures

1. VRE

Campy CVA agar (BBL)

2. MRSA

After isolation and identification of *Staphylococcus aureus* from the routine surveillance culture, MHA supplemented with 4% sodium chloride and 6 µg of oxacillin per ml can be used (oxacillin screen agar; BBL).

ANALYTICAL CONSIDERATIONS

V. INCUBATION

Observe standard precautions.

A. General surveillance culture for bacteria and yeasts

Incubate culture at 35°C in 5% CO₂ and examine after 24 and 48 h of incubation.

B. Selective bowel culture

Incubate culture at 35°C in 5% CO₂. Examine after 24 and 48 h of incubation. Incubate anaerobic cultures at 35°C in an anaerobic environment. Examine after 48 h of incubation. Additional incubation may be required depending on expected anaerobic growth.

C. Selective surveillance cultures

1. Incubate at 35°C in 5% CO₂. Examine after 24 h of incubation.

2. Oxacillin screen agar

Incubate at 35°C (no higher) in ambient air for a full 24 h. Examine for any evidence of growth, which indicates resistance.

VI. CULTURE WORKUP

A. Quantitation

Semiquantitate the colonies according to the laboratory protocol for quantitating microorganisms, e.g., few (1 to 10 CFU), moderate (11 to 100 CFU), and many (>100 CFU).

B. Identification

1. Yeasts

Isolate and identify all yeasts to the species level.

2. Gram-negative bacilli

Identify all gram-negative bacilli to the species level. If the intent of the various cultures is to determine the presence or absence of microorganisms, a presumptive identification only may be necessary. Alternatively, the gram-

VI. CULTURE WORKUP (continued)

negative bacilli may be initially identified to the species level, with presumptive identification on subsequent cultures.

3. Gram-positive bacteria

a. Skin microbiota

Gram-positive organisms are not identified, except for specific bacteria associated with infections in this patient population.

b. VRE

See procedure 13.17.

c. MRSA

See procedure 13.17.

VII. SUSCEPTIBILITY TESTING

Perform routine susceptibility testing according to the laboratory policies on gram-negative bacilli and gram-positive cocci. Reporting of the antimicrobial agents should follow laboratory policy for selection reporting.

POSTANALYTICAL CONSIDERATIONS

VIII. REPORTING RESULTS

Report presumptive and definitive identification along with semiquantitation of each species.

IX. INTERPRETATION

Colonization does not imply infection but may predict systemic infection. Organisms that are identified as resistant to the antimicrobial agent(s) in the patient bowel decontamination regimen may warrant altering the antimicrobial agent regimen. Isolation of selective organisms may also alert the infection control practitioners of a possible nosocomial spread. The infection control policies may be implemented for isolation of the patient.

X. QUALITY IMPROVEMENT

A. QC

Routine medium QC testing is sufficient if selective media are appropriately tested for their selectivity.

B. QA

Surveillance culturing should be continuously monitored as to the value and use of the results. Monitoring should be performed as a team approach with the medical staff and infection control and laboratory personnel for the specific protocol regimen.

I. PRINCIPLE

Intravascular catheters are used to provide continuous vascular access to permit blood sampling; to administer blood products, medications, total parenteral nutrition, and other fluids; and, in the case of pulmonary artery catheters, to permit hemodynamic monitoring of cardiac function. Because these devices penetrate the integument, they put the patient at signifi-

cant risk for development of device-related infection. The insertion site becomes colonized by bacteria from the patient's own skin or by microorganisms carried on the hands of medical personnel (5). Organisms can also gain access through the lumen of the catheter following contamination of the hub (4) or infusion of con-

taminated fluids. Invading organisms can then colonize the intravascular catheter surfaces in the form of a biofilm and produce local infection and, in a significant number of cases, bacteremia, fungemia, suppurative phlebitis, or septic thrombosis (5). (See Appendix 13.12-1 for further discussion.)

PREANALYTICAL CONSIDERATIONS

II. SPECIMENS

Observe standard precautions.

A. Types

1. Long catheters

These catheters are surgically inserted into the central vein to provide access for administration of therapeutic agents, total parenteral nutrition, and blood products (6).

a. Long term

- (1) Percutaneous catheters: Broviac, Hickman, Raaf, Groshong, Quinton (Fig. 13.12-1)

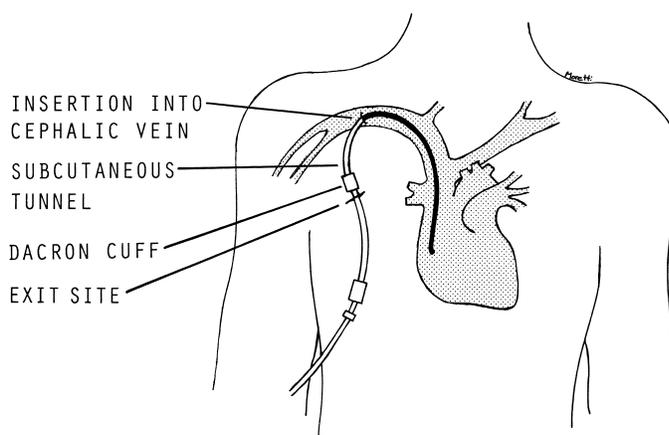

Figure 13.12-1 Placement of surgically implanted long percutaneous catheter (illustration by Carol Moretti).

II. SPECIMENS *(continued)*

These catheters are surgically inserted and subcutaneously tunneled to a chest wall exit site. A Dacron cuff facilitates growth of fibrous tissue to the catheter and inhibits migration of microorganisms along the surface of the catheter (6).

- (2) Subcutaneous ports: Infus-A-Port, Port-A-Cath, Med-i-Port (Fig. 13.12–2)

These systems can be entered by inserting a needle through the septum of the reservoir (6).

- b. Short-term percutaneous catheters: Swan-Ganz (plus introducer), Intracath, Cordis, multilumen, Udall (for hemodialysis) (Fig. 13.12–1)

2. Short catheters

These catheters are inserted into various sites and are used for short-term vascular access.

- a. Peripheral
- b. Steel needles
- c. Umbilical
- d. Arterial

B. Collection and transport

1. Collection

To prevent contamination by skin microorganisms and antimicrobial ointment, clean the skin insertion site with iodophor and alcohol prior to removal of the cannula. Remove the cannula in an aseptic manner once the alcohol has dried. If purulence of the catheter exit site is evident, send pus for culture and Gram stain (5).

a. Long catheters

Two portions of long catheters should be sent for culture: the distal intravascular tip and the proximal transcutaneous segment. Each segment should be approximately 2 to 3 cm long (Fig. 13.12–3).

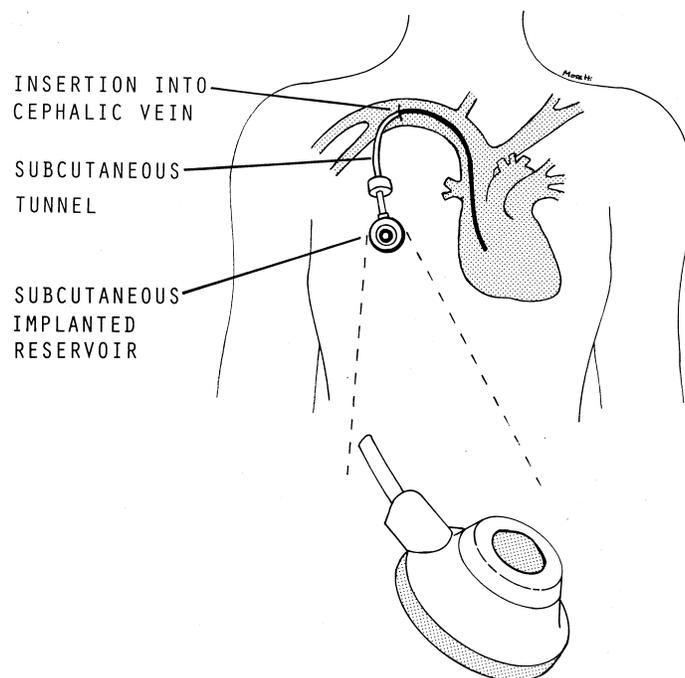

Figure 13.12–2 Placement of surgically implanted subcutaneous port (illustration by Carol Moretti).

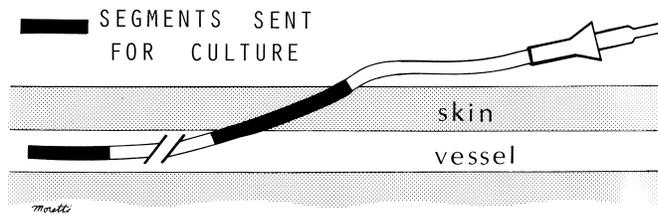

Figure 13.12-3 Segments of long catheter for culture (illustration by Carol Moretti).

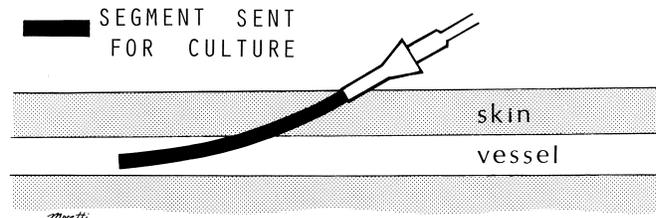

Figure 13.12-4 Segment of short catheter for culture (illustration by Carol Moretti).

II. SPECIMENS (continued)

b. Short catheters

The cannula is cultured in its entirety following removal of the hub. To remove the hub, use sterile scissors, or snap off steel needles with a sterile hemostat (5) (Fig. 13.12-4).

2. Transport

Transport catheter tips in a sterile container. If tips are cut to proper length, there is no need to bend them for insertion into transport container. Culture tips within 2 h of collection to prevent desiccation of microorganisms.

III. EQUIPMENT, SUPPLIES, AND REAGENTS

- A. 100-mm 5% BAP
- B. Forceps
- C. 95% Alcohol
- D. Sterile TSB

- E. 100- μ l pipette and sterile tips
- F. Sterile 1-ml syringe and needle
- G. Sterile test tubes (12 by 75 mm) with caps

ANALYTICAL CONSIDERATIONS

IV. PROCEDURE

Observe standard precautions.

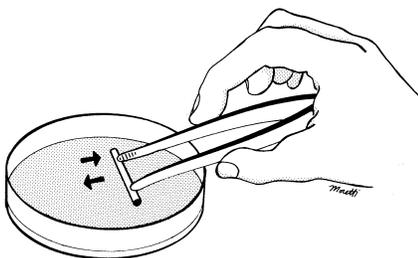

Figure 13.12-5 Maki roll technique (illustration by Carol Moretti).

A. Semiquantitative culture, Maki method

1. Dip forceps in 95% alcohol, and flame sterilize. Allow to cool.
2. If the catheter segment is too long to be rolled on the plate, cut it in half with sterile scissors and culture each segment separately.
3. Use sterile forceps to transfer catheter tip from transport container to a BAP.
4. Using slight pressure, roll catheter tip back and forth across agar surface at least four times. It is essential that the catheter tip have good contact with the surface of the plate. If tip is bent and hard to roll, use forceps to pick up tip, and rub all surfaces onto plate (Fig. 13.12-5).
5. Dip forceps in 95% alcohol, and flame sterilize.
6. Incubate plate for at least 72 h at 35°C in a CO₂ incubator. It is not necessary to routinely culture for anaerobic bacteria, fungi, or mycobacteria.

B. Culture of implanted subcutaneous ports

At this time, there is no standardized method available for culturing implanted subcutaneous ports. If sepsis is suspected, quantitative blood cultures may be done without necessitating removal of the device. If the port is subsequently

IV. PROCEDURE (*continued*)

removed, the distal catheter tip is also cultured (7). When a subcutaneous infection is suspected, culture an aspirate or tissue sample of the wound site. There is no evidence that suggests that culturing the port itself is of any value.

C. Culture of the lumen

1. Aseptically transfer catheter segment from transport container to a sterile test tube (12 by 75 mm).
2. Use a sterile syringe to draw up 1 ml of sterile TSB.
3. Place needle into lumen of catheter, and dispense broth through catheter segment.
4. Cap tube, and vortex to dislodge adherent bacteria.
5. Serially dilute sample 100-fold.
6. Inoculate 100 μ l of each dilution onto a 100-mm BAP. Cross-streak for well-isolated colonies.
7. Incubate plate for at least 72 h at 35°C in a CO₂ incubator. It is not necessary to routinely culture for anaerobic bacteria, fungi, or mycobacteria.

V. INTERPRETATION**A. Semiquantitative culture, Maki method**

Identify and perform susceptibility testing on each organism that produces ≥ 15 colonies. *Note:* Some authors use five colonies as the cutoff (2, 3).

B. Culture of implanted subcutaneous ports

Identify and perform susceptibility testing on all organisms isolated.

C. Culture of the lumen

Calculate the number of CFU per milliliter by multiplying the number of colonies by 10 times the dilution factor and then dividing by the volume of broth used (1 ml). Identify and perform susceptibility testing on all organisms present at $>1,000$ CFU/ml (1).

VI. LIMITATION OF THE PROCEDURE

Fastidious organisms will not be detected.
CHOC may help detect these organisms.

VII. QUALITY CONTROL

Perform QC on media according to your laboratory procedure. Report catheter-associated infections to the appropriate committee (e.g., Infection Control, Catheter Care) for QA review.

POSTANALYTICAL CONSIDERATIONS**VIII. REPORTING RESULTS****A. Semiquantitative culture, Maki method**

For each organism that produces >15 CFU, include actual colony count with the organism identification and susceptibility report. If there is confluent growth, report as such.

B. Culture of implanted subcutaneous ports

Report qualitatively (e.g., few, moderate, many) when organism identification and susceptibility are reported.

C. Culture of lumen

For each organism that produces $>1,000$ CFU/ml, include dilution amount with the identification and susceptibility report.

APPENDIX 13.12–1

Device-Related Infections

Intravascular-device-related infections are most often caused by endogenous skin microbiota (Table 13.12–A1). Some organisms, such as coagulase-negative staphylococci and *Corynebacterium jeikeium*, that were previously considered contaminants are now recognized as major pathogens in device-related infections. Accurate diagnosis of device-related infection can be difficult, since true infection must be distinguished from contamination of the catheter during its removal from the patient. When device-related infection is suspected, the entire catheter (short catheters) or 2- to 3-cm segments from both the distal tip and the transcutaneous portions (long catheter) should be submitted for culture (5). The clinical microbiology laboratory must be able to identify and quantitate the microorganisms present.

Qualitative culture of the catheter, in which the segment is incubated in liquid medium, is a sensitive technique for diagnosis of infection but provides no information about the number of microorganisms present (7); i.e., the presence of a single contaminant can lead to

Table 13.12–A1 Bloodstream pathogens suggestive of intravenous-infusion-related septicemia^a

Probable source	Pathogens
Peripheral intravenous catheters	Coagulase-negative staphylococci, <i>Staphylococcus aureus</i> , enterococci, <i>Candida</i> spp.
Central venous catheters	<i>Candida</i> spp., coagulase-negative staphylococci, <i>S. aureus</i> , <i>Corynebacterium</i> spp. (especially <i>C. jeikeium</i>), <i>Klebsiella</i> spp., <i>Acinetobacter</i> spp., <i>Fusarium</i> spp., <i>Malassezia furfur</i>

^a Modified from reference 6.

APPENDIX 13.12-1 (continued)

a positive culture. In an effort to improve the specificity of catheter cultures, quantitative techniques that demonstrate a sensitivity comparable to that of broth culture but with superior specificity and predictive value have been developed. Detection of catheter-related infections is also possible by microscopic examination of the catheter surfaces following Gram (2) or acridine orange (10) staining. This allows rapid detection, preliminary characterization, and quantitation of the organisms present. Although these staining techniques show promise, they are not feasible for all types of catheters and are technically quite demanding and labor-intensive.

Maki et al. (7) developed a semiquantitative technique in which the catheter segment is rolled back and forth across the surface of a BAP. Colonies are counted after incubation, and the presence of ≥ 15 indicates local infection. Because the technique samples only the exterior portion of the catheter, it may not detect infections originating in the lumen of the catheter. It has been suggested that colonization of the lumen may be an important reservoir of infection in some catheter infections (1, 3, 4, 8). Cleri et al. (1) developed a quantitative technique in which the catheter lumen is flushed with liquid medium and agitated vigorously to dislodge adherent microorganisms. The suspension is then serially diluted and plated. The presence of $> 1,000$ CFU/ml suggests bacteremia. The theoretical advantage of this approach is that both the interior and exterior surfaces of the catheter are sampled. Thus, a modified procedure for such culture is also included. Rello et al. suggest that using both the semiquantitative culture of the exterior catheter surface and the quantitative culture of the lumen increases the detection of catheter colonization (9).

I. PRINCIPLE

Transfusion of blood and blood components is usually a safe and effective form of therapy. However, untoward effects can occur. These untoward effects, called "transfusion reactions," may present immediately or be delayed, and they may or may not be immunologically mediated. A serious complication of transfusion therapy is the transmission of infection by many different kinds of microorganisms,

such as viruses (hepatitis) (7), spirochetes (*Borrelia burgdorferi*) (4), and other bacteria, for example, *Yersinia* spp. This procedure focuses only on culture of suspected bacterial agents in blood and blood products. A list of some bacterial agents implicated in transfusion reactions is shown in Table 13.13–1.

The use of a closed system for blood collection in sterile disposable bags, the

implementation of rigid standards for blood bank operations, and more stringent attention to skin disinfection have contributed to the reduction of bacterial contamination. Although bacterial contamination of blood and blood products is rare, it remains a significant concern (15). (See Appendix 13.13–1 for further discussion.)

Table 13.13–1 Bacterial organisms implicated in transfusion reactions

Organism(s)	Reference(s)
Coagulase-negative staphylococci	1, 12
<i>Enterobacter agglomerans</i>	2
<i>Enterobacter cloacae</i>	5, 6, 19
<i>Escherichia coli</i>	3, 12

<i>Staphylococcus aureus</i>	1, 12
<i>Staphylococcus epidermidis</i>	6
<i>Yersinia enterocolitica</i>	2, 10, 17

PREANALYTICAL CONSIDERATIONS

II. MATERIALS

- A. Aerobic and anaerobic blood culture bottles**
One of each type of bottle constitutes one set. The broth medium used in the culture bottles is dependent on the blood culture system used in your laboratory. If the lysis centrifugation system is in use, additional plated media for room temperature (25°C) and anaerobic incubation should be employed.
- B. BAP**
- C. CHOC plates**
- D. Anaerobic blood agar plates**
- E. Gram stain reagents**
- F. Alcohol**
- G. Iodophor**
- H. Needle and 20-ml syringe**

ANALYTICAL CONSIDERATIONS

III. PROCEDURE

Observe standard precautions.

- A. Wear gloves and a face shield at all times when handling blood or blood products.** For each unit of blood and/or blood component to be cultured, have two sets of blood culture bottles. A set is one aerobic and one anaerobic bottle. Alternatively, one adult Isolator 10 tube may be used.
- B. Cleanse the rubber septum of each blood culture bottle and the port(s) of the blood bag with alcohol and/or iodophor, scrubbing with the antiseptic for at least 1 min.**
- C. Using a needle and syringe, aseptically remove approximately 20 ml of blood or blood product from the suspect unit.**
- D. Inoculate approximately a 3- to 5-ml sample into each of the four blood culture bottles.** If less than 20 ml of blood is available for culture, dispense equal amounts into the blood culture bottles. The final dilution of blood to culture broth should be 1:10. Reserve approximately 0.5 to 1 ml of blood for Gram stain. If lysis centrifugation is the blood culture method in use, prepare plates for 35°C, room temperature, and anaerobic incubation. Observe daily for up to 4 days for aerobic organisms and for up to 6 days for anaerobic organisms.
- E. Prepare a slide for Gram stain (see procedure 3.2.1).** If organisms are observed, directly inoculate plated media (CHOC and blood agar), and incubate at 35°C in CO₂.
- F. Depending on the blood culture system, use one of the following methods (13).**
 - 1. Manual method**
 - a. Incubate one set of blood culture bottles at 35°C in CO₂ and the other set at 25°C.**
 - b. Daily, for up to 7 days, examine bottles macroscopically (visually) for growth.**
 - c. Perform blind subculture at 18 and 48 h.** Cleanse the bottle septum as described above. Remove approximately 0.2 to 0.5 ml of blood and inoculate a CHOC plate. Incubate the CHOC plate for 48 h under the incubation conditions for the bottle sampled before discarding it as negative. At 48 h, perform a blind subculture onto an anaerobic blood agar plate. Incubate this plate in an anaerobic environment for 48 h before discarding it as negative.
 - d. If macroscopic examination of the bottles indicates growth (turbidity, hemolysis, gas, etc.), subculture the bottle to a blood agar plate, CHOC plate, and anaerobic blood agar plate.** Incubate the blood agar and CHOC plates at 35°C in CO₂. Incubate the anaerobic blood agar plate in an anaerobic environment at 35°C. Prepare a Gram stain from the bottle at the same time. Subculture the bottles incubated at room temperature onto plates incubated at both room temperature and 35°C.

III. PROCEDURE (continued)

- e. If the Gram stain indicates the presence of bacteria, appropriate presumptive tests should be performed from the blood culture broth, but final confirmatory identification must be based on the evaluation of a pure culture isolate.
2. Automated blood culture system
If using a continuous monitoring system or a daily-read system, follow the manufacturer's recommendations for reading the blood culture bottles. If bottles are flagged as positive, use subculturing methods as described above. Examine the bottles macroscopically before discarding as negative.

POSTANALYTICAL CONSIDERATIONS

IV. INTERPRETATION

A negative culture makes it very unlikely that the blood or blood product was significantly contaminated with bacteria at the time of transfusion. However, a positive culture does not positively identify infection as the etiology of the transfusion reaction, since the organism cultured may be a minor contaminant. A positive culture of the blood or blood product does not establish the source of the contamination (blood collection, blood bank, ward, etc.) unless both blood bank and patient's blood samples yield identical organisms.

Whenever clinical circumstances lead to culture of a blood unit, the recipient patient's blood should be cultured simultaneously. Since intravascular therapy has been implicated as the source of sepsis, the catheter and fluid should be cultured as well (8). The supplier of the blood, blood product, intravenous fluid, etc., should always be notified if the culture of the specific product is positive.

APPENDIX 13.13–1

Sources of Bacterial Contamination of Blood and Blood Products

Both warm (mesophilic) and cold (psychrophilic) growing organisms have been incriminated in bacterial transfusion reactions. Predominance of gram-negative bacilli in blood for transfusion has been attributed to the ability of these organisms to proliferate at 0 to 6°C, the temperatures at which blood is stored. *Yersinia enterocolitica*, *Pseudomonas fluorescens*, *Pseudomonas putida*, and *Enterobacter* species are examples of such organisms. Some gram-negative bacteria produce endotoxins whose presence in the bloodstream may cause rapid and sometimes irreversible shock (3). Even low levels of bacterial contamination can result in a blood product that contains high concentrations of endotoxin and/or bacteria after 2 to 3 weeks of storage. Gram-positive organisms grow poorly in the cold and rarely contaminate blood stored under these conditions. On the other hand, platelets are routinely stored for long periods at room temperature (22°C) and thus provide an excellent medium for this type of bacterial growth. As a result, platelets are now the most common cause of transfusion-related sepsis caused by organisms such as diphtheroids, *Staphylococcus epidermidis*, *Staphylococcus aureus*, *Pseudomonas* spp., and *Enterobacter cloacae* (2). Documented cases of bacterial contamination are listed in Table 13.13–1.

Contamination of blood products can occur via several routes: skin microbiota (1, 4), environmental organisms introduced at the time of collection or during processing (1, 5), or a bacteremia (asymptomatic) in the blood of a healthy donor. Water baths in which frozen blood products are thawed can also be a source of contamination (5). The American Association of Blood Banks recommends keeping blood bag ports dry and water baths clean to avoid contamination by this route (6).

The clinical manifestations associated with bacterial contamination mimic those seen in a hemolytic transfusion reaction unrelated to infection. After immunological and other non-infectious sources are ruled out, bacterial contamination should be considered. The blood product must be examined for evidence of bacterial contamination (change in color or presence of clots). In addition, Gram stain and cultures should be performed.

I. PRINCIPLE

The severe morbidity associated with infection following implantation of orthopedic prosthetic devices or repair of bone fractures at septic trauma sites requires early and accurate microbiological assessment of these sites for successful management. Although no procedural or interpre-

tive standards for culture of these sites have been established, the following is a set of procedures often used by surgical teams to assess microbial load or, along with other laboratory findings, to confirm the presence of an infection. These procedures include (i) enumeration of bacte-

ria in tissue from a contaminated trauma site prior to repair of fracture, (ii) intraoperative culture of a site selected for implantation of a prosthesis, (iii) culture of fluid removed from the joint, and (iv) intraoperative culture of a failed prosthesis site.

PREANALYTICAL CONSIDERATIONS

II. SPECIMEN

Observe standard precautions.

Gram stain any purulent material that arrives.

A. Collection

1. Septic trauma site

Collect 1 cm³ of tissue at debridement from the trauma site that is not grossly contaminated. Biopsy material, including that obtained by punch biopsy (for quantitative analysis), from this site can also be used. Make sure the biopsy tissue is not submitted in formalin.

2. Implantation site

Samples are collected during surgery after exposure of the implantation site. Use sterile swabs to sample surfaces of the site that will receive the prosthesis. Although no standard has been set, four to six samples could be taken depending upon the practice of the surgical team.

3. Septic prosthesis site

a. Fluid withdrawn by aspiration from joint. Cleanse the surface of the skin through which the specimen will be aspirated as you would for collecting blood for culture. Use a needle and syringe to withdraw fluid from the joint space. Because of the high viscosity of purulent fluid found in an infected site, a large-bore needle, 18 gauge, should be used.

b. Samples collected after exposure of the prosthesis and site at or prior to surgery—multiple swab samples from the site, including the prosthesis and surrounding tissue. Four to six samples may be collected. This procedure is usually performed because acute infection of the prosthesis is not apparent. Other materials might be collected during surgery, including tissue surrounding the device, granulomatous tissue, capsular material, or pus. These materials should be sent in sterile containers as described below.

II. SPECIMEN (continued)

B. Specimen transport

1. For tissue specimens, use a sterile, airtight container, such as a plastic jar, plastic tube, or *sterile* Vacutainer tube. Do not push the tissue into the sheath of a swab transport system—small pieces of tissue can be lost, and large pieces are difficult to remove. Large pieces of tissue, 1 cm² or larger, need only be protected from desiccation. Smaller pieces of tissue, such as those obtained by punch biopsy, should be placed onto a piece of sterile gauze moistened with sterile, nonbacteriostatic saline and then placed into a container as described above.
2. Swabs used to collect samples should be part of a commercial swab transport system. The system should be sterile inside and out to minimize the possibility of contaminating the surgical field during use. Preferred systems use a simple liquid transport medium, not a semisolid. Smears for Gram stain should be prepared at the site and accompany the culture swabs to the laboratory.
3. Depending upon infection control practices of the institution, fluid withdrawn by aspiration can be sent to the laboratory in the syringe used to collect the sample. The needle must be removed or should be a type that is shielded during transport. Preferably, transfer the fluid to a secondary device, such as a sterile tube, commercial fluid transport system, or, if standard practice in your laboratory, a blood culture bottle. The Isolator tube may also be used, but host cells will be destroyed, thus limiting the ability to evaluate the specimen for infection.

III. MATERIALS

A. Septic trauma site

1. Sterile disposable plastic tissue grinder or mechanical homogenizer with sterile sample bag
2. Inoculating loop or glass rod “hockey stick”
3. Sterile pipettes, 1 and 2 ml
4. Dilution blanks, 9.9 ml of sterile 0.85% NaCl
5. TSA with 5% defibrinated sheep blood agar plate (SBAP)
6. CDC anaerobic sheep blood agar plate or another nonselective anaerobic agar medium supplemented with hemin and vitamin K

B. Specimens collected on swabs

1. SBAP
2. Tube of fluid THIO medium

C. Fluid withdrawn by aspiration

Follow standard practice in your laboratory for processing specimens collected by aspiration of normally sterile body sites.

D. Tissue from septic implantation site

Follow standard practice in your laboratory for processing tissue specimens.

ANALYTICAL CONSIDERATIONS

IV. SPECIMEN PROCESSING

Observe standard precautions.

A. Initial processing

Assess the integrity of the sample and transport device. Note the type of device received, along with a brief description of the appearance and approximate volume of the specimen.

B. Septic trauma site—quantification of organisms in tissue from a contaminated trauma site

1. Weight the barrel of a sterile tissue grinder to at least 0.01 g.
2. With sterile forceps, aseptically place the piece of tissue being cultured into the barrel and reweigh to determine the mass of the sample. This value will be used in calculating CFU per gram of original sample.
3. If a mechanical homogenizer is used, take the weight of a sterile sample bag supplied with the device.

IV. SPECIMEN PROCESSING

(continued)

4. For a sample that weighs ≤ 1.0 g add 0.5 ml of sterile, nonbacteriostatic saline; for larger samples, add 1.0 ml.
5. Thoroughly grind or homogenize the sample.
6. Withdraw the entire volume of the homogenate into a sterile pipette large enough to determine the total volume.
7. Dispense 0.1 ml of the homogenate into a 9.9-ml dilution blank.
8. Shake vigorously or vortex the mixture to disperse the homogenate. This yields a 1:100 dilution of the original homogenate.
9. Transfer 0.2 ml of the final dilution to each of two BAPs and two anaerobic agar plates.
10. Using a sterile inoculating loop or glass rod hockey stick, spread the inoculum over the surface of each plate, and allow it to dry completely before moving plates into the incubator.

C. Implantation site

1. Multiple swab samples are usually received for culture. Each sample should be processed individually; do not combine the samples.
2. Rinse each swab into a tube of THIO by inserting the swab about 2 cm below the surface and gently squeezing it against the wall of the tube while twisting it. Discard the swab.
3. No Gram stain is performed.

D. Fluid withdrawn by aspiration

Process fluid withdrawn by aspiration as a routine body fluid culture, making certain to include culture media and incubation conditions to recover both fastidious and nonfastidious aerobic and anaerobic bacteria, and a Gram stain. Refer to your standard laboratory protocol and appropriate sections in this handbook for details of these procedures.

E. Tissue collected from septic implantation site

Process tissue collected from a septic implantation site as a routine tissue specimen, making certain to include culture media and incubation conditions to recover both fastidious and nonfastidious aerobic and anaerobic bacteria, and Gram stain. Processing should include dispersion of the material by homogenization or grinding. Refer to your standard laboratory protocol or procedure 3.13.2 for details of these procedures.

V. INCUBATION

Incubate aerobic agar plates for 18 to 24 h at 35°C under an atmosphere enriched with carbon dioxide (5 to 8%) and elevated humidity (60 to 80% relative humidity). Incubate anaerobic plates for 48 h at 35°C in an anaerobic atmosphere. Incubate THIO at 35°C for 24 h.

VI. LABORATORY EVALUATION

A. Septic trauma site

1. 24 h
 - a. Examine aerobic plates for growth.
 - b. If discrete, mature colonies are present, count all and calculate the total colony count in the original sample as described below in item VI.A.4.
 - c. Gram stain each distinct colony type. A complete identification of each type of bacterium present is not necessary at this time, nor is susceptibility testing. This procedure is a measure of the bacteriological burden at the site known to be contaminated. Culture plates should be saved in the event that additional workup is requested.
 - d. If organism identifications are requested, proceed according to your standard laboratory procedures or appropriate sections of this handbook.

VI. LABORATORY EVALUATION (continued)

- e. If the growth on the plates is too small to evaluate, or if there was no growth, incubate the plates for an additional 24 h.
 - f. At the end of the first day's work, prepare a preliminary report of the count of bacteria, if possible, along with Gram stain results. Make sure to indicate that anaerobic culture is pending.
2. 48 h
 - a. Examine primary plates incubated from the previous day for growth. If, at this time, the primary plates have no growth, discard them.
 - b. Examine primary anaerobic plates for growth. To confirm the anaerobic nature of colonies observed on these plates, subculture a representative colony onto aerobic and anaerobic agar and incubate accordingly.
 - c. Gram stain each distinct colony type.
 - d. At the end of the second day's work, update the preliminary report with any additional findings.
 3. 72 h
 - a. Examine the subcultures set up the previous day. Compare growth and colony morphology seen on the subculture plates with those seen on the primary aerobic and anaerobic plates to determine the actual anaerobic populations in the original sample.
 - b. Do a final reconciliation of the total count to include the true anaerobic component.
 - c. Discard all plates except those containing isolates that will be saved in case additional workup is requested.
 4. Calculations
Determine the number of organisms using the following equation (modified from reference 2): $CFU/\text{gram of tissue} = (N \times D \times V \times 5)/W$, where N is the number of colonies on the agar plate, D is the reciprocal of the dilution, V is the total volume of the original homogenate divided by 0.1, 5 is the factor to compensate for a 0.2-ml inoculum size, and W is the weight of the original sample.
 5. Report
The final report should include the calculated total microbial count as CFU per gram of tissue at the original site, indicating growth of aerobic and anaerobic microbiota as appropriate, and listing of the types seen on Gram stain.

B. Implantation site

1. 24 h
 - a. Examine the inoculated broths for evidence of growth.
 - b. Prepare a smear from each broth showing growth, and Gram stain.
 - c. Subculture each broth onto SBAP and incubate for 18 to 24 h.
 - d. Enter a preliminary report describing the Gram stain morphology of organism detected in how many tubes out of how many are growth positive.
 - e. Reincubate any broths with no growth.
 - f. At the end of the first day's work, prepare a preliminary report of the number of positive broth cultures, along with Gram stain results.
2. 48 h
 - a. Examine broths. Where growth is now evident, process as described above.
 - b. Examine subcultures from positive broths from the previous day.
 - c. Identify these organisms. Refer to your laboratory protocols or appropriate sections of this handbook for identification methods.
 - d. Depending upon laboratory practice, antimicrobial susceptibility testing may be done at this time or may be delayed until additional instructions are received from the requesting physician.

VI. LABORATORY EVALUATION *(continued)*

- e. Save any isolates in accord with laboratory policy for any requests for additional workup.
 - f. Reincubate any subcultures from positive broths from the previous day.
 - g. Discard broths with no growth.
 - h. At the end of the second day's work, update the preliminary report with any additional findings.
3. 72 h
- a. Examine all reincubated plates for evidence of growth.
 - b. Proceed with identification of any new growth.
 - c. Discard all plates with no growth.
 - d. At the end of the third day's work, update the preliminary report with any additional findings.
4. Fourth and fifth days
- a. Examine the broth cultures each day and proceed as described above when growth appears.
 - b. If no growth appears after day 5, discard the broth and report as no growth.
5. Report
- Prepare a final report including any the identities of organisms isolated from the broth cultures, the number of broths in which each isolate was found, and the results of any antimicrobial susceptibility testing done.

C. Septic implantation site

Swab cultures from this site should be evaluated as described in item VI.B. Culture of fluid and tissue are evaluated as defined for routine sterile body fluid or tissue specimen. Refer to your standard laboratory protocols or appropriate sections of this handbook.

POSTANALYTICAL CONSIDERATIONS

VII. LIMITATIONS OF THE PROCEDURE

As with any culture procedure, the quality of the results obtained is directly related to the care taken in collecting and transporting the specimen, which is beyond the control of the laboratory. Specimens obtained from patients on antimicrobial therapy may yield false-negative results. Fastidious organisms, or organisms that have slow growth times, such as *Mycoplasma* spp., certain mycobacteria, or fungi, for example, may not be recovered using these methods.

VIII. INTERPRETATION

As always, clinical correlation of results rests with the physician. The following are general guidelines for interpretations of culture results derived from relevant studies in the literature.

- A. If the patient has received no antimicrobial therapy for several weeks prior to collection of the specimen, culture of multiple specimens of periprosthetic tissue is 100% diagnostic, while culture of arthrocentesis fluid is 85 to 98% sensitive for detection of infection at the site of the prosthesis (1).
- B. A colony count of >100,000 CFU/g of tissue excised from a contaminated trauma site is predictive of septic complications at the healing site unless closure is delayed and accompanied by appropriate antimicrobial therapy (2).
- C. Any organism isolated from a supposedly sterile site should be considered potentially significant, even organisms such as coagulase-negative staphylococci and *Corynebacterium* spp., especially if the organism is (i) isolated in high numbers or (ii) isolated repeatedly from the same site. For swab samples, three or more positive swabs growing identical organisms from a normally sterile site are indicative of infection (1, 3).

IX. QUALITY CONTROL AND QUALITY ASSURANCE
A. QC**1. Culture media**

Standard procedures for verifying the quality and performance of culture media used in these procedures should be performed and documented. Of particular importance is sterility testing of media prepared in-house and for those to which sterile enrichments are added after sterilization.

2. Reagents and equipment

Procedures for ensuring the quality and performance of reagents and equipment used for these analyses must be performed and documented.

B. QA

Results of the culture procedures described above can be used to monitor one aspect of the quality of care. Reduction of surgical procedure failure rates attributed to postsurgical infection are best evaluated by a multidiscipline team including hospital infection control, the microbiology laboratory, and the medical department delivering care. Action taken to improve care, if deemed necessary, and follow-up culturing to assess the impact of such actions should be decided upon by the same team.

13.15

Quantitative Culture of Small-Bowel Contents

I. PRINCIPLE

The microbial content of the normal gastrointestinal tract varies with the precise site (2, 5). The concentration of bacteria in gastric aspirates from fasting patients is fewer than 10^3 /ml. Duodenal and jejunal organisms are normally present at fewer than 10^5 /ml (3) and consist of primarily gram-positive bacteria (staphylococci, streptococci, and lactobacilli) and yeasts.

Members of the family *Enterobacteriaceae* are occasionally present in small numbers. Strict anaerobes are notably absent. Postprandially, the microbial content of the proximal small bowel is increased by the introduction of food and oropharyngeal microorganisms. The ileal microbiota more closely resembles that of the colon, with the ileocecal valve incom-

pletely regulating backwash from the colon. In the distal ileum, the bioload consists of 10^7 to 10^8 aerobes and anaerobes per ml, whereas in the colon, a significant rise in anaerobes to 10^{10} to 10^{11} organisms per ml and of aerobes to 10^8 organisms per ml is found (3). (See Appendix 13.15–1 for further discussion.)

PREANALYTICAL CONSIDERATIONS

II. SPECIMEN

A. Specimen collection

The small-bowel aspirate for bacteriological culture is obtained endoscopically with a sterile catheter or simple sterile tube (3, 4). Be careful not to inject air into the bowel during collection so that anaerobic growth will not be compromised.

B. Specimen volume

Collect at least 1 ml of fluid.

C. Specimen transport

No special transport device is necessary, but anaerobic transport devices may be used. Specimens should be delivered immediately to the laboratory and processed as soon as possible (1). If immediate processing or transport is not possible, refrigerate and process within 2 h.

D. Specimen rejection

Reject all specimens not properly transported. Do not accept any solid fecal matter; accept only fluid bowel contents.

III. MEDIA

A. Plated media

1. TSA with sheep blood and/or CHOC
2. Nonselective anaerobic agar such as CDC anaerobic blood agar or brucella blood agar

B. Broth diluents

1. Schaedler broth
2. Other broths, such as Mueller-Hinton or even THIO, may be substituted.

ANALYTICAL CONSIDERATIONS

IV. SPECIMEN PROCESSING

Observe standard precautions.

A. Dilution

1. Invert specimen at least three times, or vortex for 10 s to mix well.
2. Prepare 10^{-2} dilution by placing 0.01 ml of specimen into 0.99 ml of Schaedler broth. (Use a 0.01-ml calibrated loop or 10- μ l pipette.) Mix well.
3. Prepare 10^{-4} dilution by placing 0.01 ml of the 10^{-2} dilution into 0.99 ml of Schaedler broth. Mix well.
4. Prepare 10^{-6} dilution by placing 0.01 ml of the 10^{-4} dilution into 0.99 ml of Schaedler broth. Mix well.

B. Plating

1. Remove 0.01 ml from the 10^{-2} dilution to one each of a blood agar or CHOC plate and an anaerobic blood agar plate. Inoculate the broth across the center of the plate, and then streak it back and forth perpendicularly to the original streak. Label the plates with the proper dilution factor.
2. Repeat with the 10^{-4} and 10^{-6} dilutions.

C. Incubation

1. Place blood agar and/or CHOC plates in a CO_2 incubator at 35°C for 16 to 24 h.
2. Place anaerobic blood agar plates into any available anaerobic incubation system at 35°C for 72 h.

V. RESULTS

A. Evaluation of cultures: quantitation of aerobes

After incubation, examine aerobic plates and count the colonies on the plate containing 30 to 300 colonies. Discard other plates. To calculate the number of organisms per milliliter, use the formula given below.

B. Calculations

Organisms/milliliter of specimen = number of colonies/plate \times

$$\frac{1}{\text{dilution of plate counted}} \times \frac{1}{\text{volume plated}}$$

Example: If there are 10 colonies on the 10^{-4} dilution agar plate, then

$$10 \times \frac{1}{10^{-4}} \times \frac{1}{10^{-2}} = 10^7 \text{ organisms per ml.}$$

Report this figure for total aerobes.

C. Quantitation of anaerobes

Select the anaerobic plate containing 30 to 300 colonies. Discard other plates. Choose one colony representing each type present, note the colony count, and subculture aerobically and anaerobically. Incubate for 48 h under appropriate atmospheres. If there is growth anaerobically but not aerobically, the growth represents the strict anaerobes. Count the anaerobic colonies on the plate, and compute the organisms per milliliter by using the above formula. Report this figure for total anaerobes.

POSTANALYTICAL CONSIDERATIONS

V. RESULTS (*continued*)**D. Reporting results**

Add aerobic and anaerobic counts to produce total bacterial count. Report results as follows.

total aerobic count = ___ organisms/ml

total anaerobic count = ___ organisms/ml

total bacterial count = ___ organisms/ml

If there are fewer than 10 colonies on the 10^{-2} dilution plate, report "fewer than 10^5 organisms/ml." If there are more than 100 colonies present on the 10^{-6} dilution and they cannot be estimated, report "more than 10^{10} organisms/ml." If plates are overgrown with swarming *Proteus* spp., report "no quantitation possible."

E. Identification and susceptibility testing

Since the goal of this procedure is to detect overgrowth, no identification or susceptibility testing need be done routinely. All plates with representative organisms should be saved for 7 days so that additional testing can be done if indicated. In order to save time, some microbiologists proceed with identification tests immediately.

VI. LIMITATIONS OF THE PROCEDURE

In this procedure, the dilution protocol will not reveal the presence of organisms present at normal levels (fewer than 10^5 /ml) in the duodenal fluid. Since the goal of the procedure is to detect overgrowth rather than to evaluate normal conditions, this approach minimizes the effort while maximizing information applicable to detection of the overgrowth syndrome.

This test will not detect parasites, which require a separate examination. Very strict anaerobes and fastidious organisms also may not be detected by this technique. Since the sole purpose of this test is to detect bacterial overgrowth of the small intestine, other applications of the information provided may not be appropriate.

VII. INTERPRETATION

A total colony count of fewer than 10^5 organisms per ml in a duodenal-fluid specimen is considered a normal result. A total colony count of more than 10^5 organisms per ml may indicate that overgrowth of bacteria has occurred in the small bowel.

VIII. QUALITY CONTROL AND QUALITY ASSURANCE

A. QC

QC is conducted for the volumetric devices and media as described elsewhere in this handbook.

B. QA

This test would not normally be subject to a QA monitor, as it should be a rare test. Excessive test ordering should, however, precipitate a QA intervention.

APPENDIX 13.15–1

Bacterial Overgrowth in the Small Bowel

There is a common misconception that the stomach and small intestine are sterile; close examination of the literature (2, 6) shows that modifiers such as “functionally” or “effectively” are generally employed in association with the term “sterile.” For someone working with colon or oral microbiota, where dilutions of 10⁻⁸ are necessary to achieve isolated colonies, specimens from the stomach (10³/ml), duodenum-jejunum (10⁵/ml), and even ileum (10⁷ to 10⁸/ml) would appear sterile.

Overgrowth of bacteria in the healthy small bowel is prevented by various natural regulatory mechanisms. The most important appears to be normal small-intestine peristalsis. Other mechanisms include gastric acid, gastrointestinal tract mucus, bile, and inhibitory properties of the gastric and jejunal mucosa (5).

Surgical procedures (3, 7) or physiological conditions that interfere with intestinal motility are a primary cause of microbial overgrowth (2, 4, 6). Numerous other conditions, both anatomic (e.g., diverticular strictures, fistulas) and nonanatomic (e.g., scleroderma, diabetes, cirrhosis) (5), also contribute. Age may also be a risk factor for bacterial overgrowth and its consequences (11). Once overgrowth has occurred, metabolic consequences follow, and diarrhea, steatorrhea, anemia, and malabsorption, which is manifested clinically as weight loss and malnutrition (5, 8), may result.

Detection of bacterial overgrowth may be accomplished directly by quantitative culture of fluid from the duodenum or indirectly by detection of microbial metabolites with breath tests (9, 12). Cultures of duodenal aspirates or string test samples (10) may indicate overgrowth (1, 8). Such cultures are considered important as infection control cultures because they represent an adverse microbiological consequence of a medical procedure.

13.16.1

Introduction

Numerous methods exist for characterizing microorganisms beyond the species level. Methods include but are not limited to determining antimicrobial resistance patterns, biotyping, serotyping, and using molecular techniques such as plasmid analysis and restriction enzyme analysis of plasmid or chromosomal DNA. These methods are used when it is necessary to separate organisms more finely for clinical and epidemiologic purposes. In order to

have wide application, laboratory techniques for typing organisms in the clinical microbiology laboratory must be easy to perform with readily available reagents and materials. A valid typing technique must be reproducible, standardized, and stable over time. It must be sensitive enough to distinguish epidemiologically related and unrelated strains. No single method of strain subtype delineation has proved to be ideal. Most often, a combi-

nation of several systems of characterization is used to evaluate a group of organisms. The fundamental principle in the application of any technique to the typing of organisms is that the entire group must be tested as a batch. All organisms must be run in parallel on the same day by the same laboratory and the same personnel with identical reagents. (*See* Appendix 13.16–1 on p. 13.16.5.1 for further discussion.)

13.16.2

Dienes Typing for *Proteus* spp.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Two different strains of *Proteus* form a line of inhibition where the swarms meet. Two identical *Proteus* organisms swarm together smoothly.

II. MATERIALS

- A. Test isolates of swarming *Proteus* spp.
- B. Blood agar plates
- C. Motility media

III. QUALITY CONTROL

- A. Negative control: the same *Proteus mirabilis* strain (isolate) spotted twice on the plate; no inhibition
- B. Positive control: two different *Proteus* strains spotted opposite each other; inhibition line (not identical)

ANALYTICAL CONSIDERATIONS

IV. PROCEDURE

Observe standard precautions.

- A. The organisms to be tested must be swarming. If this characteristic has been lost, passage the organisms once through motility medium to help them recover the ability to swarm.
- B. Inoculate by placing a loopful of each of two to four test isolates near the edges of a blood agar plate. The spots should be about 6 cm apart (Fig. 13.16.2-1). All pairs of organisms to be compared must be spotted on the same plate.
- C. Incubate the plates for 18 to 24 h at 35°C.
- D. Observe plates for a line of inhibition at the conjunction of the swarming zones. The line is more easily seen at the edges of the plate. Organisms that swarm together smoothly are similar. Those that inhibit each other are different.
- E. Strains that fail to swarm or that swarm too slowly cannot be typed by this technique.

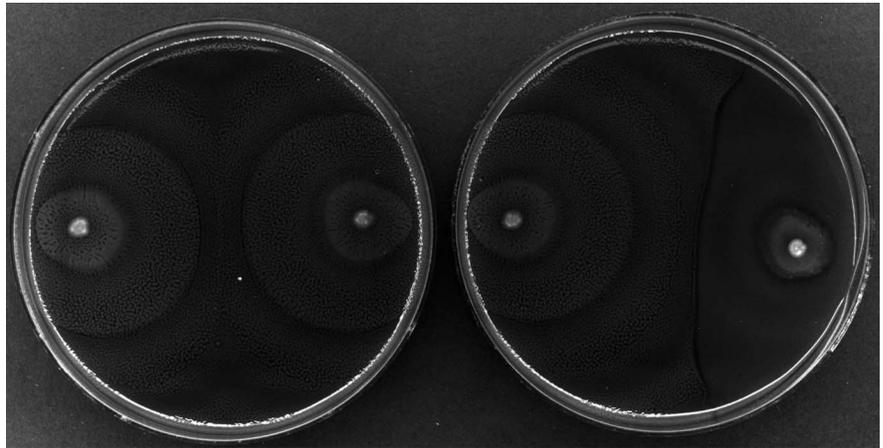

Figure 13.16.2–1 Dienes typing: negative (left) and positive (right) tests.

13.16.3

Slime Test for Staphylococci

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Slime, a heteropolysaccharide loosely associated with cells of some staphylococci, promotes adherence to smooth surfaces. The presence of slime can be detected on glass tube surfaces by staining with saf-

ranin. Slime production can be used as a phenotypic strain marker but may not predict the potential pathogenic nature of an isolate.

II. MATERIALS

A. TSB (BBL)

B. Glass screw-cap round-bottom tubes (16 by 125 mm)

C. Safranin O stock (2.5 g of safranin O in 100 ml of 95% ethanol)

D. Safranin working solution (1:10 dilution of stock in water)

E. Pipette

III. QUALITY CONTROL

Test at least weekly.

A. Positive: slime-producing *Staphylococcus epidermidis*

B. Negative: *Staphylococcus haemolyticus*

ANALYTICAL CONSIDERATIONS

IV. PROCEDURE

Observe standard precautions.

A. Inoculate a 5-ml tube of TSB with a few representative colonies. Incubate at 35°C for 48 h.

B. Aspirate all broth, being careful not to disturb the sides of the tube.

C. Add 5 to 10 drops of safranin, recap, and gently rotate tube to stain all inner surfaces. Invert tube to drain.

D. Slime production is present if a visible stained film lines the walls of the tube. A ring at the liquid-air interface is not considered positive.

E. Grade as follows.

Negative: no staining of walls

1 + : very slight color on side of tube

2 + : light staining along walls of tube

3 + : heavy staining along walls of tube

F. Grades negative and 1 + are reported as slime test negative; grades 2 + and 3 + are reported as slime test positive.

Christensen, G. D., W. A. Simpson, A. L. Bisno, and E. H. Beachey. 1982. Adherence of slime-producing strains of *Staphylococcus epidermidis* to smooth surfaces. *Infect. Immun.* **37**:318–326.

13.16.4

Synergistic Hemolysis

PREANALYTICAL CONSIDERATION

I. PRINCIPLE

Some isolates of staphylococci produce a hemolysin that will give synergistic or complete hemolysis with beta-toxin-producing *Staphylococcus intermedius*. This test can be used as a strain marker.

II. MATERIALS

- A. BAP
- B. *S. intermedius* ATCC 49052
- C. *Staphylococcus epidermidis* negative control

III. QUALITY CONTROL

- A. Test with every batch.
- B. Negative control: all test isolates tested in duplicate with *S. epidermidis* negative control
- C. Positive control: *S. epidermidis*, which produces synergistic hemolysis

ANALYTICAL CONSIDERATIONS

IV. PROCEDURE

Observe standard precautions.

- A. Inoculate a BAP with *S. intermedius* ATCC 49052 as a line down the center of the plate.
- B. Inoculate a second BAP with the negative control, *S. epidermidis*, in the same way.
- C. Streak each test strain in a line perpendicular to but not touching the center lines, about 0.5 cm from the inoculum (Fig. 13.16.4-1).
- D. Incubate at 35°C. Read plates at 16 to 18, 24, and 48 h.
- E. A zone of complete hemolysis within the partial hemolysis zone of *S. intermedius* is a positive test. It will appear as an arrowhead similar to that produced in the CAMP test for identification of group B streptococci.
- F. All tests must be negative with the *S. epidermidis* negative control strain.
- G. Staphylococcal isolates can be designated as displaying the following.
 - 1. Complete hemolysis: beta-hemolysis without *S. intermedius*
 - 2. Synergistic hemolysis: clear zone with *S. intermedius*
 - 3. No hemolysis

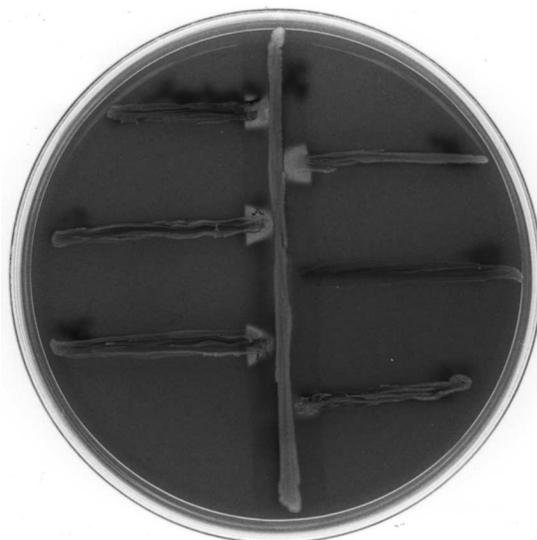

Figure 13.16.4-1 Synergistic hemolysis test: positive tests, left and upper right; weak positive test, lower right; negative test, center right.

APPENDIX 13.16-1

Biotyping and Antibigrams

Biotyping and antibiograms are readily available in most clinical microbiology laboratories. Caution must be used in the application of these for organism characterization. Most identification systems and antibiotic panels are designed to identify species and to define clinically useful antibiotics and are not sensitive or reproducible enough for strain delineation by themselves. There are several simple and practical additional tests that can be used to subtype selected nosocomial microorganisms in most clinical microbiology laboratories. Four of these tests, Dienes test for swarming *Proteus* spp., pyocin typing for *Pseudomonas aeruginosa*, and synergistic hemolysis and slime tests for staphylococci, provide excellent results and are relatively easy to perform. Procedures and references are provided in this procedure. Additional methods of characterization and variations on biotyping and antibiograms designed for specific species are in use in many research laboratories. In the future, some of these will be in the realm of the clinical laboratory as the problems of stability, reproducibility, and labor intensity are solved.

Prospective, Focused Surveillance for Oxacillin-Resistant *Staphylococcus aureus* and Vancomycin-Resistant Enterococci

I. PRINCIPLE

This procedure focuses on selective detection of oxacillin-resistant *Staphylococcus aureus* (ORSA) and vancomycin-resistant *Enterococcus* (VRE) from colonized sites of patients, hospital staff, or the environment.

PREANALYTICAL CONSIDERATIONS

II. PROCEDURE FOR ORSA SCREENING

A. Specimen

1. Site of collection

Common sites cultured for colonization by ORSA are the nose, sputum, skin, surgical wounds, intravenous-line and catheter sites, burns, or decubitus ulcers.

■ In investigations of epidemics, patient surveillance cultures often include samples from the anterior nares, groin, surgical wounds, and decubitus ulcers. The anterior nares are the usual site cultured for hospital staff (4).

2. Method of collection

Swab the site. If the site is dry, premoisten swab with nonbacteriostatic saline.

B. Materials

1. BAP or phenylethyl alcohol plate. BAP (with or without mannitol salt agar) is used with sites not heavily colonized with other organisms, e.g., anterior nares.

2. Mannitol salt agar (MSA) (3), MSA with 4 to 6 µg of oxacillin (1, 2, 5), or lipovitellin salt-mannitol with a 4-µg oxacillin disk (6). These are useful for sites colonized with organisms in addition to *S. aureus*.

3. Broth enrichment media with 6.5% NaCl (3), or staphylococcal enrichment broth (M-Staph broth) containing 7.5% NaCl, 1% mannitol, 0.2% lactose, and 0.25% yeast extract in a tryptone broth base (7, 8). The broth enrichment is used to increase the efficiency of detection of ORSA.

4. Most of these media are available commercially as prepared plated media. Lipovitellin salt-mannitol is available through Bristol Laboratories (Syracuse, N.Y.). M-Staph broth can be obtained from Difco/Becton Dickinson Laboratories. Antimicrobial agent-containing MSA is prepared from dehydrated media.

C. QC performed daily

For mannitol salt-oxacillin agar, use ORSA (suitable reference strain and *S. aureus* ATCC 25923 or ATCC 29213).

ANALYTICAL CONSIDERATIONS**II. PROCEDURE FOR ORSA SCREENING** (*continued*)**D. Method**

1. Inoculate selective and nonselective media, and incubate them for 72 h.
2. After 18 to 24 h of incubation, subculture the broth to BAP and mannitol salt-oxacillin agar.
3. Examine for colonies resembling those of *S. aureus*. If there is growth resembling staphylococci on both selective and nonselective media, test each colony type for *S. aureus* by routine methods.
4. Subculture to BAP for purity, and test for ORSA from this subculture.
5. Test for ORSA with Mueller-Hinton-oxacillin agar as described in procedure 5.4.

ANALYTICAL CONSIDERATIONS**III. PROCEDURE FOR VRE SCREENING**

- A. While there may be many approaches to sampling for VRE, environmental sampling and blind surveillance sampling of patients need not be routinely performed. Surveillance may be performed on known positive patients, i.e., those patients that have had VRE isolated. Once determined to be positive for VRE, the patient may be placed in isolation depending on the infection control issues of the case.
- B. Perianal or rectal swab specimens should be obtained for surveillance. Cultures are not performed for roommates of positive patients. A floor nurse, at the request of Infection Control, obtains the surveillance specimen. Specimens for follow-up surveillance cultures are to be obtained in the morning prior to bathing.
- C. Perianal cultures are obtained with a swab premoistened with sterile saline. Thoroughly swab the perianal skin in a circular motion, insert the swab into the transport container, and transport it to the laboratory. Rectal specimens are obtained by inserting the swab through the anal sphincter and removed. The swab should show feces.
- D. Break the swab tip into a selective enterococcus broth such as Enterococcosel broth with 6 µg of vancomycin per ml (BBL). Broths are incubated in air at 35°C for 48 h and observed for distinct color change from amber to brown-black indicating esculin hydrolysis. Those tubes exhibiting a distinct color change are subcultured onto BAPs and incubated overnight at 35°C.
- E. Colonies with a yellow pigment as determined either by direct colony observation on blood agar or by pigment seen on a swab are disregarded. Colonies growing on the inhibitory medium may be identified using L-pyrrolidonyl-S-naphthylamide and leucine amino peptidase tests or other rapid methods. A Gram stain should be performed on all rapid-test-positive colonies.
- F. Presumptive enterococcal colonies are inoculated onto a commercially prepared or in-house vancomycin screen agar containing 6 µg of vancomycin per ml to test for vancomycin resistance. The medium is observed for growth after 24 h of incubation at 35°C. Those isolates exhibiting growth are reported as VRE positive without further confirmatory testing. Further confirmation with an MIC either by automated system or E-test is not performed unless the specimen is from a clinical source.
- G. Once the patient is determined to be positive for VRE, the infection control policy of the hospital will determine the disposition of the patient, i.e., the patient may be placed on isolation or on special precautions until three negative surveillance cultures are obtained. The surveillance cultures must be 1 week apart.

POSTANALYTICAL CONSIDERATIONS

IV. INTERPRETATION AND REPORTING

These studies are conducted under the aegis of the infection control team, and the data are released as determined by the study plan. The interpretation of the data is determined by the design of the study plan and the results of the study.

14.4. Preparation and Quality Control of Laboratory Water	
<i>John L. Kempf, David L. Sewell, and Stephen G. Jenkins</i>	14.4.1

On 24 January 2003, the *Federal Register* published the Centers for Medicare and Medicaid Services and the CDC's final rule on the requirements for laboratory director personnel qualifications and certain QC provisions under the Clinical Laboratory Improvement Amendments of 1988. The final rule, effective 24 February 2003, mandated that all new directors of high-complexity laboratories who hold a doctoral degree also be board certified. The rule grandfathered certain non-board-certified individuals with a doctoral degree who had served or were serving as the director of a laboratory performing high-complexity testing on the effective date of the rule.

This final rule also consolidated and reorganized the requirements for patient test management, QC, and QA and modified the consensus required for grading proficiency testing challenges. The resulting changes to the QC provisions became effective on 24 April 2003. To the extent possible, this section reflects the final rule changes.

14.1

Quality Assessment and Improvement (Quality Assurance)

I. DEFINITIONS, PRINCIPLES, AND OBJECTIVES

QA is a process of monitoring the functional components of a system and correcting defects when unacceptable performance is identified. Quality is characteristically assessed by specifying performance indicators and setting targets (thresholds) for acceptable proficiency. Limits may be set so that action is taken only when the number of deficiencies exceeds a specified threshold, or a limit may be defined as a sentinel event that requires

review and action whenever it is encountered. The functional attributes of a QA plan are listed in Table 14.1–1.

Quality management also entails quality improvement objectives, which address methods of continuously improving reliability, efficiency, and utilization of laboratory services (Fig. 14.1–1). The importance of quality improvement should not be underestimated, since experience in

other service industries has proven that the most effective and long-lasting improvements are those achieved by anticipating and preventing problems rather than by identifying and correcting defects after they have occurred (6, 7, 21, 22, 38, 40). This procedure will describe basic quality assessment and quality improvement procedures, but not QC procedures, for reagents, methods, and equipment.

II. MATERIALS AND RESOURCES

A. Personnel

Active participation by all individuals working in the system is essential to meet quality standards and continuously improve performance. Table 14.1–2 describes the roles of various participants in an institution’s quality management structure.

B. Information

Quality assessment is information intensive, requiring multiple sources of data and a substantial amount of record keeping in order for compliance with goals to be demonstrated. Worksheets are helpful for documenting results and observations. A computerized system for managing and analyzing the large volume of data associated with quality assessment is a valuable and labor-saving resource.

Table 14.1–1 Attributes of a QA plan

Planned, systematic, and ongoing
Comprehensive
Based on indicators and criteria with consensus approval
Routine surveillance and analysis of data
Documentation of problem identification and resolution
Continuous activity to ensure that quality performance is sustained
Integrated and interdepartmental

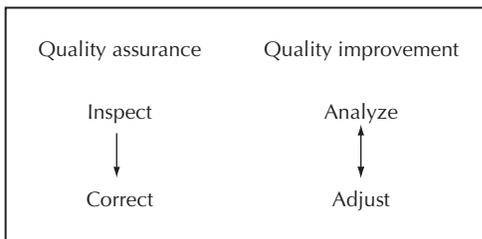

Figure 14.1–1 Differences between QC and quality improvement QA objectives are met by continuously monitoring a process, identifying defects, and correcting them. Quality improvement objectives are met by analyzing and understanding how a process works so that adjustments can be made to prevent defects from occurring.

Table 14.1–2 Roles of personnel in quality management organization

Personnel	Function
Hospital administrator	Provides leadership and support for institutional quality improvement
Chief of staff and clinical executive committee	Reviews and approves policies and procedures required to achieve quality improvement goals
QA committee	Fosters interdisciplinary communication, facilitates problem solving, and documents results of QA activities
Laboratory director; pathologist	Allocates resources and assigns personnel for departmental quality improvement activities, delineates departmental goals, reviews procedures, interprets QA data, and acts as liaison with other institutional units
Section supervisor	Implements procedures and manages data in accordance with QA goals; provides recommendations to director for improving products and services
Microbiologist-technologist	Participates in monitoring and evaluating laboratory services; provides recommendations for improving products and services

II. MATERIALS AND RESOURCES *(continued)*

C. Problem-solving skills

Quality improvement is often implemented by analyzing various components of a process with the aim of looking for ways to permanently remove obstacles to success (4, 30). Data collection, data analysis, and creative problem solving are the key components of this process. Information derived from QA procedures may be useful for detecting flaws in the system, but rarely does it point to a specific solution. The most valuable resources in problem solving are the observations by and recommendations from those who regularly work with the processes under consideration. Problem solving often requires the participation of members of other departments in the institution. Tools for successful problem solving include a thorough understanding of how the process works, good communication skills, consensus building, and, perhaps most importantly, a mind open to new ideas.

D. Procedure development

Because QA is an information-driven process, substantial attention has focused on choosing indicators. A clinical indicator (or monitor) is a measurable variable related to some aspect of care (5). Initiation of the process establishing a quality assessment and improvement procedure by specifying indicators prior to defining how the information will actually be used decreases the possibility of achieving a successful QA program (30).

Objectives for quality improvement should be clearly established *before* sources of data to be used for monitoring and evaluation are defined. This avoids the natural tendency to develop a procedure based on ease of data collection rather than on the potential utility of data derived from the process for dealing with a specific quality assessment and improvement objective. It is important to understand that useful indicators may require access to sources of information (such as charts and clinical staff) that are not readily available from the laboratory database (26). Under such circumstances, data collection is labor-intensive and may put a strain on limited resources. It is therefore essential to initially establish a carefully defined goal that considers how information that is generated will actually be employed to monitor and improve microbiology services.

QA data are usually collected to monitor and maintain a process at a targeted level of performance. For quality improvement purposes, however, information

II. MATERIALS AND RESOURCES (continued)

should be used for analysis of how a process is functioning in order to find the causes of expected or unexpected deficiencies. This knowledge is then used to implement adjustments that will prevent future deficiencies and thereby create sustained improvement.

The following outline delineates the steps that should be considered for development of a quality assessment and improvement procedure. Specific examples will follow.

1. Objectives

Objectives may be based on suggestions from the medical staff, a deficiency noted in the laboratory, or a generally accepted pattern of appropriate laboratory practice. General categories to be considered include specimen collection and transport, test selection, and utilization of results from microbiology examinations. During the planning stage, it may be useful to create a fishbone chart that explains specific aspects of the process and that may direct attention to specific problem-prone areas (Fig. 14.1-2). A proposal outlining an analysis of the process and a basis for undertaking the quality improvement procedure should be established.

2. Consensus

Quality improvement requires that all participants involved in the process comprehend the objectives and possess a commitment to improvement. Openness and communication are the key ingredients for developing constructive attitudes toward change and improvement. Most importantly, everyone must have an opportunity for input, agree on what is appropriate, and endorse the plan (7, 21, 38).

3. Quality indicators

Choose data elements that discriminate between a system that is operating appropriately and one that is faulty (28, 39). Table 14.1-3 lists examples of quality indicators appropriate for medical microbiology practice.

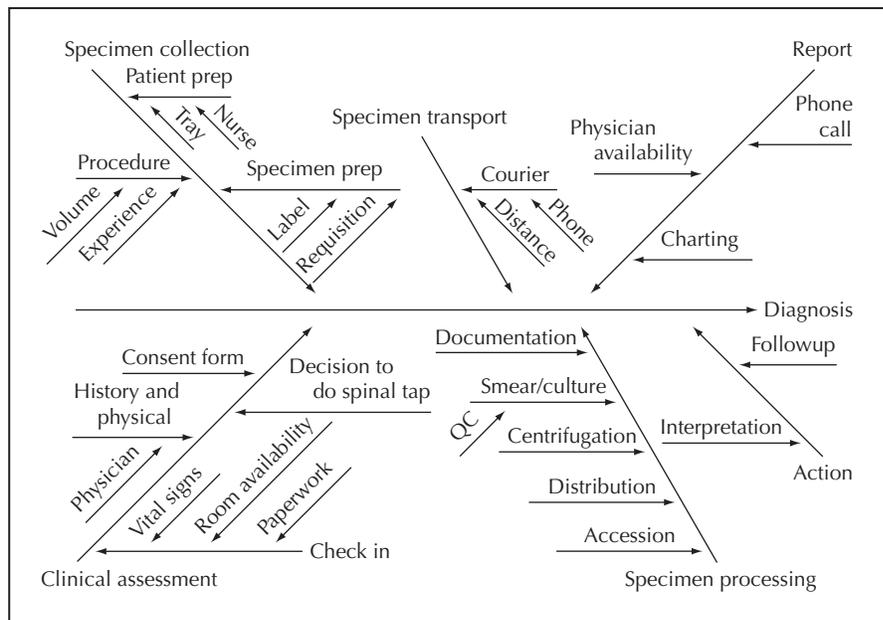

Figure 14.1-2 Fishbone diagram of bacterial meningitis diagnosis. A fishbone diagram displays important components of a process and their interrelationships. Examination of a process from this perspective helps demonstrate potential weaknesses and reveals how improvements in the process might be achieved.

Table 14.1–3 Examples of quality indicators for medical microbiology

Procedure or specimen	Objective	Indicator	Analysis
Blood culture	Appropriate use	Solitary or >3 collections/ 24 h	Determine prevalence and reason for solitary and excessive blood cultures.
	Adherence to aseptic collection and processing procedures	Contaminated cultures	Determine percentage of contaminants, rates overall, and rates per phlebotomist, ward, etc. Review procedures when high rate is identified.
Sputum	Appropriate collection	Specimens with >25 epithelial cells/low-power field (smear)	Determine percentage of specimens and rates overall and per specific location. Educational intervention when high rates are identified.
	Appropriate use	Solitary collections for acid-fast bacilli	Determine percentage of specimens and rate overall and per specific location. Determine reasons for solitary collections.
	Accuracy of smear interpretation	Repeat cultures on same patient Correlation of smear and culture results	Determine reasons for submission of multiple specimens. Review discrepancies and reasons for misinterpretation of smear results.
Stool	Appropriate use	Ovum and parasite examination or bacterial cultures ordered after ≥ 3 hospital days	Determine percentage of positive results (should be very low or 0) and reasons for requests. Determine whether <i>Clostridium difficile</i> etiology was considered.
CSF	Appropriate collection	Sufficient volume for requested tests	Determine no. with insufficient volume; calculate rates overall and by service or location. Review procedures and reasons when high rate is identified.
		Contaminated cultures	Determine no. of contaminants; calculate rates overall and by service or location. Review on increasing trend (laboratory or collection deficiency?).
	Appropriate use	Orders for syphilis serology, cryptococcal antigen, or mycobacterial cultures with otherwise-normal CSF findings	Determine percentage of positive results and reasons for test selection. Develop algorithms for testing.
	Use of results	Therapeutic response to preliminary Gram smear report	Determine percentage of patients treated with antibiotics after positive Gram smear reported (should be 100% in unambiguous cases).
Urine	Appropriate collection	No. of cultures with (≥ 3 different) organisms	Determine percentage of specimens overall and per location. Determine reasons (delayed transport, collection problem, patient selection, etc.).
	Appropriate use	No. of cultures without concomitant urinalysis (for pyuria determination)	Determine percentage of specimens overall and per location. Determine reasons urinalysis was not ordered and whether urine culture is indicated.
		Repeated cultures on same patient	Determine reason for >2 specimens/week. Urinary tract infection suspected or confirmed?
Reporting errors	Accuracy of reports	Random review of worksheets with final charted results	Review all discrepancies. Determine reasons for clerical errors and their effects on patient outcome.
Susceptibility tests	Use of results	Correlation of antimicrobial therapy with susceptibility testing results	Record percentage of appropriate and discrepant treatments. Immediately notify physician of discrepancies.
	Antimicrobial agent use	Cumulative antimicrobial susceptibility rate	Publish data for empirical therapy decisions, and review them for endemic-resistance trends.

II. MATERIALS AND RESOURCES (continued)

4. Data analysis and strategies for improvement

Specifications for meeting QA goals (also referred to as thresholds) are used for defining acceptable performance and as grounds for initiating actions when an undesirable trend is identified. Thresholds are established on the basis of experience, appropriate medical requirements, and scientific data. Practice guidelines may also be considered (9, 37). In some circumstances, the goals are clear (e.g., no CSF specimen should ever be lost). Despite the theoretical value of aiming for a zero-defect process, such a goal may be unnecessarily restrictive and wasteful. For example, it may be inefficient to track down the cause of excessive urine cultures if such excess occurs infrequently and has no detrimental consequence. On the other hand, setting thresholds with too much tolerance can lead to a false sense of security or conceal potential avenues for improvement. Interinstitutional comparisons (referred to as “benchmarking”) can also be utilized to help establish guidelines for setting thresholds (19). This is discussed in item III below. As an alternative to setting exact thresholds, it may be more valuable in some situations to analyze both the sources of error and their prevalence. In this manner, the most significant improvements are accomplished by addressing the most prevalent problems(s). This type of analysis is typically displayed as a Pareto chart (Fig. 14.1–3).

5. Documentation

Procedures, data, and actions must be documented. Data collection can be facilitated by using a log sheet that specifies the indicator, results, criteria for analyzing data (e.g., thresholds), and actions. *Documentation is not an end in itself.* Data are most valuable when they facilitate the understanding of how flaws in the system develop in order that appropriate adjustments can be made for improvement. Requiring that the monitor’s quality improvement objective be specified helps direct attention toward the purpose of the objectives. Appendix 14.1–1 provides an example of how quality assessment data can be summarized and used to document quality improvement.

It is also important to recognize that QA endeavors are continuous and that improvement often occurs in small increments. Therefore, expectations for progress should not be set too high, nor should efforts abate when accomplishments appear to be meager in relationship to established goals (7).

E. Examples

It is not feasible to provide an exhaustive list of quality assessment and improvement procedures. These activities must be individualized based upon the needs and resources of each institution. Furthermore, these procedures should be modified as permanent solutions are attained and new problems evolve. In general, it is worthwhile to evaluate specimen collection and transport, test selection, and result utilization for each major category of microbiology test (tests can conveniently be stratified by specimen source, e.g., urine, blood, or respiratory). Four specific examples of basic QA procedures for specimen collection, turnaround time, clerical-error tracking, and utilization of antimicrobial susceptibility test results are described below. Use these examples only as a general guide for developing and implementing quality assessment and improvement procedures that pertain specifically to your individual laboratory and institutional needs.

Quality improvement procedures have special characteristics that do not conform easily to the guidelines recommended by the NCCLS for technical procedure manuals or by JCAHO for institutional quality assessment and improvement. A combination of these two formats was employed to create a generic laboratory quality assessment and improvement procedure that is described in Appendix 14.1–2. This may be used as a general blueprint requiring modification as applicable to the specific needs of each laboratory.

Solitary blood cultures January – March 2003

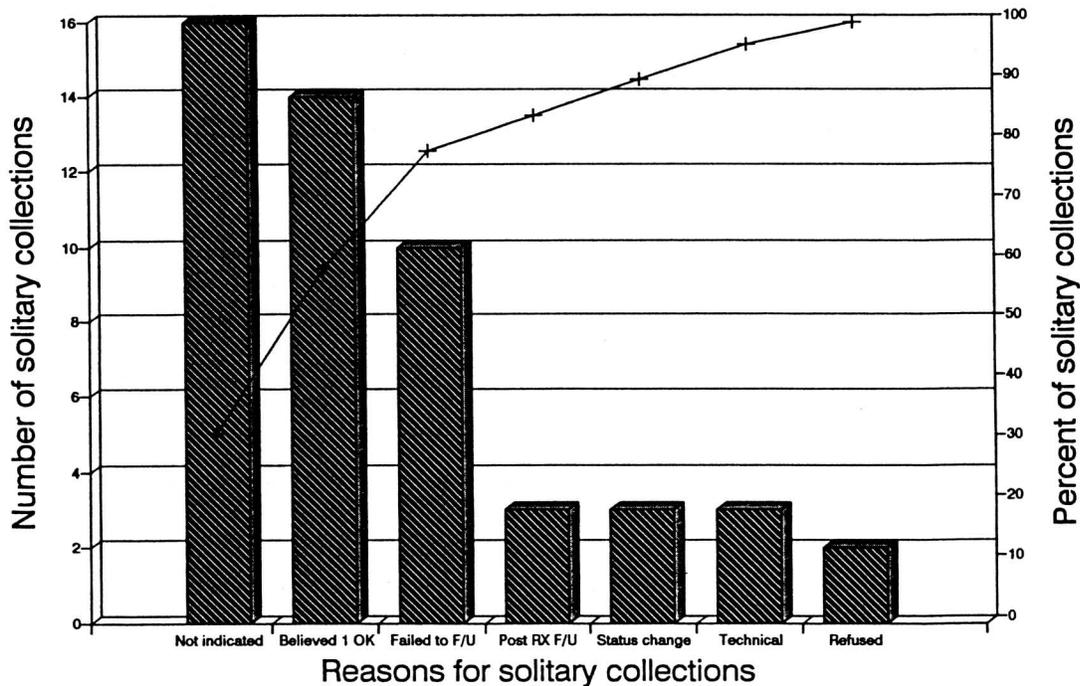

Figure 14.1-3 Pareto chart of solitary blood cultures. On the horizontal axis, the Pareto chart displays specific categories or groupings, beginning with the most prevalent type of event and continuing with other events in descending order of prevalence. The absolute numbers in each category are shown on the left vertical axis, and cumulative distributions (from 0 to 100%) are displayed on the right vertical axis. Making a change in the most prevalent category will have the most significant impact on overall improvement. Displaying quantitative relationships between groups in this way facilitates anticipation of the most likely sources of difficulty and sets priorities for improvement (32).

II. MATERIALS AND RESOURCES *(continued)*

1. Specimen collection and transportation (*see* Appendix 14.1-3)
Examples of specimen collection and transportation indicators include transport times, sputum quality by cytologic examination, and presence of “contaminants” in blood, urine, and other specimens. Monitoring trends may be more effective when data are stratified by specific components of the process involved in specimen collection and transport. This makes it easier to detect factors in the process that may be responsible for longer-than-average specimen transport times, disproportionately large numbers of sputum samples with excessive epithelial cells, or contaminated cultures (Table 14.1-4).
2. Error tracking (*see* Appendix 14.1-4)
An ongoing system that actively searches for errors in reported results by retrospective comparison of results on worksheets, instrument logs, etc., should be employed. Results should be placed in the patient’s record (17). The clinical significance of errors discovered after the report is available should be classified and periodically reviewed to determine if modifications in procedures or policies are warranted.
3. Turnaround time (*see* Appendix 14.1-5)
One of the first steps in developing a turnaround time procedure is the establishment of measurable goals (15) based on both the time constraints

Table 14.1–4 Example of results from sputum quality monitor

Ward	No. of specimens	
	Total	With ≥ 25 SEC/LPF (%) ^a
A	12	2 (17)
B	29	7 (24)
C	6	3 (50) ^b
D	71	18 (25)
E	33	4 (12)
F	9	7 (78) ^b
G	11	1 (9)
Total (average)	171	42 (25)

^a SEC, squamous epithelial cells; LPF, low-power field.

^b These units need more intensive instruction on specimen collection or indications for sputum culture.

II. MATERIALS AND RESOURCES (continued)

associated with performing the test and the realistic and medically relevant expectations of the physician. Turnaround time goals should always be developed by consensus of those involved in the process to ensure that the goals are realistic and that everyone understands how the system functions. Discussion also affords an opportunity for proffering suggestions to improve the process.

The effect of the turnaround time of laboratory tests on patient care is a function of numerous factors, many of which are external to laboratory processing. Tracking only internal laboratory turnaround times is simple but insufficient. Instead, the entire process must be examined. Whenever possible, record the times that specimens are collected as well as the times that results are appropriately interpreted *and used (not just reported)*. For example, reporting “pleomorphic gram-negative bacilli with numerous inflammatory cells” for a CSF specimen would invoke a procedure to verify that the patient receives timely and appropriate antimicrobial therapy.

4. Monitoring and evaluating tests and use of test results (see Appendix 14.1–6)

The most important goal of quality improvement procedures for test utilization should be to optimize the contribution to patient care that laboratory services make while avoiding deleterious effects. To achieve these goals, laboratorians must ensure that testing is purposeful and efficient. Improvement in test utilization has traditionally been measured by the degree to which the volume of testing is reduced. However, an association between reduced testing and clinical outcome is difficult to document. An alternative argument might be that it is actually better to test somewhat excessively than to risk missing an important clinical finding (20). In some cases, however, certain tests that are costly or have limited value may be restricted (Table 14.1–5). In other cases, such as solitary blood cultures or single sputum cultures for mycobacteria, underutilization may be problematic (8, 31).

While restriction policies may reduce unnecessary testing (and workload), they provide little direct benefit to the patient. Ensuring that appropriate test orders are placed when indicated (as opposed to preventing unnecessary tests from being ordered when they are not indicated) and that results from such testing are being utilized optimally represent quality improvement objectives that directly benefit patients, especially if corrective action can be simultaneously linked to the monitoring and evaluation processes.

The clinical importance of microbiology examinations may not be adequately recognized when information about the patient’s therapy and clinical

Table 14.1–5 Examples of indications for restricting microbiology testing

Routine stool bacterial culture and ovum and parasite examinations on specimens collected from patients hospitalized for >3 days (33, 41)
<i>Clostridium difficile</i> toxin testing on hospitalized inpatients who have not been treated with antimicrobial agents over the preceding month and who do not have significant diarrhea and/or abdominal pain (13)
CSF culture for mycobacteria on specimens with normal cell counts and glucose and protein (12) levels
Urine cultures for asymptomatic patients receiving antimicrobial agents (18)
In other than immunocompromised individuals, sputum cultures for mycobacteria from patients who have not had a tuberculin skin test and chest roentgenogram examination (34)
Venereal disease research laboratory and antigen testing of CSF before initial CSF findings are reviewed (1)
More than one specimen from same site by same method of collection received each day (except blood cultures, CSF, and feces) (3)
Bacterial culture of poor-quality specimens: mouth, bowel contents, perirectal abscess, decubiti, pilonidal abscess, lochia, Foley catheter tip, vomitus, placenta (vaginally delivered) (3)
Anti-hepatitis A virus (immunoglobulin M) testing in patients with normal liver enzymes (10)

II. MATERIALS AND RESOURCES *(continued)*

condition is unavailable. Nevertheless, the microbiology laboratory is the earliest source of critical diagnostic information that can directly benefit the patient. Any deficiency in the system can result in significant delays in therapeutic adjustments, i.e., even when all the necessary information is available to the “system,” the patient does not immediately benefit if the data are not integrated in a timely and effective fashion.

Since the turnaround times for culture and susceptibility testing are long, antimicrobial therapy is initiated empirically until such time as laboratory results either support the therapeutic decision(s) or suggest alternative antimicrobial agent choices. Assuming that culture and susceptibility testing results are valid guides to therapeutic response, any further delays in applying this information can compromise the use of these tests in a number of ways. First, an extended lapse between the time test results are reported and the time they are evaluated by a physician can have serious consequences if such a lapse delays either recognition of a significant infection or modification of treatment. Physicians are reluctant to change therapy when a patient shows improvement, even when test results indicate that less expensive or less toxic agents might be prescribed. This reluctance to modify therapy becomes even stronger as the time between specimen collection and evaluation of results by the physician lengthens (27, 35, 36). Computerized systems that link pharmacy information with data from the microbiology laboratory are now available from manufacturers of automated antimicrobial susceptibility testing instruments. Reports generated by these systems can be used to identify patients who are receiving either inappropriate or less-than-ideal therapy. Application of these sources of information with effective intervention strategies may prove to be one of the most important quality improvement foci in medical microbiology.

III. EXTERNAL QUALITY ASSURANCE PROGRAMS

Table 14.1-6 QA issues examined by CAP interlaboratory Q-Probes program with application to microbiology in years 1989 to 1991

Blood culture utilization
Nosocomial infections
Cumulative antimicrobial susceptibility test results
Antimicrobial agent usage
Turnaround time
Error reporting
Sputum quality

Q-Probes is a national interlaboratory QA program developed by the CAP for the assessment of QA practice (2). A series of quality assessment studies containing data collection methods, worksheets, and input forms are distributed throughout the year to >1,000 subscribers. Participants conduct each study for a specified time and return the results for comparative analysis. A separate data analysis is computed for each institution and is accompanied by a critique of the study's general findings and recommendations for implementing additional quality improvement procedures. The data generated by Q-Probes are particularly useful for comparing an institution's performance with that of others, a process referred to as benchmarking. For example, a survey of over 400 clinical laboratories conducted as part of the CAP Q-Probes QA program found that the median turnaround time for processing, examining, and reporting CSF Gram smears was 45 min (16). The target turnaround time that laboratories established for this procedure was <60 min for 45% of specimens, 60 min for 47%, and >60 min for 8%. The Q-Probes survey demonstrated that these goals were met, on average, 62% of the time; 15.3% of participants met the goal 100% of the time. Examples for other Q-Probes studies relevant to microbiology practice are shown in Table 14.1-6.

IV. INFECTION CONTROL AND CUMULATIVE ANTIMICROBIAL SUSCEPTIBILITY REPORTS

Properly organized laboratory information can be used for identifying clusters of infections that might be caused by a breakdown in technique or by cross-infections (14, 23). Information systems, such as the Sunquest FlexiLab System, that compare current data with earlier records provide an ever more powerful method for detecting epidemiologically significant trends (Fig. 14.1-4) (24, 31). Perhaps less well recognized is the ease of estimating total or specific nosocomial-infection rates by simply calculating the ratio of positive cultures from patients who have been hospitalized for several days to the total number of hospital admissions or discharges (11, 29). It has become increasingly common and useful to express rates of infection as the number of infections per 1,000 patient days. This ratio permits intra- and extrainstitutional comparisons in any chosen period. Such rates are very accurate reflections of the real situation even when the numbers of patients involved differ. It also proves useful for purposes of providing in-service education to attending physicians, house officers, and nursing personnel. The laboratory should also track cumulative antimicrobial susceptibility patterns and make this information available to the medical staff, as well as to ancillary medical personnel on a need to know basis (25). Such information aids in the empirical selection of antimicrobial agents, formulary development by the pharmacy and therapeutics committee of the medical staff, and trend analysis of endemic resistance by infection control practitioners (Fig. 14.1-5: see p. 14.1.11 and 14.1.12 for an example of a cumulative susceptibility report published for the medical staff of Magnanimous Medical Center).

Figure 14.1-4 Computerized trend analysis of culture results for the identification of clusters that may have epidemiologic significance (courtesy of Misys Healthcare [Sunquest Information Systems], Tucson, Ariz.). Analysis of positive culture results may be employed to identify clusters of related infections that might signify an infection control problem. This requires analysis of positive-culture rates over an extended period. In this example from a commercial software program, a potential cluster is flagged as a positive-culture rate for a specific species, *Stenotrophomonas maltophilia*, recovered in respiratory cultures at more than twice the running monthly baseline. Although patient identifier information has been deleted from this example for confidentiality purposes, the report includes the following information on each patient from whom this organism was recovered in culture: collection date (in chronological order), history number, name, sex, location, sample accession number, specimen type, and antimicrobial agents to which the isolate was resistant. This information can be used to detect potential outbreaks at a very early stage.

- Clavulanic acid, ceftazidime, ceftoxitin, and imipenem are all strong inducers of class C β -lactamases in many nosocomial gram-negative organisms.
 - Antibiotics demonstrating in vitro activity against <70% of all isolates of a given bacterial species are shaded in the table to underscore less than optimal activity.
 - 22% of pneumococci at Magnanimous Medical Center now display high-level resistance to penicillin (MIC \geq 2.0 μ g/ml), and 31% are macrolide resistant.
 - In serious or deep-seated infections (such as pneumonia, meningitis, osteomyelitis, or sepsis) with *Enterobacter* spp., *Stenotrophomonas maltophilia*, *Serratia* spp., *Pseudomonas aeruginosa*, *Citrobacter* spp., *Morganella morganii*, *Providencia* spp., *Proteus vulgaris*, and *Acinetobacter baumannii*, treatment with two antibiotics (e.g., a β -lactam plus an aminoglycoside or a fluoroquinolone) should be considered to increase clinical efficacy and decrease the chances for the development of resistance.
 - Deep-seated enterococcal infections (e.g., endocarditis) should be treated with ampicillin or vancomycin plus low-dose (e.g., peak 3 to 5 μ g/ml) gentamicin or streptomycin.
 - 55% of all *Staphylococcus aureus* isolates recovered from inpatients are now resistant to oxacillin and nafcillin (MRSA).
- These recommendations should be used as empirical guidelines only until specific antimicrobial susceptibility testing results are available. If additional or more specific information is required, contact the microbiology lab at extension X-XXXX.

APPENDIX 14.1-1

Example of Quality Assessment and Improvement Data Summary for Urine Specimen Examinations**Table 14.1-A1** Procedures for quality assessment of urine specimen examinations

Objective	Indicator	Standard	Threshold (%)
Improve test interpretation	Concomitant urinalysis	Number and % with concomitant urinalysis	>90
Improve test utilization	Duplicate cultures	No more than 1 culture/patient/day	100
Improve patient treatment (inpatients)	Positive culture with no treatment	Clinical pharmacy review of case and recommendations, when appropriate	100

Table 14.1-A2 Summary of data for urine specimen examinations

Mo	No. of urine cultures		
	Total (% with UA ^a)	Duplicate (% duplicates)	Significant (% reviewed)
January	134 (92)	40 (10)	36 (91)
February	120 (84)	34 (12)	30 (100)
March	166 (98)	51 (10)	46 (100)
April	111 (94)	28 (0)	26 (100)
May	133 (95)	30 (3)	26 (100)
June	Discontinued	40 (0)	38 (100)
July			
Cumulative (2002)	1,521 (94)	321 (13)	279 (92)

^aUA, urinalysis.**Review and action summary**

January: Pharmacist was not available to review weekend laboratory reports. Three urinary tract infections (untreated for >24 h) on the urology service were identified. Chief of service was contacted, and physicians on this service were reminded about reviewing culture and susceptibility reports on computer terminal.

February: Ward unit clerks reminded to check with physician whenever urine culture ordered without urinalysis (UA). Reviewed duplicate urine cultures in January and February. Cause was determined to be combination of doctors' orders with addition of standing admission orders for urine cultures for all urology patients having a TURP (transurethral prostatic resection; seven of eight cases). This problem will be discussed with urology section for suggestions on how to avoid duplication.

March: Improvement in UAs noted. Assistant supervisor suggested automatic UA for all urine culture requests. Will discuss with laboratory director. Urology decided to remove standing urine culture orders from admission orders.

April: Data reviewed; no action. Laboratory director reports having support from medical staff about policy for automatic UA testing and will present idea to Clinical Executive Board. Duplicate urine cultures reduced after standing admission orders revised.

May: Data reviewed; no action. Medical Staff Executive Board approved automatic UA for all urine culture requests. Will implement in June and discontinue checking for concomitant UA. Staff asked for ideas on how to monitor urine cultures for appropriate indications.

June: Data reviewed. Concomitant UA monitor discontinued. Laboratory staff presented ideas for appropriate indication monitor and suggested review of cases with pyuria (by UA) but no pertinent microbiologic examinations (e.g., urine culture, *Chlamydia trachomatis* screen, etc.). This idea was presented to laboratory director.

APPENDIX 14.1-2**Outline for Quality Assessment and Improvement Procedure**

- I. OBJECTIVE
To describe the purpose of the quality improvement procedure.
- II. PRINCIPLE
Describe the rationale for performing the quality improvement procedure, including how the procedure and data to be collected will meet the objective.
- III. INDICATOR(S)
Describe the specific elements of data and source(s) of information.
- IV. DATA COLLECTION
Describe in step-by-step fashion how the data will be collected and recorded. Refer to worksheets, computer databases, or other pertinent sources. Describe who is responsible for each aspect of data collection and the amount of data (by period of time, proportion of larger pool of data, etc.) to be obtained. If the plan is complex, an organizational flowchart may prove useful.
- V. DATA ANALYSIS
As specifically as possible, explain how the data are to be analyzed and interpreted. This may include the establishment of thresholds for evoking action or examination of trends. In some instances, data are collected to define the source of a problem. In such a situation, describe how the data will be used to identify potential flaws. Describe any special calculations or data presentations in this section. A statement such as “data will be reviewed monthly” is not sufficient.
- VI. ACTION
Precisely describe the actions that will be taken when analysis of the data suggests a problem. Describe arrangements for interdepartmental interactions and communications. Define any ongoing procedures and their documentation as they relate to preventing defects (e.g., periodic educational activities, solicited feedback, review of committee reports, incident reports, etc.).
- VII. IMPROVEMENT
Describe how improvement will be defined and measured. Improvement may take the form of a trend or a change in a process. In some situations, improvement may be demonstrated by showing that a process will probably deteriorate without implementation of the plan.
- VIII. DOCUMENTATION
Describe how the effectiveness of the quality improvement plan will be recorded and communicated. Documentation usually takes the form of periodic written summary reports to the supervisor, laboratory director, and/or appropriate laboratory or institutional committees or departments.

APPENDIX 14.1-3**Quality Assessment and Improvement of Collections of Expectored Sputa**

- I. OBJECTIVE
To collect expectorated sputum specimens in a manner that will provide the best opportunity for generation of an accurate diagnostic result.
- II. PRINCIPLE
The quality (probable diagnostic value) of expectorated sputum specimens can be measured by cytologic examination. Specimens with large numbers of squamous epithelial cells (SECs) are presumed to contain a large complement of oropharyngeal microbiota that can obscure or misrepresent microbiologic findings associated with lower respiratory tract infections. The quality of sputum specimens largely depends upon the conscientiousness displayed in the instruction of patients in how to collect samples. This task generally falls upon the nursing staff. It is useful to monitor the quality of sputum specimens by specific nursing unit in order to define areas that show proportionately large numbers of sputum samples with oropharyngeal contamination. Such a finding would lead to the conclusion that more-intensive educational activities, changes in collection procedures, or other corrective measures are warranted. Likewise, continued monitoring will be useful in demonstrating the success or failure of attempts to maintain good-quality sputum collections.

APPENDIX 14.1–3 (continued)

III. INDICATOR

The quantity of SECs observed per low-power field (LPF) in specimens collected from patients for whom microscopic examination of smears prepared from expectorated sputum are performed is used as a measure of the quality of sputum collections.

IV. PROCEDURE

- A. After each sputum Gram smear is examined, record the results on the Sputum Gram Smear Worksheet (*see* Appendix 14.1–6, p. 14.1.22) by placing a mark in the section corresponding to the hospital unit and number (≥ 25 or < 25) of SECs per LPF.
- B. At the end of each month, the supervisor will tally the results as described below and record them in the yearly Sputum Quality Data Summary report (*see* Appendix 14.1–6, p. 14.1.23).

V. DATA ANALYSIS

A. Calculations

Count the number of specimens with ≥ 25 or < 25 SECs per LPF for each unit and as a grand total. Calculate the percentage of specimens for each unit with ≥ 25 SECs per LPF as follows: $(\text{number of specimens with } < 25 \text{ SECs/LPF}) \times 100 / [(\text{number of specimens with } \geq 25 \text{ SECs/LPF}) + (\text{number of specimens with } < 25 \text{ SECs/LPF})]$.

- B. The threshold for action is any consecutive 2 months in which the proportion of sputum samples having ≥ 25 SECs per LPF exceeds 25% on any unit or any single month in which the percentage is $> 50\%$.

VI. ACTION

- A. Perform targeted educational activities at each location for which thresholds for evaluation reveal excessive rates of unacceptable sputum specimen quality.
- B. Provide cumulative data summaries to nursing service monthly.
- C. Conduct global educational activities yearly by written communication to all nursing staff. Include summarized feedback of the surveillance data. Emphasize the following points.
 1. Instruct patients to produce a specimen only from a deep cough.
 2. Instruct patients to avoid, as much as possible, mixing the specimen with saliva or nasal secretions.
 3. Ensure that patients understand the difference between spit (from the mouth) and sputum (from the chest).
 4. Gargling with tap water immediately prior to specimen collection may improve the quality of the specimen.
 5. The likelihood of obtaining a good quality specimen is reduced if the nurse simply hands a container to the patient with instructions to cough into it and then leaves the room.
- D. Once each year, ask the nursing staff and the pulmonary section for suggestions as to how best to improve specimen collection.

VII. IMPROVEMENT

Improvement is demonstrated by documenting a decline in SEC counts after intervention by targeted educational activities, changes in procedures, or recommendations from nursing staff or other departments. Sustained improvement will be shown by maintenance of a low proportion of specimens with ≥ 25 SECs/LPF.

VIII. DOCUMENTATION

Discuss summarized reports, trend analysis, modification of criteria, problem identification, and problem resolution at the laboratory's monthly QA meeting. Report results to the nursing service QA committee.

Supplemental Reading

Bartlett, R. C. 1985. Cost containment in microbiology. *Clin. Lab Med.* 5:761–792.

APPENDIX 14.1–4

Quality Assessment and Improvement in Result Reporting

- I. OBJECTIVE
To monitor the quantity, causes, and clinical significance of clerical reporting errors and to reduce the adverse impact of reporting errors by (i) swift intervention when serious errors are recognized and (ii) understanding the reasons for reporting errors so that procedural adjustments can be implemented to prevent recurrences.
- II. PRINCIPLE
One of the more important factors in communication of microbiology results to clinical personnel is the accuracy of the information. Reporting errors may result in adverse clinical consequences. It is therefore essential to actively seek out mistakes and investigate their roots. The resulting knowledge may identify reporting procedures that could be improved to prevent the recurrence of similar mistakes. Continued monitoring for errors will provide information to determine if corrective actions are successful in reducing the frequency and clinical severity of errors and if the microbiology section is able to maintain a very low incidence of errors. Sample forms are given in Appendix 14.1–6, p. 14.1.24, 14.1.25, and 14.1.26.
- III. INDICATOR
 - A. Error: a verified and reported result that is made available for patient care and later discovered to contain erroneous information.
 - B. Sources of data
 1. Random review: error is detected by correlation of final report with worksheet or instrument log.
 2. Laboratory detection: error is detected by microbiologist or other laboratorian outside of the random-review process.
 3. External detection: error is reported by physician, nurse, or other health care provider external to the laboratory.
- IV. DATA COLLECTION PROCEDURES
 - A. Random review
 1. Select five reports from all the final reports issued on the day of review. Reports with positive findings are preferred. Microbiologists should not review reports of cultures upon which they worked.
 2. Compare the results on the worksheet and requisition form to the final results displayed.
 3. Check for accuracy of the following.
 - a. Requisition form
Patient identification and date and time of receipt on the requisition match information on the final report. Routine and special processing requests detailed on the requisition have been accomplished or addressed appropriately.
 - b. Results worksheet
All smear, culture, and antimicrobial susceptibility testing results documented on the worksheet are accurately described on the final patient report.
 - c. Technical error
No mistakes have been made while processing specimens, performing procedures, or interpreting results. Errors detected by QC procedures have been investigated and corrected.
 4. Total the number of reports reviewed with and without detectable errors.
 5. On the Reported Error Description Log, describe in detail all detected errors and immediately provide this information to the microbiology supervisor.
 - B. Laboratory detection
Errors may be specifically identified within the laboratory when a QC problem that causes a test to be repeated is uncovered or when a data transmission problem is identified subsequent to issuance of a final report. In the error-reporting log, describe the type of errors that appeared in final reports, causing those reports to require correction. Notify the microbiology supervisor of such errors immediately.
 - C. External detection
In the error-reporting log, document errors reported in incident reports, oral communications, or others means by physicians, nurses, or others external to the laboratory. Report these to the microbiology supervisor immediately.

APPENDIX 14.1–4 (continued)

- D. Classification of errors
1. Errors are divided into three categories based on their impact on patient care.
 - a. Category A error
The primary provider has responded to the result by ordering another test, repeating the test, modifying treatment, or changing the diagnosis.
 - b. Category B error
A category B error is serious but unlikely to affect patient care. It is similar to a category A error, but the primary care provider has not yet been notified or has not acted upon the reported erroneous result.
 - c. Category C error
Category C errors are minor clerical errors resulting in “cosmetic” corrections to the report.
 2. The microbiology supervisor is responsible for determining the category of error (A, B, or C). Category A and B errors may necessitate chart review or discussions with nurses or physicians. Final classification as category A or B is made after review and verification by the laboratory director.
- E. Calculations
Every month, calculate the frequency of errors detected by random review as the total number of errors divided by the total number of cases reviewed.
- V. DATA ANALYSIS THRESHOLD FOR EVALUATION
- A. All category A and B errors are sentinel events that must be brought to the attention of the laboratory director as soon as possible for evaluation, verification, and further action as necessary.
 - B. Category C errors require no immediate action unless the random-review monthly rate exceeds 2%.
- VI. ACTION
- A. Action on category A or B errors requiring correction should address the cause and severity of the problem. Contact the primary care physician directly by phone or in a written communication for all category A errors; such contact may also be necessary for some category B errors.
 - B. Appropriate written documentation, including a review of findings after investigation of the problem and a discussion of circumstances related to the cause and effect of the error, should accompany documentation of each category A and B error. Develop a plan for corrective actions to prevent or reduce the recurrence of errors that are critical or repetitive in nature.
 - C. Category C errors that exceed the threshold for action should prompt a review of the section’s clerical and analytical procedures and the development of a plan to improve performance. Focus attention on the most common types of errors and the circumstances under which they occur. Solicit suggestions for improvement from those who are involved with reporting of the test results.
- VII. IMPROVEMENT
Improvement is measured by the extent to which the number of errors can be reduced and their recurrence limited. On a monthly basis, discuss prevention strategies for each category A error during the section meeting, and forward recommendations to the laboratory director for review and consideration.
- VIII. DOCUMENTATION
In section meeting minutes, document error-reporting data and identified sources of error that have been reviewed with the technologists and clerical support staff. Document all procedural changes that may have an impact on error reduction or prevention. Incorporate summarized error-reporting data, significant findings, plans of action, and resolution of problems into the laboratory service minutes.

APPENDIX 14.1–5

Quality Assessment and Improvement of CSF Gram Stain Turnaround Time

- I. OBJECTIVE
To maintain the shortest possible interval between the time a CSF specimen is collected and the time the Gram stain results are utilized for patient management.
- II. PRINCIPLE
Bacterial meningitis is a medical emergency requiring prompt diagnosis and treatment. A critical test for the initial stages of patient management is the Gram-stained smear examination of CSF. All components of the testing process, from specimen collection to final interpretation and use of CSF smear results, should be accomplished in a manner that minimizes delays. The times taken to complete various parts of this testing process are monitored to determine whether turnaround time goals are being met and to identify factors in the process that might further shorten total testing times.
- III. INDICATORS
The intervals between all of the following components are determined.
 - A. Time of specimen collection (source, requisition slip)
 - B. Time of specimen arrival in the laboratory for accessioning (source, requisition slip or computer entry)
 - C. Time of specimen arrival in microbiology section (source, laboratory worksheet or computer entry)
 - D. Time of verbal report of results (source, laboratory worksheet or computer entry)
 - E. Time when pharmacy receives antimicrobial therapy order (source, pharmacy department)
- IV. DATA COLLECTION
 - A. The time for each of the first four indicators is recorded on the worksheet after the CSF Gram stain smear result has been verbally reported to a medical caretaker.
 - B. If the Gram stain smear result shows evidence of bacterial or fungal infection (presence of microorganisms), call the pharmacy within 1 h of reporting results to determine whether orders for antimicrobial therapy have been received. If applicable, record the time the orders were received.
- V. DATA ANALYSIS
 - A. Threshold for evaluation
Every month, the median values for each turnaround time indicator, the total turnaround time, and the percentage of occurrences in which the times exceeded goals are calculated on the CSF Gram Stain Turnaround Time Log Sheet (*see* Appendix 14.1–6, p. 14.1.27). Reviews of procedures are initiated whenever >10% of goals for any indicator are not met or when >10% of turnaround time information is missing. Any case with a turnaround time of twice the goal for any indicator should be flagged for review by the supervisor.
 - B. Turnaround time goals
 1. 30 min
Transport time (time between specimen collection and specimen arrival in laboratory)
 2. 15 min
Accession time (time between specimen arrival in laboratory and specimen arrival in microbiology section)
 3. 45 min
Processing and reporting time (time between specimen arrival in microbiology section and smear preparation, examination, and result reporting)
 4. 60 min
Test interpretation and response to results (if positive) (time between report of results and receipt of antimicrobial orders by pharmacy)
 - C. Antimicrobial therapy
If information regarding antimicrobial treatment was obtained, check that appropriate therapy (ceftriaxone or cefotaxime, ampicillin, or a combination of the cephalosporin and ampicillin for gram-negative organisms or gram-positive rods; high-dose penicillin or cefotaxime or ceftriaxone, with or without vancomycin, for gram-positive cocci) was initiated. Refer any questions about appropriate therapy to the supervisor or laboratory director. See below for instructions on how to proceed

APPENDIX 14.1–5 *(continued)*

when potentially inappropriate therapy is prescribed or when treatment is not initiated within 1 h of reporting of the Gram stain results.

VI. ACTION

- A. Failure to meet turnaround time goals should prompt a review of applicable protocols and procedures in an effort to discover potential problems with the system that may result in unnecessary delays. If no problems are uncovered, consult with appropriate medical staff through the laboratory director, and consider revising goals. Alternatively, examine new procedures or other approaches for improving turnaround time.
- B. Failure to initiate therapy within 1 h of reporting a CSF smear with microorganisms should immediately be brought to the attention of the laboratory director or on-call laboratory physician for case review and consultation with the patient's physician. Appropriate members of the medical staff and QA committee are responsible for investigating causes of delayed therapy and for making suggestions and modifying systems for improvement.
- C. Review procedures and reinforce the importance of monitoring turnaround times with appropriate individuals when missing data are excessive.
- D. Once per year, review stat CSF smear turnaround time goals to determine whether they might be reduced.

VII. IMPROVEMENT

Improvement is measured by the extent to which turnaround times can be reduced and goals met. Evaluate recommendations for improving turnaround times and the success or failure of procedural changes as they relate to reduction in turnaround time. Successful and timely therapy of patients with meningitis should be demonstrable by this procedure.

VIII. DOCUMENTATION

- A. In monthly section meeting minutes, document turnaround times and the percentage of goals met. Document all changes in procedures or interactions with medical staff that have had an impact on CSF Gram smear turnaround times or turnaround time goals.
- B. Include summarized data, significant findings, plans of action, and resolution of problems in the quarterly laboratory service minutes. For each therapeutic delay identified, the hospital's QA committee should document recommendations for improvements and procedural and/or policy modifications.

APPENDIX 14.1–6**Quality Assessment and Improvement of Antimicrobial Susceptibility Test Results**

I. OBJECTIVE

To retrieve and analyze pharmacy and laboratory data automatically and to intervene appropriately when discrepancies are identified as a way of improving the treatment of patients with infections.

II. PRINCIPLE

An automated information system for monitoring antimicrobial agent usage is employed to link pharmacy and laboratory data. A report of these data is reviewed, and appropriate guidelines for detecting potential discrepancies between current therapy and antimicrobial susceptibility testing results are followed. In conjunction with the infectious-disease service, the laboratory identifies patients who may not be receiving appropriate therapy. Rapid transmission of these findings to the primary care physician improves the timeliness and appropriateness of antimicrobial treatment for patients with infections.

III. INDICATORS

A daily computer report contains a listing for each culture and associated antimicrobial susceptibility testing results, pertinent laboratory information, and current antimicrobial therapy. This report serves as the data source for indicators of appropriate and inappropriate therapy.

APPENDIX 14.1–6 (continued)

IV. DATA COLLECTION

- A. After all final culture and antimicrobial susceptibility testing results are entered, generate a computer report listing the patient's antimicrobial therapy and microbiology results.
- B. For each patient listed on the report, check results against the guidelines listed in item V below, and classify therapy as appropriate or inappropriate. Record the results of each analysis on the worksheet.
- C. The supervisor is responsible for reviewing the worksheet and listing all cases with potentially inappropriate antimicrobial therapy for evaluation by an infectious-disease specialist.
- D. Record the results of the infectious disease specialist's review, and return them to the microbiology supervisor.
- E. Summarize the number of cases with appropriate therapy, the number of cases reviewed, and the outcomes of such reviews.

V. DATA ANALYSIS

- A. Threshold for case review
 1. Urine: >10,000 CFU/ml or a single or predominant organism *with* documented pyuria (if urinalysis has been performed).
 2. Blood or other usually sterile body fluid (CSF, joint, etc.): any positive result. Exclude cases with coagulase-negative staphylococci or diphtheroids, except for blood cultures when more than one culture is positive.
 3. Sputum or bronchoalveolar lavage fluid: predominant organism with Gram stain and culture yielding a predominant morphotype and the Gram stain exhibiting many inflammatory cells with few or no epithelial cells present.
 4. Wound, tissue, aspirate, or cutaneous specimen: *Staphylococcus aureus*-, β -hemolytic streptococci, or predominant organism with inflammatory cells seen on Gram smear.
- B. Antimicrobial therapy
Patient either is not receiving antimicrobial therapy or is receiving an agent to which the organism is resistant.

VI. ACTION

- A. It is typically the infectious-disease specialist's responsibility to review the cases and, if necessary, to contact the physician for recommendations regarding modifications in the patient's therapy. Record the results of all actions, and transmit them to the laboratory.
- B. Twice per year and as needed, review changes in the guidelines and selection methods used for case review with the laboratory and medical staff.

VII. IMPROVEMENT

Since this is a concurrent review and intervention procedure, improvement is obtained through the procedure itself. Without this review process, delays in antimicrobial agent therapy or inappropriate therapy would occur.

VIII. DOCUMENTATION

In the monthly general laboratory minutes, record a summary of the case reviews. Document the number and proportion of patients receiving appropriate empirical therapy, as well as the results of intervention by infectious disease specialists. Document all changes in review procedures and review criteria. The infectious disease specialist should present recommendations for improvements in empirical therapy or formulary changes to the hospital's QA committee or the pharmacy and therapeutics committee of the medical staff, as appropriate.

Sample forms are shown on p. 14.1.28 and 14.1.29.

Sputum Quality Data Summary

Dr. _____

I. INTRODUCTION

QC programs ensure that information generated by a laboratory is accurate, reliable, and reproducible. This is accomplished by assessing the quality of the specimens; monitoring the performance of test procedures, reagents, media, instruments, and personnel; reviewing test results; and documenting the validity of the test methods.

II. SOURCES FOR QUALITY CONTROL GUIDELINES

The guidelines discussed in this procedure are based upon the sources listed in Appendix 14.2–1, and the References. Federal guidelines are considered minimum standards and are superseded by higher standards imposed by states or other certifying agencies.

III. GENERAL QUALITY CONTROL PARAMETERS

Table 14.2–1 lists QC parameters.

A. Specimen collection and transport

1. Include screening tests (e.g., quantitation of WBCs and squamous epithelial cells in sputum) among the criteria for acceptable specimens (*see* section 2).
2. Do not test unacceptable specimens unless it is impossible to re-collect them. When unacceptable specimens must be processed, include a disclaimer in the patient report indicating that the specimen was not acceptable but was processed at the specific request of the physician, whose name has been recorded in the test report.

B. Procedure manual

1. The CAP requires that laboratories maintain a copy of NCCLS document GP2-A4 (13) and that procedures be written in a format largely consistent with those guidelines.
■ **NOTE:** All applicable procedures in this handbook comply with NCCLS GP2-A4.
2. Each test procedure in this handbook includes detailed instructions for the QC of that test procedure and, when appropriate, QC forms for recording of the results.

Table 14.2–1 QC parameters

QC parameter	Guidelines	Additional information
Specimen collection and transport	Provide instructions for collection and transport.	Procedures 2.1, 4.2, 8.2, and 9.2
	Establish criteria for acceptable specimens.	Procedure 2.1
	Establish rejection criteria for unacceptable specimens.	Procedure 2.1
Procedure manual	Write in NCCLS format. Group all procedures, when applicable, as preanalytical, analytical, and postanalytical	Reference 13
	Define test performance, tolerance limits, specimen acceptability, reagent preparation, QC, calculations, and reporting.	Appendix 14.2–5, sample form
	Review and initial annually.	Appendix 14.2–5, sample form
	Approve and date all changes.	Appendix 14.2–5, sample form
	Make available in work area. Retain obsolete procedure for 2 years.	
Personnel	Employ sufficient numbers of qualified personnel for volume and complexity of work.	Reference 1; reference 2 in Appendix 14.2–1
	Document continuing-education activities.	
	Provide employees with written performance standards.	
	Evaluate employees annually.	
QC records	Record all QC results on QC forms or in computer.	Appendix 14.2–5, sample form
	Report all out-of-control results to supervisor, and note corrective action(s) taken on QC forms.	Appendix 14.2–5, sample form
	Hold monthly review of QC records with supervisor.	
	Retain QC records for a minimum of 2 years.	
Patient reports	Report results only to authorized personnel.	Reference 8
	Notify test requester of “panic” values immediately.	
	When rendering verbal reports, record name of individual notified, date, and time.	
	Provide normal ranges, when appropriate.	
	Correct errors in patient reports in a timely fashion.	
	Retain records for a minimum of 2 years. <i>Note:</i> Time may vary in different states.	
Referral specimens	Use only accredited or licensed reference laboratories.	
	Include the name of the reference laboratory actually performing the testing on the patients’ reports.	
Proficiency testing	Participate in an appropriate-level external proficiency-testing program.	Appendix 14.2–2
	Consider internal proficiency-testing program.	
Instrument or equipment performance	Document function checks of equipment.	See section 12 in CMPH for discussion and sample form.
	Perform as frequently as necessary to ensure proper function or as specified by manufacturers.	
	Document routine preventive maintenance.	
	Retain maintenance records for life of instrument.	
Commercially prepared media exempt from QC	Certain primary plating media are exempt from QC testing by user.	Reference 14
	Retain manufacturer’s QC protocol.	Appendix 14.2–5, sample form
	Obtain written assurance that manufacturer follows NCCLS standards (e.g., package insert, label, protocol).	Appendix 14.2–5, sample form
	Inspect each shipment for cracked media or petri dishes, hemolysis, freezing, unequal filling, excessive bubbles, and contamination.	Appendix 14.2–5, sample form
	Document medium deficiencies and corrective action, and inform manufacturer.	
	Perform in-house QC testing until deficiency is corrected.	

(continued)

Table 14.2–1 QC parameters (*continued*)

QC parameter	Guidelines	Additional information
User prepared and nonexempt media	Record amount prepared, source, lot number, sterilization method, preparation date, pH, expiration date, and name of preparer. Check medium for proper color, consistency, depth or slant, smoothness, hemolysis, excessive bubbles, and contamination. Test medium with QC microorganisms of known physiological and biochemical properties.	Appendix 14.2–5, sample form Tables 14.2–2, 14.2–3, and 14.2–4 References 2, 3, 10, 12, 14, 15, and 17
Stains, reagents, and antisera	Label containers as to contents; concentration; storage requirements; dates prepared, received, and/or placed in service; and expiration date or shelf life. If user prepared, record volume, source, and lot number. Store according to manufacturer's recommendations. Test reagents with positive and negative controls prior to use (with each batch, lot number, and shipment). Test Gram stain reagents with control organisms with each batch, lot number, and shipment and weekly thereafter. Test methylene blue stain with QC organisms with each batch, lot number, and shipment and with each use. Check each batch, lot number, and shipment of antiserum when prepared or opened and once every 6 months thereafter with positive and negative controls. Discard outdated material and reagents that fail performance standards.	References 1, 3, and 11 References 1, 3, 5, and 11 Tables 14.2–5 and 14.2–6
Commercial kits	Test each new batch, lot, and/or shipment. Follow manufacturers' recommendations for QC testing.	

III. GENERAL QUALITY CONTROL PARAMETERS

(*continued*)

C. Personnel

- Supervisory personnel should attend courses on laboratory administration (e.g., personnel management and cost accounting).
- Regularly scheduled meetings to inform laboratory personnel of pertinent changes and to solicit their suggestions for improving the laboratory are highly advisable.

D. QC records

- When a QC result is out of range:
 - Notify the supervisor.
 - Repeat the test.
 - If the test result remains out of the acceptable control range, repeat the test with new lots of reagents and/or a fresh QC isolate from stock.
 - Record all pertinent actions.
 - If QC testing results remain outside of accepted ranges, do not test patient specimens until the problem has been resolved.
- Options for handling patient specimen results when test systems fail QC
 - Do not report patient results until the test is repeated and determined to be in control.
 - Do not report patient results until the test is repeated with an alternative test system or by a reference laboratory.
 - If erroneous patient results have been reported, contact the physician and submit a corrected report. Do not remove the erroneous result from the patient's chart.
- QC records must be retained for a minimum of 2 years in an easily accessible location.

III. GENERAL QUALITY CONTROL PARAMETERS (continued)

E. Patient reports

1. The requester of the test should be notified immediately of any life-threatening situations indicated by test results (panic values) (*see* section 2 of this handbook).
2. Options for detection of errors on patient reports
 - a. Review the hard copies of all patient reports.
 - b. Use computer flags for unusual results (e.g., *Burkholderia pseudomallei*, *Vibrio cholerae*, vancomycin-resistant staphylococci, or linezolid-resistant *Staphylococcus aureus*).
3. When applicable, the laboratory must provide information that is useful for test interpretation (e.g., normal ranges, sensitivity, specificity, precision, linearity, predictive value, accuracy, and test interferences) (*see* Appendix 14.2–4).
4. Patient reports and laboratory records must be retained for a minimum of 2 years in an easily accessible location.

■ **NOTE:** Times may vary in different states.

F. Referral specimens

1. Reference laboratories must be accredited and/or must meet city, county, or state standards.
2. Reference laboratories are used for tests that require a high level of expertise and that are infrequently performed.

G. Proficiency testing program

1. All accredited laboratories must participate in an external proficiency program that reflects the specialty (e.g., mycology) and level of expertise (e.g., reference laboratory) of the laboratory. A partial list of proficiency-testing services for hospital and office laboratories is presented in Appendix 14.2–2.

The 1988 Clinical Laboratories Improvement Amendments indicates that all laboratories must maintain an average score of 80% on proficiency tests (6).

2. Internal proficiency programs are used to monitor various aspects of laboratory work (e.g., uniformity of Gram stain interpretation and identification of parasites or fungi). Be careful to avoid reporting results of internal controls to outside health care personnel. Options for an internal proficiency program include the following.
 - a. Seed a simulated specimen with an unknown organism, and label it as an autopsy specimen or as from a fictitious patient.
 - b. Reprocess specimens for analysis by different personnel.
 - c. Send a portion of the specimen to a reference laboratory for comparison.

IV. SPECIFIC QUALITY PARAMETERS

Include QC information on reagent container and in QC records.

Table 14.2–1 lists QC parameters.

A. Instrument and equipment performance

1. Perform preventive maintenance at least as frequently as recommended by the manufacturer. See manufacturer's instructions.
2. The manufacturer, an independent service company, or the in-house biomedical engineering service can perform preventive maintenance.

B. Media

1. Commercially prepared media (exempt from QC by the user)
 - a. The primary isolation media listed in NCCLS M22-A2 (14) are exempt from QC testing by the user (except for chocolate agar, *Campylobacter* media, and media for the selective isolation of pathogenic *Neisseria* spp.) provided that the manufacturer follows NCCLS criteria for QC. The man-

IV. SPECIFIC QUALITY PARAMETERS *(continued)*

- ufacturer must indicate by a label, package insert, technical manual, or other document that the media conform to NCCLS standards. The laboratory must retain a copy of this documentation.
- b. Test nonexempt media with the QC organisms and methods listed in NCCLS M22-A2 (minimum criteria).
 - c. Maintain a record of vendor, lot number, date received, acceptable QC, and date put into service for all media shipments.
2. User- or commercially prepared media requiring QC testing
 - a. Test each new numbered lot of dehydrated medium, reagent, or ingredient in parallel with an approved lot before it is released for use. Maintain a record of the amount of medium prepared, source, lot number, sterilization method, preparation date, pH, date of initial use, expiration date, and name of preparer.
 - b. Check for contamination by incubating a 5% sample for batches of 100 or less or 10 randomly selected units from larger batches (3). Incubate the medium for 48 h at the temperature at which it will be used and then for an additional 48 h at room temperature.
 - c. QC organisms should be derived from well-characterized strains. Reference strains are available from the American Type Culture Collection, 12301 Parklawn Dr., Rockville, MD 20852-1776 [(301) 881-2600]; the Mycobacterial Culture Collection, National Jewish Center for Immunology and Respiratory Medicine, 1400 Jackson St., Denver, CO 80206 [(303) 398-1339]; commercial sources; and proficiency-testing programs.
 - d. Performance standards for commonly used media and medium-based tests are presented in Tables 14.2-2 to 14.2-4.
 - e. The QC method should conform to NCCLS M22-A2 recommendations.
 3. Guidelines for establishing expiration dating (16)
 - a. The performance and expiration dating of culture media are affected by numerous factors that may vary from laboratory to laboratory. *It is imperative that each laboratory establish its own stability testing of all products that it produces.*
 - b. Factors adversely affecting the expiration dating and performance of prepared media
 - (1) Overheating of base ingredients
 - (2) Using blood >5 days old
 - (3) Adding blood or heat-labile ingredients at >50°C
 - (4) Using improper storage temperatures
 - **NOTE:** Do not store media in a frost-free refrigerator.
 - (5) Underfilling of medium container
 - (6) Sealing plates in storage bags before they have cooled and gelled properly
 - (7) Exposing medium to light
 - (8) Alternating the storage temperature of sealed media from room temperature (22 to 25°C) to 2 to 8°C
 - (9) Using a small fill volume (<1.0 ml) for tubed media
 - (10) Using loosely capped tubed media
 - (11) Storing plates in open or improperly sealed bags (e.g., at setup or work benches) (Unsealed bags result in a variable loss of medium volume depending upon the temperature and humidity of the room.)

Table 14.2–2 Performance standards for bacteriological media

Medium	pH (± 0.2)	Method of inoculation ^a	Length of incubation	Control organism ^b	ATCC ^c no.	Expected results ^d
Acetamide agar	6.5	C	1–4 days	<i>Pseudomonas aeruginosa</i>	27853	Pink to red
				<i>Stenotrophomonas maltophilia</i>	13637	No color change
Acetate agar	6.7	C	1–2 days	<i>Escherichia coli</i>	25922	Growth; \pm blue

Table 14.2–2 Performance standards for bacteriological media (continued)

Medium	pH (± 0.2)	Method of inoculation ^a	Length of incubation	Control organism ^b	ATCC ^c no.	Expected results ^d
Xylose				<i>K. pneumoniae</i>	13883	Pink to red
				<i>M. morgani</i>	25830	No color change or yellow
Bacteroides bile esculin agar	7.0	A, B	2–3 days	<i>Bacteroides fragilis</i>	25285	Growth; blackens agar
				<i>Clostridium perfringens</i>	13124	Inhibition
β -Hemolytic <i>Streptococcus</i> agar	7.3	A, B	1 day	<i>Streptococcus pneumoniae</i>	6305	Growth; α -hemolysis
				<i>Streptococcus pyogenes</i>	19615	Growth; β -hemolysis
				<i>Staphylococcus aureus</i>	25923	Inhibition
				<i>E. coli</i>	25922	Inhibition
Blood agar base ^e	7.4	A	1 day	<i>S. pneumoniae</i>	6305	Growth; α -hemolysis
				<i>S. pyogenes</i>	19615	Growth; β -hemolysis
				<i>S. aureus</i>	25923	Growth
				<i>E. coli</i>	25922	Growth
Blood culture ^e Aerobic (vented) bottle		A	1–7 days	<i>P. aeruginosa</i>	27853	Growth
				<i>S. pneumoniae</i>	6305	Growth
				<i>Haemophilus influenzae</i>	10211	Growth
				<i>S. pneumoniae</i>	6305	Growth
				<i>B. fragilis</i>	25285	Growth
				<i>Candida albicans</i>	10231	Growth
Bordet-Gengou agar	6.7	A, B	1–4 days	<i>Bordetella bronchiseptica</i>	10580	Growth
				<i>Bordetella pertussis</i>	12742	Growth
				<i>S. aureus</i>	25923	Inhibition
Brucella anaerobic agar Brucella agar ^e	7.0	A	2–3 days	<i>Porphyromonas levii</i>	29147	Growth
				<i>Peptostreptococcus anaerobius</i>	27337	Growth
				<i>Fusobacterium nucleatum</i>	25586	Growth
				<i>C. perfringens</i>	13124	Growth; β -hemolysis
				<i>Bacteroides fragilis</i>	25285	Growth
				<i>C. perfringens</i>	13124	Growth; β -hemolysis
Brucella agar with neomycin		A, B		<i>B. fragilis</i>	25285	Growth
				<i>P. mirabilis</i>	12453	Inhibition
Laked blood agar		A, B	1–2 days	<i>C. perfringens</i>	13124	Inhibition
				<i>B. fragilis</i>	25285	Growth
				<i>E. coli</i>	25922	Inhibition
				<i>S. aureus</i>	25923	Inhibition
<i>Campylobacter</i> agars		A, B	2–3 days	<i>Campylobacter jejuni</i>	33291	Growth
				<i>Staphylococcus epidermidis</i>	12228	Inhibition
				<i>E. coli</i>	25922	Inhibition
				<i>P. mirabilis</i>	12453	Inhibition
				<i>P. aeruginosa</i>	27853	Inhibition on some selective media but growth on Campy, BAP, Skirrow, THIO
				<i>C. albicans</i>	10231	Inhibition on some selective media but growth on Campy, Skirrow, Preston
Cetrimide agar	7.2	A, B	1 day	<i>P. aeruginosa</i>	27853	Growth; fluorescein pigment
				<i>E. coli</i>	25922	Inhibition
				<i>S. maltophilia</i>	13637	Inhibition

Table 14.2-2 (continued)

Medium	pH (± 0.2)	Method of inoculation ^a	Length of incubation	Control organism ^b	ATCC ^c no.	Expected results ^d
Chocolate agar	7.2		1-3 days			
Chocolate agar		A		<i>Neisseria gonorrhoeae</i>	43069 or 43070	Growth
				<i>H. influenzae</i>	10211	Growth
Modified Thayer-Martin, Martin-Lewis, modified Martin-Lewis		A, B		<i>N. gonorrhoeae</i>	43069	Growth
				<i>Neisseria meningitidis</i>	13090	Growth
				<i>S. epidermidis</i>	12228	Inhibition
				<i>E. coli</i>	25922	Inhibition
				<i>P. mirabilis</i>	43071	Inhibition
				<i>C. albicans</i>	60193	Inhibition
				<i>Neisseria sicca</i>	9913	Inhibition
<i>Clostridium difficile</i> agar	7.4	A, B	2 days	<i>Clostridium difficile</i>	9689	Growth
				<i>C. perfringens</i>	13124	Inhibition
				<i>B. fragilis</i>	25285	Inhibition
				<i>E. coli</i>	25922	Inhibition
Columbia agar base ^e	7.3		1 day			
5% Sheep blood		A		<i>S. pyogenes</i>	19615	Growth; β -hemolysis
Colistin-nalidixic acid ^e		A, B		<i>S. pneumoniae</i>	6305	Growth; α -hemolysis
				<i>S. aureus</i>	25923	Growth
				<i>P. mirabilis</i>	12453	Inhibition
Cooked meat ^e	7.2	A	2 days	<i>C. perfringens</i>	13124	Growth; proteolysis
				<i>B. fragilis</i>	25285	Growth
Cystine lactose electrolyte-deficient agar (CLED agar)	7.3	A	1 day	<i>S. aureus</i>	25923	Growth; yellow
				<i>E. coli</i>	25922	Growth; yellow
				<i>Proteus vulgaris</i>	8427	Growth; blue-green
Cystine tryptic agar	7.3	D	1-2 days			
Cysteine proteose peptone agar	7.5	D	1-2 days			
Control (no carbohydrate added)				<i>N. gonorrhoeae</i>	43069	No color change or deep red
Glucose				<i>N. gonorrhoeae</i>	43069	Yellow
				<i>Moraxella catarrhalis</i>	25240	No color or deep red
Lactose				<i>Neisseria lactamica</i>	23971	Yellow
				<i>N. gonorrhoeae</i>	43069	No color or deep red
Maltose				<i>N. meningitidis</i>	13090	Yellow
				<i>N. gonorrhoeae</i>	43069	No color or deep red
Mannitol				<i>Enterococcus faecalis</i>	29212	Yellow
				<i>S. pyogenes</i>	19615	No color or deep red
Sorbitol				<i>E. faecalis</i>	29212	Yellow
				<i>Streptococcus bovis</i>	9808	No color or deep red
Sucrose				<i>N. sicca</i>	9913	Yellow
				<i>N. gonorrhoeae</i>	43069	No color or deep red
Decarboxylase (Moeller) broth	6.0	C	4 days			
Control (no amino acid added)				<i>K. pneumoniae</i>	13883	Yellow or no change
				<i>Enterobacter cloacae</i>	13047	Purple to yellow-purple
Arginine				<i>K. pneumoniae</i>	13883	Yellow or no change
Lysine				<i>K. pneumoniae</i>	13883	Purple to yellow-purple
				<i>E. cloacae</i>	13047	Yellow or no change
Ornithine				<i>E. cloacae</i>	13047	Purple to yellow-purple
				<i>K. pneumoniae</i>	13883	Yellow or no change

Table 14.2–2 Performance standards for bacteriological media (continued)

Medium	pH (± 0.2)	Method of inoculation ^a	Length of incubation	Control organism ^b	ATCC ^c no.	Expected results ^d
Deoxycholate agar ^e	7.3	A, B	1–2 days	<i>Salmonella enterica</i> sero- type Typhimurium	14028	Growth; colorless
				<i>S. flexneri</i>	12022	Growth; colorless
				<i>E. coli</i>	25922	Growth; pink to red
				<i>E. faecalis</i>	29212	inhibition
Egg yolk agar	7.6	A	1–2 days	<i>C. perfringens</i>	13124	Lecithinase +
				<i>Clostridium sporogenes</i>	3584	Lipase +
Eosin methylene blue ^e	7.2	A	1 day	<i>S. enterica</i> serotype Typhimurium	14028	Growth; colorless
				<i>E. faecalis</i>	29212	Inhibition (partial)
				<i>E. coli</i>	25922	Growth; blue-black with metallic sheen
Esculin						
Bile esculin agar ^e	6.6	A, B	1–3 days	<i>E. coli</i>	25922	Inhibition
Bile esculin azide agar	7.1	A, B	1–2 days	<i>E. faecalis</i>	29212	Growth; blackens agar
				<i>S. pyogenes</i>	19615	Inhibition
				<i>K. pneumoniae</i>	13883	Growth; blackens agar
Esculin agar	7.0	A	1–3 days	<i>E. coli</i>	25922	Growth
<i>Gardnerella</i> agar	7.3	A, B	1–2 days	<i>Gardnerella vaginalis</i>	14018	Growth; β -hemolysis
				<i>P. mirabilis</i>	12453	Inhibition
Gelatin	6.8	C	2–14 days	<i>S. marcescens</i>	43861	Medium liquefied
				<i>E. coli</i>	25922	Medium remains solid
Gram-negative broth ^e	7.0	A, B	2–8 days	<i>S. enterica</i> serotype Typhimurium	14028	Growth on subculture
				<i>Shigella sonnei</i>	9290	Growth on subculture
				<i>E. coli</i>	25922	Inhibited
Heart infusion fermenta- tion base	7.5		3–5 days			
Base control (no carbo- hydrate added)				<i>K. pneumoniae</i>	13883	No color change
Adonitol				<i>E. aerogenes</i>	13048	Yellow
Arabinose				<i>E. coli</i>	25922	No color change
				<i>E. aerogenes</i>	13038	Yellow
Glucose				<i>S. marcescens</i>	43861	No color change
				<i>E. coli</i>	25922	Yellow; gas
Inositol				<i>M. osloensis</i>	10973	No color change; no gas
				<i>E. aerogenes</i>	13048	Yellow
Inulin				<i>E. coli</i>	25922	No color change
				<i>S. pneumoniae</i>	6305	Yellow
Lactose				<i>S. bovis</i>	9809	No color change
				<i>E. coli</i>	25922	Yellow
Maltose				<i>P. mirabilis</i>	12453	No color change
				<i>E. coli</i>	25922	Yellow
Mannitol				<i>P. mirabilis</i>	12453	No color change
				<i>E. coli</i>	25922	Yellow
Melibiose				<i>P. mirabilis</i>	12453	No color change
				<i>E. aerogenes</i>	13048	Yellow
Raffinose				<i>S. marcescens</i>	43861	No color change
				<i>E. aerogenes</i>	13048	Yellow
Rhamnose				<i>S. marcescens</i>	43861	No color change
				<i>E. aerogenes</i>	13048	Yellow
				<i>S. marcescens</i>	43861	No color change

Table 14.2–2 (continued)

Medium	pH (± 0.2)	Method of inoculation ^a	Length of incubation	Control organism ^b	ATCC ^c no.	Expected results ^d
Salicin				<i>E. aerogenes</i>	13048	Yellow
Sorbitol				<i>Salmonella</i> sp.	35664	No color change
Sucrose				<i>E. coli</i>	25922	Yellow
Trehalose				<i>P. mirabilis</i>	12453	No color change
				<i>E. aerogenes</i>	13048	Yellow
				<i>Salmonella</i> sp.	35664	No color change
				<i>E. coli</i>	25922	Yellow
				<i>Edwardsiella tarda</i>	15947	No color change
Hektoen enteric agar ^e	7.0	A, B	1–2 days	<i>S. enterica</i> serotype Typhimurium	14028	Growth; blue-green colonies \pm black centers
				<i>S. flexneri</i>	12022	Growth; green with blue-green centers
				<i>E. coli</i>	25922	Partial inhibition; yellow colonies
Hippurate broth	7.3	C	2 days	<i>Streptococcus agalactiae</i>	12386	Precipitate that does not dissolve with shaking
				<i>S. pyogenes</i>	19615	Precipitate that dissolves with shaking
<i>Legionella</i> ^e agars	6.9–7.0	A, B	4 days	<i>Legionella pneumophila</i>	33152	Growth
				<i>Legionella bozemanii</i>	33217	Growth
				<i>S. aureus</i>	25923	Inhibition
				<i>E. coli</i>	25922	Inhibition
Loeffler	7.1	C	1 day	<i>Corynebacterium diphtheriae</i>	13812	Growth
				<i>Corynebacterium pseudodiphtheriticum</i>	10700	Growth
Lysine iron agar	6.7	D	1 day	<i>P. mirabilis</i>	12453	Red slant; H ₂ S; acid butt
				<i>S. enterica</i> serotype Typhimurium	14028	Alkaline slant; H ₂ S; alkaline butt
				<i>S. flexneri</i>	12022	Alkaline slant; acid butt
MacConkey MAC ^e	7.1	A, B	1–2 days	<i>P. mirabilis</i>	12453	Colorless colony; inhibition of swarming
				<i>E. coli</i>	25922	Red colony
				<i>S. enterica</i> serotype Typhimurium	14028	Colorless colony
				<i>E. faecalis</i>	29212	Inhibition
MacConkey-sorbitol agar	7.1	A, B	1–2 days	<i>E. coli</i> O157:H7	43888	Colorless colony
				<i>E. coli</i>	25922	Red colony
				<i>E. faecalis</i>	29212	Inhibition
Malonate broth	6.7	C	1–2 days	<i>E. coli</i>	25922	Green or yellow
				<i>K. pneumoniae</i>	13883	Blue to Prussian blue
Mannitol salt agar ^e	7.4	A, B	1–2 days	<i>S. aureus</i>	25923	Colonies have yellow zones
				<i>S. epidermidis</i>	12228	Colonies have red zones
				<i>P. mirabilis</i>	12453	Inhibition
Methyl red–Voges-Proskauer	6.9	C	1–5 days	<i>E. coli</i>	25922	MR +; VP –
				<i>K. pneumoniae</i>	13883	MR –; VP +
Motility-indole-lysine	6.6	D	1 day	<i>E. coli</i>	25922	Mot +; Ind +; Lys –
				<i>K. pneumoniae</i>	13883	Mot –; Ind –; Lys +

(continued)

Table 14.2–2 Performance standards for bacteriological media (continued)

Medium	pH (± 0.2)	Method of inoculation ^a	Length of incubation	Control organism ^b	ATCC ^c no.	Expected results ^d
Motility-indole-ornithine	6.5	D	1 day	<i>E. coli</i>	25922	Mot +; Ind +; Orn +
				<i>K. pneumoniae</i>	13883	Mot –; Ind –; Orn –
Motility test	7.3	D	1 day	<i>E. coli</i>	25922	Positive
				<i>K. pneumoniae</i>	13883	Negative
New York City agar	7.2	A, B	1–2 days	<i>N. gonorrhoeae</i>	43069	Growth
				<i>N. meningitidis</i>	13090	Growth
				<i>N. sicca</i>	9913	Inhibition
				<i>S. epidermidis</i>	12228	Inhibition
				<i>P. mirabilis</i>	43071	Inhibition
				<i>C. albicans</i>	60193	Inhibition
				<i>E. coli</i>	25922	Inhibition
Nitrate reduction (agar or broth)	7.0	C	1–5 days	<i>P. mirabilis</i>	12452	Positive \pm gas
				<i>P. aeruginosa</i>	27253	Positive + gas
				<i>Acinetobacter baumannii</i>	15308	Negative
Nutrient base ^e Broth	6.9	A	1 day	<i>S. aureus</i>	25923	Growth
				<i>E. coli</i>	25922	Growth
Agar	6.8	A	1 day	<i>S. aureus</i>	25923	Growth
				<i>E. coli</i>	25922	Growth
Oxidative-fermentative Hugh-Leifson	6.8	D	1–5 days

				<i>S. aureus</i>	25923	Growth
				<i>E. coli</i>	25922	Growth
Tryptone	7.0	C	1 day	<i>E. coli</i>	25922	Positive for indole
				<i>K. pneumoniae</i>	13883	Negative for indole
Urea broth or agar	6.8	C	1 day	<i>P. mirabilis</i>	12453	Pink to red
				<i>E. coli</i>	25922	No change or pale yellow
Vaginalis agar	7.3	A	2–3 days	<i>G. vaginalis</i>	14018	Growth; β -hemolysis
				<i>S. pneumoniae</i>	6305	Growth; α -hemolysis
Wilkins-Chalgren anaero- bic ^e						
Agar	7.2	A	1–2 days	<i>F. nucleatum</i>	25586	Growth
Broth	7.1	C		<i>P. levii</i>	29147	Growth
				<i>P. anaerobius</i>	27337	Growth
				<i>B. fragilis</i>	25285	Growth
				<i>C. perfringens</i>	13124	Growth
Xylose lysine deoxycho- late agar ^e (XLD)	7.4	A, B	1–2 days	<i>S. enterica</i> serotype Typhimurium	14928	Red colony with black center
				<i>S. flexneri</i>	12022	Red colony
				<i>E. coli</i>	25922	Partial inhibition; yellow colony
				<i>E. faecalis</i>	29212	Inhibition
<i>Yersinia</i> selective agar ^e ; CIN agar (cefsulodin- irgasan-novobiocin agar)	7.4	A, B	1 day	<i>Y. enterocolitica</i>	27853	Red “bull’s eye” cen- ter with translucent border
				<i>P. aeruginosa</i>	25922	Inhibition
				<i>E. coli</i>	12453	Inhibition
				<i>P. mirabilis</i>	29212	Inhibition
				<i>E. faecalis</i>		Inhibition

^a Abbreviations are as follows. A, for testing nutritive properties. Dilute standardized cell suspension (0.5 McFarland standard) 1:100 (0.1 ml of suspension plus 9.9 ml of saline). Inoculate each medium with 10 μ l of dilution. If isolated colonies are not obtained, use 10-fold-lighter inoculum. B, for testing selective properties. Dilute standardized cell suspension (0.5 McFarland standard) 1:10 (0.1 ml of suspension plus 0.9 ml of saline). Inoculate each medium with 10 μ l of dilution. C, for testing tubed media. Inoculate medium with 10 μ l of the standardized suspension (0.5 McFarland standard). Adjust the inoculum if heavier or lighter growth is required. D, for testing biochemical media. Inoculate each medium according to the procedure for the routine use of the medium. E, for testing transport media. Place a sterile swab in the standardized suspension (0.5 McFarland standard), squeeze out excess fluid on the wall of the tube, and submerge the swab in the transport medium. Hold at room temperature, and plate on the appropriate medium.

^b Organisms recommended for QC testing of media (2, 7–12, 14, 16, 17). Although American Type Culture Collection strains are listed, any organism that will yield an identical result is acceptable.

^c ATCC, American Type Culture Collection.

^d MR, methyl red; VP, Voges-Proskauer; Mot, motility; Ind, indole; Lys, lysine; Orn, ornithine; +, positive; –, negative; oxidation, color change in open tube; fermentation, color change in overlaid tube.

^e Exempt from QC by user (14). Applies only to commercially prepared media.

Table 14.2-3 Performance standards for mycobacterial media and tests

Medium ^a	pH (± 0.2)	Length of incubation	Control organism ^b	ATCC ^c no.	Expected results
Arylsulfatase agar	7.0	3 days, 14 days	<i>Mycobacterium fortuitum</i>	6841	Positive; pink to red
			<i>Mycobacterium intracellulare</i>	13950	Negative (no color change)
Catalase test 68°C Semiquantitative		2 weeks	<i>Mycobacterium tuberculosis</i>	25177	Negative (no bubbles)
			<i>M. fortuitum</i>	6841	Positive (bubbles)
		2 weeks	<i>M. fortuitum</i>	6841	Positive (>45-mm column of bubbles)
			<i>M. intracellulare</i>	13950	Negative (<45-mm column of bubbles)
Dubos broth	6.6	4–8 weeks	<i>M. tuberculosis</i>	25177	Growth
			<i>M. intracellulare</i>	13950	Growth
Iron uptake		4 weeks	<i>M. fortuitum</i>	6841	Positive (rusty-brown colonies)
			<i>Mycobacterium chelonae</i>	35751	Negative (colonies not rusty brown)
Kirchner	7.3	4–8 weeks	<i>M. tuberculosis</i>	25177	Growth
			<i>M. intracellulare</i>	13950	Growth
Lowenstein-Jensen ^d	6.9	4–8 weeks	<i>M. tuberculosis</i>	25177	Growth
			<i>M. intracellulare</i>	13950	Growth
			<i>Mycobacterium kansasii</i>	12478	Growth
			<i>Mycobacterium scrofulaceum</i>	19981	Growth
			<i>M. fortuitum</i>	6841	Growth
			<i>Escherichia coli</i>	25922	Inhibition
MAC (without crystal violet)	7.4	5 days, 11 days	<i>M. fortuitum</i>	6841	Positive (growth)
			<i>Mycobacterium phlei</i>	11758	Negative (no growth)
Middlebrook ^d (selective)	6.6	4–8 weeks	<i>M. tuberculosis</i>	25177	Growth
			<i>M. intracellulare</i>	13950	Growth
	<i>M. scrofulaceum</i>		19981	Growth	
	<i>M. kansasii</i>		12478	Growth	
	6.9		<i>M. fortuitum</i>	6841	Growth
	<i>E. coli</i>	25922	Inhibition		
Niacin		4–6 weeks	<i>M. tuberculosis</i>	25177	Positive (yellow)
			<i>M. intracellulare</i>	13950	Negative (no color change)
Nitrate reduction		3–4 weeks	<i>M. kansasii</i>	12478	Positive (pink to red)
			<i>M. intracellulare</i>	13950	Negative (no color change)
Pigment production		2 weeks	<i>M. kansasii</i>	12478	Positive (yellow after light exposure)
			<i>M. intracellulare</i>	13950	Negative (no color change)
Pyrazinamidase	6.6	4 days	<i>M. intracellulare</i>	13950	Positive (pink band in agar)
			<i>M. kansasii</i>	12478	Negative (no band in agar)
Salt tolerance		4 weeks	<i>M. fortuitum</i>	6841	Positive (growth)
			<i>Mycobacterium gordonae</i>	14470	Negative (no growth)
Tellurite reduction		7 days	<i>M. intracellulare</i>	13950	Positive (black precipitate)
			<i>M. tuberculosis</i>	25177	Negative (no black precipitate)
Thiophen-2-carboxylic acid hydrazide susceptibility		3 weeks	<i>Mycobacterium bovis</i>	35734	No growth
			<i>M. tuberculosis</i>	25177	Growth
Tween hydrolysis		1, 5, 10 days	<i>M. kansasii</i>	12478	Positive (pink to red)
			<i>M. intracellulare</i>	13950	Negative (no color change)
Urease broth		1–3 days	<i>M. kansasii</i>	12478	Positive (pink to red)
			<i>M. intracellulare</i>	13950	Negative (no color change)

^a Inoculate primary plating media according to method A or B (detailed in Table 14.2-2, footnote a). Inoculate biochemical test media according to the procedure for each test.

^b Organisms recommended for QC testing of media and tests (2, 7–12, 14, 15, 17). Although American Type Culture Collection strains are listed, any organism that will yield an identical result is acceptable.

^c ATCC, American Type Culture Collection.

^d Exempt from QC by user (14). Applies only to commercially prepared media.

Table 14.2-4 Performance standards for mycologic media

Medium ^a	pH (±0.2)	Length of incubation	Control organism ^b	ATCC ^c no.	Expected results
Ascospore agar	6.5	1-4 weeks	<i>Saccharomyces cerevisiae</i> <i>Candida albicans</i>	9763 10231	Ascospores No ascospores
BHI Plain ^d	7.4	1-3 days	<i>C. albicans</i>	60193	Growth
+ Sheep blood ^d			<i>Trichophyton mentagrophytes</i> <i>T. mentagrophytes</i> <i>C. albicans</i> <i>C. albicans</i>	9533 9533 60193 10231	Growth Growth Growth Growth
+ Sheep blood + an- timicrobial agent ^d			<i>T. mentagrophytes</i> <i>Escherichia coli</i> <i>Aspergillus niger</i>	9533 25922 16404	Growth Inhibition Inhibition in presence of cyclohexi- mide
Birdseed (niger) agar	6.5	1-14 days	<i>Cryptococcus neoformans</i> <i>Cryptococcus laurentii</i>	32045 18803	Growth; brown pigment Growth; no pigment
Bromcresol green agar	6.1	3 days	<i>C. albicans</i> <i>Candida krusei</i> <i>E. coli</i>	10231 6258 25922	Growth; pale yellow-green Growth; pale yellow-green; dry Inhibition
Casein agar	7.0	1-3 weeks	<i>Nocardia brasiliensis</i> <i>Nocardia asteroides</i>	19296 19247	Hydrolysis No hydrolysis
Cornmeal agar ± Polysorbate (Tween) 80	5.8	3 days	<i>C. albicans</i> <i>Candida pseudotropicalis</i>	10231 8553	Growth; chlamydospores Growth; no chlamydospores
+ Glucose	5.8	1-4 weeks	<i>Trichophyton rubrum</i> <i>C. albicans</i>	28188 10231	Growth; red Growth
Czapek-Dox agar	7.3	1-2 weeks	<i>A. niger</i> <i>N. asteroides</i>	16404 19247	Growth Growth
Dermatophyte test ^d	5.5	7 days	<i>T. mentagrophytes</i> <i>C. albicans</i> <i>A. niger</i> <i>E. coli</i>	9533 10231 16404 25922	Growth; red Reduced growth Inhibition Inhibition
Fungus selection agar ^d	6.9	4 weeks	<i>T. mentagrophytes</i> <i>C. albicans</i> <i>A. niger</i> <i>E. coli</i>	9533 10231 16404 25922	Growth Growth Inhibition Inhibition
Inhibitory mold agar ^d	6.7	4 weeks	<i>A. niger</i> <i>C. albicans</i> <i>E. coli</i> <i>T. mentagrophytes</i>	16404 10231 25922 9533	Growth Growth Inhibition Growth
Nickerson-bismuth sul- fite-glucose-glycine- yeast agar	6.8	3 days	<i>C. albicans</i> <i>C. krusei</i> <i>E. coli</i>	10231 6258 25922	Growth; colonies smooth; dark brown Growth; colonies flat; dark brown; sur- rounded by halo Inhibition
Potato dextrose agar ^d	5.6	4 weeks	<i>C. albicans</i> <i>T. mentagrophytes</i>	60193 9533	Growth Growth
Rice extract agar	5.8	1-2 days	<i>C. albicans</i> <i>C. krusei</i>	10231 6258	Growth; chlamydospores Growth; chlamydospores absent
Sabouraud ^d Emmons modification ^d	5.6 6.9	4 weeks	<i>C. albicans</i> <i>T. mentagrophytes</i> <i>E. coli</i> <i>A. niger</i>	60193 9533 25922 16404	Growth Growth Inhibition with antimicrobial agents Inhibition with cycloheximide; growth with gentamicin or chloramphenicol
Trichophyton agar	6.8	2-4 weeks	<i>T. mentagrophytes</i> <i>Trichophyton equinum</i> <i>T. mentagrophytes</i> <i>Trichophyton tonsurans</i>	9533 9533 9533 28942	Growth Inhibition Growth Inhibition

Trehalose			<i>C. laurentii</i>	18803	Growth
			<i>C. krusei</i>	6258	No growth
Xylose			<i>C. laurentii</i>	18803	Growth
			<i>C. krusei</i>	6258	No growth
Yeast carbohydrate fermentation broth	7.1	3 days			
Control (no carbohydrate added)			<i>C. albicans</i>	10231	Negative; no gas
Cellobiose			<i>C. krusei</i>	6258	Negative; no gas
			<i>Candida lusitaniae</i>	34449	Positive; gas
Galactose			<i>C. albicans</i>	10231	Negative; no gas
			<i>Candida kefyfyr</i>	2512	Positive; gas
Glucose			<i>C. laurentii</i>	18803	Negative; no gas
			<i>C. albicans</i>	10231	Positive; gas
Lactose			<i>C. laurentii</i>	18803	Negative; no gas
			<i>C. kefyfyr</i>	2512	Positive; gas
Maltose			<i>C. laurentii</i>	18803	Negative; no gas
			<i>C. albicans</i>	10231	Positive; gas
Sucrose			<i>C. kefyfyr</i>	2512	Negative; no gas
			<i>C. kefyfyr</i>	2512	Positive; gas
Trehalose			<i>C. krusei</i>	6258	Negative; no gas
			<i>Candida tropicalis</i>	13803	Positive; gas
		<i>C. laurentii</i>	18803	Negative; no gas	

^a Media can be inoculated directly from working slants. The inoculum is not standardized.

^b Organisms recommended for QC of media and test (2, 7–12, 14, 15, 17). Although American Type Culture Collection strains are listed, any fungus that yields identical results is acceptable.

^c ATCC, American Type Culture Collection.

^d Exempt from QC by user (14). Applies only to commercial prepared media.

IV. SPECIFIC QUALITY PARAMETERS *(continued)*

- c. Expiration-dating guidelines for plated media sealed in plastic (polyethylene or similar film), 10 plates per bag, at 2 to 8°C (unpublished data)
 - (1) Up to 20 weeks
Plain medium with a heavy fill (25 to 40 g); e.g., Sabouraud dextrose agar
 - (2) Up to 16 weeks
 - (a) Plain medium with standard fill (18 to 20 g); e.g., TSA
 - (b) Nonselective sheep blood agar
 - (c) Medium containing aseptically added supplements; heavy fill
 - (d) Enteric medium
 - (e) Selective and nonselective chocolate media
 - (f) Mueller-Hinton agar in 150-mm-diameter dishes
 - (3) Up to 12 weeks
 - (a) Medium with aseptically added supplements; standard fill
 - (b) Blood agar other than sheep blood
 - (c) Anaerobic sheep blood agar
 - (d) Selective sheep blood agar
 - (4) Up to 8 weeks
 - (a) Brucella sheep blood agar
 - (b) Rabbit blood agar
 - (c) Azide blood agar
 - (d) Campylobacter blood agar with antimicrobial agents
 - d. Expiration dating of tubed or bottled media (unpublished data)
 - **NOTE:** Tubed and bottled media with tight caps may be stored at room temperature or at 2 to 8°C, depending on the presence of heat-labile components or dyes, tendency of media to darken at higher temperatures, or other factors.
 - (1) Up to 18 months
 - (a) Broth media with no aseptically added supplements; stored at 2 to 25°C; e.g., TSB or BHI
 - (b) Solid media with no aseptically added supplements; e.g., triple sugar iron agar (2 to 8°C) or nutrient agar (2 to 25°C)
 - (2) Up to 12 months
 - (a) Broth media with aseptically added supplements; 25°C; e.g., Middlebrook 7H9 broth
 - (b) Semisolid media with or without aseptically added supplements; 2 to 8°C; e.g., cystine tryptic agar or motility-nitrate medium
 - (c) Solid media with aseptically added supplements but no blood or serum; 2 to 8°C; e.g., chocolate agar slant or Middlebrook 7H10 agar
 - (3) Up to 6 months
Solid medium containing blood or serum and aseptically added supplements; e.g., BHI agar with sheep blood
4. Test procedure
 - a. Inoculum
 - (1) Suspend three to five isolated colonies of the test strain in 1 to 2 ml of soybean-casein digest medium, incubate for 4 to 5 h at 35°C, and adjust the turbidity to match that of a 0.5 McFarland standard.
 - (2) Alternatively, use a thawed stock culture suspension adjusted to a 0.5 McFarland standard.
 - (3) For mycobacteria, emulsify the growth in filter-sterilized diluent containing 2 g of bovine serum albumin and 0.2 ml of polysorbate (Tween) 80 per liter of deionized water (2). Add 8 to 12 sterile glass beads and vortex vigorously for 10 min. Let stand for 3 h to allow

IV. SPECIFIC QUALITY PARAMETERS *(continued)*

large particles to settle, and transfer the supernatant to sterile vials. Adjust the cell suspension to match a 0.5 McFarland standard and freeze. These vials may be stored for up to 6 months.

- b. Inoculate media as described in Table 14.2–2 footnotes. The method is dependent on whether the medium is nutritive, selective, or diagnostic.
- c. Incubate all test media under conditions normally used for media inoculated with clinical specimens.
- d. Document all results on medium QC forms. See Appendix 14.2–5 and the specific procedures for examples of these forms.
- e. Working control strains (14)
 - (1) Primary working control
Up to two serial subcultures of the primary control may be prepared.
 - (2) Secondary working control
Prepared from primary working control or its subculture and stored at 2 to 8° C or room temperature (22 to 25° C) for up to 4 weeks.
Up to two serial subcultures of the secondary working control may be prepared. These subcultures are the tertiary controls.
 - (3) Inoculate medium to be tested from frozen stock vials or from primary, secondary, or tertiary working controls.
 - (4) Replace primary working control after two serial subcultures.

Include QC information on reagent container and in QC records.

C. Stains, reagents, and antisera (Tables 14.2–5 and 14.2–6)

- 1. Antisera are tested according to the manufacturer's recommendations in parallel with the current lot before use and every 6 months thereafter. The recommended frequency of testing varies with the accreditation organization (1).
- 2. The CAP accreditation program allows laboratories to use certain expensive reagents that are out of date. The laboratory must have a written policy specifying such reagents, the circumstances when extended usage applies, the special control procedures to be implemented, and the person authorizing usage (4).

D. Commercial kits

- 1. Perform QC on each new shipment and each lot of the product according to the manufacturer's recommendation.
- 2. Components of a kit may not be interchanged with those of another kit of a different lot number unless specified by the manufacturer.

E. QC of mycology procedures

See section 8 of this handbook.

F. QC of parasitology procedures

See section 9 of this handbook.

G. QC of virology procedures

See section 10 of this handbook.

H. QC of antimicrobial susceptibility testing

See section 5 of this handbook.

Include QC information on reagent container and in QC records.

Table 14.2-5 Performance standards for stains

Stain	Control organism ^a	ATCC ^b no.	Expected results	Frequency of testing
Acid-fast				
Fluorochrome	<i>Mycobacterium tuberculosis</i>	25177	Yellow-green fluorescing bacilli	Each lot and each day of use
Modified (<i>Nocardia</i>)	<i>Escherichia coli</i>	25922	No fluorescing bacilli	Each lot and each day of use
	<i>Nocardia asteroides</i>	19247	Pink-red bacilli	
	<i>Streptomyces</i> sp.		Blue bacilli	
Ziehl-Neelsen	<i>M. tuberculosis</i>	25177	Pink-red bacilli	Each lot and each day of use
	<i>E. coli</i>	25922	Blue bacilli	
Acridine orange	<i>E. coli</i>	25922	Fluorescent bacilli	Each lot and each day of use
	<i>Staphylococcus aureus</i>	25923	Fluorescent cocci	
Calcofluor white	<i>Candida albicans</i>	60193	Fluorescent yeast cells	Each batch, lot number, and shipment when prepared or opened
	<i>E. coli</i>	25922	No fluorescence	
Flagellum	<i>Proteus mirabilis</i>	12453	Petritrichous flagella	Each lot and each use
	<i>Klebsiella pneumoniae</i>	13883	No flagella	
Giemsa	Thin-film blood smear		Distinct staining of WBCs and RBCs	Each lot and each week of use
Gram	<i>E. coli</i>	25922	Gram-negative bacilli	Each lot and each week of use
	<i>S. aureus</i>	25923	Gram-positive cocci	
Iodine solution	Formalin-treated specimen with cysts		Visible cyst nuclei	Each lot
Methenamine-silver nitrate	Tissue containing fungus or <i>Pneumocystis jiroveci</i>		Gray-black fungus or <i>P. jiroveci</i> cysts	Each use
Periodic acid-Schiff	Specimen containing fungus		Magenta fungus; light-pink background	Each use
Spore	<i>Bacillus</i> sp.		Spores stain one color and bacillus stains with counterstain	Each lot and each week of use
Trichrome	Smear of polyvinyl alcohol-fixed specimen with protozoan		Nuclear components clearly stained	Each lot and each week of use

^a Organisms recommended for QC testing of stains (2, 7-12, 15, 17). Although American Type Culture Collection strains are listed, any organism that yields identical results is acceptable.

^b ATCC, American Type Culture Collection.

Table 14.2-6 Performance standards for reagents used for bacteria

Organism and reagent	Control organism ^a	ATCC ^b no.	Expected results	Frequency of testing
Aerobic bacteria				
Aminolevulinic acid, porphyrin test	<i>Haemophilus parainfluenzae</i>	7901	Positive; red fluorescence	Each batch, lot number, and shipment
	<i>Haemophilus influenzae</i>	43065	Negative; no fluorescence	
Bacitracin disk	<i>Streptococcus pyogenes</i>	19615	Zone of inhibition	Each batch, lot number, and shipment
β-Lactamase disks	<i>Streptococcus agalactiae</i>	12386	No zone of inhibition	Each lot and each day of use (other than cefinase) Each batch, lot number, and shipment (cefinase)
	<i>Staphylococcus aureus</i>	25923	Positive; red	
	<i>H. influenzae</i>	10211	Negative; no color change	
Campy-Pak envelope	<i>Campylobacter jejuni</i>	33291	Growth after 48 h	Each batch, lot number, and shipment
Catalase (3% H ₂ O ₂)	<i>S. aureus</i>	25923	Positive (bubbles)	Each batch, lot number, and shipment
	<i>S. pyogenes</i>	19615	Negative (no bubbles)	
Coagulase	<i>S. aureus</i>	25923	Positive (any clotting)	Each batch, lot number, and shipment
	<i>Staphylococcus epidermidis</i>	12228	Negative (no clotting)	
Deoxycholate (10%) (bile solubility test)	<i>Streptococcus pneumoniae</i>	6305	Positive (lysis)	Each batch, lot number, and shipment
	<i>Enterococcus faecalis</i>	29212	Negative (no lysis)	
Ferric chloride (10%)	<i>Proteus vulgaris</i>	33420	Positive (green)	Each batch, lot number, and shipment
	<i>Escherichia coli</i>	25922	Negative (no color change)	
Indole (spot, Kovacs, or Ehrlich)	<i>E. coli</i>	25922	Positive (color depends on reagent)	Each batch, lot number, and shipment
	<i>Pseudomonas aeruginosa</i>	27853	Negative (no color change)	
Lead acetate strips (H ₂ S)	<i>P. vulgaris</i>	33420	Positive (brown)	Each batch, lot number, and shipment
	<i>Klebsiella pneumoniae</i>	13883	Negative (no color change)	
Methyl red	<i>E. coli</i>	25922	Positive (red)	Each batch, lot number, and shipment
	<i>K. pneumoniae</i>	13883	Negative (no color change)	
Ninhydrin	<i>S. agalactiae</i>	12386	Positive (purple)	Each batch, lot number, and shipment
	<i>S. pyogenes</i>	19615	Negative (no color change)	
Nitrate reagents	<i>E. coli</i>	25922	Positive (red)	Each batch, lot number, and shipment
	<i>Acinetobacter baumannii</i>	19606	Negative (no color change)	
ONPG ^c	<i>E. coli</i>	25922	Positive (yellow)	Each batch, lot number, and shipment
	<i>Proteus mirabilis</i>	29245	Negative (no color change)	
Optochin disk (10 mm)	<i>S. pneumoniae</i>	6305	Zone of inhibition ≥ 16 mm	Each batch, lot number, and shipment
	<i>E. faecalis</i>	29212	No zone of inhibition	
Oxidase	<i>P. aeruginosa</i>	27853	Positive (red to blue-black)	Each batch, lot number, and shipment
	<i>E. coli</i>	25922	Negative (no color change)	
Voges-Proskauer	<i>Enterobacter cloacae</i>	13047	Positive (red)	Each batch, lot number, and shipment
	<i>E. coli</i>	25922	Negative (no color change)	
X, V, and XV disks or strips	<i>H. influenzae</i>	10211	Growth around XV and only between X and V when closely spaced	Each batch, lot number, and shipment
Anaerobic bacteria disk tests				
Bile	<i>Bacteroides vulgatus</i>	8482	No zone of inhibition	Each batch, lot number, and shipment
	<i>Fusobacterium nucleatum</i>	25586	Zone of inhibition	
Colistin (10 µg)	<i>B. vulgatus</i>	8482	Resistant (<10-mm-diameter zone)	Each batch, lot number, and shipment
	<i>F. nucleatum</i>	25586	Susceptible (≥10-mm-diameter zone)	
Kanamycin (1,000 µg)	<i>B. vulgatus</i>	8482	Resistant (<10-mm-diameter zone)	Each batch, lot number, and shipment
	<i>F. nucleatum</i>	25586	Susceptible (≥10-mm-diameter zone)	

Table 14.2-6 (continued)

Organism and reagent	Control organism ^a	ATCC ^b no.	Expected results	Frequency of testing
Sodium polyaneth- olsulfonate	<i>Peptostreptococcus anaero- bius</i>	27337	Zone of inhibition	Each batch, lot number, and shipment
Vancomycin (5 µg)	<i>B. vulgatus</i>	8482	Resistant (<10-mm-diameter zone)	Each batch, lot number, and shipment
	<i>Clostridium perfringens</i>	13124	Susceptible (≥10-mm-diam- eter zone)	
Ferric ammonium cit- rate (1%)	<i>Bacteroides fragilis</i>	25285	Positive (brown)	Each batch, lot number, and shipment
	<i>Porphyromonas asaccharoly- tica</i>	25260	Negative (no color change)	
GasPak envelope	<i>Clostridium novyi</i>	19402	Growth in 48 h	Each batch, lot number, and shipment
Indole (Ehrlich)	<i>P. asaccharolytica</i>	25260	Positive (red)	Each batch, lot number, and shipment
	<i>B. fragilis</i>	25285	Negative (no color change)	
Nagler's test	<i>C. perfringens</i> (+ antitoxin)	13124	Positive (precipitin formed upon addition of antitoxin)	Each batch, lot number, and shipment
	<i>C. perfringens</i> (– antitoxin)	13124	Negative (no precipitin formed upon addition of antitoxin)	
Nitrate	<i>C. perfringens</i>	13124	Positive (red)	Each batch, lot number, and shipment
	<i>B. fragilis</i>	25285	Negative (no color)	

^a Organisms recommended for QC testing of reagent (2, 7–12, 15, 17). Although American Type Culture Collection strains are listed, any organism that yields identical results is acceptable.

^b ATCC, American Type Culture Collection.

^c ONPG, *o*-nitrophenyl-β-D-galactopyranoside.

V. MAINTENANCE OF STOCK BACTERIOLOGY CULTURES

Include QC information on reagent container and in QC records.

A. Long-term storage (≥1 year) (3, 14)

1. Lyophilization

Obtain strains from commercial sources or prepare in-house. May be stored for years.

2. Frozen

a. Preparation of storage media

- (1) Dispense sterile defibrinated sheep blood, rabbit blood, or soybean-casein digest broth containing glycerol (15% [vol/vol]) into plastic or glass vials. An alternative storage medium is sterile skim milk.
- (2) The soybean-casein digest broth may be stored at 4°C for up to 6 months.
- (3) Label vials with the date frozen and the organism code. Maintain an alphabetical listing of QC organisms with codes for the sources of the isolates.

b. Inoculation of storage medium

- (1) From overnight growth on an appropriate nonselective medium prepare a dense suspension of cells. Vortex well.
- (2) Prepare enough vials to provide stock strains for 1 year. Keep two vials as permanent stocks. Label these vials as permanent stocks.
- (3) Freeze at –50° C or below. At –50°C, strains may be kept for 1 year. At –70°C or in liquid nitrogen, strains may be kept indefinitely. As a general rule, replace nonfastidious organisms every 5 years and fastidious organisms every 3 years.

V. MAINTENANCE OF STOCK BACTERIOLOGY CULTURES

(continued)

- c. Retrieval of frozen stock strains
 - (1) Remove vial and thaw contents rapidly in warm water. Use contents to initiate test, or subculture to a solid medium. Do not refreeze vial.
 - (2) Alternatively, remove vial and remove a portion of the frozen bacterial suspension with a wooden stick or loop. Subculture to a solid medium. Return vial immediately to freezer. Strains should be subcultured twice before being used as controls.
 - (3) Check strains annually for viability.
3. Alternative methods

Prepare soybean-casein digest deeps. Stab the deep with a nonfastidious QC strain, incubate overnight, and seal tube with Parafilm. Store at room temperature for 1 to 2 years.
- B. Short-term storage (<1 year) (3, 14)**
 1. Media (available from commercial sources)
 - a. Cystine-tryptic agar without carbohydrate

Inject 1 ml of sterile horse serum into cystine-tryptic agar deeps for staphylococci, streptococci, and fastidious organisms.
 - b. Cooked meat without glucose (for anaerobes and facultative anaerobes)

Store at room temperature.
 - c. Soybean-casein digest deeps (for fastidious organisms)
 - d. Blood agar and chocolate agar slants (for fastidious streptococci and *Haemophilus* spp.)

Store for up to 2 weeks.
 2. Inoculation of storage media
 - a. Label each tube with strain code and date of inoculation.
 - b. Inoculate with overnight growth of QC strain.
 - c. Incubate overnight, cap, and store at room temperature or 5°C.
 3. Retrieval of stock strains
 - a. Remove a portion of the contents.
 - b. Subculture to a solid medium and incubate overnight.
 - c. Prepare new stock as needed or at 6 months.

VI. MAINTENANCE OF STOCK MYCOLOGY CULTURES

Include QC information on reagent container and in QC records.

- A. Long-term storage (≥ 1 year) (3, 11)**
 1. Water culture method (simplest and most reliable)
 - a. Add 2 to 3 ml of sterile water to an actively sporulating culture on a potato dextrose agar slant.
 - b. Gently tease surface of growth to dislodge conidia without disrupting the medium.
 - c. Remove the suspension, and dispense it into sterile screw-cap vials.
 - d. Label vials with QC strain code and date of preparation.
 - e. Store vials tightly capped at room temperature. Organisms remain viable for years.
 - f. To retrieve stock organism, shake well and inoculate a drop to potato dextrose medium.
 2. Sterile mineral oil overlay (sloppy and easily contaminated)
 - a. Cover the entire slant of an actively sporulating culture on potato dextrose agar with water-free sterile mineral oil.
 - b. Cap the tube tightly, and store at room temperature.
 - c. To retrieve stock organism, flame mouth of tube, obtain portion of growth (avoid aerial strands) with sterile inoculating wire, drain oil, and inoculate Sabouraud broth or slant. Incubate at 30°C until growth occurs.

VI. MAINTENANCE OF STOCK MYCOLOGY CULTURES

(continued)

3. Frozen culture
 - a. Freeze an actively sporulating culture on potato dextrose agar at -70° C. Tube must be high-quality glass or it may break.
 - b. To retrieve stock organism, remove from freezer, immediately tease some of the growth from the slant, and inoculate potato dextrose agar.
 - c. Return stock to freezer. If the slant thaws, prepare a new culture.

B. Short-term storage (<6 months) (3, 11)

1. Store an actively sporulating culture on potato dextrose agar at 4° C for up to 6 months. Fastidious organisms require more frequent subculturing.
2. Frequent subculturing results in atypical or nonviable organisms.

VII. MAINTENANCE OF STOCK MYCOBACTERIOLOGY CULTURES

Include QC information on reagent container and in QC records.

A. Long-term storage (≥ 1 year) (3, 14)

1. Frozen
 - a. Grow isolate in Middlebrook broth, and dispense in vials labeled with organism's code and date of freezing. Place in a -70° C freezer.
 - b. Alternatively, suspend growth in skim milk or brucella broth plus 15% glycerol. Place in -70° C freezer.
 - c. To retrieve strain, thaw rapidly in a 37° C water bath. The stock suspension may be thawed and refrozen many times without loss of viability.
2. Refrigerated
 - a. Grow isolate on egg-based medium slants.
 - b. Store at 4° C for up to 1 year.

B. Short-term storage (<6 months) (3, 14)

1. Grow isolate on egg-based medium slants.
2. Store at room temperature in the dark for up to 6 months.

VIII. MAINTENANCE OF STOCK VIROLOGY, CHLAMYDIA, AND CHLAMYDOPHILA CULTURES

Include QC information on reagent container and in QC records.

Long-term storage of *Chlamydia* and *Chlamydophila* cultures (see section 8 of this handbook)

- A. Pass a stock strain in cell culture until the monolayer is 80 to 100% infected.
- B. Add 2 ml of sucrose phosphate glutamate to five infected tubes, and sonicate or vortex with glass beads for 2 min.
- C. Pool the contents of the vials, and dispense 0.02 ml into small vials.
- D. Freeze at -70° C.
- E. To retrieve organism, rapidly thaw a vial.

IX. SELECTION OF TEST METHODS

See Appendix 14.2–3.

X. VALIDATION OF TEST METHOD

See Appendix 14.2–4.

APPENDIX 14.2–3

Selection of Test Method (1)**I. OBJECTIVE**

To identify, from the numerous tests available, the procedure that will be the best predictor of the presence or absence of disease. The final selection of the best test procedure is based upon consideration of the following factors applied to each unique situation.

II. FACTORS FOR CONSIDERATION

- A. Clinical need for test
 - 1. Test volume
 - 2. Requirements of test requester (e.g., screening or diagnostic)
 - 3. Turnaround time (e.g., stat or routine)
- B. Seriousness and treatability of disease
- C. Prevalence of disease
- D. Economic, social, and psychological consequences of a false test result
- E. Range of available test options (i.e., different test methods)
- F. Comparison of test methods (e.g., accuracy, precision, sensitivity, specificity, and predictive value)
- G. Test costs (e.g., reagents, labor, overhead)
- H. Specimen and requisition requirements
 - I. Availability of technically skilled personnel to perform tests
 - J. Physical-plant requirement (e.g., space and utilities)

Reference

APPENDIX 14.2–4

Validation of the Test Method

I. INTRODUCTION

The laboratory must document the performance and comparability of a new test method before it is used routinely (3). The 1988 Clinical Laboratories Improvement Amendments does not dictate specific threshold values that determine the acceptability of a test method. Rather, *each laboratory is expected to document the performance of the test and make this information available to the clinician for use in the interpretation of a test result.* The procedure for the evaluation of a test method should include, where applicable, the precision, linearity, accuracy, sensitivity, specificity, and predictive value of a test and reference ranges for the patient population. In general, precision and linearity are not determined for culture methods. When noncultural methods are assessed, precision checks may be performed on control samples to determine the mean and standard deviation of replicate determinations. Linearity may be determined through the use of serial dilutions of external control materials or by utilizing extremely elevated patient samples. Interference checks may be accomplished by reviewing the literature or by the addition of recognized interfering substances to samples.

II. COMPARABILITY OF TEST METHODS

A. Methods of assessing test comparability

1. Test patient samples in parallel with an established test.
2. Test specimens with known potencies.
3. Compare test results with the actual diagnosis by chart review.

B. Statistical methods used for evaluation of test results

1. Linear regression analysis
2. Coefficient of variation
3. Mean and standard deviation
4. Predictive value, sensitivity, specificity, and efficiency
5. Confidence intervals (CIs)

III. DETERMINATION OF THE SENSITIVITY, SPECIFICITY, PREDICTIVE VALUE, AND EFFICIENCY OF A TEST (1, 4)

A. Necessary conditions

1. The test provides a negative or positive result.
2. The true patient status is known.

B. Arrange data in a two-way frequency table (Table 14.2–A1).

C. Calculate statistical parameters.

1. Sensitivity is the frequency of positive tests in patients with the disease (percentage of true positives among all positive patients): $\text{sensitivity} = [a/(a + c)] \times 100$, where a is the number of true negatives and c is the number of false negatives.
2. Specificity is the frequency of a negative test in patients not infected (percentage of true negatives among all negative patients): $\text{specificity} = [d/(b + d)] \times 100$, where d is the number of true negatives and b is the number of false positives.
3. Predictive value of a positive test (PVP) is the probability that a positive result indicates that a patient has the disease (percentage of true positives among all positive tests): $\text{PVP} = [a/(a + b)] \times 100$.
4. Predictive value of a negative test (PVN) is the probability that a negative result indicates that the patient is not infected (percentage of true negatives among all negative tests): $\text{PVN} = [d/(c + d)] \times 100$.

Table 14.2–A1 Format for a positive-negative diagnostic test

New test result	Possible interpretation when disease ^a :	
	Exists	Does not exist
Positive	a (true positive)	b (false positive)
Negative	c (false negative)	d (true negative)

^a True positive, number of diseased patients correctly identified by test; false positive, number of nondiseased patients incorrectly identified by test; true negative, number of nondiseased patients correctly identified by test; false negative, number of diseased patients incorrectly identified by test.

APPENDIX 14.2–4 (continued)

5. Efficiency, or accuracy, is the frequency with which patients are correctly identified by the test result: $\text{efficiency} = [(a + d)/(a + b + c + d)] \times 100$.
- IV. EFFECT ON STATISTICAL PARAMETERS $[(a + c)/(a + b + c + d)]$ OF DISEASE IN THE POPULATION (5)
- A. The sensitivity and specificity of a test are independent of the prevalence of the disease in a population.
- B. PVP, PVN, and efficiency are dependent on the sensitivity and specificity of the test and on the prevalence of the disease.
- C. Example (Table 14.2–A2)
- Assume that two populations of 100 patients each are tested with two tests with different sensitivities and specificities. The prevalence of disease is 50% in population A and 5% in population B. This comparison highlights several interactions.
1. Increasing the prevalence of the disease increases the number of positive and false-negative results, which increases the PVP but decreases the PVN.
 2. Decreasing the prevalence of the disease increases the number of true negatives and false-positive results, which increases the PVN but decreases the PVP.
 3. The PVP and PVN are affected more by the prevalence of the disease than by the sensitivity and specificity of the test.
 4. In populations with a low prevalence of disease, negative test results are better predictors of the disease state than positive test results.
 - a. A test with high sensitivity is used to screen a low-prevalence population. In this situation, a negative test accurately reflects the absence of disease.
 - b. A second test method with high specificity is used to evaluate the positive specimens. This greatly improves the PVP.
- V. USEFULNESS OF CIs FOR THE COMPARISON OF TEST METHODS (2, 6)
- A. The CI is the interval containing the unknown true value of the parameter with a known probability.
- B. CIs are used to indicate the precision (or imprecision) of the statistical parameter of the test as the population varies.
- C. CIs are affected by the sample size and the level of confidence (e.g., 90, 95, or 99%).
- D. The larger the CI, the less precise the estimate of sensitivity, specificity, PVP, and PVN.
- E. CIs can be found in statistical tables or calculated (Table 14.2–A3)

Table 14.2–A2 Effects of sensitivity, specificity, and disease prevalence on test parameters

Parameter or result	Population A		Population B	
	Test 1	Test 2	Test 1	Test 2
Prevalence (%)	50	50	5	5
Sensitivity	0.7	0.9	0.7	0.9
Specificity	0.9	0.7	0.9	0.7
True positive (no.)	35	45	4	5
False positive (no.)	5	15	9	28
True negative (no.)	45	35	86	67
False negative (no.)	15	5	1	0
PVP	0.88	0.75	0.31	0.15
PVN	0.75	0.88	0.99	1.00
Efficiency	0.80	0.80	0.90	0.72

APPENDIX 14.2-4 (continued)

Table 14.2-A3 Determination of CI^a

Test	Sample size (no. of patients)	Sensitivity (%)	95% CI (%) ^b
A	50	80	68-92
B	50	90	82-98

^a Standard error (SE) = $[p(1 - p)]/n$, where p is the proportion of subjects with a parameter (e.g., sensitivity) in a sample size n . SE = $[0.8 \times (1 - 0.8)]/50$; SE = 0.06.

^b Calculation of CI with 95% confidence level. 95% CI = $p - (1.96 \times SE)$ to $p + (1.96 \times SE)$; 95% CI = $0.8 - (1.96 \times 0.06) = 68$; 95% CI = $0.8 + (1.96 \times 0.06) = 92$. Normal distribution values for confidence levels are 1.65 for 90%, 1.96 for 95%, and 2.58 for 99%.

14.3

Laboratory Records

I. INTRODUCTION

“If it hasn’t been recorded, it hasn’t been performed.” This sentence summarizes the absolute requirement for detailed and accurate record retention for all aspects of the clinical microbiology laboratory. Records serve at least four purposes. (i) They document what has transpired without re-

course to memory (they provide a paper or electronic audit trail), (ii) they serve as a point of reference for developing the facts regarding any incident, (iii) they assist in the recognition of trends and the resolution of problems, and (iv) they establish the laboratory’s credibility. The standards

for record keeping and the length of time records must be maintained are established by the agencies presented in Appendix 14.3–1. Federal guidelines should be considered minimum standards and are superseded by the standards established by the states or other certification agencies.

II. FORMAT

A. Style

Most records are paper forms that are manually completed by personnel or that may involve specialized computer software programs that generate hard copies as necessary.

B. Organization

Most records are organized and stored in a chronological, numerical, or alphabetical system. Whichever approach is most efficient for the specific needs of the laboratory is acceptable.

III. RECORD RETENTION

A. Length of retention

Suggested guidelines for the retention of laboratory records are presented in Table 14.3–1. As a general guideline, records must be retained for a minimum of 2 years. Exceptions include instrument records, which are retained for the life of the instrument, and personnel and safety records, which must be held for a minimum of 5 years.

B. Accessibility

Records must be readily accessible for review.

IV. ESSENTIAL LABORATORY RECORDS

A. Accession list (*see* Appendix 14.3–2, p. 14.3.7)

1. Principle

The accession list provides a record of all specimens received by the laboratory.

2. Requisite information

a. Patient name

b. Patient identifying number (social security, hospital, or laboratory accession number)

c. Specimen source and type

d. Test(s) requested

Table 14.3–1 Suggested guidelines for minimal time of retention for laboratory records

Record	Retention period (yr)	Comments
Accession list	2	May also function as a work list.
Requisition	2	May be combined with test result form.
Work card	2	Store with requisition and patient test result(s).
Test report	2	Includes all preliminary reports. Place in patient's hospital record. Identical legally reproduced copy is retained by laboratory.
QC/QA	2	Store originals of manuals and test procedures that have been modified or replaced for 2 years.
Instrument maintenance	2	Store records in close proximity to instrument and assure access by instrument users.
Incident report	2	
Safety	5	
Reportable disease	2	<i>Note:</i> Reportable disease requirements may vary by state.
Personnel	5	

IV. ESSENTIAL LABORATORY RECORDS *(continued)*

- e. Collection date and time
- f. Date and time of receipt and processing of specimen in microbiology laboratory
- 3. Specimen acceptability
 - a. Document reason(s) for the rejection of a specimen (e.g., improper labeling, collection, or specimen transport).
 - b. Document specimen disposition (e.g., "Specimen grossly and microscopically resembles saliva; please resubmit").
- B. Requisition** (*see* Appendix 14.3–2, p. 14.3.8)
 - 1. Principle

The requisition is a record of the test(s) on the specimen requested by the patient's physician.
 - 2. Requisite information
 - a. Patient name
 - b. Patient identifying number (e.g., social security, hospital, or laboratory accession number)
 - c. Specimen source and type
 - d. Laboratory test(s) requested
 - e. Date and time of specimen collection
 - f. Date and time of receipt and processing of the specimen in the microbiology laboratory
 - g. Physician's name
 - h. Patient's location
 - 3. Additional useful information
 - a. Pertinent clinical information (e.g., diagnosis, antimicrobial therapy, etc.)
 - b. Contact information for patient's physician (e.g., telephone number, pager number, or cellular telephone number)
- C. Work card or LIS electronic specimen worksheet** (*see* Appendix 14.3–2, p. 14.3.9 through 14.3.11)
 - 1. Principle

A work card or unique laboratory accession number with associated electronic worksheet is assigned to each specimen so that procedures performed on the specimen, notes made by microbiology laboratory personnel, results obtained, and interactions between physicians and microbiology staff can be

IV. ESSENTIAL LABORATORY RECORDS (continued)

recorded. A properly completed work card or laboratory information system (LIS) specimen worksheet can be used to reconstruct and assess the accuracy of the final report.

2. Requisite information
 - a. Patient name
 - b. Patient identifying number (e.g., social security, hospital, or laboratory accession number)
 - c. Source and type of specimen
 - d. Test(s) requested
 - e. Initials of laboratory personnel performing procedures
 - f. Procedure, date performed, and (when applicable) medium, reagent, or stain used
 - g. Preliminary and final results (e.g., Gram stain results, description and quantification of growth, or antimicrobial susceptibility testing results)
 - h. Specific details of verbal or telephone discussions with health care personnel
 - (1) Time and date of telephone call
 - (2) Nature of call
 - (3) Name of individual initiating the call
 - (4) Name of person receiving the information

D. Test reports (see Appendix 14.3–2, p. 14.3.12)

1. Principle

Test reports convey laboratory data to the requesting physician. The report becomes a permanent component of the patient's hospital record.
2. Requisite information
 - a. Patient's name and location
 - b. Patient identifying number (e.g., social security, hospital, or laboratory accession number)
 - c. Name of physician ordering the test
 - d. Type and source of specimen
 - e. Test(s) requested
 - f. Time and date of specimen receipt in the microbiology laboratory
 - g. Time and date of test completion
 - h. Name(s) of laboratory personnel completing the test(s)
3. Types of reports
 - a. Telephone report: to report information that is critical for care of the patient. Examples include positive microscopic smears, antigen detection tests, growth from normally sterile body sites (e.g., CSF, blood, or other usually sterile body fluids), and detection of causative agents of highly infectious diseases (e.g., positive smear or growth in culture of mycobacteria).
 - b. Preliminary report: to report status of test within 24 to 48 h after specimen receipt.
 - c. Final report: to convey results after test completion. Results should be reviewed for erroneous information prior to placement in the patient's medical record.
 - d. Corrected report
 - (1) Contact the physician and explain that an erroneous test result was reported.
 - (2) Reissue a report clearly indicating that it represents a corrected report.
 - (3) Do not remove the original erroneous report from the patient's chart.
4. Characteristics of reports
 - a. Whenever possible, include interpretive statements (e.g., gram-positive lancet-shaped diplococci resembling *Streptococcus pneumoniae*).

IV. ESSENTIAL LABORATORY RECORDS *(continued)*

- b. Report Gram stain and bacterial growth results in a semiquantitative manner (e.g., 1+, 2+, 3+, 4+, few, moderate, or many).
 - c. Include statements regarding any recognized improper storage, collection, or handling.
 - d. Include normal range values with numerical data.
 - e. Report all isolates recovered from normally sterile body sites.
 - f. Report only relevant antimicrobial susceptibility testing results (e.g., do not report the results for nitrofurantoin for isolates recovered from other than urinary tract specimens).
 - g. Report negative results for applicable tests (e.g., “no *Salmonella*, *Shigella*, *Campylobacter* spp., or *E. coli* O157:H7 recovered”).
- E. QC and QA** (*see* Appendix 14.3–2, p. 14.3.13 through 14.3.15)
See procedures 14.1 and 14.2 above and Appendix 14.3–2 for examples of records.
- 1. Principle
The records of control values for procedures, tests, and equipment are used to detect and identify problems and trends within the laboratory. QA reports assist in the identification of problems and trends associated with the application of laboratory data by the end user.
 - 2. Requisite information
 - a. Name of test, procedure, or equipment
 - b. Date
 - c. Name of person(s) performing the test or recording the data
 - d. Tolerance limits (acceptable range of values)
 - e. Control result
 - f. Lot number(s) of reagent(s) used
 - g. Expiration date(s) of reagent(s) used
 - h. Corrective action(s)
 - i. Name of person reviewing results
 - 3. Types of QC records
 - a. Media
 - b. Tests and procedures
 - c. Proficiency tests
 - d. Temperature records for water baths, incubators, refrigerators, etc.
 - e. Reviews of procedure manuals
 - f. Equipment preventive maintenance, troubleshooting, and repair records. These records should be kept in proximity to the instrument.
 - g. Equipment function checks
 - 4. Review of records
 - a. *All QC records must be reviewed and signed at least monthly by the supervisor or director of the laboratory.*
 - b. When results exceed predefined tolerance limits, identify the problem and document on the form any corrective action(s) taken
- F. Incident (problem) reports** (*see* Appendix 14.3–2, p. 14.3.16)
- 1. Principle
Incident reports document problems related to the performance of care givers (e.g., collection, labeling, or transport of specimens; complaints; uncooperative behavior) and microbiology laboratory personnel (e.g., specimen processing, failure to follow procedures, safety violations). Equally as important, the incident reports may be used to document commendable performance.
 - 2. Requisite information
 - a. Identification of the problem
 - b. Date
 - c. Name(s) of individual(s) involved

IV. ESSENTIAL LABORATORY RECORDS *(continued)*

- d. Corrective action(s) taken
- e. Name(s) of reviewer(s)
- f. Date(s) of review(s)
- G. Safety records** *(see Appendix 14.3–2, p. 14.3.17)*
 - 1. Principle
Safety records provide documentation that all employees with a potential occupational exposure to hazardous chemicals or potentially infectious material have participated in an appropriate training program at the time of hire and annually thereafter.
 - 2. Requisite information
 - a. Dates of training sessions
 - b. Contents or summary of training sessions
 - c. Name(s) of individual(s) conducting training
 - d. Name(s) of person(s) attending training
- H. Reportable-disease record** *(see Appendix 14.3–2, p. 14.3.18)*
 - 1. Principle
The reportable-disease record reports cases of infectious diseases as required by municipal, county, and/or state public health departments. The report may be based upon a clinical syndrome, isolation of a microbial species, or a positive serologic test.
 - 2. Requisite information
 - a. Demographics of patient (as available)
 - (1) Name
 - (2) Address
 - (3) Telephone number
 - (4) Social security number
 - (5) Occupation
 - b. Disease
 - c. Test result(s)
 - d. Name and address of patient's physician
- I. Personnel record** *(see Appendix 14.3–2, p. 14.3.19)*
 - 1. Principle
The personnel record includes information on ongoing personnel training, as well as the levels of certification and training of microbiology laboratory personnel.
 - 2. Requisite information
 - a. Employee name
 - b. Past training and education
 - (1) College
 - (2) Specialized laboratory training in certified programs
 - (3) Certifying agency or agencies
 - (4) Certificate and/or registration number(s)
 - (5) Experience
 - c. On-the-job training
 - (1) Document tasks and procedures that the person is trained to perform.
 - (2) Explain nature of training.
 - d. Continuing-education training
Document courses attended by the employee.
 - e. Performance appraisal(s)

Performance appraisal

I. PRINCIPLE

The objectives of this procedure are to describe methods of preparation and QC testing of water used in microbiology laboratories and to compare water specifications published by the NCCLS (4), the American Society for Testing and Materials, the Environmental Protection Agency

(2), the American Public Health Association-American Water Works Association-Water Pollution Control Federation (3), CAP (1), the American Chemical Society, and the U.S. Pharmacopeial Convention.

Classification of water (types I, II, III, and IV) is not based upon the method of

preparation (e.g., distillation or deionization), which is typically how most individuals characterize water, but on a series of tests the water passes. The recommendations found in this chapter are largely based upon those published by the NCCLS (4).

II. SPECIMENS

A. Specifications

1. The specifications for various levels of water quality are presented in Table 14.4-1. A consensus is lacking among the various organizations regarding the specific parameters that should be tested and the criteria that should be met for defining the level of water quality.
2. The minimum testing criteria for defining a level of water quality acceptable for the procedures performed in a microbiology laboratory are defined by the NCCLS as follows.
 - a. Resistivity
 - b. pH
 - c. Silicate content
 - d. Bacterial count
 - e. Particulate matter
Particulate matter is a process specification achieved by filtration of type I water through a 0.22- μ m-pore-size filter. It is not measured by the user and is not a requirement for other types of water.
 - f. Organic content
Organic content is a process specification for type I water achieved through pretreatment of raw water supplies with activated carbon or by posttreatment for applications requiring low levels of organic material.
3. The specifications published by the NCCLS (4) and the CAP (1) are most applicable to a clinical microbiology laboratory and will be the primary focus throughout the remainder of this procedure.

B. Types of water

1. Type I
 - a. Must be utilized immediately after preparation.
 - b. Must not contain particulate matter any larger than 0.2 μ m in diameter. Many systems use a vinyl membrane filter with a pore size of 0.1 μ m for removal of particulate contaminants.

Table 14.4-1 Laboratory pure-water specifications

Parameters ^a	Specification for water by ^b :																					
	NCCLS			ASTM				EPA				SM			CAP		ACS	USP				
	I	II	III	I	II	III	IV	I	II	III	IV	I	II	III	I	II	III

^a HPC, heterotrophic plate count; TOC, total organic carbon.^b ASTM, American Society for Testing and Pharmacopeia; EPA, Environmental Protection Agency; SM, Standard Methods for the Examination of Water and Wastewater (3); ACS, American Chemical Society; USP, U.S. Pharmacopeia; NA, not applicable; ND, not done; CFR, Code of Federal Regulations.^c For microbiological use.

II. SPECIMENS (continued)

Include QC information on reagent container and in QC records.

- c. The process of reverse osmosis, distillation, or passage through activated carbon removes most organic constituents.
2. Other types
Specifications for other levels of water quality are presented in Table 14.4–1.
3. Purchased or bottled water
 - a. Type I water cannot be bottled and sold because of degradation during storage.
 - b. Do not use sterile (pharmaceutical) water, as it does not meet the specifications for laboratory water.
 - c. Diluted water provided by a manufacturer can be used only for that specific system.
 - d. Purchase only water that is labeled as to bacterial count, resistivity, silicate content, and pH, as applicable.
 - e. At the time that the container is opened, determine the resistivity and bacterial count of the water.
 - f. Pour the water into a secondary container for use. Never dip pipettes into the original container. Discard water 7 days after a container is opened (3).
4. Special reagent water
Water quality greater than type I may be required for special procedures, such as high-performance liquid chromatography (HPLC), cell culture, or direct bacterial detection, that mandate the removal of specific contaminants.

C. Preparation methods

1. All methods producing water meeting the specifications listed in Table 14.4–1 are acceptable.
2. Water pressure, pH, temperature, pattern of usage (intermittent or continuous), and concentrations of contaminants in the feed water source influence each preparation method. Seek assistance from reputable manufacturers prior to purchasing a system.
3. Method of preparation (Table 14.4–2)
 - a. Distillation: a separation process that heats water to vapor phase and then condenses it back to a liquid, removing all nonvolatile contaminants
 - b. Deionization (demineralization or ion exchange)
 - (1) Process removes ionized molecules (anions and cations) as the feed water moves through a synthetic polymer resin.

Table 14.4–2 Comparison of water preparation methods^a

Preparation method	Efficacy for classes of contaminants ^b					
	Dissolved ionized solids	Dissolved ionized gases	Dissolved organics	Particulates	Bacteria	Pyrogens and endotoxins
Distillation	E, G	P	G	E	E	E
Deionization	E	E	P	P	P	P
Reverse osmosis	G	P	G	E	E	E
Carbon adsorption	P	P	E, G	P	P	P
Microfiltration	P	P	P	E	E	P
Ultrafiltration	P	P	G	E	E	E
UV oxidation	P	P	E, G	P	P	P

^a Adapted from reference 4 with permission. The current C3 edition may be obtained from NCCLS, 940 West Valley Rd. Suite 1400, Wayne, PA 19087.

^b E, excellent (capable of complete or nearly complete removal); G, good (capable of removing large percentages); P, poor (little or no removal).

II. SPECIMENS *(continued)*

- (2) Resin types
 - (a) Weak and strong acid cation resins remove cations.
 - (b) Strong basic anion resins eliminate CO₂ and silica.
 - (c) Weak basic anion resins remove anions but not CO₂ or silica.
 - (d) Mixed-bed resins are made up of a mixture of anion and cation resins.
- (3) Feed water pretreatment may be essential to eliminate pyrogens, bacteria, heavy metals, and organic contaminants.

c. Reverse osmosis

- (1) Process in which water is forced under pressure through a semipermeable membrane, effectively removing soluble ionic and organic contaminants, as well as insoluble contaminants.
- (2) Removal efficiency depends upon the membrane type utilized (e.g., acetate, cellulose, polysulfone, or polyamide) and the feed water quality. Dissolved gases and low-molecular-weight organic compounds are not significantly reduced by reverse osmosis.
- (3) Feed water pretreatment may be required if high levels of organic contaminants, bacteria, or insoluble materials are present.

d. Carbon adsorption

- (1) Process utilizes a porous carbon material for adsorption of chlorine, organic contaminants, and gases.
- (2) Adsorption efficiency depends upon the type of carbon, flow rate (contact time), filter depth, molecular size and solubility, and feed water quality.
- (3) Process may be used as a pretreatment prior to reverse osmosis for removal of free chlorine or as a posttreatment of deionized water to eliminate trace organic materials.

e. Filtration

- (1) Microfiltration utilizes membranes with pore sizes in the range of 0.1 to 10 µm for removal of impurities with molecular sizes of >10⁶ Da. Microfiltration is useful for the removal of yeast cells, bacteria, fungi, and other large particles.
- (2) Ultrafiltration is a process in which water is forced under pressure through membranes with pore sizes in the range of 0.001 to 0.1 µm for removal of impurities with molecular sizes of 10⁴ to 10⁶ Da. This process is utilized as a posttreatment after reverse osmosis, distillation, or deionization for removal of pyrogens and microorganisms.

f. UV oxidation

- (1) UV oxidation converts trace organic materials to CO₂ and controls bacterial growth within the system.
- (2) UV light (185-nm wavelength) is utilized as a posttreatment after deionization or reverse osmosis to oxidize trace organic materials.
- (3) UV light (254-nm wavelength) is applied at various points in the water system (especially in holding tanks) to inhibit bacterial growth. The efficiency of this method depends upon the contact time, light intensity, and turbidity and the susceptibility of the microorganisms.

D. Storage and distribution of laboratory water

1. The construction and design of a water distribution system significantly influences the quality of the end product. Refer to NCCLS guidelines (4) for discussion of the important features of a water distribution system.
2. Storage containers should be constructed of polypropylene reinforced with stainless steel or fiberglass. Glass is inadequate.
 - a. Type I water cannot be stored and must be used immediately upon preparation.

II. SPECIMENS (continued)

- b. Type II water may be stored for short periods.
- 3. In general, storage of laboratory grade water for long periods is unacceptable because of unpredictable deterioration rates.

E. Applications

1. The effect of reagent grade water on the various procedures performed in the clinical microbiology laboratory is, at best, poorly documented. Therefore, to obviate any unknown potential issues, the user is advised to use type I water whenever feasible. Realistically, most clinical microbiology laboratories will utilize deionized water meeting the criteria for type II water.
2. Suggested uses for various water types are presented below. This list is not intended to be exhaustive, but rather a presentation of common examples.
 - a. Type I
Use whenever feasible and particularly when a test method mandates minimal interference from water. Examples of situations in which Type I water might be used include enzyme immunoassays, radioimmunoassays, immunofluorescence assays, preparation of buffers, standard solutions, or reagents that will not contain preservatives, electrophoresis reagents, and virology and cell culture materials.
 - b. Type II
Use for most procedures unaffected by the presence of bacteria and not requiring type I water. Examples might include media and stains, and reagents that will be subsequently sterilized or to which preservatives will be subsequently added.
 - c. Type III, type IV
Utilize for washing and preliminary rinsing of glassware.
 - d. Special
In certain circumstances, water with other special properties may be required. Examples might include specific chromatographic procedures and the need for pyrogen-free water in certain tissue or cell culture media.

III. QUALITY CONTROL

A. Testing frequency (Table 14.4-3)

1. Perform QC procedures more frequently if any components of the production or distribution system are changed, if problems possibly related to the water occur during testing procedures, or if QC tests do not meet tolerance limits.
2. For some contaminants, the testing frequency may be seasonally dependent.

Table 14.4-3 Specifications and frequency of QC testing of laboratory water^a

Test	Frequency	Tolerance limit ^b		
		Type I	Type II	Type III
Bacterial content (CFU/ml)	Weekly	≤10	≤1,000	NS
pH	With use	NS	NS	5.0–8.0
Resistivity (MΩ—cm at 25°C)	Type I, daily (in-line)	10	1.0	0.1
	Type II, daily (in- or off-line)			
	Type III, with use (off-line)			
Silicate (mg/liter)	Initially and annually thereafter	0.05	0.1	1.0

^b NS, not specified.

III. QUALITY CONTROL (continued)

B. Tests

See Appendixes 14.4–1 to 14.4–4 for test procedures.

1. The number of tests performed may vary based on the specific accreditation body. As a minimum, pH, bacterial content, resistivity, and silica content should be determined (4).
2. Organic content
 - a. The purification system should include a process that significantly reduces concentrations of organic contaminants.
 - b. Water contamination with organic compounds can be determined by spectrophotometric evaluation of a sample in the far-UV range or by HPLC (4).
3. The total bacterial count may be determined using a standard plate count technique, a commercial filtration kit, a large-volume filtration methodology, or a commercial bacterial sampler method (4). Refer to Appendix 14.4–1 for the standard plate count methodology.

APPENDIX 14.4–1

Determination of Total Bacterial Counts: Standard Plate Count

- I. PRINCIPLE

The total bacterial count of a water sample measures the CFU of aerobic and facultatively anaerobic bacteria that will grow under incubation conditions.
- II. SPECIMENS

Type I, II, and III water produced by a purification system
- III. MATERIALS
 - A. Reagents and media: any clear medium capable of supporting growth of aerobic and facultatively anaerobic gram-negative bacilli (e.g., TSA, BHI agar, standard plate count agar)
 - B. Supplies
 1. Petri plates (15 by 100 mm)
 2. Micropipettors or pipettes
 3. Sterile tubes
 - C. Equipment
 1. Incubator, ambient air
 2. Vortex mixer
- IV. QUALITY CONTROL

See procedure 14.2.

APPENDIX 14.4-1 (continued)

- V. PROCEDURE
 - A. Flush the system by allowing water to flow for 1 min.
 - B. Collect a minimum of 10 ml of water in a sterile container. Process the sample within 1 h or within 6 h if stored at 5°C.
 - C. Melt 15 ml of the agar medium and cool it to 46 to 50°C.
 - D. Vortex the 10-ml sample or invert it multiple times to mix.
 - E. Transfer a 1-ml aliquot of the water sample to a petri plate. Pour the molten agar into the plate and mix by careful rotation.
 - F. After the agar has solidified, invert the petri plate and incubate at $36 \pm 1^\circ\text{C}$ for 24 h and then at $23 \pm 3^\circ\text{C}$ for 24 h.
- VI. RESULTS
 - A. Count the colonies. Use a dissecting microscope with $\times 10$ to $\times 15$ magnification or a Quebec colony counter for optimal observation of growth.
 - B. Acceptable results
 - 1. Type I, ≤ 10 CFU/ml
 - 2. Type II, $\leq 1,000$ CFU/ml
- VII. RESULT REPORTING
 - Report the CFU in 1 ml of sample
- VIII. PROCEDURAL LIMITATIONS
 - Not all bacteria produce detectable colonies under these growth conditions.

Supplemental Reading

NCCLS. 1997. *Preparation and Testing of Reagent Water in the Clinical Laboratory*, 3rd ed. Approved Guideline C3-A3. NCCLS, Wayne, Pa.

APPENDIX 14.4-2

Determination of pH of Laboratory Water

- I. PRINCIPLE
 - Because type III water has so few ions present, potassium chloride (KCl) must be added to obtain a stable pH reading.
- II. SPECIMEN
 - Type III laboratory water
- III. MATERIALS
 - A. Reagents
 - 1. Reference buffer solutions
 - Use two commercial reference buffers at pH 4.0 and 7.0.
 - 2. KCl, saturated
 - Slowly add KCl crystals to warm type II water. Stir constantly until the crystals no longer go into solution. Store indefinitely at room temperature (RT) in a stoppered glass or plastic container.
 - 3. Type I water in a squirt bottle for rinsing electrodes between measurements
 - B. Supplies
 - 1. Large-mouth beaker for rinsing
 - 2. Small plastic tubes or beakers
 - C. Equipment
 - 1. pH meter and electrode
 - 2. Stirring heating plate
 - 3. Thermometer
- IV. QUALITY CONTROL
 - Refer to procedure 12.16 in CMPH for QC of pH meters.
- V. PROCEDURE
 - A. Allow all solutions to come to RT. Measure the temperature of the solution and adjust the temperature control on the pH meter to coincide with the reading.
 - B. Standardize the pH meter (refer to procedure 12.16 in CMPH).
 - C. Rinse the electrode a minimum of three times with a flowing stream of water.
 - D. Add 1 drop of saturated KCl to a 50-ml sample of water to be tested.

APPENDIX 14.4–2 (continued)

- VI. RESULTS
 A. Record the pH as quickly as possible.
 B. The pH of type III water should be 5.0 to 8.0.
- VII. RESULT REPORTING
 Report the pH to the nearest 0.1.

Supplemental Reading

NCCLS. 1997. *Preparation and Testing of Reagent Water in the Clinical Laboratory*, 3rd ed. Approved Guideline C3-A3. NCCLS, Wayne, Pa.

APPENDIX 14.4–3

Determination of Laboratory Water Resistivity

- I. PRINCIPLE
 Resistivity is inversely proportional to the concentration of ionized compounds in the water.
- II. SPECIMENS
 Type I, II, and III water
- III. MATERIALS
 A. Reagents
 1. Potassium chloride (0.01 mol/liter)
 Dissolve 0.7440 g of KCl in type I water. Dilute to 1 liter at 20°C.
 2. Type I water in a rinse bottle
 B. Supplies
 Water sample containers
 C. Equipment
 1. Resistivity meter
 a. In-line meter (built into the purification system)
 (1) Measures the resistivity of type I or type II water as it is produced.
 (2) Follow manufacturer's instructions.
 b. Off-line, dip-type meter
 (1) Manually measures the resistivity of type II and II water.
 (2) The accuracy of the meter must be $\pm 3\%$ of the full scale or $\pm 5\%$ of the actual reading.
 2. Thermometer: graduations of 0.1°C
- IV. QUALITY CONTROL
 A. In-line meters
 Follow manufacturer's instructions.
 B. Off-line (dip-type) meters
 1. Follow manufacturer's instructions.
 2. Measure the resistivity of the 0.01-mol/liter KCl solution daily or with each meter use.
 3. The 0.01-mol/liter KCl has a resistivity of 708 Ω -cm at 25°C if the resistivity of the water used in the KCl is not taken into consideration.
- V. PROCEDURE
 A. Type I water
 Resistivity can only be measured using an in-line meter. Measure daily.
 B. Type II and III water
 1. Follow manufacturer's instructions.
 2. Rinse the container and the meter cell a minimum of three times with separate aliquots of the water to be tested.
 3. Place the cell in the water. Move it up and down in a circular fashion to eliminate any trapped bubbles. Read immediately, because dissolving atmospheric CO₂ will result in a falsely low resistivity reading.
 4. If the resistivity meter does not automatically compensate for temperature, simultaneously measure the temperature to the nearest 0.1°C. Following the instructions, correct the resistance reading to 25°C.

APPENDIX 14.4–3 (continued)

- VI. RESULTS
 - A. Type I water, 10 M Ω -cm at 25°C
 - B. Type II water, 1 M Ω -cm at 25°C
 - C. Type III water, 0.1 M Ω -cm at 25°C
- VII. RESULT REPORTING
 - Record the meter reading in megaohms per centimeter at 25°C.
- VIII. PROCEDURE NOTES
 - A. The resistance of pure water varies significantly, depending upon the temperature.
 - B. Dissolving atmospheric CO₂ will result in lower resistivity readings.

Supplemental Reading

NCCLS. 1997. *Preparation and Testing of Reagent Water in the Clinical Laboratory*, 3rd ed. Approved Guideline C3-A3. NCCLS, Wayne, Pa.

APPENDIX 14.4–4

Determination of Soluble Silica by the Molybdate Method

- I. PRINCIPLE
 - Soluble silica in source water is a major problem in some geographical areas. Silicates react with the molybdate ions to form complexes that generate a blue color after reduction by 1-amino-2-naphthol-4-sulfonic acid.
- II. SPECIMENS
 - Type I, II, or II water
- III. MATERIALS
 - A. Reagents
 - 1. 1-Amino-2-naphthol-4-sulfonic acid solution (14.45 mmol/liter)
 - a. Dissolve 1 g of sodium sulfite (Na₂SO₃) in 50 ml of type I water.
 - b. Add 0.5 g of 1-amino-2-naphthol-4-sulfonic acid. Mix.
 - c. Add this solution to 100 ml of a solution containing 30 g of hydrogen sulfite (NaHSO₃).
 - d. Dilute to 200 ml.
 - e. Store in a dark polyethylene bottle at room temperature (RT) for up to 2 weeks.
 - 2. Ammonium molybdate solution, 100 g/liter (85.9 mmol/liter)
 - a. Dissolve 10 g of ammonium molybdate in type II water and dilute to 100 ml.
 - b. Store in a polyethylene bottle at RT for up to 3 months.
 - 3. Hydrochloric acid
 - a. Slowly add 100 ml of concentrated HCl to 100 ml of type II water.
 - b. Store indefinitely in a polyethylene bottle at RT.
 - 4. Oxalic acid solution, 100 g/liter (1.11 mmol/liter)
 - a. Dissolve 10 g of oxalic acid in type II water and dilute to 100 ml.
 - b. Store in a polyethylene bottle at RT for up to 3 months.
 - 5. Silica standard solution (1 ml = 1 mg of SiO₂; 16.64 μ mol)
 - a. Dissolve 4.732 g of sodium metasilicate (Na₂SiO₃ · 9H₂O) in type II water and quantity sufficient to 1 liter
 - b. Store in a polyethylene bottle at RT for up to 3 months.
 - B. Equipment
 - 1. Spectrophotometer with capability to read at 700-to 850-nm wavelength
 - 2. Balance with capability to measure to the nearest milligram
- IV. QUALITY CONTROL
 - A. Purchase or prepare QC standards containing silica over the range 0.01 to 1.0 mg/liter.
 - B. Assay QC standards with each use.
- V. STANDARD-CURVE PREPARATION
 - A. Prepare a series of 0.01-, 0.05-, 0.1-, and 1.0-mg/liter SiO₂ standards (100 ml each) by diluting the stock SiO₂ solution in type I water.
 - B. Treat 50-ml samples of each standard as described in item VI below.
 - C. Use 50 ml of assayed type I water as a blank. This water must not generate any visible blue color in the assay procedure.

APPENDIX 14.4-4 (continued)

VI. PROCEDURE

- A. Transfer 50-ml aliquots of the water samples, standards, and blank to polyethylene containers.
- B. Add, in rapid succession, 1 ml of the HCl solution and 2 ml of ammonium molybdate. Mix well. Let stand for 5 min.
- C. Add 1.5 ml of the oxalic acid solution. Mix. Let stand for 1 min.
- D. Add 2 ml of amino-naphthol-sulfonic acid solution. Mix well. Let stand for 10 min.
- E. Zero the spectrophotometer with the blank. Measure the A_{803} of the standards and the samples.

VII. RESULTS

- A. Record the absorbance of each sample and standard.
- B. Prepare a standard curve by plotting the absorbance values of the standards against the known silicate concentration in milligrams of SiO_3 per liter.

VIII. RESULT REPORTING

- A. Determine the silica concentrations of the samples using the calibration curve.
- B. Report the concentrations in milligrams per liter.
- C. Acceptable values for laboratory grade water
 1. Type I, 0.05 mg/liter
 2. Type II, 0.1 mg/liter
 3. Type III, 1.0 mg/liter

IX. PROCEDURE NOTES

- A. A commercially prepared kit methodology may be used as a substitute.
- B. Ideally, the silica content of the source water should be determined and a water purification system should be designed to yield low levels of silicates, which would obviate the need to test routinely for silicates.

Laboratory workers are at high risk for occupational exposure to infectious agents. Infections can be acquired from exposure to contaminated blood, tissue, and other material. The greatest risks for clinical microbiologists are associated with the processing of specimens and the manipulating of pathogens isolated from these materials. The actual incidence of laboratory-acquired infections is probably higher than recognized due to subclinical symptoms and poor compliance in reporting.

Laboratory practices that can reduce the risk of infection include standard precautions, PPE, safety devices, and the proper decontamination and disposal of biohazardous material. The concept of standard precautions evolved by incorporating the 1991 OSHA standard for occupational exposure to blood-borne patho-

gens, universal precautions, and the 1996 Hospital Infection Control Practices Advisory Committee guidelines for isolation precautions in hospitals, body substance isolation. The intent of standard precautions is to include a broader range of pathogens than universal precautions implied. Standard precautions recognize that all patient specimens should be handled as if they are infectious and capable of transmitting disease. This applies to all body fluids, secretions, excretions, and tissue specimens, regardless of whether they contain visible blood, as well as QC strains and proficiency test samples.

A renewed interest in improving safety in the laboratory has occurred because of the recognition of new infectious agents, emergence of antimicrobial resistance, new diagnostic and treatment methods,

and the potential threat of agents of bioterrorism. Numerous guidelines for the prevention of laboratory-associated infections have appeared in the literature. Adherence to these guidelines can reduce, but not eliminate, the risks of occupational exposure to infectious agents.

This section deals with basic strategies and procedures for the prevention, containment, and management of laboratory-acquired infections in the microbiology laboratory. The items in Supplemental Reading below include examples of laboratory-associated infections and published guidelines and regulations for improving laboratory safety. Additional biosafety information can be found on the following websites: <http://www.cdc.gov/od/ohs/biosfty/bmbi/> and <http://www.osha-sk.gov>.

15.2.1

Routes of Infection and Laboratory Activities

Many different categories of microbiological hazards are encountered from the time a specimen is collected until it is disposed of permanently. The management of risks engendered by working with pathogens is accomplished by the development and im-

plementation of standard procedures and practices for handling infectious material and will prevent microbial transmission. “Infection” as used in this procedure implies overt clinical manifestations of disease. Exposure to infectious agents can

occur by several routes. The actual occurrence of an infection depends on the concentration and virulence of the infecting agent, the route of exposure, and the susceptibility of the host.

I. INHALATION: ACTIVITIES THAT GENERATE AEROSOLS

Selected agents may include *Bacillus anthracis*, *Brucella* species, *Coxiella burnetii*, *Burkholderia pseudomallei*, *Francisella tularensis*, and *Mycobacterium tuberculosis*.

A. Manipulating needles and syringe

1. Expelling air from tubes or bottles
2. Withdrawing needles from stoppers
3. Separating needles from syringes

B. Manipulating inoculation needles or loops

1. Flaming loops
2. Cooling loops in culture media
3. Subculturing and streaking culture media

C. Manipulating pipettes

1. Mixing microbial suspensions
2. Spilling microbial suspensions on hard surfaces

D. Manipulating specimens and cultures

1. Centrifugation
2. Mixing, blending, grinding, shaking, sonication, and vortexing of specimens or cultures
3. Pouring or decanting fluids
4. Removing caps or swabs from culture containers
5. Spilling infectious material
6. Filtering specimens under vacuum

II. INGESTION: ACTIVITIES RELATED TO ORAL TRANSMISSION

Selected agents may include *Salmonella* species, *Shigella dysenteriae*, *Campylobacter jejuni*, *Escherichia coli*, *Vibrio cholerae*, *Yersinia pestis*, and *Giardia lamblia*.

A. Pipetting by mouth

B. Splashing contaminated material into the mouth

C. Placing contaminated material or fingers in the mouth

D. Eating, drinking, using lipstick, and smoking in the workplace

III. INOCULATION: ACTIVITIES RELATED TO DIRECT INTRAVENOUS AND SUBCUTANEOUS TRANSMISSION

Selected agents may include human immunodeficiency virus, hepatitis B and C viruses, *Plasmodium vivax*, and Venezuelan equine encephalitis virus.

- A. Manipulating needles and syringes**
- B. Handling broken glass, scalpels, and other sharp objects**

IV. INOCULATION: ACTIVITIES RELATED TO CONTAMINATED SKIN AND MUCOUS MEMBRANES

Selected agents may include *Streptococcus pyogenes*, *Staphylococcus aureus*, *Neisseria meningitidis*, and *Cryptococcus neoformans*.

- A. Splashing or spilling material into eyes, mouth, and nose and onto skin**
- B. Exposing nonintact skin to contaminated material**
- C. Working on contaminated surfaces**
- D. Handling contaminated equipment**
- E. Inappropriate handling of loops, inoculating needles, or swabs containing specimen or culture material**

All laboratory personnel must follow standard precautions guidelines. Specimens received in the laboratory cannot be distinguished between containing potentially infectious and noninfectious material. The implementation of safe work practices is essential for the prevention of laboratory-associated infections.

I. HANDLING OF SPECIMENS

A. Gloves and gowns

1. Wear gloves and gowns (impervious to liquids) at all times when handling and processing patient specimens, decontaminating instruments and countertops, and cleaning spills. Coats with snug-fitted sleeves and aprons are optional.
2. Bandage open cuts and scratches on hands and then wear gloves.
3. Wear gloves (e.g., latex free or vinyl) when performing phlebotomy and when handling actual blood specimens.
4. Wash hands immediately after gloves are removed, after a task that involves heavily contaminated matter, and before leaving the laboratory.

B. Specimen transport

1. Place specimens in plastic bags and transport in leakproof containers with the biohazard symbol affixed (*see* Fig. 15.5–4).
2. *Do not* accept grossly soiled or contaminated specimens. Notify an individual responsible for submitting such a specimen immediately, and follow the laboratory's specimen rejection policy.

C. Needles and syringes

1. Use needle-locking syringes or plastic disposable syringe-needle units.
2. Never recap or bend needles or remove them from syringes.
3. *Do not* accept specimens received in syringes with needles attached. Notify the individual responsible for submitting such a specimen immediately and follow the laboratory's specimen rejection policy.
4. Discard in a puncture-resistant container that has the biohazard symbol affixed.
5. Use needleless systems for blood samples if available.
6. Use mechanical devices or one-handed techniques when handling sharp objects.
7. Secure blood culture bottles before inserting needles into the bottles (e.g., place bottles in support racks).

I. HANDLING OF SPECIMENS*(continued)***D. Tubes**

1. Carry tubes in racks.
2. Use plastic tubes when possible.
3. Uncap tubes behind a clear plastic shield to contain splashes or sprays (e.g., when removing tops from vacuum tubes).

E. Centrifuges

1. Centrifuge tubes must be intact and properly balanced when centrifuged.
2. Centrifuge tubes used in mycobacteriologic areas must be enclosed in sealed safety cups.
3. Use aerosol-free centrifuges when possible (e.g., in the mycobacteriology laboratory).
4. Centrifuge safety cups must be opened in a biological safety cabinet (BSC) after centrifugation.
5. *Do not* place tabletop centrifuges in a BSC because air turbulence within the cabinet can allow aerosols to escape.

F. Hand washing

1. Perform frequent hand washing after removing gloves, before leaving the laboratory, and before eating, drinking, or applying cosmetics.
2. Use nonirritating soap for routine washing.
3. Use antiseptic soap or an alcohol planchet followed by thorough hand washing for accidental skin contamination.

II. PROCESSING OF SPECIMENS

- A. Process all specimens in a BSC (*see* procedure 15.3.4 for BSC operating procedures).
- B. Sterilize bacteriological wire needles and loops to avoid spattering of material on heating.
 1. Use electric incinerators if available.
 2. Use Bunsen burners equipped with a safety sleeve.
 3. Cool needle and loop tips enough to avoid searing the surface of the medium.
 4. Alternatives to wire needles and loops which require no heating include plastic disposable loops and spreaders for streaking plates and spreading material onto slides.
- C. Mix or transfer liquids by using disposable plastic pipettes and a rubber bulb. Alternatively, use mechanical pipetting devices.
- D. Cover tubes when mixing, blending, vortexing, etc. (e.g., cap tubes or cover them with Parafilm).
- E. Work over an absorbent covering or disinfectant-moistened mat (e.g., phenolic-compound-soaked pad for *Mycobacterium tuberculosis*).
- F. Plan tasks to minimize exposure to known hazards.
- G. Follow standard precautions when performing nonculture techniques (e.g., antibody, antigen, and molecular detection methods).

III. HOUSEKEEPING AND MISCELLANEOUS SAFE PRACTICES**A. General**

1. Avoid or minimize activities associated with the transmission of infectious agents.
2. Designate clean and contaminated work areas.
 - a. Wear gloves in contaminated areas.
 - b. Clean and disinfect all surfaces after spills and at the end of each work shift.
3. Keep all work areas neat and uncluttered.
 - a. *Do not* store personal items in the work areas.
 - b. *Do not* store large quantities of disposable items in the work areas.

III. HOUSEKEEPING AND MISCELLANEOUS SAFE PRACTICES *(continued)*

4. Remove coats and gowns before leaving the laboratory. Place contaminated laundry (e.g., reusable lab coats and gowns) in designated bag for cleaning by the institution.
5. Dispose of all contaminated material in containers for treatment (e.g., by autoclaving).

B. Compressed gases

1. Secure cylinders in an upright position with wall mounts.
2. Store cylinders away from open flames and sources of heat.
3. Use the correct pressure regulators.
4. Verify the contents of the cylinder before gas is used.
5. Transport cylinders in secured hand trucks or carts.

C. Chemicals

1. Wear appropriate PPE when handling hazardous chemicals.
2. Label all reagents with their chemical names and appropriate hazard warnings provided from the MSDS information.
3. Keep MSDSs for all chemicals, either in the laboratory or in a nearby office.
4. Store flammable and combustible liquids in fire-rated storage cabinets and explosion-proof refrigerators.
5. Store all hazardous chemicals, including reagents and dyes, below eye level.
 - a. Use plastic bottles when appropriate.
 - b. Store on the bench volumes necessary for daily work.
6. Place chemical waste in a fume hood until final disposal.

15.2.3

Decontamination

Routine decontamination and cleaning of the work environment are the responsibility of all laboratory workers at both the basic and highly sophisticated laboratory levels. To accomplish this effectively, the work areas should be uncluttered, with clean and dirty materials separated and clearly identified. Table 15.2.3–1 lists procedures and products commonly used for sterilization and disinfection (1). The manufacturer’s instructions for preparation and use should be carefully followed. No

single product and procedure, however, are adequate for all decontamination purposes. When selecting a procedure, the degree of microbial killing, nature and composition of the surface or device to be treated, cost, safety, and ease of use of available agents should be considered. More information on Environmental Protection Agency (EPA)-approved general-purpose disinfectants and Food and Drug Administration (FDA)-regulated sterilants

and high-level disinfectants can be found on the websites <http://www.epa.gov/epahome/seatch.html> and <http://www.fda.gov/cdrh/index.html>. A new website, <http://www.sustainablehospitals.org>, is also available that provides information on safer alternatives to products containing latex, polyvinyl chloride, mercury, and disinfectants. This procedure presents common decontamination practices used in the microbiology laboratory.

Table 15.2.3–1 Activity levels of selected liquid germicides^a

Procedure and product	Aqueous concn	Activity level
Sterilization		
Glutaraldehyde	Variable	
Hydrogen peroxide	6–30%	
Formaldehyde	6–8%	
Chlorine dioxide	Variable	
Peracetic acid	Variable	
Disinfection		
Glutaraldehyde	Variable	High to intermediate
<i>ortho</i> -Phthalaldehyde	0.5%	High
Hydrogen peroxide	3–6%	High to intermediate
Formaldehyde	1–8%	High to low
Chlorine dioxide	Variable	High
Peracetic acid	Variable	High
Chlorine compounds	500–5,000 mg of free, available chlorine/liter	Intermediate
Alcohols	Ethyl, isopropyl: 70%	Intermediate
Phenolic compounds	0.5–3%	Intermediate to low
	30–50 mg of free iodine/liter; up to 10,000 mg of available iodine/liter	Intermediate to low
Quaternary ammonium compounds	0.1–0.2%	Low

^a Reproduced with permission from reference 2. A large number of commercial products based on the generic compounds listed can be considered for use. Users should ensure that commercial formulations are registered with the EPA or by the FDA.

I. MATERIALS

- | | |
|---|---|
| <p>A. Alcohol (e.g., 70% ethanol, isopropanol)
Use to decontaminate work surfaces only.</p> <p>B. Glutaraldehyde or suitable alternative</p> <ol style="list-style-type: none"> 1. Dirty glassware 2. Equipment decontamination | <p>C. Chlorine, iodophors, phenolic compounds, quaternary ammonium compounds (e.g., T.B.Q., germicidal detergent; Calgon Vestal Labs, St. Louis, Mo.)</p> <ol style="list-style-type: none"> 1. Work surfaces 2. Dirty glassware 3. Equipment decontamination |
|---|---|

II. PROCEDURES

- A. Preparation of 10% household bleach (0.5% sodium hypochlorite), working solution**
1. Prepare fresh daily.
 2. Add one part household bleach to nine parts tap water (5,000 mg of available chlorine per liter).
 3. Dispense in wash bottles.
 4. Record the date prepared on the bottles.
 5. Leave wash bottles in the work areas.
 6. After 24 h, pour unused bleach solution down the drain and flush the drain with running water to prevent corrosion of pipes.
 7. Allow bottles to air dry.
- B. Decontamination of work surfaces**
1. Follow manufacturer's instructions for cleaning and appropriate disinfecting solutions. Allow bleach solutions to air dry (minimum contact time should be 10 min).
 2. Use a paper towel or soft cloth soaked with the recommended disinfectant solution.
 3. Decontaminate
 - a. Before and at the end of the work shift
 - b. Upon completion of a procedure
 - c. When surfaces become overtly contaminated. *See* procedure 15.2.4.
- C. Decontamination of equipment (including vortex, centrifuge, and telephone)**
1. Follow manufacturer's instructions for cleaning and suitable disinfecting solutions.
 2. Use a soft cloth moistened with recommended disinfecting solution.
 3. Decontaminate
 - a. Upon completion of a procedure
 - b. When surfaces become overtly contaminated. *See* procedure 15.2.4.
 - c. Rinse equipment with tap water (except when alcohol is used).
 4. If the equipment needs to be replaced or serviced, it must be decontaminated before removal.
- D. Decontamination of reusable biohazard pail**
1. Remove biohazard lining bags and tape shut with white tape.
 - a. If a bag is ripped or torn, place it inside a second bag.
 - b. Place red biohazard tape on each bag.
 - c. Place each bag on a biohazard cart or in a waste dumpster for disposal.
 2. Wipe the entire inside surface of the pails with soft cloths soaked with a fresh solution of 10% bleach.
 3. Allow a pail to air dry before placing a new biohazard lining bag into it.
 4. Inspect each pail for holes or leakage.
 5. Decontaminate
 - a. Whenever the biohazard lining bag is changed or at least once per week
 - b. Whenever a biohazard lining bag is torn

II. PROCEDURES (*continued*)**E. Decontamination of computer keyboards**

1. Clean and disinfect keyboards at the end of every shift and when the keyboards are visibly contaminated.
2. Unplug the keyboard from the computer.
3. Clean the keyboard surface with a soft cloth moistened with 70% ethanol, or use an alcohol prep pad.
 - a. If the keyboard has a fitted cover, inspect the cover for holes or tears.
 - b. If the keyboard is uncovered, avoid spilling alcohol underneath the keys.
4. Plug the keyboard back into the computer.
5. If the computer is overtly contaminated with a specimen, clean with a 10% bleach solution and rinse with water.

III. LIMITATIONS OF THE PROCEDURES

- A. Disposable gloves, impervious gowns, eye protection, and masks should be worn when preparing disinfectants and when cleaning and decontaminating soiled equipment.
- B. Overtly contaminated reusable equipment and surfaces should be cleaned with an aqueous detergent solution before application of the disinfectant for optimum effectiveness.
- C. *Do not* use alcohol solutions for equipment decontamination in poorly ventilated areas or near open flames.
- D. *Do not* use sodium hypochlorite solutions on metal parts (aluminum and stainless steel) because they may cause rusting and pitting.
- E. *Do not* use glutaraldehyde solutions as general surface disinfectants because of their irritating vapors and prolonged contact time.
- F. Inactivation of the causative agent of transmissible spongiform encephalopathies, or prion disease (e.g., Creutzfeldt-Jakob disease), is not achieved by conventional inactivation procedures, heat, irradiation, and chemical germicides. Specimens containing prion proteins include tissues of the central nervous system (high risk); CSF, lymph nodes, spleen, pituitary gland, and tonsils (medium risk); and bone marrow, liver, lungs, thymus, and kidneys (low risk). Blood samples carry no risk of transmitting prion disease.
 1. Avoid the generation of aerosols or droplets during the manipulation of tissues or fluids and during necropsy of experimental animals.
 2. Wear gloves for all activities that skin contact with infectious tissues and fluids may occur.
 3. Use disposable plasticware whenever possible.
 4. Formaldehyde-fixed and paraffin-embedded tissues, especially of the brain, remain infectious (they may be immersed for 30 min in 96% formic acid or phenol before processing, but this may distort microscopic neuropathology or alter immunohistochemical reactions).
 5. Contaminated surfaces should be cleaned and then decontaminated with a 1:10 dilution of sodium hypochlorite.
 6. Contaminated items and medical devices should be decontaminated by either of the following conditions (2).
 - a. 134°C for 18 min in a prevacuum sterilizer (liquids must be removed before sterilization)
 - b. 121 to 132°C for 1 h in a gravity displacement sterilizer
 - c. Soak in 1 N NaOH or 2.5% NaOCl for 1 h at room temperature.
 7. For reusable instruments, the World Health Organization (3) recommends more stringent guidelines for disinfection (e.g., combined use of 1 N NaOH and autoclaving at 134°C).

III. LIMITATIONS OF THE PROCEDURES *(continued)*

8. Instruments too delicate for harsh treatments or difficult to clean devices should be discarded.
9. Decontaminate paraformaldehyde-vaporized biosafety hoods with 1 N NaOH, followed by 1 N HCl, and rinse with water. HEPA filters should be autoclaved or incinerated.

IV. QUALITY CONTROL

Sign initials in the appropriate box on the decontamination worksheet after completion of each task. See Appendix 15.2.3–1 for a sample QC daily recording worksheet.

15.2.4

Biohazardous Spills

Management of accidental biohazardous spills depends on the infectious agent, the quantity of the material spilled, and whether an aerosol was generated. A number of effective disinfectants have been described for decontamination; however, a

tuberculocidal (e.g., T.B.Q.) disinfectant is appropriate for most spills. This procedure is for the management of accidental biohazardous spills of infectious material or release of infectious microorganisms into the laboratory. Factors that can influ-

ence the effectiveness of decontamination procedure include the volume of the spill, type of body fluid, protein content, infectious agent present and concentration, and spill surface (porous or water resistant).

I. MATERIALS

(Keep readily available.)

A. Disinfectants

1. 10% Household bleach
2. See Table 15.2.3-1.

B. Equipment and supplies

1. Paper towels
2. PPE
3. Autoclavable squeegee and dust pan

4. Tongs, forceps, or hemostats

5. Autoclavable plastic bags

6. Biohazardous-waste container

7. BioZorb (biological absorbent and disinfectant; Ulster Scientific, Inc., Highland, N.Y.)

II. PROCEDURE

A. Cleanup of major spills (possible aerosol formation)

1. Evacuate the area or room, taking care not to breathe in aerosolized material.
2. Alert personnel in the laboratory to evacuate the area.
3. Close the doors to the affected area.
4. After 30 min, when aerosols have settled, enter the area to clean.
 - a. Cleanup should be performed by the individual who committed the spill or by assigned personnel.
 - b. PPE should include gloves (e.g., heavyweight utility), disposable booties or water-impermeable shoe covers, long-sleeved gowns, and masks.
 - c. For high-risk agents, a full-faced respirator or HEPA-filtered mask should also be used.
5. Remove and discard any broken glass or other objects.
 - a. *Do not* allow contact with hands.
 - b. Use rigid cardboard or squeegee and dustpan, tongs, forceps, or hemostats.
 - c. Discard these items into a plastic biohazardous-waste container.
6. Cover the spill with disposable absorbent material (e.g., paper towels).
7. After absorption of liquid, discard all contaminated material in a biohazardous-waste container.
8. Carefully clean the spill site of any visible material, from the edges of the spill into the center, with an aqueous detergent solution.

II. PROCEDURE *(continued)*

9. Pour fresh disinfectant on the spill site or wipe down the site with disinfectant-soaked disposable towels.
10. Allow disinfectant to remain on the site for 20 min.
11. Absorb disinfectant solution with disposable material or allow the disinfectant to dry.
12. Rinse the spill site with water, and air dry to prevent slipping.
13. Discard all paper towels, gloves, and other disposable items into an autoclavable plastic bag or biohazardous-waste container.
14. Place gowns in a container for autoclaving after the cleanup process is completed.
15. Wash hands with soap and water.

B. Cleanup of minor spills

1. PPE should include gloves, gowns, and facial protection.
2. Wipe up contaminated material or spilled material with disinfectant-soaked paper towels.
3. Rinse materials with water if necessary.
4. Discard all materials in a biohazardous-waste container.
5. Wash hands with soap and water.

C. Cleanup of spills in biological safety cabinet (BSC)

1. See procedure 15.3.4 for operation of the BSC.
2. *Do not* turn off the cabinet.
3. Pour disinfectant (e.g., T.B.Q.) over the spill area and then apply paper towels to absorb liquids. *Do not* use alcohol.
4. Allow 20 min of contact with the disinfectant.
5. Discard paper towels in a biohazardous-waste container.
6. Using a soft cloth soaked in disinfectant, wipe down all cabinet surfaces and equipment as needed.
7. If spills leak through the vent cover, remove and clean the gutter area with disinfectant.
8. Place gowns in a container for autoclaving after the cleanup process is completed.
9. Allow the cabinet blower to run for 10 min before resuming activity.
10. For major spills of potentially infectious materials, contact a technical service consultant for decontamination.
11. *Do not* turn off the cabinet.

D. Commercial products (BioZorb)

1. Apply powder liberally over small spills, and wait until the spill has been completely absorbed.
2. Remove the absorbed material with the disposable scoop and scraper provided.
3. Rinse spill site with water, and air dry to prevent slipping.
4. Discard all materials in a biohazardous-waste container.
5. Wash hands with soap and water.

III. LIMITATIONS OF THE PROCEDURE

- A. *Do not* pour hypochlorite solutions into pools of urine, blood, or feces. Highly irritating gases may be produced.
- B. *Do not* use low-level disinfectants, such as quaternary ammonium compounds, for disinfecting spills.

IV. QUALITY ASSURANCE

Complete Biohazardous-Spill Report and submit it to a laboratory safety committee representative. See Appendix 15.2.4–1 for a sample report form.

15.3.1

Introduction

In addition to implementing standard microbiological procedures and practices, management of the biohazards associated with working with pathogens includes physical barriers and administrative con-

trols. Physical barriers include primary safety equipment and secondary facility design. Procedures 15.3.2 through 15.3.5 describe general physical and administrative controls for microbial containment.

15.3.2

Risk Assessment

Table 15.3.2–1 outlines a sample risk assessment and exposure control plan. Individual laboratories should modify this table to conform with the requirements in their own institution. The risk assessment should focus on the appropriate safety practices for handling infectious materials and cultures rather than on specific infectious agents.

SUPPLEMENTAL READING

Gilchrist, M. J. R., J. Hindler, and D. O. Fleming. 1992. Laboratory safety management, p. xxix–xxxvii. In H. D. Isenberg (ed.), *Clinical Microbiology Procedures Handbook*, vol. 1. American Society for Microbiology, Washington, D.C.

^a P, prohibited; R, required; D, discretionary; A, one of the required alternatives; AST, antimicrobial susceptibility testing; BSC, biological safety cabinet; CPE, cytopathic effect.

^b Remove PPE when leaving the laboratory.

^c Gowns with solid front and impervious to liquid. Many employers provide and launder gowns, thus replacing the need for lab coats.

^d Recapping of needles should be prohibited. Carry tubes in racks, or use plastic tubes. Plan each task to minimize known hazard. Wash hands when leaving the laboratory.

^e Sharps include scalpel blades, pipettes, plastic loops, sticks, needles, syringes, slides, and coverslips.

^f Open sealed cups only in BSCs.

^g Use a BSC or acrylic splash shield.

^h Requires surveillance and action plan for occasional isolation of BSL 3 organisms (e.g., *Brucella* species, *Francisella* species, *Mycobacterium* species, and systemic fungi), especially if plates are held for ≥ 3 days.

ⁱ *M. tuberculosis* requires a BSC and safety centrifuge.

^j Requires a contingency plan for breakage of culture containers.

^k Mycobacteria other than those causing tuberculosis (MOTT group) may be handled at BSL 2; however, use BSL 3 practices since most manipulations precede organism identification.

^l Use HEPA-filtered mask or respirator in addition to BSC for culture of *M. tuberculosis* group.

^m Special precaution for BSL 4 agents (e.g., hemorrhagic fever virus) should be arranged (e.g., call CDC).

ⁿ Vortexing or other splatter-generating steps require use of a BSC or safety shield.

^o Requires BSL 3 practices if there is a potential for aerosols.

15.3.3

Biosafety Levels

BSLs are guidelines that describe appropriate containment equipment, facilities, and procedures for use by laboratory workers. The BSLs range from BSL 1 to BSL 4. Each BSL is based on the increased risk associated with the pathogenicity of the microorganisms encountered. Most clinical microbiology laboratories

follow BSL 2 practices. When working with highly infectious agents for which the risk of aerosol transmission is greater (e.g., *Brucella* species, *Francisella* species, *Mycobacterium tuberculosis*, and systemic fungi), clinical microbiology laboratories should follow BSL 3 practices.

Because of the threat of bioterrorism, new facility designs for public health laboratories are conforming to BSL 3 requirements. Information on BSL recommendations for specific microorganisms can be found on the website <http://www.cdc.gov/od/ohs/biosfty/bmbl/bmbl~1.htm>.

I. BSL 1

BSL 1 is recommended for work with microorganisms not known to cause disease in healthy adults (e.g., *Bacillus subtilis*).

- A. Restrict access to authorized personnel.
- B. Make sinks for hand washing readily accessible.
- C. Make eyewash stations readily accessible.
- D. Make appropriate PPE available and ensure use.
- E. Ensure that laboratory bench tops are impervious to liquids and resistant to chemicals.
- F. Ensure that laboratory surfaces and equipment are easily cleaned and disinfected and that these procedures are done on a regular basis or whenever the surfaces or equipment is contaminated.
- G. Decontaminate solid waste within the laboratory (e.g., by autoclaving), or package the waste to be transported off-site.

II. BSL 2

BSL 2 is recommended for microorganisms associated with human disease but not transmitted by aerosols (e.g., *Salmonella* species).

- A. Follow BSL 1 practices plus the following.
- B. Display universal biohazard signs outside of the laboratory (*see* Fig. 15.5–4).
- C. Perform specimen processing in a biological safety cabinet (BSC) (*see* procedure 15.3.4).
- D. Perform centrifugation of mycobacteriologic specimens by using centrifuge safety cups (*see* procedure 15.4.3).
- E. Ensure that an autoclave or other decontamination equipment is available and used for treatment of infectious waste (*see* procedures 15.4.2 and 15.7).
- F. Use the appropriate PPE (e.g., gowns, gloves, and facial barriers).
- G. Place all sharps carefully in conveniently located, puncture-resistant containers.
- H. Trained personnel must observe good microbiological practices and techniques.

III. BSL 3

BSL 3 is recommended for hazardous microorganisms primarily transmitted by aerosols (e.g., *M. tuberculosis*).

- A. Follow BSL 1 and BSL 2 practices plus the following.
- B. Control access to the laboratory.
- C. Perform all manipulations of cultures and clinical material in a BSC (class II).
- D. Maintain a negative-pressure airflow in the laboratory.
- E. Include double doors and an anteroom in the laboratory design.
- F. Discharge HEPA-filtered exhaust air from BSCs outside the facility.
- G. Use all appropriate PPE and containment devices.
- H. Use HEPA-filtered respirators or masks when aerosols may be generated.
- I. Collect baseline serum samples from all personnel for serological determination of immune status.

IV. BSL 4

BSL 4 is recommended for agents causing life-threatening or untreatable diseases by aerosols or unknown transmission (e.g., Ebola virus).

- A. Follow BSL 3 practices plus the following.
- B. Change to protective clothing before entering, and shower on exit.
- C. Decontaminate all waste on exit.
- D. Use a BSC (class III) and full-body, air-supplied, positive-pressure suit for all procedures.
- E. Locate facility with specialized ventilation and waste management systems separate from other laboratories.

Voss, A. 1999. Prevention and control of laboratory-acquired infections, p. 165–173. *In* P. R. Murray, E. J. Baron, M. A. Pfaller, F. C. Tenover, and R. H. Tenover (ed.), *Manual of Clinical Microbiology*, 7th ed. ASM Press, Washington, D.C.

15.3.4

Biological Safety Cabinet

The biological safety cabinet (BSC) is the most important primary containment equipment in the clinical microbiology laboratory. Class IIA laminar-flow cabinets are the most commonly used for BSL 2 and 3 practices. Air is drawn into the cabinet by negative air pressure and passes through a HEPA filter. The air flows in a vertical sheet that serves as a barrier be-

tween the outside and the inside of the cabinet. The cabinet exhaust air is also passed through HEPA filters. Aerosols are contained within the BSC, and the work area is protected from outside contamination when the cabinet is operating under the manufacturer's recommended conditions. The class III BSC is a completely enclosed, ventilated cabinet of airtight

construction and provides the highest level of protection to laboratory workers and the environment. Class III cabinets are used for working with agents that require BSL 3 or 4 containment. More detailed information on the selection, installation, and use of BSCs can be found on the website <http://www.cdc.gov/od/ohs/biosfty/bsc/bsc.htm>.

I. MATERIALS

A. Disinfectants

1. 10% Household bleach solution (0.5% sodium hypochlorite). Metal surfaces must be rinsed to avoid corrosion.
2. 70% Ethanol. Store outside of the cabinet.
3. See Table 15.2.3–1. Follow the manufacturer's directions for preparation.

B. Common supplies

1. Sterile disposable loops and spreaders
2. Bacteriological wire needles and loops

3. Sterile swabs

4. Sterile disposable pipettes
5. Sterile forceps
6. Glass slides
7. Absorbent mats or towels

C. Common equipment

1. Incinerator
2. Heat block
3. Vortex
4. Sonicator
5. Tissue grinders
6. Filtering apparatus
7. Pipetting devices
8. Test tube rack
9. Discard container

II. PROCEDURES

A. Start-up

1. Turn on blowers for at least 10 min before QC checks and specimen processing.
2. Open the viewscreen to operating height (8 in.).
3. Turn off UV lights (if present).
4. Turn on a fluorescent light.
5. Perform daily QC as outlined in item III.A below.
6. Clean the cabinet working surfaces with appropriate disinfectant.

B. Operation

1. Avoid outside sources of air currents (e.g., personnel walking by, doors being opened or closed, etc.).
2. Wear long-sleeved coats or cuffed gowns and gloves during specimen processing.

II. PROCEDURES *(continued)*

3. Place all items that will be used in a planned activity inside the cabinet prior to starting work.
 - a. Segregate clean from contaminated materials.
 - b. Place the minimum number of large devices and supplies inside the cabinet.
 - (1) *Do not* block intake or rear grills.
 - (2) *Do not* place sterile material or specimens near the sides, front, or back of the cabinet.
 - (3) *Do not* place or tape paper notes or procedures on the window.
 - (4) *Do not* use a flame in the cabinet.
 - (5) *Do not* operate centrifuges in the cabinet.
4. Plan work flow to minimize movements.
 - a. Work at least 6 in. inside the front grill intake.
 - b. Avoid rapid arm movement in and out of the cabinet while a procedure is in progress.
 - c. If necessary, slowly move arms in and out of the cabinet.

C. Shutdown

1. Allow the cabinet to continue running for 15 to 20 min after work is completed and before removing materials.
2. Allow the cabinet to continue running for at least 3 h after processing acid-fast or fungal specimens.
3. Place contaminated materials in covered containers or closed bags, or immerse them in disinfectant, before removal from the cabinet.
4. Disinfect the surfaces of any contaminated materials before removal from the cabinet.
5. Clean up spills by following the steps outlined in procedure 15.2.4, item II.C.
6. Clean interior surfaces with disinfectant (e.g., 70% ethanol)
7. Turn off the blower and lights.
8. Turn on UV light (if present).
9. Close viewscreen (if present).
10. *Do not* shut down cabinets that function 24 h a day, unless a malfunction occurs or routine maintenance is required.

III. QUALITY CONTROL**A. Daily**

1. Disinfect all cabinet surfaces while cabinet is running.
2. Check air velocity (recommended for BSCs not equipped with velocity gauges and airflow indicators in the work area).
 - a. Place a Vaneometer (Lab Safety Supply, Janesville, Wis.) at the opening of the cabinet toward the work space area but not on the airflow grill.
 - b. Level the Vaneometer and record face airflow velocity.
 - (1) The air velocity should be greater than 100 ft/min.
 - (2) *Do not* use the BSC if velocity remains less than 100 ft/min. Contact a technical service consultant.
3. Check the blower function.
 - a. Record the manometer gauge reading (if provided).
 - b. Perform a visible-smoke test.
 - (1) Pass a smoke source (e.g., smoke bottle or smoke stick; Lab Safety Supply) from one end of the cabinet opening to the other.
 - (2) The smoke should show a smooth downward flow with no dead spots or reflux.
 - (3) Record results.

III. QUALITY CONTROL*(continued)*

- c. Observe airflow check strips (optional).
 - (1) Strips should be drawn toward the work space area.
 - (2) Record results.
- B. Weekly
Clean UV lights (if present) with 70% ethanol.
- C. Monthly
Clean the gutter area with disinfectant.
- D. Semiannually
 - 1. Have mycobacteriology and mycology BSCs recertified by certified personnel.
 - 2. Have certified personnel measure UV light output (if present).
- E. Annually (or every 1,000 h)
Have routine and virology BSCs recertified by certified personnel.
- F. Complete and initial the Biological Safety Cabinet Quality Control and Maintenance Record worksheet after each task is completed (*see* Appendix 15.3.4-1).

IV. LIMITATIONS OF THE PROCEDURES

- A. BSCs should not be used as fume hoods.
 - 1. Toxic, radioactive, or flammable vapors or gases are not removed by HEPA filters.
 - 2. Potentially hazardous amounts of volatile material may build up in class II-type cabinets.
 - 3. Exhausted vapors can be vented into the laboratory air.
- B. The use of gloves when performing routine manipulations should not substitute for proper hand washing practices. Wash hands with soap and water between tasks and when heavily soiled with clinical material.

I. PPE AND OSHA STANDARDS

OSHA standards for exposure to blood-borne pathogens require the laboratory to provide PPE for its employees.

- A. Protective clothing is worn while in the laboratory. When leaving the laboratory, either dispose of protective clothing in the laboratory or have it laundered by the institution.
 - 1. Coat, gowns, smocks, or aprons impervious to liquids
 - 2. Garments fitted snugly around the wrists
- B. Gloves are worn when handling infectious materials, contaminated surfaces, or equipment. Dispose of gloves when contaminated, after handling infectious materials is completed, and before leaving the laboratory. Carefully remove gloves by folding cuff back over exposed portion (or inside out) without creating an aerosol. Hands should be washed before and after each use.
 - 1. Disposable and powderless gloves (should not be washed or reused)
 - 2. Glove liners
 - 3. Hypoallergenic or latex-free gloves
- C. Face and eye protection is used when splashes or sprays of infectious materials may occur outside the biological safety cabinet (BSC). Laboratory workers who wear contact lenses should also wear protective eyewear.
 - 1. Masks (e.g., N-95)
 - 2. Goggles or safety glasses
 - 3. Face shields
 - 4. Acrylic splash shields

II. ENGINEERING CONTROLS

Engineering controls should be in place within the laboratory. The controls outlined below are designed to help prevent or minimize infectious aerosols, splashes, or sprays and sharps injury. The OSHA standard for occupational exposure to blood-borne pathogens (1) requires employers to select safer needle devices as they become available. Information on safe needle devices can be found on the website <http://www.sustainablehospitals.org>.

- A. Automatic or mechanical pipetting devices
- B. Bench tops impervious to water and resistant to acids
- C. Biohazard bags
- D. Biohazard labels are required on the following.
 - 1. Refrigerators and freezers containing blood or infectious materials
 - 2. Containers used to store, transport, or ship regulated waste, blood, or infectious materials

II. ENGINEERING CONTROLS

(continued)

3. Sharps containers
4. Contaminated equipment
- E. BSC
- F. Centrifuge safety cups
- G. Containers
 1. Secondary containers (transport of specimens)
 2. Sharps (puncture resistant)
 3. Waste (including stainless steel buckets)
- H. Eyewash stations
- I. Hand washing sinks
- J. HEPA-filtered respirators or masks
- K. Laboratory furniture that is sturdy and accessible for cleaning
- L. Plasticware (substitute for glassware)
- M. Syringes
 1. Needle-locking syringes or disposable syringe-needle units
 2. Syringes that resheath needles
 3. Needleless systems or other safe devices
- N. Waste collection carts

III. COMMERCIAL SAFETY PRODUCTS

Numerous commercial safety products are available for laboratory use. A partial list of common devices or instruments used in the microbiology laboratory is given below. Manufacturers of instruments (e.g., autoanalyzers, centrifuges) are encouraged to incorporate new safety design features and decontamination procedures during regular use and before servicing.

- A. Needle stick prevention devices (e.g., those from Becton Dickinson Microbiology Systems, Cockeysville, Md.)
- B. Ergonomic pipettes (Rainin Instrument Company, Inc., Emeryville, Calif.)
- C. Biogel Revel glove (Regent Hospital Products, Greenville, S.C.)
- D. Automated petri dish streaking instrument (e.g., Isoplater 180; Vista Technologies, Inc., Edmonton, Alberta, Canada)
- E. Automated tissue processor (e.g., Stomacher; Seward Medical Ltd., London, United Kingdom)

15.4.1

Introduction

Procedures 15.4.2 through 15.4.6 describe common operational procedures performed in the clinical microbiology laboratory. They are intended to present proper safety practices when working with equipment and handling infectious material.

15.4.2

Autoclave

An autoclave or steam sterilizer is an insulated pressure chamber in which saturated steam is used to elevate temperature above the normal boiling point of water. A gravity displacement autoclave, in which lighter steam is fed into the chamber to displace heavier air, is the most common type used in the laboratory. The higher the temperature and pressure, the shorter the time required to kill microor-

ganisms. In addition to time, temperature, and direct steam contact, other factors which can effect kill include density, physical state and size, and organic content of the material treated. Autoclaves are used for sterilization of both culture media and heat-stable supplies and the treatment of infectious waste. Many operating rooms and laboratories today use a rapid enzy-

matic indicator to monitor the sterilization process (<http://www.3m.com/healthcare>). The activity of a *Bacillus stearothermophilus* enzyme is measured by reading a fluorescent product produced by the enzymatic breakdown of a nonfluorescent substrate. Detection of the enzyme after 1 to 3 h of incubation indicates a sterilization process failure.

I. MATERIALS

A. Physical monitors (recorder chart)

1. Exposure time
2. Exposure temperature
3. Chamber pressure

B. Biological indicators (*B. stearothermophilus*)

1. Ampoule
2. Spore strip
3. Enzymatic (Attest Rapid Readout Biological Indicators and Monitoring System; 3M, St. Paul, Minn.)

C. Chemical indicators

1. Chemical-impregnated strip
2. Autoclave tape

D. Containers and packaging

1. Autoclave bags, trays, or pans
2. Metal pails
3. Linen packs

E. PPE

1. Splash goggles
2. Heat-resistant gloves

II. PROCEDURES

A. Media, supplies, and linen packs

1. Initial preparation
 - a. Loosen all caps or lids.
 - b. *Do not* fill vessels more than two-thirds full.
 - c. Place autoclave tape on items to be sterilized.
2. Load the autoclave with material to be sterilized.
 - a. Allow adequate space between objects (at least 2 in. apart).
 - b. Use test tube or other wire racks to allow the free flow of steam.
3. Close the autoclave and set the sterilization time and temperature (*see* manufacturer's instructions).
 - a. Autoclave culture media for 15 min at 121°C, with a 15-min exhaust time. Suggested autoclaving times are 18 min for 500 ml, 21 min for 1,000 ml, and 24 min for 1,500 ml. A general rule is to add 3 min more for each 500 ml of medium.
 - b. Autoclave dry-wrapped material for 25 min at 121°C with fast exhaust and a 30-min dry cycle.

II. PROCEDURES *(continued)*

4. Start the cycle and confirm that temperature and pressure monitors are functioning.
5. After the cycle has ended and the chamber pressure has reached 0 lb/in², open the door slowly.
 - a. Stand behind the door to avoid steam.
 - b. Wear eye protection and heat-resistant gloves.
 - c. Allow 20 min for contents to cool.
 - d. Handle all liquid material gently to prevent splattering of hot fluid.
6. Carefully remove material from the autoclave and place on designated area (e.g., bench top or cart) labeled “autoclaved.”
7. Tighten caps.

B. Infectious waste

1. For initial preparation, infectious waste should be clearly marked and separated from microbiological media and supplies to be sterilized.
2. Autoclave bags
 - a. Place infectious waste in double autoclave bags with biohazard labels.
 - b. Fill bags no more than three-fourths full.
 - c. Tie bags loosely or add 1 cup of water to bags before sealing (optional).
 - d. Place autoclave tape on the outside of bag.
 - e. Place the bags on autoclave pans or trays.
 - f. Place liquid waste in vessels (not to exceed two-thirds full) in pails.
3. Load autoclave bags on pans or trays or in pails to be sterilized.
4. For routine waste, set the time and temperature for 15 min at 121°C, with a 15-min exhaust time.
5. For mycobacteriology waste (e.g., stock cultures), set the time and temperature for 30 to 45 min and 121°C, with a 15-min exhaust time.
6. Proceed as outlined in item II.A above.
7. Drain excess fluid from the pans and clean them with soap and water. Allow molten agar to solidify and then discard it in normal trash.

III. LIMITATIONS OF THE PROCEDURES

- A. Steam under pressure and at high temperature presents the risks of scalding and explosion to the operator.
- B. Antineoplastic agents, toxic chemicals, or radioisotopes in waste may not be destroyed. In the microbiology laboratory, the most likely types of radiation are ¹⁴C and ³H, which can be autoclaved without any radiation hazard.
- C. Highly volatile chemicals could become vaporized and disseminated by heat and ignited by a spark from operating equipment.

IV. QUALITY CONTROL

A. Each run

1. Check the data recorder to verify correct time and temperature.
2. Check the autoclave tape, chemical indicator strip, or rapid enzymatic indicator to verify operating conditions.

B. Daily

1. Remove the sediment screen from the chamber drain hole and clean thoroughly.
2. Periodically clean accessories such as shelves, racks, and trays with soap and water.

C. Weekly

Include a biological indicator ampoule or spore strip in a routine run based on the manufacturer's instructions.

D. Troubleshooting and maintenance

Contact a technical service representative.

SUPPLEMENTAL READING

Joslyn, L. J. 2001. Sterilization by heat, p. 695–728. In S. S. Block (ed.), *Disinfection, Sterilization, and Preservation*, 5th ed. Lippincott Williams & Wilkins, Philadelphia, Pa.

15.4.3

Centrifuge

A centrifuge produces centrifugal force that is used to separate particles of various densities. In the microbiology laboratory, centrifugation is used for concentrating microorganisms and cells, separating components of body fluids or mixed sus-

pensions, and removing particulate matter. Cyto-centrifugation is also used in the laboratory as a rapid means of concentrating small volumes of body fluid specimens for staining. This procedure focuses on gen-

eral safety issues related to centrifugation. The laboratory should follow the manufacturer's recommendations for the operation and maintenance of specific instruments.

I. MATERIALS

A. Supplies

1. Disinfectants and cleaning solutions
2. Paper towels
3. Gloves, gowns, masks (for spills)

B. Equipment

1. Centrifuge
 - a. Horizontal rotor, fixed-angle rotor, microtube, etc.
 - b. Cyto-centrifuge (Shandon, Inc., Pittsburgh, Pa.)

2. Centrifuge tubes, bottles
3. Blank containers
4. Safety cups with O-rings
5. Balance (two pan)
6. Calibrated thermometer
7. Tachometer (e.g., photoelectric)

II. PROCEDURE

A. Balancing of load

1. Weigh similar items and balance to within 0.5 g.
2. Use blank tubes or containers filled with water for balancing.
3. Weigh buckets with tubes.
 - a. Add balance tubes until both buckets are equal in weight.
 - b. Distribute tubes and adapters in rotor or bucket holder in a symmetrical arrangement.
 - c. Place all buckets (empty or full) in place.

B. Containment of material

1. All specimens must be capped or covered.
2. Use nonbreakable plastic screw-cap tubes.
3. Place tubes in tightly covered safety cups or rotors (e.g., tubes containing specimens of mycobacteria and systemic fungi)
4. Use aerosol-free centrifuges if available.
5. Cyto-centrifuge (double-enclosed system)
 - a. *Do not* overfill specimen containers.
 - b. All cytospin funnels must be capped.
 - c. Open sealed heads in a biological safety cabinet (BSC).
6. Open sealed safety cups in a BSC after centrifugation.

II. PROCEDURE *(continued)***C. Operation**

1. Set appropriate time, rotation speed, temperature, and brake speed (if necessary).
2. Close and lock the top.
3. Turn the centrifuge on. For manual speed adjustment, slowly increase the speed until the desired number of revolutions per minute is reached.
4. Once the desired speed is reached, check for undue vibration.
 - a. Turn the centrifuge off if excess vibration occurs.
 - b. *Do not* apply the brake.
5. *Do not* open the top of the centrifuge until it has come to a complete stop.

III. QUALITY CONTROL**A. Each run**

1. Check tubes for cracks.
2. Check inside of carrier cups for rough walls or glass and other debris, and remove any of these from the base of the cushion.
3. Check that each load is properly balanced.
4. Check the operating temperature.
5. Clean up any spills immediately (*see* procedure 15.2.4).
 - a. Use a 10% bleach solution, and rinse surfaces thoroughly after cleaning.
 - b. Use alternative disinfectants (*see* Table 15.2.3–1).

B. Daily

1. Clean inside of the bowl with disinfectant and rinse thoroughly.
2. Refrigerated centrifuges
 - a. Allow the bowl to dry if the centrifuge is turned off at night.
 - b. Leave the top closed when the unit is under refrigeration.

C. Weekly

1. Clean and open all vents.
2. Clean and disinfect rotors, carriers, and the inside of the bowl. Rinse and dry thoroughly.

D. Monthly

1. Vacuum clean the condenser coils, fan, screens, and filters (refrigerated centrifuges).
2. Check brushes.
3. Check electrical connections.

E. Semiannually

1. Check the internal temperature of refrigerated units with calibrated thermometer.
2. Check brushes.
3. Calibrate speed with a photoelectric tachometer.

F. Annually

Have speed and temperature control recertified by qualified personnel.

IV. TROUBLESHOOTING**A. Vibration**

1. Check for proper balance.
2. Check all tube holders and buckets.
3. Check that the centrifuge is on a level surface.

B. Breakage

1. Check balance.
2. Check tubes for proper size or use.
3. Check tube holders for proper cushion.

IV. TROUBLESHOOTING*(continued)*

- C. Corks or stoppers pop off.
 - 1. Use screw-cap top.
 - 2. Use Parafilm over the stopper.
 - 3. Use clean tube holders, free of glass.
 - 4. Use lower temperature in (refrigerated) centrifuge.
- D. Fine gray dust in rotor chamber
 - 1. Thoroughly vacuum clean the chamber, and run the centrifuge empty several times.
 - 2. Clean between operations until dust is gone.

V. LIMITATIONS OF THE PROCEDURE

- A. *Do not* centrifuge large volumes of flammable liquids which could become vaporized and then be ignited by a spark from operating equipment.
- B. Concentration of infectious material for culture, such as bronchoalveolar lavage specimens, by cyto centrifugation may be performed in the routine culture area. Preparations should not produce spatters or aerosols if specimen containers are properly filled.
- C. Samples of infectious material prepared for smears by cyto centrifugation for detection of acid-fast bacilli should be pretreated with equal amounts of fresh 5% sodium hypochlorite (household bleach).

SUPPLEMENTAL READING

Saceanu, C. A., N. C. Pfeiffer, and T. McLean. 1993. Evaluation of sputum smears concentrated by cyto centrifugation for detection of acid-fast bacilli. *J. Clin. Microbiol.* **31**:2371–2374.

Laboratory personnel should be cognizant of hazards from compressed gases. A falling cylinder can cause physical injury to personnel. A gas cylinder with ruptured pressure-reducing fittings or broken valve heads can become an “unguided missile,” destroying everything in its path. Some gases may be toxic and/or flammable. If heated, cylinders may explode.

I. PROCEDURE

A. Transportation

1. *Do not* move a cylinder with a regulator attached. Valve safety covers must be tightened securely during transport.
2. *Do not* drag or roll cylinders.
 - a. Use hand trucks, dollies, carts, etc., to move cylinders.
 - b. Properly secure cylinders to hand trucks, etc.
3. *Do not* place cylinders in a horizontal position.

B. Storage

1. *Do not* accept cylinders that are marked with wired-on tags or are color coded. All cylinders must be labeled with the name of the contents and appropriate warning labels (e.g., U.S. Department of Transportation labels).
2. Secure all gas cylinders in an upright position in secure racks or to wall mounts.
3. *Do not* remove valve safety covers until pressure regulators are attached.
4. *Do not* store cylinders with or near flammable material.
5. *Do not* store cylinders with highly combustible material in the laboratory. A separate room or enclosure should be reserved for stored cylinders.
6. *Do not* store cylinders at temperatures of $>125^{\circ}\text{F}$ (55°C).
7. *Do not* discard empty cylinders.
 - a. Mark cylinders as empty and keep them secured in an upright position with safety cover in place.
 - b. Return empty or unused cylinders to the manufacturer.

C. Pressure regulators and needle valves

1. Use only designated fittings for gases indicated.
2. *Do not* use oil, grease, or lubricants on valves, regulators, or fittings. Threads and surfaces should be clean and tightly fitted.
3. *Do not* attempt to repair damaged cylinders or to force open frozen cylinder valves.
4. Use a proper-size wrench to tighten regulators.

I. PROCEDURE (*continued*)

5. Open the diaphragm control knob completely before the control valve is opened.
6. Open all valves slowly.
 - a. Stand to the side of gauges.
 - b. *Do not* force valves that stick.
7. Check all connections for leaks.
 - a. Test before and after regulators or gauges are attached.
 - b. Test piped lines before use and periodically thereafter.
 - c. Use a “snoop” or soap solution.
8. Leave valve handles attached to cylinders.
9. Regulation of gas flow rate
 - a. Use high-pressure valve on the cylinder to set the maximum rate of gas flow.
 - b. Use needle valve for fine tuning of gas flow.
10. Shut off valves on gas cylinders when not in use.

II. QUALITY CONTROL

Complete and initial the Gas Cylinder Quality Control Record worksheet after each task is completed (*see* Appendix 15.4.4-1).

SUPPLEMENTAL READING

NCCLS. 1994. *Clinical Laboratory Safety*. Document GP17-T, p. 20-22. NCCLS, Villanova, Pa.

15.4.5

Pneumatic Tube System

A safe and efficient way to transport specimens and materials from one point to another is through an automated and computerized pneumatic tube system. Such a system typically consists of carriers, sending/receiving stations, blowers, transfer

units, and a control center. The primary concern in the transportation of clinical specimens in a pneumatic tube system is leakage of the specimen into the carrier and potentially the system tubing, thus ex-

posing workers to hazardous materials. The system should be operated according to the manufacturer's instructions. All specimens must be handled in accordance with standard precautions.

I. MATERIALS

- A. Primary containers (e.g., clear plastic biohazard Ziploc bags)
- B. Secondary containers (e.g., conical, hard plastic devices which close when latches are engaged)
- C. Foam liner/packing material
- D. Laboratory requisition slips
- E. PPE

II. PROCEDURE FOR SENDING SPECIMENS

- A. Ensure that container tops are tightly secured.
- B. Place specimen in biohazard Ziploc bag and secure it.
- C. Place requisition slip in the outer pouch of the biohazard Ziploc bag.
- D. Select the appropriate foam liner/packaging material for the specimens.
 - 1. Use slotted foam for shipping Vacutainer tubes.
 - 2. Select material to provide immobility to the specimen.
- E. Place the foam liner/packaging material in the carrier.
- F. Place the biohazard Ziploc bag with specimens inside the packing material in the carrier.
- G. Secure the carrier lid tightly, making sure that no packing material is visible outside the carrier.
- H. Holding the carrier in both hands, flip it over and back in a smooth but quick fashion, and observe for movement in the carrier. If movement is detected, repeat the packing procedure until the specimen is immobile.
- I. Place the closed carrier in the dispatcher unit, select the destination address, and press send.

III. PROCEDURE FOR RECEIVING CARRIERS

- A. An incoming carrier message should be displayed on the control panel indicating that the station has been selected by a user to receive a carrier.
- B. The carrier is then dropped from the dispatcher into a bin at the station.
- C. Remove the carrier from the bin.
- D. Examine all specimens for visible contamination or breakage before removing from the secondary container.

III. PROCEDURE FOR RECEIVING CARRIERS *(continued)*

- E. If contamination is detected, the following should be carried out.
 - 1. Primary containers should be decontaminated before being sent to the work areas for testing or contents should be transferred to a clean container.
 - 2. Laboratory requisition slips should be discarded and replaced.
 - 3. Padding material should be decontaminated or discarded.
 - 4. Remove the carrier from the system for cleaning if contaminated.
 - 5. Clean contaminated material with bleach, wearing appropriate PPE.
- F. If a spill has occurred or if the leak has escaped into the system, notify maintenance personnel so that appropriate decontamination procedures may be done (e.g., use of bleach canister).
- G. Sign off the pneumatic tube system at your location so the carriers do not accumulate in the bin.

IV. QUALITY CONTROL

- A. Complete a Biohazard Spill Report (*see* Appendix 15.2.4–1) and submit it to a laboratory safety committee representative.
- B. Report improperly packaged specimens to a manager or regulatory specialist for follow-up with the sending unit.

V. LIMITATIONS OF THE PROCEDURES

- A. Approximately 95% of all system problems are a result of user error in packaging and sending specimens. Cloth towels are not acceptable as padding.
- B. Blood culture bottles are especially prone to breakage if not properly packaged.
- C. Items with screw caps, such as urine and stool containers, are prone to leakage if caps are not fastened tightly.
- D. Syringes with needles are not acceptable for transport.

15.4.6

Specimen/Microorganism Storage and Retention

Clinical specimens and microorganisms are routinely stored for extended periods of time for retrieval and testing or before shipment to other laboratories. Specimens should be stored in a secure, well-orga-

nized area separate from reagents. Microorganisms should be stored in an area with restricted access and clearly identified. All containers (e.g., tubes, vessels) should be placed in appropriate racks, baskets,

freezer boxes, or other devices to maintain them upright. Standard precautions should be followed at all times when handling these specimens as well as QC and proficiency test microorganisms.

I. ROOM TEMPERATURE STORAGE

- A. Store culture plates and capped tubes in suitable racks or baskets in the work area for 1 to 2 weeks.
- B. Store samples away from high-traffic areas (e.g., in cabinets).

II. REFRIGERATOR STORAGE

- A. Store specimens in a designated refrigerator designed for easy access and cleaning.
- B. Maintain a reasonable cleaning schedule to prevent contamination.

III. FREEZER STORAGE

- A. Place specimens or microorganisms to be frozen in containers or freezer vials designed for low-temperature storage (e.g., Protect tubes).
- B. Use plastic containers whenever possible.
- C. Fill containers to no more than two-thirds of their capacity.
- D. Freeze specimens horizontally at a 45° angle before storing them upright.
- E. Place culture tubes in a designated secondary freezer box.
- F. Remove any broken tubes in the freezer using appropriate PPE, and decontaminate the area.
 - 1. Remove and decontaminate any intact tubes.
 - 2. Place frozen specimens into a secondary container, allow to thaw, and then transfer to a new container and refreeze (if needed).
 - 3. Disinfect the freezer before further use.

IV. LIQUID NITROGEN STORAGE

- A. Handle cryogenic liquid nitrogen containers with care.
 - 1. Use insulated thermal gloves when handling any object that has been in contact with liquid nitrogen.
 - 2. Safety glasses are recommended during transfer of liquid nitrogen.
 - 3. *Do not* allow objects cooled by liquid nitrogen to touch bare skin.
- B. Cryobiological storage container
 - 1. Storage
 - a. Always store in an upright position.
 - b. Store only in areas that are fully ventilated.
 - c. Store in clean dry areas.

IV. LIQUID NITROGEN STORAGE *(continued)*

2. *Do not* roll, drag, or tip containers.
3. *Do not* vibrate, jolt, or drop a container (which might damage its vacuum insulation system).
4. *Do not* overfill containers.
5. *Do not* seal containers tightly.
6. *Do not* tamper with relief valves.
7. Use solid metal or wooden dipsticks.
8. Avoid moisture, caustic cleaners, chemicals, or other substances that might cause corrosion.

SUPPLEMENTAL READING

NCCLS. 2001. *Protection of Laboratory Workers from Occupationally Acquired Infections*. Document M29-A2. NCCLS, Wayne, Pa.

15.4.7

Other Equipment and Devices

Preventative maintenance and decontamination procedures for all instruments and devices should be performed per the manufacturer's instructions. Copies of these instructions must be available in the lab-

oratory, including biological-hazard information. All activities performed on these devices should follow standard precautions. Prior to maintenance or repair, contaminated devices or the portion to be

worked on should be decontaminated. All repairs should be performed by properly trained personnel. Service personnel need to wear the appropriate PPE and follow the laboratory safety policies.

15.5

Packaging and Shipping Infectious Substances

Clinical specimens for microbiological testing are broadly regulated for transportation based on the assumption that those materials most likely to contain an etiologic agent will be treated like infectious substances. Any specimen that is likely to contain a pathogen is considered a high-risk specimen and is tightly controlled. Packaging that includes the Shipper's Declaration for Dangerous Goods (DGR) document is acceptable under all regulations, and this labeling is required by

many couriers. The International Air Transport Association (IATA) (Montreal, Canada) regulations are satisfactory for most shippers. The reader should be aware that the U.S. Department of Transportation (USDOT) is proposing to change the current standards for ground transportation of infectious substances to be consistent with IATA regulations (see the website <http://www.hazmat.dot.gov/rulemake.htm#nprm>). Shippers using private commercial carriers should consult them for

shipping requirements. This procedure complies with IATA regulations to ensure maximum protection for those handling the shipment of infectious substances both in transit and after it arrives at the laboratory (IATA infectious substance shipping guidelines can be ordered at <http://www.iataonline.com>). Documentation of training, including a written test, for individuals responsible for packing and shipping specimens is required by the IATA and USDOT.

I. SPECIMENS

- A. Clinical specimens should be submitted in screw-cap glass, metal, or plastic tubes or vials (not to exceed 50 ml).
- B. Bacterial cultures should be submitted as agar slants, agar stabs, or lyophilized cultures or on swab transport devices.

II. MATERIALS

- A. Leakproof containers (caps or lids taped)
 - 1. Primary container (can be transport medium tube with organism)
 - 2. Secondary container (can be outer canister)
- B. Outer shipping container (can be cardboard or Styrofoam)
- C. Shock-absorbent material
- D. United Nations (UN)-certified containers with proper labels and instructions can be purchased.
 - 1. AIR SEA ATLANTA (<http://www.airseatlanta.com>)
 - 2. COM-PAC International (<http://www.com-pac.com>)
 - 3. EXAKT Technologies, Inc. (<http://www.exaktpac.com>)
 - 4. SAF-T-PAK, Inc. (<http://www.safetpak.com>)
- E. Diamond-shaped label "INFECTIOUS SUBSTANCE 6" (Fig. 15.5-1)
- F. Shipper's DGR (Fig. 15.5-2)
- G. Miscellaneous Dangerous Goods, Class 9 diamond label (Fig. 15.5-3)
- H. U.S. Public Health Service label (Fig. 15.5-4)
- I. Postal-service label or other shipping document
- J. Plastic sleeve for placement of shipper's DGR

III. PROCEDURE

- A. Provide at least two completed copies of DGR forms to the airlines.
 - 1. Fill in the shipper's box with the name, address, and phone number of the center shipping the material.
 - 2. Fill in the airports of departure and destination.

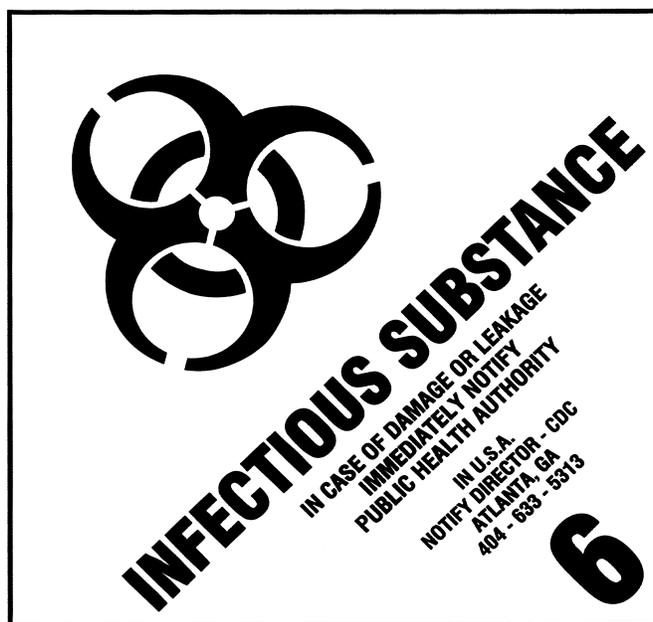

Figure 15.5-1 International label for packages containing infectious substances or etiologic agents.

III. PROCEDURE (continued)

3. Cross out the box labeled "RADIOACTIVE."
 4. Cross out the box labeled "PASSENGER AND CARGO AIRCRAFT."
 5. Under "Proper Shipping Name" write "Infectious Substances Affecting Humans" and list each isolate type (genus and species) included in the box.
 6. Write "6.2" under "Class or Division."
 7. Write "UN 2814" under "UN or ID No."
 8. Write "None" under "Subsidiary Risk."
 9. Under "Quantity and type of packing" write "1 Fiberboard box × ___ ml."
 10. Under "Additional Handling Information" write "PRIOR ARRANGEMENTS AS REQUIRED BY IATA DANGEROUS GOODS REGULATIONS 1.3.3.1 HAVE BEEN MADE." Include a 24-h emergency telephone contact number of sender.
 11. Each copy must have an original signature. Complete "Name/Title of Signatory" and "Place and Date."
 12. Fold both forms together in half lengthwise and again by width. Place forms in a clear sleeve and attach the sleeve to the outer container. Do not seal the sleeve.
- B. Inside packaging**
1. Seal the tube or vial with waterproof tape.
 2. Pack absorbent material around the tube or vial. If tubes are to be shipped, wrap each tube individually with paper towels.
 3. Place tube(s) in a watertight secondary container. Add enough absorbent material between the primary and secondary containers to absorb the total fluid volume of the transport medium.
 4. Seal the secondary container and place in an outer shipping container.
 5. Provide list of organisms being shipped.
 6. Seal the outside shipping container securely.

SHIPPER'S DECLARATION FOR DANGEROUS GOODS

Shipper		Air Waybill No	
Consignee		Page of Pages Shipper's Reference Number	
Two completed and signed copies of this Declaration must be handed to the operator.		WARNING Failure to comply in all respects with the applicable Dangerous Goods Regulations may be in breach of the applicable law, subject to legal penalties. This Declaration must not, in any circumstances, be completed and/or signed by a consolidator, a forwarder or an IATA cargo agent.	
TRANSPORT DETAILS			
This shipment is within the limitations prescribed for (<i>delete non-applicable</i>)		Airport of Departure	
PASSENGER AND CARGO AIRCRAFT	CARGO AIRCRAFT ONLY		
Airport of Destination		Shipment type: (<i>delete non-applicable</i>) <input type="checkbox"/> NON-RADIOACTIVE <input type="checkbox"/> RADIOACTIVE	
NATURE AND QUANTITY OF DANGEROUS GOODS			
Dangerous Goods Identification			
Proper Shipping Name	Class or Divi- sion	UN or ID No.	Pack- ing Group
			Subsi- diary Risk
			Quantity and Type of packing
			Packing Inst.
			Authorization
Additional Handling Information			
Emergency Telephone Number			
I hereby declare that the contents of this consignment are fully and accurately described above by the proper shipping name, and are classified, packaged, marked, and labelled/placarded, and are in all respects in proper condition for transport according to applicable international and national governmental regulations.			Name/Title of Signatory Place and Date Signature (<i>see warning above</i>)
IF ACCEPTABLE FOR PASSENGER AIRCRAFT, THIS SHIPMENT CONTAINS RADIOACTIVE MATERIAL INTENDED FOR USE IN, OR INCIDENT TO, RESEARCH, MEDICAL DIAGNOSIS, OR TREATMENT			

Figure 15.5-2 DGR form required by IATA and U.S. Postal Service to accompany air shipments of infectious substances.

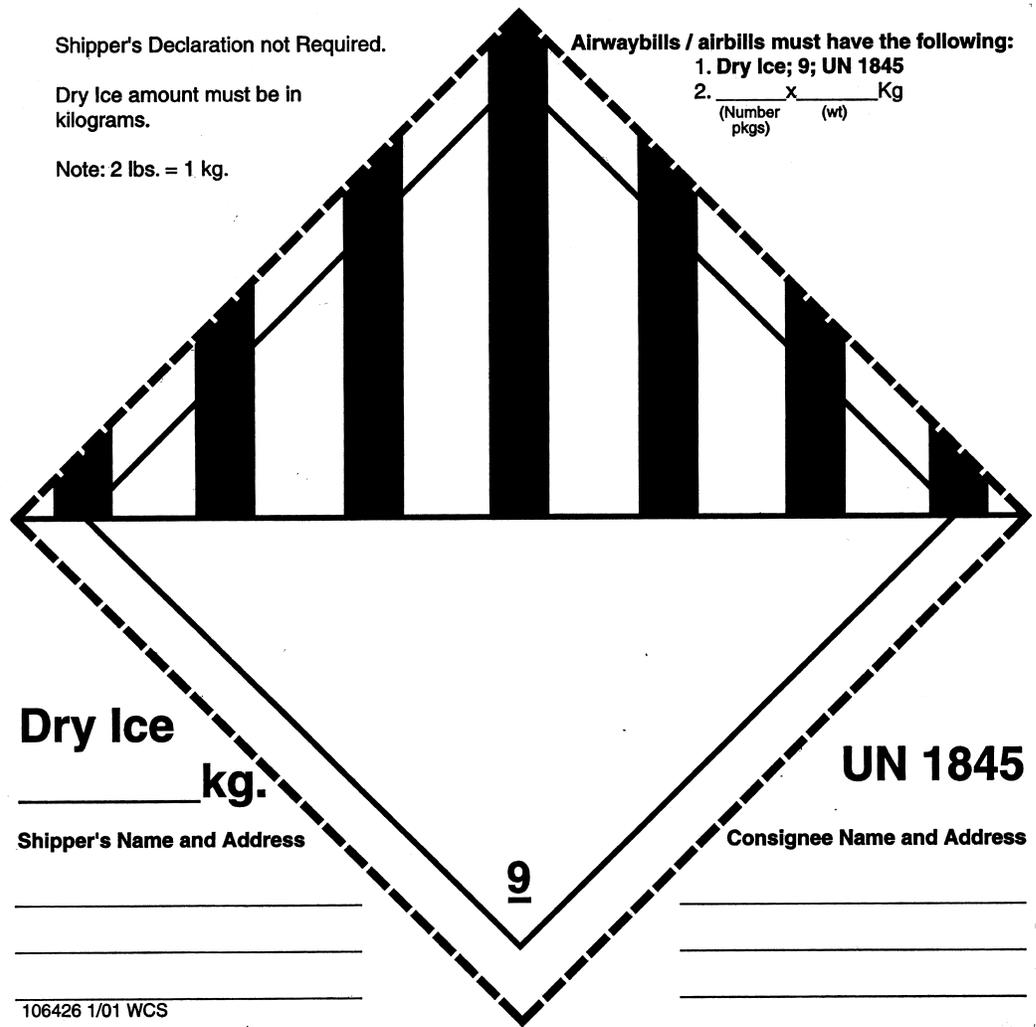

Figure 15.5-3 Class 9 diamond label for dry ice showing UN 1845 and the weight of the dry ice.

Figure 15.5-4 U.S. Public Health Service label required by U.S. Postal Service on packages containing etiological agents.

III. PROCEDURE *(continued)*

- C. Outside-box labeling
1. Attach postal-service label or shipping document with name, address, and phone number of the recipient.
 2. Label all organisms contained in the box.
 3. Label “Infectious Substances, Affecting Humans UN 2814.”
 4. Label contact person name and phone number.
 5. Attach the DGR.
 6. Attach a diamond-shaped label, “INFECTIOUS SUBSTANCE 6.”
 7. If transported media are liquid, use “up arrows” to show the correct orientation for shipment.
 8. Attach U.S. Public Health Service label as specified by U.S. Postal Service Regulations.

IV. SHIPPING FROZEN SPECIMENS

- A. If dry ice is used as a refrigerant, it must be placed outside the secondary container.
- B. Affix the “Infectious Substance” description label (UN 2814) to the outer container.
- C. Affix the “UN 1845” label (Fig. 15.5–3) to outer container and record the amount of dry ice in kilograms (also record weight on air bill).
- D. Record under “Nature and Quantity of Dangerous Goods” on the shipper’s DGR.
1. Write “Dry Ice” for “Proper Shipping Name.”
 2. Write “9” for “Class or Division.”
 3. Write “UN 1845” for “UN or ID No.”
 4. Write “III” for “Packing Group.”
 5. Write “__ kgs, all packed in 1 fiberboard box” for “Quantity and Type of packing.”
 6. Write “904” for “Packing Inst.”
- E. Affix the “Cargo Aircraft Only” label to outer container.
- F. Seal the outer container with clear packing tape, being careful not to cover any of the labels.

V. PROCEDURE NOTES

- A. A shipper’s DGR is not required for shipping diagnostic specimens.
- B. If more than 50 ml of an infectious substance is shipped, a “Cargo Aircraft Only” label must be added to the outer container.
- C. When possible, ship material so that it will arrive at its destination at the beginning or middle of the workweek.
- D. On the day of shipment, fax a copy of the air bill or call recipient for advance notification of shipment.

VI. SOURCES OF INFORMATION

- A. For specimens sent by mail, follow U.S. Postal Service Dangerous Goods Regulations.
- B. For specimens sent by ground courier, follow USDOT regulations.
- C. For specimens sent by air, follow IATA and International Civil Aviation Organization (Montreal, Canada) regulations.

VII. LIMITATIONS OF THE PROCEDURE

If shipping BSL 4 pathogens (e.g., Ebola virus), dangerous stock cultures, or agents used for bioterrorism (e.g., pathogens and toxins causing anthrax, botulism, brucellosis, plague, Q fever, and tularemia), contact CDC for special requirements.

15.6

Management of Laboratory Accidents

Despite improved control measures (engineering controls, safe work practices, and PPE), laboratory workers remain at risk for acquiring laboratory-associated infections. Recent cases of fatal meningococemia in clinical laboratory workers underscore the potential risks of handling clinical samples (2). Every laboratory (e.g., anatomic pathology, clinical diag-

nostic, reference, and research laboratories) should implement a biosafety plan. The essential components of the plan should include written procedures to reduce risks of occupational exposure and mandatory training, health assessment of employees, and record keeping of all exposures and treatments. A risk assessment of the procedures carried out on samples,

including the frequency of positive samples, should be determined. The potential risk of disease should also be evaluated along with the availability of postexposure prophylaxis (PEP) and preventive vaccines. The benefits and side effects of PEP and immunization must also be considered.

I. MANAGEMENT OF OCCUPATIONAL BLOOD-BORNE EXPOSURES

-
- A. Provide immediate care to the exposure site.
 1. Wash wounds and skin with soap and water.
 2. Flush mucous membranes and conjunctiva sites with water.
 - B. Report the incident to a supervisor and complete an exposure report (Appendix 15.6–1).
 1. Record date and time of exposure.
 2. Record the procedure performed, including when, where, and how the exposure occurred and with what type of device, including brand name.
 3. Record details of the exposure, including route, body substance involved, volume, and duration of contact.
 4. Record information regarding source person, human immunodeficiency virus (HIV) status, stage of disease, history of antiretroviral therapy, and viral load status, if known.
 5. Record information about counseling, postexposure management, and follow-up.
 - C. Evaluate the risk of exposure.
 1. Appraise type of fluid (e.g., blood, visibly bloody fluid, concentrated virus).
 2. Appraise type of exposure (e.g., percutaneous, mucous membrane, or non-intact skin, bite resulting in blood exposure).
 - D. Evaluate the exposure source.
 1. Assess the risk of infection using available information. If the source of the exposure is unknown, further evaluation is required.
 2. Test known sources for HBsAg, anti-hepatitis C virus (anti-HCV), and HIV antibody (consider rapid testing if available).
 3. *Do not* test discarded needles, syringes, and other devices for virus contamination.
 - E. Evaluate the exposed person.

Assess the immune status for HBV infection using history of hepatitis B vaccination and tests for anti-HBs antibody.
-

I. MANAGEMENT OF OCCUPATIONAL BLOOD-BORNE EXPOSURES *(continued)*

- F. Provide PEP based on the risk of infection transmission and institutional policy.
 - 1. HBV: see Appendix 15.6–2 (3)
 - 2. HCV: PEP is not recommended.
 - 3. HIV: see Appendixes 15.6–3 and 15.6–4 (3)
 - a. Initiate PEP as soon as possible (within a few hours of exposure).
 - b. Offer pregnancy testing to all women of childbearing age not known to be pregnant.
 - c. Seek consultation if viral resistance is suspected.
 - d. Administer PEP for 4 weeks if tolerated.
- G. Perform follow-up testing and provide counseling.
 - 1. Advise exposed workers to seek medical evaluation for any acute illness occurring during the follow-up periods.
 - 2. HBV exposures
 - a. Test for anti-HBs 1 to 2 months after the last dose of vaccine was administered if only a vaccine was given.
 - b. *Do not* follow up exposed workers if immune to hepatitis B or given hepatitis B immune globulin (HBIG) PEP.
 - 3. HCV exposures
 - a. Perform baseline and follow-up testing for anti-HCV and alanine aminotransferase activity 4 to 6 months after the exposure.
 - b. Perform HCV RNA testing at 4 to 6 weeks, if an earlier diagnosis for HCV infection is desired.
 - c. Confirm repeatedly reactive anti-HCV EIAs with supplemental tests.
 - 4. HIV exposures
 - a. Perform HIV antibody testing for at least 6 months postexposure.
 - b. Perform HIV antibody testing if an illness compatible with an acute retroviral syndrome occurs.
 - c. Advise exposed worker to use precautions to prevent secondary transmission during the follow-up period.
 - d. Evaluate exposed worker taking PEP within 72 h after exposure and monitor for drug toxicity for at least 2 weeks.

II. MANAGEMENT OF OTHER LABORATORY-ASSOCIATED EXPOSURES

- A. Provide immediate care to the exposed sites.
 - 1. Wash wounds and skin with soap and water.
 - 2. Flush contaminated mucous membranes and conjunctiva sites with water.
 - 3. Rinse contaminated mouth with an antiseptic mouthwash.
- B. Report the incident to a supervisor according to institutional policy (Appendix 15.6–1). Immediate reporting of an accident will help establish a time relationship if infection develops and allow preventative measures to be taken.
- C. Evaluate the risk of exposure.
 - 1. Appraise type of infectious material (e.g., clinical specimens, stock cultures, infectious waste).
 - 2. Appraise type of exposure (e.g., inhalation, ingestion, direct contact, or percutaneous inoculation).
 - 3. Appraise the volume of material or concentration of microorganisms tested.
- D. Evaluate the exposed worker.
 - 1. Assess the immune status for infection using history of vaccination or tests (e.g., tuberculin skin test). Specific recommendations for the immunization of laboratory workers in high-risk situations are listed in Appendix 15.6.5.
 - 2. Collect baseline serum and follow-up serum for testing for specific agents when appropriate.

II. MANAGEMENT OF OTHER LABORATORY-ASSOCIATED EXPOSURES *(continued)*

- E. Provide medical evaluation and follow-up.
 1. Seek medical evaluation by an occupational health or private physician.
 2. Exposed workers are advised to seek medical attention for any acute illness during the follow-up period.
 3. Receive appropriate postexposure treatment and prophylaxis. Specific recommendations for exposure treatment and prophylaxis depend on the infectious agent and the assessment of the risk of infection (1).
- F. Analyze incident reports.
 1. Maintain all written records (e.g., accident reports, sharps exposure log) following any exposure to infectious agents.
 2. Review accident report data to identify any common patterns and eliminate risk factors.
 3. Develop a correct action plan to prevent or minimize future incidents.

APPENDIX 15.6-1

Employee Accident and Exposure Report

Instructions for use:

Employee: 1) Fill out completely and promptly—within 24 hours. 2) Take report to supervisor for signature. 3) Take/mail form to your campus Employee Occupational Health Services (EOHS).

Supervisor: 1) Complete supervisor section and sign report. 2) Retain copy for your file. 3) Send employee for medical care, if requested.

Medical Care: 1) If treatment is required, employee to report to EOHS (or emergency room [ER] if EOHS closed) with complete report. 2) If no treatment is requested, mail form to your campus EOHS.

Blood and Body Fluid Exposures and Needle Sticks: Bring completed form to your campus EOHS for evaluation.

Employee Information <i>(to be completed by the employee)</i>	Name (Print): _____				
	Signature: _____		Date Signed: _____

APPENDIX 15.6–2

Recommended PEP for exposure to HBV^a

Vaccination and antibody response status of exposed workers ^b	Treatment		
	Source HBsAg positive	Source HBsAg negative	Source unknown or not available for testing
Unvaccinated	HBIG ^c × 1 and initiate HB vaccine series	Initiate HB vaccine series	Initiate HB vaccine series
Previously vaccinated			
Known responder ^d	No treatment	No treatment	No treatment
Known nonresponder ^e	HBIG × 1 and initiate revaccination or HBIG × 2 ^f	No treatment	if known high-risk source, treat as if source were HBsAg positive
Antibody response unknown	Test exposed person for anti-HBs 1. If adequate, ^g no treatment is necessary 2. If inadequate, ^g administer HBIG × 1 and vaccine booster	No treatment	Test exposed person for anti-HBs 1. If adequate, ^g no treatment is necessary 2. If inadequate, ^g administer vaccine booster and recheck titer in 1–2 months

^a From **Centers for Disease Control and Prevention**. 2001. Updated U.S. Public Health Service guidelines for the management of occupational exposures to HBV, HCV, and HIV and recommendations for postexposure prophylaxis. *Morb. Mortal. Wkly. Rep.* 50(RR-11):1–42.

^b Persons who have previously been infected with HBV are immune to reinfection and do not require PEP.

^c Dose is 0.06 ml/kg intramuscularly.

^d A responder is a person with adequate levels of serum antibody to HBsAg (i.e., anti-HBs ≥10 mIU/ml).

^e A nonresponder is a person with inadequate response to vaccination (i.e., serum anti-HBs <10 mIU/ml).

^f The option of giving one dose of HBIG and reinitiating the vaccine series is preferred for nonresponders who have not completed a second three-dose vaccine series. For persons who previously completed a second vaccine series but failed to respond, two doses of HBIG are preferred.

APPENDIX 15.6–3

Recommended HIV PEP for percutaneous injuries^a

Exposure type	Recommendation with the following infection status of source				
	HIV positive, class 1 ^b	HIV positive, class 2 ^b	Source with unknown HIV status ^c	Unknown source ^d	HIV negative
Less severe ^e	Recommend basic 2-drug PEP	Recommend expanded 3-drug PEP	Generally, no PEP warranted; however, consider basic 2-drug PEP ^f for source with HIV risk factors ^h	Generally, no PEP warranted; however, consider basic 2-drug PEP ^f in settings where exposure to HIV-infected persons is likely	No PEP warranted
More severe ^g	Recommend expanded 3-drug PEP	Recommend expanded 3-drug PEP	Generally, no PEP warranted; however, consider basic 2-drug PEP ^f for source with HIV risk factors ^h	Generally, no PEP warranted; however, consider basic 2-drug PEP ^f in settings where exposure to HIV-infected persons is likely	No PEP warranted

^a From **Centers for Disease Control and Prevention**. 2001. Updated U.S. Public Health Service guidelines for the management of occupational exposures to HBV, HCV, and HIV and recommendations for postexposure prophylaxis. *Morb. Mortal. Wkly. Rep.* 50(RR-11):1–42.

^b HIV positive, class 1, asymptomatic HIV infection or known low viral load (e.g., <1,500 RNA copies/ml); HIV positive, class 2, symptomatic HIV infection, AIDS, acute seroconversion, or known high viral load. If drug resistance is a concern, obtain expert consultation. Initiation of PEP should not be delayed pending expert consultation, and because expert consultation alone cannot substitute for face-to-face counseling, resources should be available to provide immediate evaluation and follow-up care for all exposures.

^c E.g., deceased source person with no samples available for HIV testing.

^d E.g., a needle from a sharps disposal container.

^e E.g., solid needle and superficial injury.

^f The designation “consider PEP” indicates that PEP is optional and should be based on an individualized decision between the exposed person and the treating clinician.

^g E.g., large-bore hollow needle, deep puncture, visible blood on device, or needle used in patient’s artery or vein.

^h If PEP is offered and taken and the source is later determined to be HIV negative, PEP should be discontinued.

APPENDIX 15.6–4Recommended HIV PEP for mucous membrane exposures and nonintact skin^a exposures^b

Exposure type	Recommendation with the following infection status of source				
	HIV positive, class 1 ^c	HIV positive, class 2 ^c	Source with unknown HIV status ^d	Unknown source ^e	HIV negative
Small volume ^f	Consider basic 2-drug PEP ^g	Recommend basic 2-drug PEP	Generally, no PEP warranted; however, consider basic 2-drug PEP ^g for source with HIV risk factors ^h	Generally, no PEP warranted; however, consider basic 2-drug PEP ^g in settings where exposure to HIV-infected persons is likely	No PEP warranted
Large volume ^f	Recommend basic 2-drug PEP	Recommend expanded 3-drug PEP	Generally, no PEP warranted; however, consider basic 2-drug PEP ^g for source with HIV risk factors ^h	Generally, no PEP warranted; however, consider basic 2-drug PEP ^g in settings where exposure to HIV-infected persons is likely	No PEP warranted

^a For skin exposures, follow-up is indicated only if there is evidence of compromised skin integrity (e.g., dermatitis, abrasion, or open wound).^b From **Centers for Disease Control and Prevention**. 2001. Updated U.S. Public Health Service guidelines for the management of occupational exposures to HBV, HCV, and HIV and recommendations for postexposure prophylaxis. *Morb. Mortal. Wkly. Rep.* 50(RR-11):1–42.^c HIV positive, class 1, asymptomatic HIV infection or known low viral load (e.g., <1,500 RNA copies/ml); HIV positive, class 2, symptomatic HIV infection, AIDS, acute seroconversion, or known high viral load. If drug resistance is a concern, obtain expert consultation. Initiation of PEP should not be delayed pending expert consultation, and because expert consultation alone cannot substitute for face-to-face counseling, resources should be available to provide immediate evaluation and follow-up care for all exposures.^d E.g., deceased source person with no samples available for HIV testing.^e E.g., splash from inappropriately disposed blood.^f I.e., a few drops.^g The designation “consider PEP” indicates that PEP is optional and should be based on an individualized decision between the exposed person and the treating clinician.^h If PEP is offered and taken and the source is later determined to be HIV negative, PEP should be discontinued.ⁱ I.e., major blood splash.**APPENDIX 15.6–5**Immunization available for laboratory workers in special circumstances^a

Generic name	Primary and booster dose schedule	Indications	Major precautions or contraindications
BCG vaccine (tuberculosis)	One percutaneous dose of 0.3 ml; no booster dose recommended	Not routinely indicated. Laboratory personnel who process large volumes of specimens from which <i>Mycobacterium tuberculosis</i> is isolated or high proportion of <i>M. tuberculosis</i> resistant to isoniazid and rifampin	Immunocompromised state and pregnancy
Hepatitis A vaccine	Two doses i.m., either (HAVRIX) 6–12 mo apart or (VAQTA) 6 mo apart	Not routinely indicated. Laboratory personnel who work with HAV-infected primates or with HAV in a research setting	History of anaphylactic reaction to alum or the preservative 2-phenoxethanol. Vaccine safety in pregnant women has not been evaluated; risk to fetus is likely low and should be weighed against the risk of hepatitis A in women at high risk
Meningococcal polysaccharide vaccine (quadrivalent A, C, W 135, and Y)	One dose in volume and by route specified by manufacturer; need for boosters is unknown	Not routinely indicated. Research, industrial, and clinical laboratory personnel who are routinely exposed to <i>Neisseria meningitidis</i> in solutions that may be aerosolized	Vaccine safety in pregnant women has not been evaluated; vaccine should not be given during pregnancy unless risk of infection is high

APPENDIX 15.6–5 (continued)Immunization available for laboratory workers in special circumstances^a (continued)

Generic name	Primary and booster dose schedule	Indications	Major precautions or contraindications
Polio vaccine	IPV, two doses s.c. given 4–8 wk apart followed by 3rd dose 6–12 mo after 2nd dose; booster doses may be IPV or OPV	Laboratory personnel handling specimens that may contain wild poliovirus	History of anaphylactic reaction after receipt of streptomycin or neomycin; safety in pregnant women has not been evaluated.
Rabies vaccine	Primary, HDCV or RVA, i.m., 1.0 ml (deltoid area), one each on days 0, 7, 21, and 28, or HDCV, i.d., 1.0 ml, one each on days 0, 7, 21, and 28; booster, HDCV or RVA, i.m., 0.1 ml (deltoid area), day 0 only, or HDCV, i.d., 0.1 ml, day 0 only	Laboratory personnel who work with rabies or infected animals in diagnostic or research activities	The frequency of booster doses should be based on frequency of exposure.
Tetanus and diphtheria (Td) vaccine	Two doses i.m. 4 wk apart; 3rd dose 6–12 mo after 2nd dose; booster every 10 yr	All adults; tetanus prophylaxis in wound management	First trimester of pregnancy; history of a neurologic reaction or immediate hypersensitivity reaction. History of (Arthustype) reaction after previous dose of Td vaccine should not be given further routine or emergency dose of Td for 10 yr
Typhoid vaccine (i.m., s.c., and oral)	i.m. vaccine: one 0.5 ml dose, booster dose of 0.5 ml every 2 yr (Vi capsular polysaccharide). s.c. vaccine: Two 0.5-ml doses, ≥ 4 wk apart, booster 0.5 ml s.c. or 0.1 ml i.d. every 3 yr if exposure continues. Oral vaccine: four doses on alternate days; (Ty21a) vaccine manufacturer's recommendation is revaccination with the entire four-dose series every 5 yr.	Personnel in microbiology laboratories who frequently work with <i>Salmonella enterica</i> serovar Typhi	Severe local or systemic reaction to a previous dose of typhoid vaccine; Ty21a vaccine should not be given to immunocompromised personnel or individuals receiving antimicrobial agents
Vaccinia vaccine (smallpox)	One dose administered with a bifurcated needle; boosters every 10 yr	Laboratory personnel who directly handle cultures of or animals contaminated with recombinant vaccinia viruses or orthopox viruses that infect humans	Pregnancy, presence or history of eczema, or immunocompromised status in potential vaccinees or in their household contacts

^a Modified from **Centers for Disease Control and Prevention**. 1997. Immunization of health-care workers: recommendations of the Advisory Committee on Immunization Practices (ACIP) and the Hospital Infections Control Practices Advisory Committee (HICPAC). *Morb. Mortal. Wkly. Rep.* **46**(RR-18):1–42. Abbreviations: HDCV, human diploid cell rabies vaccine; RVA, rabies vaccine absorbed; IPV, inactivated poliovirus vaccine; OPV, oral poliovirus vaccine; i.d., intradermally; i.m., intramuscularly; s.c., subcutaneously.

I. PLAN DEVELOPMENT

For effective and efficient management of infectious wastes, a comprehensive waste management plan is essential in order to ensure the safety of the employees handling the waste, compliance with the various regulatory requirements (14, 17, 18, 20), meeting the standards of the JCAHO (11) and the guidelines of other professional groups such as the NCCLS (13), and implementation of cost-effective strategies for waste disposal. In developing a comprehensive plan for infectious-waste management, consider the following factors because of the constraints that they impose.

A. Regulatory requirements

1. Federal regulations
 - a. Comply with the requirements in OSHA's standard for exposure to blood-borne pathogens (14) that apply to infectious ("regulated") waste, especially those pertaining to contaminated sharps, sharps containers, other regulated waste, and hazard communication.
 - b. Comply with the requirements in the U.S. Department of Transportation's (USDOT's) regulations for transport of hazardous materials that apply to intrastate and interstate transport of "regulated medical waste," especially those pertaining to packaging and labeling (17, 18).
2. Federal guidelines
 - a. Follow CDC guidelines for the management of infectious wastes (1–4).
 - b. Follow CDC and NIH guidelines for the management of infectious wastes from microbiological and biomedical laboratories (5).
3. State regulations
Comply with state regulations that pertain to infectious-waste management and transport (e.g., definitions and requirements for packaging and labeling, transport, and treatment).
4. Local ordinances
Comply with local ordinances that pertain to infectious-waste management (e.g. restrictions on wastewater discharges and landfill disposal).

B. Management of other wastes

1. Microbiology laboratories generate various types of wastes, including infectious waste, chemical waste (some of which is probably hazardous per Resource Conservation and Recovery Act of 1976 regulations), radioactive waste, and wastes with mixed hazards, in addition to general trash and wastewater.
2. Institute an overall management system, with the infectious-waste management plan an integral part of the system (9, 13, 15).

I. PLAN DEVELOPMENT*(continued)***C. Availability of treatment equipment and services**

1. On-site treatment option. Review available treatment equipment (9).
 - a. Will it meet regulatory requirements? (For example, does your state require destruction of the waste, and if so, does the available equipment both treat and destroy the waste?)
 - b. How much of the infectious-waste stream can it treat? Is the capacity sufficient?
 - c. What are the operating and maintenance costs?
 - d. Is use of this equipment cost-effective?
2. Off-site treatment option. Consider the following.
 - a. Is such a service available?
 - b. Is this an appropriate option?
 - c. What are the reliability and record of the vendor(s) offering such service?
3. Decision factors. Determine the following.
 - a. What are the relative costs of on-site and off-site treatments?
 - b. What are the liability considerations for your institution?

D. Waste minimization

1. Waste minimization decreases the quantities of infectious waste generated and/or the quantities of waste that must be managed as infectious, with a resultant reduction in the costs of infectious-waste management, handling, treatment, and disposal.
2. Institute waste minimization techniques (8), including the following.
 - a. Define infectious wastes precisely.
 - b. Separate waste streams at the source (i.e., point of discard).
 - c. Segregate the infectious-waste stream throughout subsequent handling.
 - d. Use new technology such as test miniaturization.
 - e. Replace products using those that generate less waste.
 - f. Reuse and recycle wastes.
 - g. Treat wastes on-site.

II. MANAGEMENT PLAN

The elements of a comprehensive infectious-waste management plan are as follows.

A. Identification of infectious wastes

1. Institute a clear policy on waste identification. Such a policy will accomplish the following.
 - a. It will help ensure that all infectious waste are directed into the infectious-waste stream.
 - b. It will avoid risk and liability from infectious wastes that are not managed properly.
 - c. It will keep noninfectious wastes out of the infectious-waste stream and thereby to eliminate the cost of unnecessarily managing as infectious other wastes that do not need such management.
2. Consult various definitions of infectious waste in the OSHA blood-borne-pathogen regulations (14), the USDOT regulations (18), and the Environmental Protection Agency (EPA) regulations (20); the definitions in the guidelines issued by the CDC (1–4, 7), CDC and NIH (5), and EPA (17); and discussions in the literature (6, 9, 10, 15).
3. Define precisely the types of laboratory wastes that are managed as infectious.
 - a. Human blood and blood products
 - (1) All human blood, serum, plasma, and blood products
 - (2) Blood-contaminated tubes, microscope slides, and coverslips
 - (3) Blood-soaked bandages

II. MANAGEMENT PLAN (continued)

- b. Contaminated waste from patient care
Suction canisters, tubing, and hemodialysis wastes
 - c. Cultures and stocks of infectious waste
 - d. Other contaminated laboratory waste
 - (1) Specimens and containers (cups, bottles, tubes, and flasks)
 - (2) Culture plates and devices used to transfer, inoculate, and mix cultures (swabs, pipettes, etc.)
 - (3) Diagnostic-kit components
 - (4) PPE grossly contaminated with blood, body secretions, or cultures (gloves, masks, gowns, or coats)
 - e. Contaminated sharps
 - (1) Hypodermic needles, syringes, and scalpel blades
 - (2) Disposable pipettes, capillary tubes, microscope slides, coverslips, and broken glass
 - f. Pathology waste
 - (1) Body tissue, organs, and body parts
 - (2) Body fluids removed during surgery, autopsy, or biopsy
 - g. Discarded live and attenuated vaccines
 - h. Contaminated animal waste, including carcasses, body parts, and bedding.
- B. Waste discard**
- 1. Use distinctive containers appropriate for the type of waste.
 - a. Place sharp objects directly into impervious, rigid, and puncture-resistant containers and plastic bags (“red bags”) for most other types of infectious waste.
 - b. Place glass and liquids in disposable cardboard containers and leakproof boxes or containers with secure lids.
 - c. Comply with the OSHA requirements for container specifications and labeling and placement of sharps containers (14).
 - 2. Institute source separation by a user knowledgeable about the nature of the waste directly into the specific container that is designated for that particular type of waste (e.g., general trash or infectious waste).
 - a. Eliminates the need for subsequent sorting of the waste.
 - b. Avoids hazards and expense of waste sorting.
 - 3. Segregate mixed waste (infectious and radioactive or infectious and toxic chemical waste) and direct it to the appropriate treatment procedure based on the relative severity of the hazards.
- C. Waste handling and collection**
- 1. Seal waste containers before their removal from point of use.
 - 2. Establish schedule for emptying, removal, and replacement of waste containers.
 - 3. Use collection carts that are appropriate for various types of waste containers.
 - 4. Determine best times and routes for movement of waste collection carts.
 - 5. Disinfect waste collection carts routinely.
- D. Waste storage**
- 1. Treat all infectious waste as soon as possible.
 - 2. When necessary, store the waste until it can be treated or shipped off-site for treatment.
 - 3. Set aside a separate storage area for infectious wastes.
 - 4. Post biohazard signs.
 - 5. Limit access to authorized personnel.
 - 6. Comply with state regulations that specify storage conditions (e.g., minimum temperature and maximum duration).

II. MANAGEMENT PLAN*(continued)***E. Waste treatment (6, 9, 10, 12, 16)**

1. Select treatment technology(ies) appropriate to types and quantities of infectious waste.
2. Use traditional treatment technologies.
 - a. Steam sterilization.
 - b. Incineration
3. Use alternative treatment technologies.
 - a. Chemical agents (sodium hypochlorite, chlorine dioxide, or peracetic acid).
 - b. Microwaves
 - c. Dry heat
 - d. Radio waves
 - e. Infrared radiation
4. Use combination treatment technologies.
 - a. A mechanical process (such as shredding) before treatment to facilitate treatment
 - b. A mechanical process (such as compaction) after treatment to facilitate subsequent handling
 - c. Sharps destruction as part of the treatment process to eliminate risk of physical injury
 - d. Rendering pathological wastes unrecognizable prior to disposal because of aesthetic considerations
5. Comply with state regulations requiring the following.
 - a. That treatment equipment be tested and certified
 - b. That medical wastes be unrecognizable at time of disposal

F. Disposal of untreated infectious waste

Two options may be available for disposal of untreated infectious waste depending on local ordinances.

1. Landfill disposal
Meet any restrictions imposed by the locality or the landfill operator (e.g., a requirement that the waste not be recognizable as medical waste)
2. Sewer disposal
 - a. Prevent employee exposure to splashing and aerosols that can be generated when liquid infectious wastes are poured down the drain.
 - b. Meet the parameters set by the local publically owned treatment works for wastewater constituents.

G. Off-site waste treatment

1. Consider the factors listed in item I.C.
2. Properly package the waste for transport to the facility.
 - a. Pack plastic bags in rigid containers (e.g., plastic barrels or heavy cartons).
 - b. Transport in closed leakproof dumpsters or trucks.
 - c. Mark containers with universal biohazard symbol.

H. Contingency planning

1. Plan for treatment alternatives before the need arises.
2. Develop contingency plans that can be implemented when necessary.
3. Consider various alternatives.
 - a. A mutual agreement with another generator
 - b. Provision for ample storage space
 - c. Arrangements for use of a vendor's services for off-site treatment on an as-needed basis

II. MANAGEMENT PLAN (continued)

I. Emergency response

1. Incorporate emergency response procedures in the waste management plan.
2. Specify procedures for the following.
 - a. Delineation of the affected area
 - b. Use of PPE
 - c. Spill cleanup
 - d. Decontamination of personnel, area, and equipment
 - e. Reporting
 - f. Record keeping
 - g. Incident analysis

J. Training

1. Comply with the OSHA blood-borne-pathogen regulations that require appropriate training of all employees who handle wastes contaminated with blood-borne pathogens and other infectious materials (14).
2. Train all personnel who generate or handle any type of infectious waste. Include in the training the following.
 - a. The risks of exposure to infectious materials
 - b. The policies and procedures that have been adopted
 - c. Their own duties and responsibilities for implementation of the infectious-waste management plan

K. Record keeping

1. Comply with the various federal requirements for record keeping (e.g., OSHA requirements that pertain to medical records, exposures, and training [14]).
2. Comply with the particular record keeping requirements of your state. These may include quantities of waste generated, waste treatment procedures and validation testing, and tracking of untreated waste shipped off-site.
3. Use records of waste management activities (e.g., waste quantities, costs, and a record of accident and incidents) as a database for analysis and review of the effectiveness of the waste management plan.
4. Regard record keeping as documentation of the written policies and procedures, training sessions, medical activities (vaccinations, incident follow-up procedures), etc. Use it as an invaluable resource in contesting enforcement actions by regulatory agencies and in liability suits.

L. QA and QC

1. Institute QA and QC measures. Include, for example, the following.
 - a. Periodic validation testing of treatment protocols
 - b. Policy of collecting only properly packaged waste
2. Use QA and QC to gauge implementation and to evaluate the functioning of the waste management plan.
3. Use QA and QC for identifying problems, minimizing exposures, and preventing untreated or improperly treated waste from leaving the facility as treated waste.

M. Incident and accident analysis

1. Analyze periodically the data on incidents and accidents that result in employee exposure, patterns of occurrence, problems in the waste management system, etc.
2. Modify the waste management plan accordingly.

III. IMPLEMENTATION

- A. Incorporate the following essential elements to ensure successful implementation of the waste management plan.
 1. Enlist the involvement and support of management.
 2. Grant authority for implementing the plan to appropriate personnel.
 3. Train all personnel who handle infectious waste in any way (in waste generation, collection, or treatment) so that they understand the following.
 - a. All aspects of the plan and its importance
 - b. The possible consequences to themselves and to the institution of not following procedures
 - c. Individual responsibilities for plan implementation
- B. Implement the waste management plan.

IV. REVIEW

- A. Review the infectious-waste management plan annually.
- B. Examine the data to determine the following.
 1. How well the system is functioning
 2. Whether it is current relative to wastes generated in the laboratory
 3. Whether it is current relative to regulatory requirements
 4. Which areas need improvement or change

V. BENEFITS

Realize the benefits of a comprehensive infectious-waste management plan, including the following.

- A. **Compliance with regulatory requirements**
- B. **Meeting of standards required for professional certification**
- C. **Minimization of hazards and occupational exposures**
- D. **Greater efficiency and reduced costs**
- E. **Minimization of risk and liability**

16.1

General Introduction to Bioterrorism

No one knows when. No one knows where. But experts agree that it is only a matter of time before a bioterrorist act or a biocrime is committed. As an integral member of the “first-responder” team in recognizing or suspecting an act of bioterrorism, the clinical laboratory, especially the clinical microbiology laboratory, will serve as a sentinel in the detection, recovery, characterization, and identification of the biological agent(s). In preparation for responding to a biological terrorism event, the clinical microbiologist is encouraged to participate in and follow the guidelines of the Laboratory Response Network (LRN). Members of the laboratory staff should be formally trained and knowledgeable in the following areas: (i) the BSL of their laboratory; (ii) principles of specimen collection, preservation, packaging, labeling, and shipment; (iii) criteria for recognizing or suspecting a potential bioterrorist activity and the institutional chain of communication; (iv) biothreat levels as designated by the LRN; (v) diagnostic testing according to consensus protocols; (vi) timely and accurate testing and reporting; and (vii) the chain of communication linking local, state, and federal agencies. Although it is not anticipated to be a major factor, members of the microbiology staff should have an understanding of the chain-of-custody guidelines being practiced in their institution. It is vitally important for a laboratory to be familiar with its role in response to a suspected or confirmed bioterrorist event and to develop formal standard operations procedures (SOP) which describe how the laboratory will function in the event of a biological incident. The SOP should be part of an institution wide SOP that is a

multidisciplinary document comprised of policies from Infection Control, Public Relations, Risk Management, Pharmacy, Security, Medical Staff, and Administration. The primary role of the clinical microbiology laboratory in responding to a bioterrorist event will be no different from its present role: to detect, recover, and characterize or identify the etiological agent(s). Of utmost importance are maintaining awareness that an event may be occurring and raising *suspicion* that requires further investigation. Secondary roles include maintaining an active surveillance and a continuous monitoring program. The primary focus of this section and associated procedures is to provide the clinical microbiologist with guidance and information for use in preparing for and responding to a *suspected* or *confirmed* bioterrorist event. Critical issues to be addressed in this document include the types of bioterrorist events; laboratory capacity; laboratory safety, including the packaging, labeling, and shipment of specimens and cultures; and diagnostic testing protocols for those biological agents targeted as being most likely to be released in an event because they can be easily disseminated or transmitted person to person, they cause high mortality with the potential for major public health impact, they might cause public panic and social disruption, and they require special action for public health preparedness (R. Timperi, personal communication). These agents, currently classified as category A agents, include (i) *Bacillus anthracis*, the agent of anthrax; (ii) botulinum toxin, produced by *Clostridium botulinum*; (iii) *Brucella* spp., the agents of brucellosis; (iv) *Yersinia pestis*,

the agent of plague; (v) *Francisella tularensis*, the agent of tularemia; and (vi) variola virus, the agent of smallpox. However, it is important to realize that any microbial agent can potentially be used in the commission of a biocrime or act of terrorism.

Since most microbiologists have not experienced or been involved with bioterrorist activity, the following definitions are provided as background information. Terms such as “bioterrorist agents,” “biothreat agents,” “biocrime,” and “biothreat” are used interchangeably and are defined as follows: “bioterrorist agents” or “biothreat agents” refers to microbial pathogens and/or toxins which have been considered for or used in biological warfare and recent terrorist events; “biothreat” is the suspected but unconfirmed release of a biological agent(s); “biocrime” is a criminal act involving the use of biological agents or weapons.

■ **NOTE:** After this section was typeset, the LRN was revised in response to recommended laboratory designations and to reflect expansion to include additional specialty laboratories. Laboratories previously designated as level A are now designated as sentinel laboratories; level B, C, and D laboratories are designated as confirmatory/reference laboratories. The respective roles and responsibilities of these laboratories have not changed, i.e., “rule out and refer” (sentinel) and “rule in and confirm” (confirmatory/reference). The LRN has been expanded to include chemical, veterinary, water, radiological, environmental, and selected military laboratories. Please note these revisions when reviewing this section.

I. TYPES OF BIOTERRORISM EVENTS

Bioterrorism events are classified as either overt or covert (2). In an overt event, the agent is announced. For example, the numerous reported hoaxes that have occurred since 1998 have involved letters or environmental samples in which it was stated that “you have just been exposed to anthrax.” A covert event, which is most likely to occur, is unannounced and is much more of a challenge to detect. Detection of a covert event is similar in many ways to the daily examination and interpretation of cultures in which the microbiologist attempts to determine if a pathogen is present in addition to the nature or type of pathogen. Therefore, the focus of preparation in the clinical microbiology laboratory should be on the recognition of the covert form of bioterrorism. Dissemination of a biological agent as an aerosol or through contamination of water or food supplies will not have an immediate impact because of the delay between exposure and the onset of illness (the incubation period [Table 16.1–1]). As a result, physicians and health care workers, including the staff of the microbiology laboratory, will be the first to identify patients or to suspect a bioterrorism-related event. Epidemiological clues should be used to assess whether a patient’s presentation is typical of an endemic disease or is an unusual event that should raise concern. Laboratory and epidemiological features that should alert microbiologists and other health care providers to the possibility of a bioterrorism-related outbreak include the following.

- A. A rapidly increasing disease incidence (e.g., within hours or days) in an otherwise healthy population
- B. An epidemic curve that rises and falls during a short period
- C. An unusual increase in the number of people seeking care, especially with fever, respiratory, or gastrointestinal complaints
- D. An endemic disease rapidly emerging at an uncharacteristic time or in an unusual pattern
- E. Any patient presenting with a disease that is relatively uncommon and has bioterrorism potential (e.g., pulmonary anthrax, tularemia, or plague) who is without any risk factors for the disease (e.g., travel to the Southwest for plague)
- F. A large number of rapidly fatal cases
- G. An increase in the number of specimen types submitted for microbiological analysis (e.g., respiratory specimens and blood cultures)
- H. Higher-than-normal clustering of a specific organism
- I. Recovery of an unusual or rarely encountered microorganism
- J. A higher-than-normal patient admission rate to the emergency room or hospital
- K. Receipt of information by the microbiology laboratory that a clinician suspects a specific agent (e.g. “I suspect tularemia in this patient”)

Table 16.1–1 Incubation periods of select agents

Disease	Time to disease onset	
	Usual	Range
Anthrax	48 h	Hours to days
Botulism	12–36 h	Several days
Brucellosis	5–60 days	Several months
Plague	2–4 days	1–7 days
Tularemia	3–5 days	1–14 days

II. LRN

In response to the threat of bioterrorism, a four-tiered LRN was established by the CDC and the Association of Public Health Laboratories for the purpose of providing a network of public and private laboratories that can detect and identify biological agents and communicate information to the appropriate individuals in time to treat cases and prevent the spread of disease, guide public health and safety interventions, and support planning and decision making for national preparedness and response to bioterrorism, as well as other epidemic and outbreak events that may occur, e.g., pandemic influenza or suspected Ebola virus infections (1, 2, 3). It has been designed in an effort to link all clinical laboratories to public health agencies in all states, districts, and territories with access to state-of-the-art facilities for the analysis of suspected biological agents. The LRN defines four laboratory levels, designated A through D (Fig. 16.1–1). As the front line in a bioterrorism event, the LRN must provide (i) early detection and identification of an event; (ii) accurate, credible, and timely test results; and (iii) communication of data and information through secure electronic reporting systems (1).

Level A laboratories include smaller public health laboratories and most private laboratories (in hospitals, clinics, and physicians' offices, as well as commercial laboratories) with low-level biosafety facilities (BSL 2). These laboratories will use clinical data and standard microbiological tests to decide which specimens and isolates should be forwarded to higher-level biocontainment laboratories. Level A laboratory personnel will be trained in the safe collection, packaging, labeling, and shipping of samples that may contain dangerous pathogens (1). Although considerable expertise in microbiological analysis and diagnostic testing is available in the private sector, the LRN was also designed to minimize the hazards associated with handling of biological agents due to the realization that most clinical laboratories are limited to a containment capacity of BSL 2. In addition, with the emphasis on safety, a major objective of the LRN is to limit complex and sophisticated diagnostic testing of suspected agents, as well as access to reagents, quality control strains, and proficiency testing, to a few highly specialized laboratories. By limiting or restricting diagnostic testing to a small number of selected laboratories, security measures can be more easily controlled, and thus the access of potential terrorists or known enemies to information can be limited. If a level A laboratory wishes to

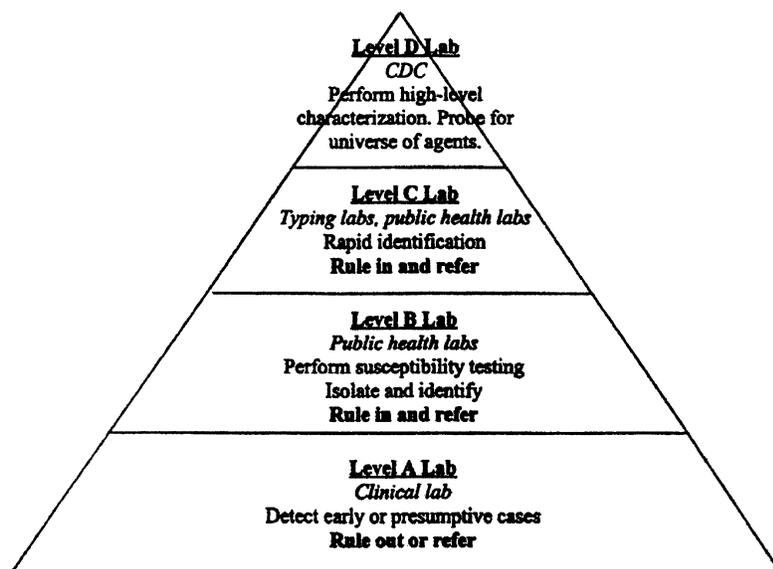

Figure 16.1–1 LRN.

II. LRN (continued)

function as a level B facility, it must make application to the state health department and specify which agent(s) it wishes to attain level B testing status for. Furthermore, the applying laboratory must meet the physical requirements of a BSL 3 containment facility. The primary responsibility of a level A laboratory is to rule out possible identifications and refer the suspected agent to the next-higher level, level B, level C, or level D, depending on the suspected agent. A major responsibility of level A laboratories is to raise the suspicion that something unusual is occurring based on the recommended clues listed above. It is not the responsibility of the level A laboratory to confirm or announce that a bioterrorist event has taken place. *The laboratory should notify the institutional infection control or epidemiology personnel, who are responsible for assessing the situation and notifying local or state public health officials, who will make the final decision and notify federal officials.* Laboratory personnel should be familiar with the morphological, cultural, and identification characteristics of those agents that have been targeted for dispersal in a bioterrorism event, in addition to the clinical syndromes they produce. Standardized, consensus-based testing protocols that utilize standard microbiological tests have been developed through a partnership consisting of the American Society for Microbiology, CDC, and the Association of Public Health Laboratories. The protocols have been designed to facilitate the ruling out of a potential or suspected agent prior to shipping a specimen to the next-higher level. The diagnostic procedures described in the preceding sections of this handbook are based on the current level A testing protocols. Access to testing protocols utilized in level B laboratories and above is restricted to designated public health laboratories and requires an assigned password issued by the CDC before admission to the CDC secure website can be obtained.

Level B laboratories are primarily state and local public laboratories that can test for specific agents and forward organisms or specimens to higher-level biocontainment laboratories. Level B laboratories will minimize false-positive results and protect level C laboratories from overload. Ultimately, level B laboratories will maintain the capacity to perform confirmatory and susceptibility testing.

Level C laboratories possess the same testing capabilities as a level B laboratory and may be located at state health agencies, academic research centers, or federal facilities. In addition, the level C laboratory has the capability to perform toxicity testing and to employ advanced diagnostic technologies (e.g., nucleic acid amplification and molecular fingerprinting). These laboratories are responsible for participating in the evaluation of new tests and reagents, and they determine which assays could be transferred to level B laboratories.

Level D laboratories have the highest level of containment (BSL 4) and expertise in the diagnosis of rare and dangerous biological agents. These are specialized federal laboratories with unique experience in the diagnosis of rare diseases (e.g., smallpox and Ebola virus disease). A level D laboratory will develop or evaluate new tests, reagents, and methods; archive organism isolates for future characterization and comparisons; identify chimeras (recombinant agents); detect genetically engineered agents; and perform advanced functions, such as identification of organisms deemed too hazardous for levels A to C.

If you are uncertain or have any questions regarding your laboratory's capacity or the disposition of samples and/or cultures suspected of being potential biological agents, contact your local or state health department for consultation and guidance.

III. CHAIN-OF-CUSTODY GUIDELINES

Following confirmation by the Federal Bureau of Investigation (FBI), a biocrime or act of bioterrorism is regarded as a criminal offense. The clinical microbiology laboratory may be required to save specimens or isolates suspected of being linked to or associated with the crime under investigation and thus must preserve what is regarded as evidence. Protection of evidence must adhere to the security process known as the chain of custody. Although level A laboratories will not handle or analyze environmental samples (e.g., soil, bone, hair, surface swabs, water, food, or letters) that are collected in an overt event in which chain of custody is required, it is important for the microbiology staff to be familiar with the process. Unless otherwise specified by the FBI, which is the ultimate authority, all environmental specimens should be transported directly to a level B laboratory. If the laboratory is called upon to handle an environmental sample, all activities, beginning with the receipt and examination of the sample, must be documented using a chain-of-custody form (Fig. 16.1–2). The key elements of this form include (i) the document number assigned and the date that the evidence was received, (ii) the specimen identification number, (iii) a brief description of the evidence (e.g., specimen type and biological agent), (iv) the date of final disposition, (v) signatures of all personnel who handled and examined the evidence, and (vi) remarks.

Figure 16.1–2 Chain-of-custody form.

IV. RECOMMENDATIONS FOR THE LEVEL A LABORATORY

The following recommendations are provided as a checklist for use by the level A laboratory.

- A. Refer all environmental samples to a level B laboratory (local or state health department).
- B. Refer specimens suspected of containing botulinum toxin directly to the local or state health department. Prior notification and consultation with the representatives at the local or state health department regarding disposition of the sample is advised.
- C. Refer specimens suspected of containing the agent of smallpox to the CDC. Prior notification and consultation with the CDC is recommended before shipment of the specimen or tissue culture.
- D. Maintain an active system of surveillance and monitoring of microorganisms recovered in the laboratory—establish a baseline incidence for each organism.
- E. Establish a line of communication within your institution for reporting suspicious, unusual, or known organisms encountered in higher-than-normal frequency. Microbiology laboratory personnel should notify Infection Control directly of such incidences; Infection Control is responsible for notifying local or state health department officials.
- F. Establish a line of communication with other local and/or regional laboratories.
- G. Develop and maintain a bioterrorism SOP. Elements for inclusion in the SOP include (i) level A testing protocols, (ii) policies (e.g., chain of communication, internal contacts, surveillance processes, personnel safety, and packaging, labeling, and shipping), (iii) current literature references, and (iv) documentation of staff attendance at and participation in continuing education activities.
- H. Assess the BSL capacity of the laboratory.
- I. Schedule periodic inservices and updates for the laboratory staff; participate in tabletop exercises and local mock exercises to evaluate laboratory preparedness.
- J. Recognize that laboratory security is related to but different from laboratory safety (4).
- K. The laboratory does not confirm or announce the occurrence of an act of bioterrorism; it only raises suspicion.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

The importance of laboratory safety must be emphasized. Laboratory workers have always been shown to be at risk for laboratory-acquired infections. Such infections include typhoid fever; Q fever; cholera; glanders; brucellosis; tetanus; tuberculosis; tularemia; shigellosis; salmonellosis; infections caused by streptococci, *Chlamydia* spp., and *Neisseria meningitidis*; and viral infections, such as those caused by the hepatitis viruses, arboviruses, and many others (1, 2, 4, 6, 7, 8, 9, 10, 11, 12, 13). Interestingly, these infections have

occurred in association with documented laboratory accidents in only 16% of the cases (13), of which 9.5% resulted in death (12, 13). No national monitoring of laboratory-associated infections exists, but one estimate derived from recent surveys suggests a rate of one to five infections per 1,000 employees (5, 10, 14). Harding and Byers have reviewed laboratory-associated infections recently (3).

■ **NOTE:** Current information reinforces the fact that a safer work environment requires strict adherence to the principles of

biological safety (15). These principles rely on a combination of microbiological practices, laboratory facilities, and safety equipment which is designed to minimize exposure of laboratory workers, their contacts, and the outside environment to potentially hazardous organisms. The use of these principles can be customized for each laboratory according to its specific needs.

II. GOOD LABORATORY PRACTICES

Observe standard precautions.

It is imperative that these cultures be handled in a biosafety hood.

All specimens containing or suspected of containing microorganisms are regarded as potentially harmful. Contact with any biological specimen must occur under controlled conditions that emphasize protection of the laboratorian. The use of standard precautions will protect the laboratory worker when handling clinical specimens. Good laboratory practice includes strict adherence to sound microbiological techniques, including containment procedures. Persons working in a laboratory environment should be given instruction in the safe handling of biological agents, be required to follow standard operating procedures, and be aware of the potential danger associated with these agents. Good laboratory practice also includes the proper use of primary and secondary barriers within the laboratory. Primary barriers include biological safety cabinets (BSCs), enclosed centrifuge cups and carriers, and PPE (i.e., gloves, safety glasses or goggles, face shields, masks, gowns, and shoe covers). Secondary barriers include factors related to facility design and construction, which consist of the location of the work area in relation to public access and the availability of an autoclave, eyewash and hand-washing facilities, specialized ventilation systems, and controlled-access zones.

III. BSLs

The combination of safe laboratory practices and the use of various primary and secondary barriers constitutes the four levels of biosafety used in the laboratory environment (6, 15). BSLs are agent dependent, are designed for the specific procedures performed by the laboratory, and take into consideration the various routes of transmission of the infective agents.

A bioterrorism act may be either covert (unannounced) or overt (announced). A covert event may be first recognized in the clinical microbiology laboratory following the isolation of an organism that is not usually found in the geographical area (e.g., *Brucella* or *Francisella* in the southeastern United States) or when testing of a *Bacillus* organism isolated from a blood culture (normally regarded as a contaminant) shows that it is neither motile nor hemolytic, and thus is a possible *Bacillus anthracis* isolate. In the case of an overt, announced bioterrorism event, level A laboratories should be prepared to send specimens to a higher-level laboratory, such as a state facility.

A. BSL 1

BSL 1 is used for undergraduate and secondary educational training and teaching laboratories (Table 16.2–1). It represents a basic level of containment that relies on standard microbiological practices (as defined in Table 16.2–1) with no special need for primary or secondary barriers other than a sink for hand washing. Representative organisms that can be safely handled in a BSL 1 laboratory are *Bacillus subtilis*, *Naegleria gruberi*, and infectious canine hepatitis virus.

B. BSL 2

BSL 2 applies to most clinical diagnostic, teaching, research, and commercial laboratories that handle a wide variety of indigenous, moderate-risk microorganisms usually present in the community and associated with human diseases of various severities (Table 16.2–2), depending on the health and immune status of the individuals in the population. BSL 2 is appropriate for working with human body fluids where the presence of a potentially infectious agent is unknown. The activities at this level can be performed on the open bench without special primary or secondary barriers other than a sink for hand washing and waste decontamination facilities. At this level, overt splashing and aerosol for-

Known to be associated with human disease	BSL 1 plus rodent and insect control program	<p>Personnel are advised of potential hazards; must follow standard operating procedures.</p> <p>Biohazard sign is posted at laboratory entrance.</p> <p>Personnel have received appropriate immunizations.</p> <p>Baseline sera may be collected.</p> <p>Personnel are knowledgeable about biosafety manual.</p> <p>Personnel receive annual updates and training for hazards.</p> <p>High degree of precaution is used when handling sharps.</p> <p>All specimens are in leakproof containers for collection, handling, processing, storage, and transport.</p> <p>Spills and accidents are reported, and medical evaluation is given.</p>	<p>BSL 1 plus:</p> <p>BSC I or II and PPE used when creating aerosols or handling high concentrations and/or volumes of agents</p> <p>PPE removed prior to leaving the laboratory</p>	<p>BSL 1 plus:</p> <p>Location away from public areas</p> <p>Eyewash station readily available</p> <p>Autoclave available</p>

III. BSLs (continued)

mation should be kept to a minimum. If splashing or aerosol formation is likely when working with a specimen or organisms in a BSL 2 laboratory, such procedures should be conducted in a class II or I BSC. BSCs are primary containment devices used in laboratories working with infectious agents. When used in conjunction with good microbiological practices, BSCs provide an effective containment system for the safe manipulation of moderate- and high-risk microorganisms. Safety centrifuge cups may be used if deemed necessary when centrifuging specimens or organisms. Other primary barriers that should be available for use if necessary include goggles, face masks and shields, gloves, and gowns. Specimens suspected of containing *B. anthracis*, *Francisella tularensis*, *Yersinia pestis*, and *Brucella* spp. can be safely processed under BSL 2 conditions. In addition, hepatitis B virus, human immunodeficiency virus, and *Salmonella* and *Toxoplasma* spp. are suitable for BSL 2 practices. The handling and manipulation of mould cultures, including *Histoplasma capsulatum*, *Blastomyces dermatitidis*, *Coccidioides immitis*, and *Aspergillus* spp., should be performed at a minimum under BSL 2 conditions, although BSL 3 is preferred and recommended.

C. BSL 3

BSL 3 is followed by clinical diagnostic, teaching, research, or production facilities where procedures are performed with agents commonly transmitted by the respiratory route and known to cause significant morbidity and mortality (Table 16.2–3). All procedures at BSL 3 must be conducted in a BSC class I or II or other enclosed equipment fitted with HEPA particulate filters. Other mandatory primary barriers include goggles, particulate respirator masks, face shields, gloves, and gowns. Secondary barriers must include controlled access to the laboratory and a ventilation system that keeps potentially contaminated air from being released from the facility. Examples of cultured organisms that can be safely worked with at this level are *B. anthracis*, *F. tularensis*, *Y. pestis*, *Brucella* spp., *Mycobacterium tuberculosis*, *Coxiella burnetii*, and St. Louis encephalitis virus. This level is also utilized when manipulating moulds, espe-

III. BSLs (continued)

cially the agents of systemic mycosis (e.g., *H. capsulatum*, *B. dermatitidis*, and *C. immitis*).

D. BSL 4

BSL 4 is used by clinical diagnostic, research, or production facilities where procedures are performed with agents that are commonly transmitted by the respiratory route and pose a high risk of life-threatening disease for which there is no vaccination or therapy (Table 16.2–4). All procedures at BSL 4 must be performed in a manner that provides complete isolation of the laboratory worker from aerosolized infectious agents. All procedures must be conducted in a BSC class III or in a full-body, air-supplied positive-pressurized suit. The BSL 4 laboratory should be located in a separate building or a remote isolated zone within a facility. This level also requires specialized secondary barriers for air ventilation and waste decontamination. Examples of agents that require handling in a BSL 4 environment include Ebola, Marburg, and Congo-Crimean hemorrhagic fever viruses.

Table 16.2–4 Summary of BSL 4

Agents	Standard micro-biological practices	Special practices	Primary barriers	Secondary barriers
High risk of life-threatening disease by aerosol transmission to humans or unknown risk of human disease	BSL 3	<p>BSL 3 plus: Logbook is signed upon entry into and exit from facility. Biohazard sign is posted listing agent(s), laboratory director, and special requirements for entry. Personnel enter and exit through clothing-changing and shower rooms, showering upon exit. Airlocks are used to enter and exit laboratory. Clothing is removed in changing room and left; only laboratory clothing is used for entry into laboratory; upon exit, laboratory clothing is left in inner changing room; soiled clothing is autoclaved before being laundered. Supplies enter through air locks, autoclaves, or fumigation chambers and are decontaminated after each use. Biological material or waste is removed through disinfectant dunk tanks, fumigation chambers, or airlocks. All materials are decontaminated prior to removal and disposal. Spills are handled by professional staff trained and equipped to work with concentrated infectious material. Laboratory accidents and absenteeism for medical surveillance are reported.</p>	<p>BSL 3 plus: All procedures done in class III BSC or class I or II BSC when used with one-piece positive-pressure suits ventilated with a life support system</p>	<p>BSL 3 plus: Location in a separate building or isolated zone Daily inspection of life support systems Sewer vents and service lines fitted with HEPA filters Hands-free or automatic hand-washing sink Self-closing access doors Break-resistant, sealed windows Double-door autoclaves Dedicated nonrecirculating ventilation system Cabinet air passed through HEPA filters HEPA filters tested and certified at least annually Communications system between laboratory and outside</p>

16.3

Packaging, Labeling, and Shipment of Infectious Specimens

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Shipping dangerous goods involves certain risks with numerous potential liabilities both criminal and civil. Proper adherence to regulations set by the International Civil Aviation Organization and the International Air Transport Association (IATA), the Canadian Transportation of Dangerous Goods Act and Regulations, and 49 Code of Federal Regulations (49 CFR) can reduce the risk of incurring unnecessary liabilities that could result in financial penalties. Proper shipment of dangerous goods also protects the sender and the recipient from exposure to the risk of contamination. It is important for the microbiology laboratory to designate members of the staff to receive training on how to properly classify, prepare, and declare

shipments of infectious substances, diagnostic specimens, and biological products. The application of proper packaging, marking, labeling, and documentation will ensure that everyone in the transportation chain knows what dangerous goods are being transported, how to properly load and handle them, and what to do if an incident or accident occurs.

For the purposes of this discussion, the terms “infectious substances,” “dangerous goods,” and “hazardous goods” all have the same meaning. Although the select-agent rule is discussed here, it *does not* apply to level A laboratories but has been included for information purposes, since many microbiologists are employed in re-

search or higher-level federal laboratories that handle many of the agents listed below under research or other analytical conditions. Level A laboratories are required to follow the infectious-substances guidelines and regulations.

■ **NOTE:** Although training in the packaging and shipping of infectious substances is not mandatory, it is highly recommended that all members of the microbiology staff receive such training. Designated training courses meet the requirements for shipping materials according to the UN4G Class 6.2 guidelines. A list of information sources for scheduling training can be found in Appendix 16.3–1 at the end of this procedure.

ANALYTICAL CONSIDERATIONS

II. SELECT-AGENT RULE: SHIPPING AND TRANSPORTATION

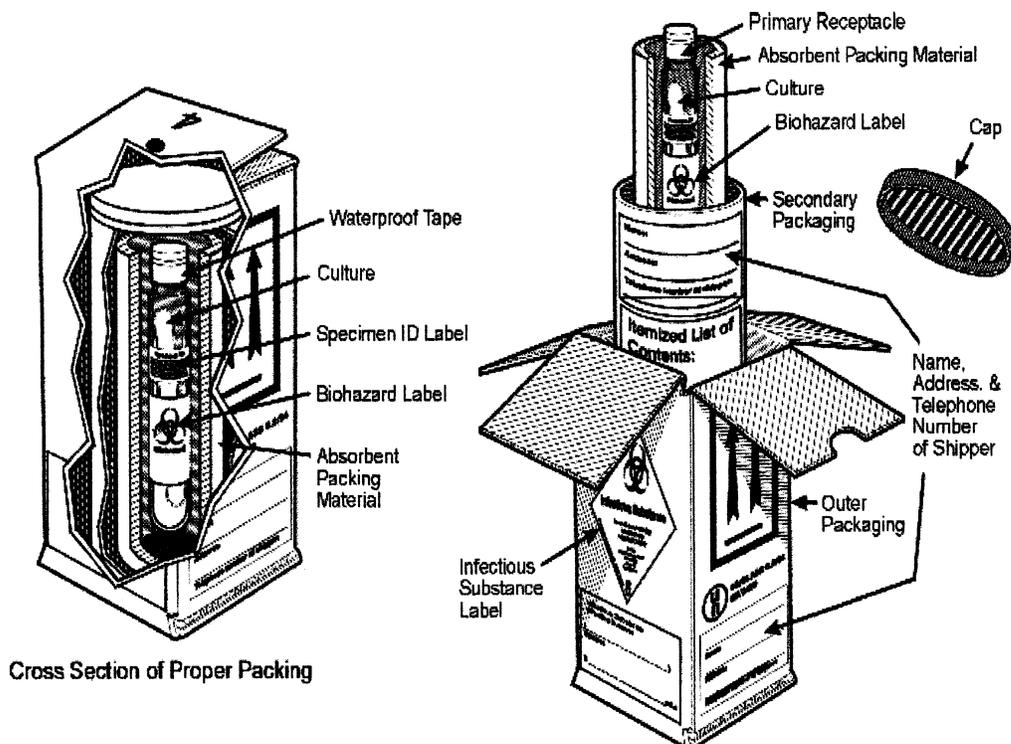

The Department of Health and Human Services issued a rule in 1997 to deal with the packaging and shipping of biohazardous materials. This rule, Additional Requirements for Facilities Transferring or Receiving Select Agents, expanded regulations already in existence. These regulations specify requirements for the packaging, labeling, and transport of select agents shipped in interstate commerce. The final rule places additional shipping and handling requirements on facilities that transfer or receive select agents that are capable of causing substantial harm to human health. Any product that is or contains a hazardous agent or material must be transported according to these requirements as outlined in the Department of Transportation (DOT) Title 49 regulations.

A facility that sends out or receives certain designated select agents, such as certain specified viruses, bacteria, fungi, and biological toxins, is also now required to apply for and receive a site registration number (SRN) from the CDC before any shipments occur. Substantial criminal penalties apply to both individuals and organizations that do not comply with the regulation requirements. Therefore, the acquisition of an SRN is imperative for any clinical microbiology laboratory, and

II. SELECT-AGENT RULE: SHIPPING AND TRANSPORTATION (continued)

registration should be sought by contacting the CDC (contact information is in Appendix 16.3–1 at the end of this procedure).

Regulations for the transportation of biological agents are aimed at ensuring that the public and the workers in the transportation chain are protected from exposure to any agent that might be in a package. Protection is achieved through (i) the requirement for rigorous packaging that will withstand rough handling and contain all liquid material within the package without leakage to the outside (Fig. 16.3–1),

Cross Section of Proper Packing

Packing and Labeling of Infectious Substances

Note: The shipper's name, address and telephone number must be on the outer and inner containers. The reader is also advised to refer to additional provisions of the Department of Transportation (49 CFR, Parts 171-180) Hazardous Materials Regulations.

Figure 16.3–1 General packaging requirements for transport of biological agents and clinical specimens. Shown is the generalized triple packaging (primary receptacle, watertight secondary packaging, and durable outer packaging) required for a biological agent of human disease or materials that are known or suspected to contain them. This packaging requires the infectious-substance label shown on the outside of the package. The packaging must be certified to meet rigorous performance tests as outlined in the DOT, U.S. Postal Service, Public Health Service (PHS), and IATA regulations. Clinical specimens with a low probability of containing an infectious agent are also required to be triple packaged, but performance tests require only that the package shall not leak after a 4-ft drop test. DOT, PHS, and IATA require a clinical-specimen label on the outside of the package.

■ **NOTE:** For further information on any provision of this regulation, contact the Centers for Disease Control and Prevention, Attn: External Activities Program, Mail Stop F-05, 1600 Clifton Rd. N.E., Atlanta, GA 30333. Phone: (404) 639-4418. Fax: (404) 639-2294.

II. SELECT-AGENT RULE: SHIPPING AND TRANSPORTATION (continued)

(ii) appropriate labeling of the package with the biohazard symbol and other labels to alert the workers in the transportation chain to the hazardous contents of the package, (iii) documentation of the hazardous contents of the package should such information be necessary in an emergency situation, and (iv) the requirement for hazardous material shipping training for personnel involved in the transportation of hazardous materials so that they are able to respond to emergency situations. Explicit information regarding personnel training for shipment of hazardous materials and how to obtain shipping materials and instructions can be found at the web sites included in Appendixes 16.3–1 and 16.3–2 at the end of this procedure. All laboratories are strongly encouraged to obtain the appropriate information and training regarding these critical issues.

III. HAZARDOUS MATERIALS (INFECTIOUS SUBSTANCES, DANGEROUS GOODS, OR HAZARDOUS GOODS)

☑ **NOTE:** Hazardous material means a substance or material that has been determined by the Secretary of Transportation to be capable of posing an unreasonable risk to health, safety, and property when transported in commerce (as defined by 49 CFR 171.8). Any product that is or contains a hazardous material, including biohazardous agents, must be transported according to the requirements outlined in the DOT Title 49 regulations.

POSTANALYTICAL CONSIDERATIONS

IV. COMMERCIAL CARRIERS OF HAZARDOUS MATERIALS

Commercial carriers authorized to ship hazardous materials include Federal Express, UPS, and Airborne Express.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Bacillus anthracis, the etiologic agent of anthrax, is among the organisms designated high priority in terms of use in a bioterrorist attack. Disease occurs most frequently in herbivorous animals (e.g., cattle, sheep, and goats) which acquire the endospores from contaminated soil. Human disease can occur in one of three forms, depending on the route of acquisition. (i) Cutaneous anthrax, responsible for >95% of naturally occurring cases, is initiated when spores of *B. anthracis* are introduced into the skin through cuts or abrasions, such as when handling contaminated wool, hides, leather, or hair products (especially goat hair) from infected animals (12, 19). There are a few case reports of transmission by insect bites, presumably after the insect fed on an infected carcass (1, 16, 17). This form is rarely fatal following appropriate antimicrobial therapy. (ii) Gastrointestinal anthrax may occur 1 to 7 days following the consumption of contaminated undercooked meat from infected animals. Pharyngeal lesions may also occur from ingestion of contaminated food. Mortality in both forms is high (16). (iii) Inhalation anthrax results from the inhalation of *B. anthracis* spores. Though treatable in its early prodromal stage, mortality remains extremely high despite antimicrobial-agent treatment if not initiated

within 48 h of the onset of symptoms (20). A single case of inhalation anthrax should alert all health care workers to the possibility of a bioterrorist event (4). Person-to-person transmission has not been confirmed (2, 7).

In the minds of most military and counterterrorism planners, the aerosolization of anthrax spores is among the most likely methods for a bioterrorism attack (6, 11). Though the minimum infectious inhaled dose has not been determined, the U.S. Department of Defense estimates that the 50% lethal dose for humans is between 8,000 and 50,000 spores (3). Once inhaled, the endospores enter pulmonary macrophages and are carried to the mediastinal lymph nodes. Germination and vegetative growth result in the production of an antiphagocytic capsule and a toxin consisting of three proteins, namely, edema factor, lethal factor, and protective antigen, which play major roles in virulence and the associated infectious and clinical manifestations (5). Following an incubation period of 1 to 6 days, the initial symptoms of inhalation anthrax are mild and relatively nonspecific, including fever, malaise, a mild cough, and chest pain. A brief interval of improvement commonly occurs over the next 2 to 3 days, followed by rapid deterioration (13). Regional

lymph nodes become overwhelmed, followed by entry of the organism into the systemic circulation. Fatal sepsis with generalized hemorrhage, massive hemorrhagic mediastinitis, and necrosis ensue. Death is universal in untreated cases and may occur in as many as 95% of treated cases if therapy is not started within 48 h following the onset of symptoms (3, 5, 13, 20).

The primary responsibility of the level A laboratory is to rule out *B. anthracis* (and other suspected bioterrorism agents) based on results generated from the level A testing protocols (see below) and then refer specimens or isolates to the nearest Laboratory Response Network (LRN) level B laboratory (usually the state health department) for rapid confirmation. It is important to retain a portion of the specimen or a subculture of the suspicious isolate before shipping the material to the nearest level B laboratory in the event that additional material is needed for retrospective studies. As indicated in procedure 16.1, a chain of custody is unlikely to be needed in the level A laboratory. However, retention of the specimen(s) and/or isolate(s) is highly recommended when it is encountered under suspicious conditions.

II. SAFETY CONSIDERATIONS

Observe standard precautions.

Members of the laboratory staff must always remember to follow the safety guidelines associated with standard precautions when handling and examining human clinical specimens and maintain the attitude that *all specimens are suspect*. BSL 2 practices, containment equipment, and facilities are permissible for activities using clinical materials and diagnostic quantities of culture material (see procedure 16.2). Strict adherence to standard microbiological practices and techniques in conjunction

II. SAFETY CONSIDERATIONS (continued)

It is imperative that these cultures be handled in a biosafety hood.

with a class II biological safety cabinet and PPE (e.g., lab coat and gloves are required; safety glasses or a face shield is recommended) will provide sufficient protection. In addition, *contaminated items, such as pipettes, needles, plastic loops, and microscope slides, should be soaked in 10% bleach or 10 to 30% formalin for 24 h before autoclaving them.* Phenolics are not sporocidal at the usual working dilutions (10, 18).

Environmental samples and samples of dry powder, such as those received in envelopes as anthrax threats, should be examined in a BSL 3 (level B or higher) laboratory. In many instances, the closest level B laboratory will be the state health department laboratory. However, if the Federal Bureau of Investigation (FBI) determines that a given situation is of low credibility, then they may request that the material be examined in a BSL 2 (level A) facility, provided that the technologist uses full-face protection in addition to the safety measures mentioned above. Extreme caution should be used during specimen handling to avoid the creation of aerosols. Vaccination is not recommended unless frequent work with infected clinical specimens or diagnostic cultures is anticipated (3, 18).

III. SPECIMEN COLLECTION

Observe standard precautions.

The specimen of choice depends on the disease presentation and the stage of the illness. Advice and information on specimen collection should be shared with emergency medical personnel, including clinicians, nurses, and supporting staff.

A. Cutaneous (19)

1. Vesicular (early) stage

Unroof vesicle and collect fluid on two sterile swabs for culture and Gram staining.

2. Eschar stage

Without removing the eschar, insert a swab beneath the edge of the eschar, rotate the swab, and collect lesion material for culture and Gram staining.

■ **NOTE:** Removing the eschar could hasten dissemination (7).

B. Gastrointestinal (19)

1. Stool—best if collected in the early stage of disease. Collect 5 to 10 g in a clean, leakproof container.

2. Blood—later stage of disease. Collect in accordance with the institution's protocol for routine blood cultures.

3. Any hemorrhagic fluid from nose, mouth, or anus should be cultured and Gram stained (15).

4. Postmortem tissues.

C. Inhalation

Inhalation is the most likely syndrome in the case of a bioterrorist attack. In a covert event, the laboratory may be the first to raise suspicion that *B. anthracis* has been recovered based on clues listed in procedure 16.1.

1. Early postexposure (0 to 24 h) following overt aerosolization of spores (12, 14)

a. Nasal and throat swabs for culture.

b. Induced respiratory secretions for culture. For optimal specimens, collection should be performed by respiratory therapy personnel. Patient preparation and collection should also be described in the institution's microbiology specimen collection manual.

c. Swabs of the haired portions of the face and head for culture

2. Prodromal phase (early nonspecific symptomology) (19)

Sputum culture and Gram stain, particularly if the patient has a productive cough; however, pneumonia is *not* a usual feature of inhalation anthrax.

III. SPECIMEN COLLECTION*(continued)*

3. Late phase (2 to 8 days postexposure) (19)
 - a. Blood culture and direct Gram stain of blood
 - b. CSF for culture and Gram staining, particularly if signs of meningitis occur (7)
4. Postmortem tissues

D. Environmental specimens—as directed by the FBI and public health authorities (9)

Soil, bone, hair, environmental swabs, swabs or material from a potential spore aerosolization device, water, or envelopes containing a powder substance are among the possible environmental sources that may be examined for *B. anthracis*. These specimens would normally be collected by the FBI during the course of a criminal investigation and transported to a level B laboratory (usually the state health department) for examination. Possibly, in cases where the FBI deems a situation to be of low credibility and there is need for rapid turnaround, a level A laboratory may be asked to examine a sample for the purpose of a fast presumptive ruling out of spores. However, unless otherwise specified, all environmental specimens should be forwarded directly to the state health laboratory. Prior to shipment of the specimens, notify the state health laboratory and follow their instructions (2).

IV. CULTURE MATERIALS*(See reference 19.)*

- | | |
|--|---|
| <ul style="list-style-type: none"> A. BAP B. MAC C. CHOC D. Phenylethyl alcohol agar (PEA) plates E. TSB F. Clean glass slides G. Sterile commercially available specimen transport swabs | <ul style="list-style-type: none"> H. Clinical centrifuge with appropriate biocontainment tube holder I. Sporocidal disinfectant (0.5% sodium hypochlorite) J. Formalin (10 to 30%) K. Sterile disposable bacteriologic inoculating loops |
|--|---|

V. SPECIMEN TRANSPORT*(See reference 8.)**Observe standard precautions.*

- A. Vesicular fluid and eschar swabs (Dacron) may be transported at room temperature if there is no more than a 24-h delay.
 - B. Stool specimens should be transported at room temperature if the delay is 1 h or less; transport at 4°C if there is >1 h delay.
 - C. Sputum specimens may be transported at room temperature if there is no more than a 2-h delay or at 4°C if there is a 2- to 24-h delay.
 - D. Blood should be inoculated directly into blood culture bottles in accordance with the institution's protocol for routine blood cultures (19).
- ☑ **NOTE:** The FBI is in charge of environmental-sample collection, laboratory selection, and transport of specimens in the event that a possible bioterrorist attack has occurred. It is also recommended that state and local public health agencies be notified. Preserve original specimens pursuant to a potential criminal investigation.

VI. SPECIMEN PROCESSING*(See reference 19.)*

- A. Cutaneous and tissue specimens (swab specimens) should be plated to BAP, MAC, and TSB as recommended by the CDC. A smear for Gram staining should also be made.
- B. Stool specimens should be plated to BAP, MAC, and PEA.
- C. Sputum specimens should be inoculated to BAP, CHOC, MAC, and TSB. A smear for Gram staining should also be made.
- D. Blood culture methods routinely performed in the laboratory are sufficient. A direct smear of the blood for Gram staining should be made.

VI. SPECIMEN PROCESSING (continued)

It is imperative that these cultures be handled in a biosafety hood.

- E. Powder substances presented in threat letters can be examined for endospores by wet-mount and phase-contrast microscopy by mixing a small amount of the material with filter-sterilized water. Apply 5 to 10 μl to a microscope slide, cover it with a coverslip, and examine it under phase microscopy at $\times 100$ magnification. Endospores will appear as bright light-refractive oval bodies approximately 2 to 6 μm in diameter, whereas vegetative cells will be larger dark rod forms. A portion of the suspension should be plated to BAP and incubated in ambient air at 35 to 37°C. These procedures are not recommended for BSL-2 (level A) laboratories (2, 8).
- F. CSF specimens should be centrifuged at $1,500 \times g$ for 15 min using a clinical centrifuge equipped with appropriate biocontainment tube holders. Open the biocontainment tube holders only under a biological safety cabinet. Inoculate the culture sediment to BAP, CHOC, and TSB. Prepare a smear for Gram staining (19).

VII. INCUBATION AND EXAMINATION OF CULTURES

(See reference 19.)

It is imperative that these cultures be handled in a biosafety hood.

- A. All cultures should be incubated at 35 to 37°C under ambient conditions.
- B. Cultures should be examined within 18 to 24 h of incubation. *However, growth of Bacillus anthracis may be observed as early as 8 h after inoculation.* This can be helpful when looking for *B. anthracis* from mixed cultures (i.e., stool or sputum).
- C. TSB cultures may be Gram stained and/or subcultured after incubation.

ANALYTICAL CONSIDERATIONS

VIII. QUALITY CONTROL

Include QC information on reagent container and in QC records.

- A. Routine QC procedures are used to check media, stain procedures, and reagents unless otherwise noted (19).
- B. An avirulent nonencapsulated strain of *B. anthracis* (Sterne strain) is available by purchasing the live veterinary vaccine (Colorado Serum Company, 4950 York St., Denver, Colo.) and plating a portion of the vaccine material to BAP. This can be used for a QC stock as well as a training organism for wet-mount and phase microscopy. By leaving a 24-h-old BAP culture at room temperature for 2 to 3 days, one can accumulate an abundance of endospores on the plate. Comparing wet mounts of these spores to similar preparations, e.g., talc and cornstarch, is a good way to prepare the laboratory technologists and check their competency.

IX. IDENTIFICATION

It is imperative that these cultures be handled in a biosafety hood.

- A. **Colony morphology (19)**
At 16 to 24 h, colonies of *B. anthracis* are 2 to 5 mm in diameter. They are irregularly round and flat or slightly convex, with a ground-glass appearance and edges that are slightly undulate. There are often comma-shaped projections from the edge of the colony, producing the “Medusa head” shape. The colonies are *nonhemolytic* on BAP and have a tenacious consistency, so that when teased with a loop, the growth will stand up like beaten egg white. *B. anthracis* does not grow on MAC or PEA.
- B. **Gram stain morphology (19)**
B. anthracis is a large (1- to 1.5 by 3- to 5- μm) gram-positive rod that forms oval central to subterminal endospores that do not swell the vegetative cell. Endospores are not seen on direct smears of clinical samples unless they have been exposed to atmospheric levels of CO_2 . Vegetative cells seen on direct Gram smears from clinical samples are in short chains of two to four cells that are encapsulated. An India ink preparation can be performed on blood and CSF

IX. IDENTIFICATION*(continued)*

Include QC information on reagent container and in QC records.

specimens to enhance visualization of the capsule (see below). It is very rare that species other than *B. anthracis* produce capsules. Gram stains from colonies grown on BAP show long chains of nonencapsulated gram-positive bacilli.

C. India ink stain (19)

India ink is useful for enhancing the visualization of encapsulated *B. anthracis* in clinical specimens, such as blood, blood culture bottle, or CSF.

1. Materials

- a. Microscope slides
- b. Coverslips
- c. India ink (may be purchased commercially prepared in droppers)

2. Controls

Use an 18- to 24-h-old stock strain of *Klebsiella pneumoniae* on BAP as a positive encapsulated control and *Escherichia coli* ATCC 25922 as the negative nonencapsulated control.

3. Procedure

- a. For the controls, transfer a small amount of growth from each control BAP into 0.5 ml of whole EDTA-treated blood or serum. Mix.
- b. Transfer 5 to 10 μ l each of the clinical specimen (blood, CSF, or blood culture) and controls to glass slides. Place a coverslip on the drop, and add 5 to 10 μ l of India ink to the edge of the coverslip. Allow the ink to diffuse under the coverslip.
- c. View the cells at $\times 100$ using oil immersion.
- d. Discard the slides in 0.5% hypochlorite solution.

4. Interpretation

The capsule appears as a well-defined clear zone around the rod forms for the positive control. No zone is observed surrounding the negative control (19).

5. Limitations

Capsules may be seen on direct smears from blood and/or CSF specimens; however, cells from growth on BAP under ambient conditions do not produce capsules and often occur as long chains of bacilli.

D. Motility test (19)

B. anthracis is nonmotile, which is rather unusual among *Bacillus* spp. and is useful in the preliminary identification.

1. Materials

- a. Microscope slides
- b. Coverslips
- c. Sterile distilled water
- d. Sterile disposable bacteriologic inoculating loops
- e. Sterile glass tubes
- f. Light microscope at $\times 400$

2. Controls

- a. Positive control: 18- to 24-h culture of *Pseudomonas aeruginosa* ATCC 35032 or equivalent
- b. Negative control: *Acinetobacter* sp. strain ATCC 49139, Sterne (vaccine) strain of *B. anthracis*, or equivalent

3. Procedure

- a. Place 2 drops of sterile distilled water into a sterile glass tube.
- b. Using the inoculating loop, suspend a small amount of the colony in a test tube.
 NOTE: A loopful of a fresh broth culture can be used.
- c. Transfer 1 drop of the suspension to a microscope slide and overlay it with a coverslip.

IX. IDENTIFICATION (continued)

- d. Examine the slides under $\times 400$ magnification.
- e. Discard the slides in 0.5% hypochlorite solution.
4. Interpretation
 - a. Motile organisms can be observed moving randomly and independently throughout the suspension.
 - b. Nonmotile organisms may show no movement at all or move with Brownian motion.
- E. **Presumptive Identification of *B. anthracis* (19)**
 1. Direct Gram staining shows large gram-positive encapsulated rods in blood, CSF, lesion material, or blood cultures. Spores are not seen on direct smears from clinical specimens, as the CO₂ levels in the body inhibit sporulation.
 2. Nonhemolytic, broad, spore-forming gram-positive rods isolated on BAP. Colonies have a ground-glass appearance. Spores are oval and nonswelling and do not exceed the diameter of vegetative cells. Cells are nonmotile and catalase positive.
 3. Be aware that most naturally occurring strains of *B. anthracis* are susceptible to penicillin; however, it is probable that a strain used for bioterrorism activity will be penicillin resistant.
 NOTE: The most common *Bacillus* sp. submitted to the CDC to rule out *B. anthracis* is *Bacillus megaterium* (nonmotile isolates).
- F. **Actions following the presumptive identification of *B. anthracis* (2, 19)**
 1. Preserve original specimens pursuant to a potential criminal investigation or at the request of the next-higher-level laboratory.
 2. Contact institutional Infection Control, which in turn contacts the local health department, which is then responsible for contacting higher levels of public health laboratories within the LRN. The original laboratory contacts the state health laboratory only when planning to send an isolate for confirmation.
 3. In conjunction with the FBI, implement a chain-of-custody system so that samples and laboratory results are protected and controlled to maintain their admissibility as evidence in a court of law.
 4. Local FBI agents will forward samples to the state health department as necessary. Consultation with the state health department is strongly encouraged as soon as *B. anthracis* is suspected. Remember that the level A laboratory rules out *B. anthracis* and does not perform confirmatory testing.

POSTANALYTICAL CONSIDERATIONS

X. SUMMARY

- A. **Basis for presumptive identification of *B. anthracis* (Fig. 16.4–1)**
 1. Large encapsulated gram-positive rods seen on direct smears from clinical specimens
 2. Large spore-forming gram-positive rods that are nonhemolytic on BAP, catalase positive, and nonmotile
- B. **Actions**
 1. Preserve all specimens and isolates.
 2. Notify the institutional infection control and state public health laboratory (or closest level B laboratory to send the specimen).
 3. Implement chain of custody for specimens and laboratory results if requested by the FBI.
 4. Work in conjunction with the local or state public health laboratory to ensure that isolates and specimens are properly handled and transported to the next-level (level B or higher) laboratory.

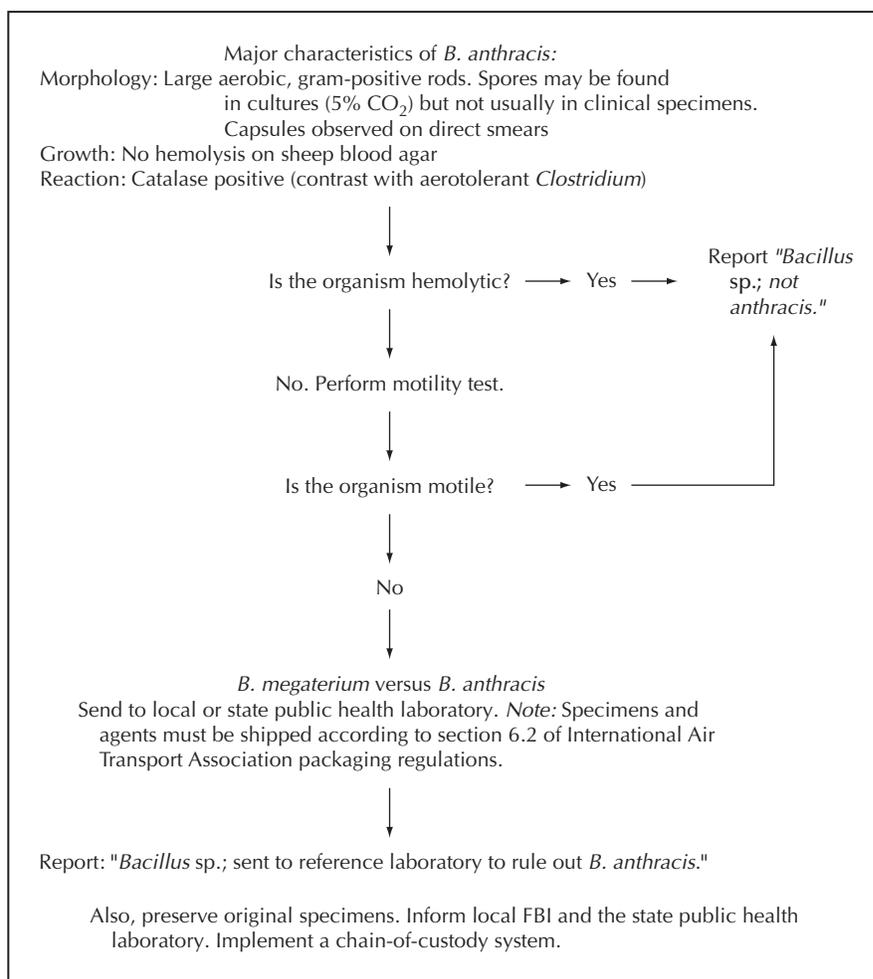

Figure 16.4–1 *B. anthracis* level A laboratory flowchart.

16.5

Botulinum Toxin—*Clostridium botulinum*

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Clostridium botulinum is an anaerobic gram-positive rod that produces spores and is ubiquitous in soil and marine sediments throughout the world. Botulism is a neuroparalytic illness resulting from the action of a toxin produced by strains of *C. botulinum*. These toxins are extremely hazardous to humans, requiring only a minute quantity to cause profound intoxication and death. There are four distinct forms of botulism: (i) food borne, (ii) wound, (iii) infant, and (iv) adult or child. Food-borne botulism, although the most common form, is relatively rare but often fatal. This form of botulism results from the ingestion of food items containing the preformed toxin. The clinical diagnosis of food-borne botulism can be confirmed by isolating the organism from the feces of the patient. Isolation of the organism from remnants of the consumed food item does not provide confirmatory evidence of botulism in the absence of other supporting laboratory data. *The demonstration of bo-*

tulinal toxin in patient feces or serum or in the suspected food item will support the clinical diagnosis. Wound botulism occurs following the colonization of the wound by *C. botulinum*. Multiplication of the organism may result in the production of toxin. Confirmation requires demonstration of the organism and toxin in serum, feces, or material from the wound. Infant botulism results when ingested spores germinate within the intestinal tract, causing toxin production. Confirmation of infection is dependent on the demonstration of botulinum toxin in the feces.

Adult or child botulism is represented by those cases in which no food source has been identified and there is no evidence of wound botulism, but there is evidence of intestinal colonization in a person over the age of 1 year.

It is anticipated that in a bioterrorism-related exposure, botulinum toxin will

most likely be transmitted by ingestion of toxin-contaminated food or possibly by aerosolization (2). With the aerosolized form, symptoms usually begin within 36 h but may take longer, depending on the magnitude of the dose. Initial symptoms involve abnormalities of cranial nerve function, leading to blurred and double vision, light-induced pain, speech disorders, difficulty in swallowing, and a descending, symmetrical skeletal-muscle paralysis (2, 3). Person-to-person transmission of botulism does not occur.

The neurologic signs and symptoms resulting from toxin production dominate the clinical syndrome of botulism, regardless of the form. There are seven recognized antigenic types of *C. botulinum*, all with similar symptomatology. The antigenic type of *C. botulinum* is determined by the complete neutralization of its toxin by the homologous antitoxin.

II. SAFETY CONSIDERATIONS

Observe standard precautions.

It is imperative that these cultures be handled in a biosafety hood.

Botulism toxins are extremely poisonous. Exposure to the toxin represents the primary laboratory hazard. The 50% lethal dose of this toxin is 0.001 µg/kg of body weight; therefore, acquisition by ingestion, inhalation, or absorption can cause intoxication and death. All materials suspected of containing toxin must be handled using standard precautions and BSL 2 containment criteria. Additional primary containment and personnel precautions, such as those recommended for BSL 3, are indicated for activities with a high potential for aerosol or droplet production (4, 5). A class II biological safety cabinet should be used when processing specimens to prevent the release of aerosols in the laboratory. *C. botulinum* is inactivated by a 1:10 dilution of household bleach. The disinfection solution must be in contact with the toxin or organism for 15 to 20 min to ensure complete inactivation.

■ **NOTE:** Exposure to bleach does not inactivate the spores of *C. botulinum*.

ANALYTICAL CONSIDERATIONS

III. SPECIMEN COLLECTION AND TRANSPORT

The diagnosis of botulism is made clinically, based on patient history and physical findings. Routine laboratory tests are of limited value in the diagnosis of botulism. Laboratory criteria for diagnosis include detection of botulinum toxin in the serum, feces, or food or isolation of *C. botulinum* from fecal cultures (1).

Level A laboratories should be familiar with and provide consultation on the proper selection, collection, transport, and shipping of appropriate specimens.

■ **NOTE:** Due to the dangers inherent in working with *C. botulinum*, level A laboratories are responsible only for the collection, packaging, and shipment of specimens suspected of containing botulinum toxin. Refrain from performing cultures and smears for microscopy.

Observe standard precautions.

A. Specimens

1. Serum

- a. Specimens should be obtained following the onset of symptoms.
- b. Specimens should be obtained prior to antitoxin treatment.
- c. Obtain 10 to 15 ml of serum for toxin analysis (equivalent to 20 to 30 ml of whole blood).
- d. Less than 3 ml of serum may result in an inconclusive examination.

2. Feces

- a. Collect 25 to 50 g of feces for testing.
- b. Specimens should be collected prior to antitoxin treatment.
- c. In cases of constipation, an enema may be given using sterile water or saline.
- d. Intestinal contents obtained at autopsy may be submitted for analysis.

3. Food samples

- a. Remnants of suspected foods may be tested.
- b. Specimens should be submitted in the original containers.

4. Wounds

Specimens include exudates, debrided tissue, or swabs (least preferred) of the wound.

5. Autopsy specimens

- a. Serum
- b. Gastric and intestinal contents

B. Specimen transport and shipping

1. Wound and fluid specimens should be shipped in a commercial anaerobic transport system.
2. Wound specimens, including swabs containing transport medium, should be transported without refrigeration.
3. All other specimens should be transported with a refrigerant (cold packs, ice, or dry ice per International Air Transport Association regulations).
4. All specimens should be transported in leakproof containers.
5. Specimens should be shipped by the most rapid means possible.
6. Packaging and shipping containers must conform to guidelines of the United States Department of Transportation.
7. Fecal and serum specimens may be frozen if a delay in testing is anticipated.
 - **NOTE:** Freezing will not affect the ability to detect toxin; however, it will compromise the isolation and recovery of the organism.

■ **NOTE:** When botulism is suspected, level A laboratories *must* contact their local or state health department laboratory before shipping specimens for testing and confirmation. Since botulism is a public health emergency even when criminal activity is not suspected, prior contact with these agencies is recommended for

III. SPECIMEN COLLECTION AND TRANSPORT (continued)

diagnostic consultation, epidemiological assistance, and diagnostic laboratory services. The Food-Borne and Diarrheal Diseases Branch of the CDC can be contacted 24 h a day, 365 days a year at (404) 639-2206 (Monday to Friday, 8:30 a.m. to 4:30 p.m. eastern standard time) or (404) 639-2888 (after hours and weekends) (3). The CDC Emergency Response Hotline is available 24 h a day at (770) 488-7100. Always notify your institutional infection control officer or nurse in the event of a suspected case(s) of botulism.

POSTANALYTICAL CONSIDERATIONS

Although the microbiology staff does not have a direct role in the detection and confirmation of botulinum toxin, it can provide consultation to the infection control team and the risk management program. For example, a fact sheet which highlights (but is not restricted to) the following information can be provided: (i) an explanation that people who are exposed to botulinum toxin are *not* contagious, (ii) a description of symptoms produced by botulinum toxin (blurred vision, drooping eyelids, and shortness of breath), and (iii) a note that if such symptoms develop or are observed, the affected individuals should report for evaluation.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Brucella is a fastidious, intracellular, aerobic, small gram-negative coccobacillus. Brucellosis is a zoonotic disease caused by four species that are recognized as human pathogens: *B. abortus* (cattle), *B. melitensis* (goats, sheep, and camels), *B. suis* (pigs), and *B. canis* (dogs).

Approximately 50 to 100 cases of brucellosis are diagnosed each year in the United States, with the majority occurring in two patient populations. The first group includes people who work with animals that have not been vaccinated against brucellosis. This group comprises farmers, veterinarians, and slaughterhouse workers who become infected by direct contact with or aerosolization of infected tissues. *B. abortus* and *B. suis* are the most common agents seen in this group. The second

group of individuals includes those that ingest unpasteurized dairy products contaminated with *Brucella* spp. These patients usually have a history of travel to or have migrated from Latin America or the Middle East, where the disease is endemic in dairy animals, especially goats and camels. *B. melitensis* is the primary agent in these cases. Infections due to *B. canis* are very rare (7).

Aerosolization of *Brucella* is predicted to be the most likely form of dispersal in the commission of a biocrime or act of terrorism. In 1954, *B. suis* was the first biological agent to be weaponized by the United States in its biological-warfare program. The infective dose for *Brucella* spp. is very low, which makes the organism a

potentially effective bioterrorism agent as well as a hazard in the clinical microbiology laboratory. Person-to-person transmission does not occur. The incubation period is highly variable, ranging from 5 days to 2 months. Clinically, *Brucella* can cause both acute and chronic infections. Acute disease is characterized by generalized symptoms, including fever, profuse sweating, headache, muscle pain, anorexia, and weight loss. The chronic form of disease resembles military tuberculosis, with lesions in the liver, bone, and spleen (7). Because of this, brucellosis is commonly included in the differential diagnosis of fever of unknown origin. The mortality rate (5%) is low and is primarily due to untreated endocarditis (7, 10).

II. SAFETY CONSIDERATIONS

It is imperative that these cultures be handled in a biosafety hood.

Brucellosis is the most commonly reported laboratory-acquired infection. Cases have occurred in clinical laboratory settings by sniffing cultures, direct skin contact with cultures, and aerosol-generating procedures. Clinical specimens that are suspected of containing *Brucella* should be handled using BSL 2 procedures. BSL 3 practices are recommended when manipulating growth from cultures believed to contain *Brucella* spp., and all plates should be sealed (6, 8). It is recommended that household bleach (1:10 dilution) be utilized to decontaminate work surfaces.

III. SPECIMEN COLLECTION

Observe standard precautions.

Recommended specimens include the following.

- A. **Blood*** (20 ml)
- B. **Bone marrow*** (0.5 to 1.0 ml collected from the iliac crest)
- C. **Other** (lymph node, aspirates from abscesses, liver and spleen biopsy specimens, and CSF)
- D. **Serum: acute (at the onset of disease)- and convalescent (3 to 4 weeks)-phase specimens**

*Diagnostic specimen of choice

|--|--|

ANALYTICAL CONSIDERATIONS

V. SPECIMEN PROCESSING

Clinical specimens should be processed within 2 h following collection. In the event of delays, refrigerate specimens at 4°C (see section 3 of this handbook).

Observe standard precautions.

A. Blood

1. Inoculate blood into a commercial blood culture system and incubate it at 35 to 37°C for a minimum of 3 weeks. Automated systems, BACTEC 9240 and BacT/Alert, have been reported to detect *Brucella* within 10 days (1, 3). Commercial, nonautomated systems which utilize a biphasic culture system, such as Septi-Chek and Opticult, are acceptable. Lysis-centrifugation methods (ISOLATOR) have also been used for the recovery of *Brucella* spp.
2. Terminal subcultures should be performed before the broth is discarded, and all subculture plates should be incubated for a minimum of 1 week (1, 2, 3).

B. Bone marrow and other fluids

Process as described for blood specimens or use standard inoculation procedures and plate directly onto sheep blood agar, CHOC, MAC, Thayer-Martin (Martin-Lewis) agar, a *Brucella* base agar, or heart infusion agar.

C. Tissue, wound specimens, and other specimens

1. Homogenize tissues aseptically in a mortar using sterile sand or Alundum and a small quantity (1 ml) of sterile broth or saline.
Caution: homogenization produces aerosols and should be performed only in a biological safety cabinet (see section 3 of this handbook). PPE, including a face shield, is recommended!
2. Inoculate tissue homogenate and wound specimens onto sheep blood agar or *Brucella* base agar, CHOC, and MAC. If contamination is suspected, inoculate Thayer-Martin (Martin-Lewis) agar.
3. Incubate plates for 7 days at 35 to 37°C in 5 to 10% CO₂.

VI. IDENTIFICATION

(See reference 9.)

A. Colony morphology

■ **NOTE:** Visible growth of *Brucella* spp. on CHOC or blood agar incubated in 5 to 10% CO₂ may require 48 h or longer (1 week). *Brucella* spp. do not grow on MAC.

Colonies of *Brucella* spp. are pinpoint, raised, white to cream, glistening, and nonhemolytic; young colonies are slightly yellow and opalescent and may darken, becoming brownish with age (3, 7).

B. Gram stain characteristics

Brucella spp. are very small, faintly staining, gram-negative coccobacilli (0.5 to 0.7 by 1.5 μm); the microscopic appearance is that of fine sand (3, 7).

■ *Organisms demonstrating this type of morphology should be handled with extreme caution until *Brucella* spp. and *Francisella* spp. have been ruled out.*

C. Presumptive identification (Table 16.6–1)

D. Level A laboratory tests for ruling out *Brucella* spp. (Fig. 16.6–1)

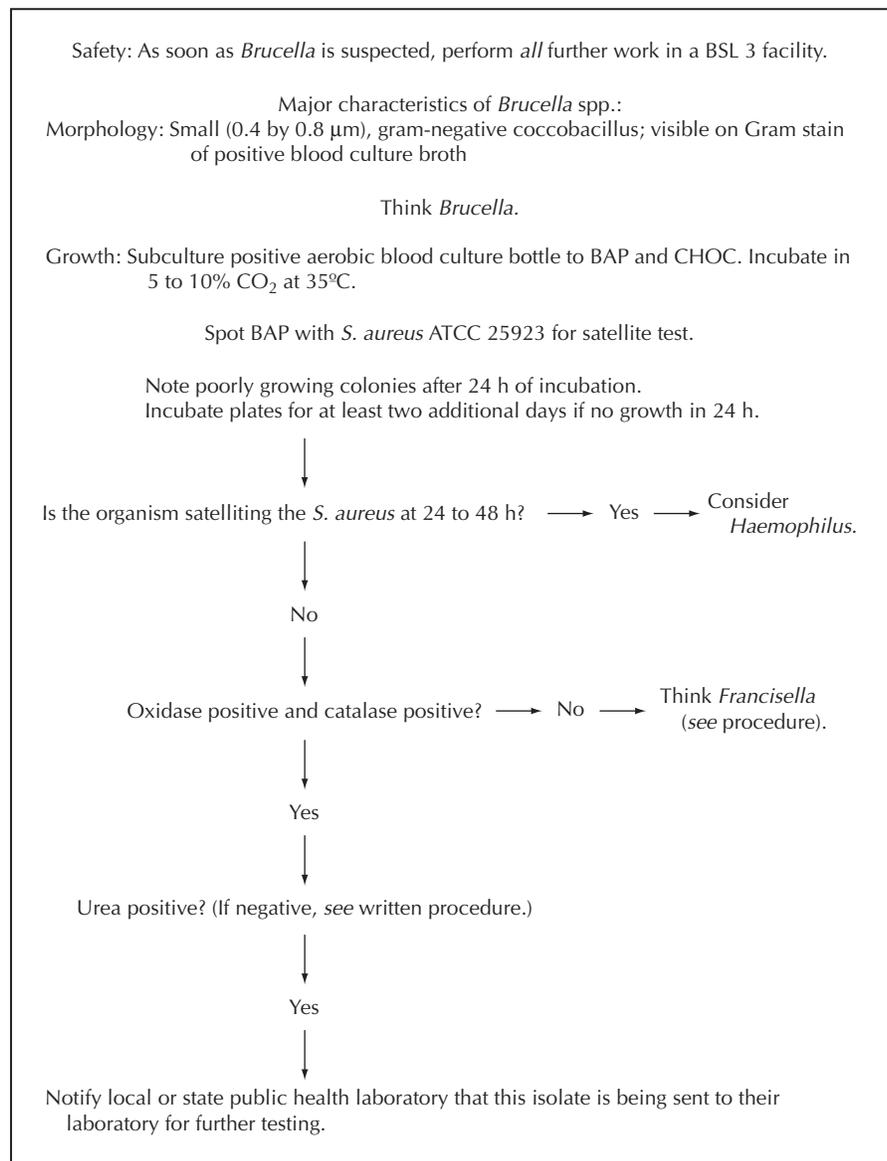

1. Oxidase (Kovács' modification) (4)
 - a. Perform test on fresh isolates grown on noninhibitory media.

Table 16.6–1 Differentiation of *Brucella* spp. from other similar organisms

Test	Result ^a			
	<i>Brucella</i> spp.	<i>Oligella</i> spp.	<i>Haemophilus influenzae</i>	<i>Francisella tularensis</i>
Gram stain	Small coccobacilli	Small coccobacilli	Small coccobacilli	Small coccobacilli
Oxidase	Positive	Positive	Variable	Negative
Urea hydrolysis	Positive	Positive	Variable	Negative
Growth on blood agar	Positive	Positive	Negative	Positive ^b

^a Specimen sources are as follows: *Brucella* spp., blood and bone marrow; *Oligella* spp., urinary tract; *H. influenzae* and *F. tularensis*, various.

^b Enhanced by cysteine (some strains fail to grow on blood agar when subcultured).

**Figure 16.6–1** *Brucella* flowchart: level A laboratory of laboratory response network.

VI. IDENTIFICATION

(continued)

- b. A positive test is indicated by the production of a blue color within 10 s; a blue color that develops after 10 s should be disregarded and considered a false positive.
 - c. *B. abortus*, *B. melitensis*, and *B. suis* are oxidase positive; *B. canis* is oxidase variable.
2. Catalase
All *Brucella* spp. are catalase positive.
 3. Satellite test
 - **NOTE:** *Brucella* spp. may be confused with *Haemophilus* spp.
Inoculate a blood agar plate with the suspect organism followed by spotting with *Staphylococcus aureus* ATCC 25923 in each quadrant. After 24 to 48 h of incubation in 5 to 10% CO₂, the absence of growth is suggestive of *Brucella*; growth is suggestive of *Haemophilus* spp.
 4. Urea hydrolysis (5)
 - a. Inoculate a urea agar slant heavily with growth from a fresh culture.
 - b. Incubate it at 35°C under aerobic conditions.
 - c. Observe it for color change (pink) within 1 h.
 - d. Most *Brucella* spp. will hydrolyze urea within 1 h.
 - e. Other organisms that are urease positive and may be confused with *Brucella* spp. include *Oligella ureolytica*, *Psychrobacter phenylpyruvicus*, *Psychrobacter immobilis*, and *Bordetella bronchiseptica*.
Caution: Do not attempt to identify *Brucella* spp. with commercial identification systems due to the high probability of misidentification.

POSTANALYTICAL CONSIDERATIONS

E. Confirmatory identification

1. Preserve original specimens and isolates as potential criminal evidence.
2. Contact the infection control officer, who is responsible for notifying the local health department that the laboratory cannot rule out *Brucella* and that the isolate is being forwarded to the state health department laboratory for confirmatory identification.
3. Consultation with the local or state health department laboratory prior to shipping is recommended as soon as *Brucella* is suspected.
4. FBI officials may forward the specimens and cultures for confirmatory testing in the event of overt activity.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Yersinia pestis is the causative agent of plague, an acute febrile infectious disease with a high fatality rate (15). Plague may present in three forms: bubonic, pneumonic, and septicemic (13). Bubonic plague is characterized by sepsis that is accompanied by the sudden onset of fever, chills, weakness, headache, and the formation of buboes and swelling of regional lymph nodes of the groin, axilla, or neck. Septicemic plague is basically the same as bubonic plague but without the swelling of the lymph nodes. Pneumonic plague, the most deadly form of the disease and the form that can spread rapidly among susceptible individuals, presents as fever

and lymphadenopathy with cough, chest pain, and often hemoptysis. Secondary pneumonia from hematogenous spread of the organisms can occur, or the organism can occasionally be passed by aerosols from human to human as primary pneumonic plague.

■ **NOTE:** Primary pneumonic plague is the form that would be seen if *Y. pestis* was used as a bioterrorism agent and would also be transmitted in aerosolized form.

A supportive diagnosis of plague is most readily made by a direct stained smear of bubo aspirates, blood, and respiratory specimens or of CSF samples in

plague meningitis (2). In addition, direct fluorescent-antibody testing of clinical samples can provide a more rapid presumptive diagnosis of plague (2, 13). This testing is usually available through state laboratories. However, recovery of the organism in culture is the most rapid and definitive means to confirm diagnosis. Serologic diagnosis is often used to verify or confirm suspected cases of plague. Alternative methods for diagnosing plague include PCR analysis and DNA hybridization studies; however, neither of these methods is generally available in the routine diagnostic laboratory (10, 11).

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

- A. The proper specimens to collect for the diagnosis of plague include aspirations of buboes, blood, respiratory tract secretions (sputum, bronchoalveolar lavage fluid, bronchial washes, tracheal or lung aspirates, and lung tissue biopsy specimens), and CSF for staining and culture (2, 13). Suitable autopsy specimens include lymphoid tissue, lung tissue, and bone marrow.
- B. Transport of these specimens using routine laboratory procedures will ensure the viability of the organisms.
- C. Paired serum samples, acute and convalescent or convalescent and postconvalescent phase, are best used to establish a diagnosis of plague by serologic means. However, a single high-titer serum sample can be used to provide a presumptive diagnosis of plague (13).

III. MATERIALS

It is imperative that these cultures be handled in a biosafety hood.

- A. Clinical material should be processed according to normal laboratory protocols in a biological safety cabinet, prepared for staining, and inoculated onto routine laboratory isolation medium.
- B. Blood agar, MAC, and CHOC should be plated.
- C. For blood cultures, process in accordance with normal laboratory protocols. It is recommended that four samples be collected at 30-min intervals (13). If blood cultures are signaled as positive, they should be stained and subcultured as described above.
- D. Serum should be separated and stored frozen until it is tested.

ANALYTICAL CONSIDERATIONS

IV. PROCEDURES**A. Stains**

1. Fix prepared, air-dried slide with 100% methanol and stain with Gram or Wright-Giemsa stain (2, 9, 13).
2. Staining with a fluorescent antibody specific for the F1 capsular antigen may be performed at a reference laboratory (13).
3. Gram stains must be performed to characterize the Gram reaction and morphology of the organism.

B. Culture

1. Inoculate properly obtained clinical material onto laboratory medium and streak for isolation.
2. Nonselective media, such as BAP or BHI agar with BHI enrichment broth, can be used for sterile sites, and MAC or cefsulodin-irgasan-novobiocin selective agar can be used for contaminated specimens.
3. All media should be incubated aerobically with increased CO₂ at 28 to 35°C for several days.
4. The optimal temperature for growth of *Y. pestis* is reported to be 28°C (2).

C. Serology

1. Serological diagnosis of *Y. pestis* infection is most commonly performed at the CDC or other large reference laboratories (6).
2. The classic serological technique used for the diagnosis of plague is the passive hemagglutination assay (PHA) (2, 3, 5, 6, 13).
3. Other assays have also been developed for testing sera for antibodies to the plague bacillus; these include ELISA (4), latex agglutination (14), and solid-phase radioimmunoassay (8).

V. RESULTS**A. Stains**

1. Staining of direct specimens that contain *Y. pestis* will reveal small gram-negative bacilli, from 1 to 2 µm in length, mostly in singles and pairs and which may stain bipolar (darker on the ends than in the middle).
2. Bipolar staining characteristics are more readily seen on a Wright-Giemsa stain and may not be apparent on a Gram stain of the specimen (7).
3. Bipolar-staining gram-negative bacilli on a routine blood film or buffy coat smear should heighten suspicion of *Y. pestis*.

B. Culture

1. *Y. pestis*, a member of the family *Enterobacteriaceae*, is a catalase-positive, oxidase-negative, non-lactose-fermenting, aerobic gram-negative bacillus that does not form spores.
2. It grows more slowly than other enterobacteriaceae on solid media and may only form visible colonies after 24 to 48 h of incubation (2, 13).
3. Colonies measure 1 to 2 µm in diameter, are gray-white, smooth, and opaque; and may have a “beaten-copper” (9) or “hammered-metal” (13) appearance.
4. The organism may grow better at 28°C than at higher temperatures.
5. If a suspect organism is grown in culture, routine biochemical testing will confirm the identification of the organism.
6. The organisms will be alkaline or acid in triple-sugar-iron agar with the key biochemical reactions shown in Table 16.7-1.
7. Any isolate showing the characteristics in Table 16.7-1 should immediately be submitted to the appropriate state public health laboratory or other reference laboratory for further identification.
8. Lysis by a specific bacteriophage can be used by the CDC to confirm the identification of cultured *Y. pestis* (1, 12).

Table 16.7–1 Key biochemical reactions for *Y. pestis*

Positive	Negative
Catalase	Oxidase
Glucose	Urea
Trehalose	Indole
	Lactose
	Citrate
	Motility (25 and 37°C)

V. RESULTS (continued)

C. Serology

1. A fourfold rise in paired acute- and convalescent-phase serum samples or a fall in titer between convalescent- and postconvalescent-phase serum samples is considered confirmatory for the diagnosis of plague.
2. A single serum sample with a PHA titer of >10 is presumptive evidence of recent infection with *Y. pestis* (13).

■ **NOTE:** A flowchart depicting an identification scheme for *Y. pestis* is shown in Fig. 16.7–1.

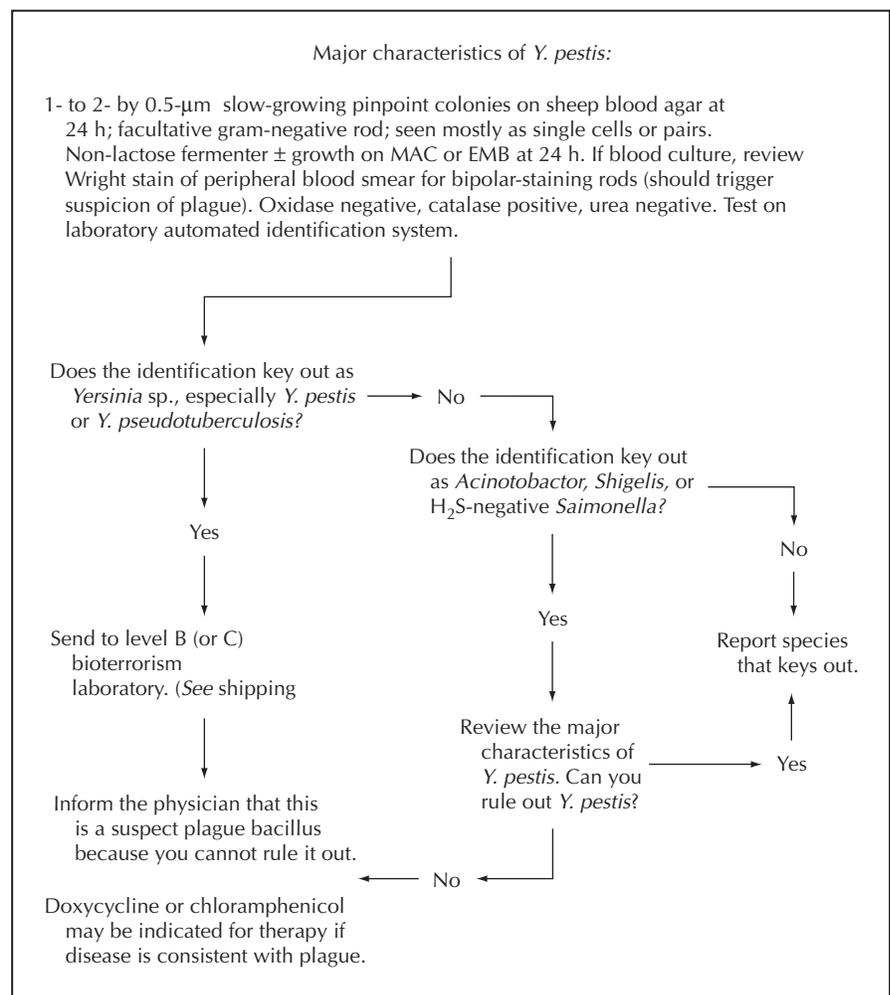

Figure 16.7–1 Plague evaluation—level A (sentinel) laboratory of laboratory response network.

VI. QUALITY CONTROL

Include QC information on reagent container and in QC records.

A. Stains

Routine QC for stains is recommended as outlined in the appropriate section of this handbook.

B. Culture

Routine QC for media and biochemicals are recommended as outlined elsewhere in this handbook.

C. Serology

Serological testing is usually performed only at the CDC or other large reference laboratories.

POSTANALYTICAL CONSIDERATIONS

VII. LIMITATIONS

A. Stains

1. Gram and Wright-Geimsa stains are nonspecific for plague, and the fluorescent-antibody stain on direct specimens is only presumptive evidence of *Y. pestis* infection (13).
2. In addition, fluorescent-antibody stains can only be performed on samples that have been refrigerated for <30 h. Longer refrigeration times can result in false-negative results (13).

B. Culture

1. Not all automated identification systems have a database that will allow the identification of *Y. pestis* (12), and some may actually misidentify the organism. In addition, due to the organism's low growth rate, initial negative results in routine biochemical testing may also be suspect (13).
2. Organisms that might be confused with *Y. pestis* include *Yersinia pseudotuberculosis*, *Shigella* spp., H₂S-negative *Salmonella*, and *Acinetobacter* spp. (16).

C. Serology

Detection of specific antibodies, while not a rapid means for diagnosing plague, is normally used retrospectively to confirm suspected cases (13).

VIII. NOTIFICATIONS

A. Notify your state health department of any suspected isolate of *Y. pestis*.

B. Consult with the state health laboratory prior to shipment of a specimen or isolate for confirmation.

C. If *Y. pestis* cannot be ruled out or is confirmed, infection control personnel should be informed for institution of infection control measures.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Francisella tularensis is a tiny, pleomorphic, nonmotile, fastidious, gram-negative, facultative intracellular coccobacillus. It is the causative agent of tularemia—a zoonotic plague-like disease distributed almost worldwide. In the United States, the main reservoir is the cottontail rabbit, but the disease may also be carried and transmitted by beavers, sheep, and muskrats. Transmission to humans is through the handling of wild-animal carriers, bites

of ticks or deerflies, or ingestion of untreated stream water.

Tularemia presents in the human population primarily as ulceroglandular disease (45 to 80%), as glandular infection (10 to 25%), and, less frequently, as oculoglandular, septic, oropharyngeal, and pneumonic (each <5%) forms. The incubation period is 2 to 10 days. The symptoms are not unique. Onset is sudden, typically with fever, chills, headache, generalized body

aches, pharyngitis, cough, and chest pain or tightness. There may be an ulcer at the inoculation site. If untreated, nonspecific symptoms may persist for several weeks, characterized by progressive weakness, sweats, and weight loss (1). Any of the principal forms of tularemia may be complicated by bacteremic spread, leading to pneumonia (common), sepsis (uncommon), and meningitis (rare) (2, 5). Person-to-person transmission does not occur.

II. SAFETY CONSIDERATIONS

It is imperative that these cultures be handled in a biosafety hood.

The organism is highly virulent and must be handled with extreme caution. Laboratory infections can be acquired through any manipulation in which aerosols or droplets are produced.

Clinical specimens suspected of containing *F. tularensis* should be handled using BSL 2 procedures. BSL 3 conditions are recommended for all culture manipulations as soon as *F. tularensis* is suspected (2, 3, 4).

III. SPECIMEN COLLECTION AND PROCESSING

Observe standard precautions.

NOTE: When *F. tularensis* is suspected, the physician must communicate this information to laboratory personnel because of the organism's danger to them.

A. Specimens of choice (1, 5) (see section 3 of this handbook)

1. Lymph node aspirate
2. Sputum, bronchial washings, and gastric washings
3. Ulcer material
4. Blood

B. Specimen transport and storage

Clinical specimens should be inoculated onto culture medium as soon as possible. If it is necessary to hold specimens for more than a few hours, refrigerate them at 4°C after moistening them with sterile broth or saline. If a specimen needs to be shipped to a distant laboratory for processing, it should be kept cold but not frozen (5).

C. Direct examination

Gram staining of biopsy material is of little value, as the small weakly staining organisms cannot be readily distinguished from background material (4).

III. SPECIMEN COLLECTION AND PROCESSING (*continued*)**D. Inoculation of specimen on medium**

1. Streak the specimen for isolation on the following media.
 - a. CHOC
 - b. BAP
 - c. MAC
 - d. Modified Thayer-Martin for contaminated specimens (*see* section 3 of this handbook)
2. Inoculate the specimen into thioglycollate broth and into BHI or TSB broth supplemented with 1% Isovitalax (2).
3. Incubate it at 35°C. in ambient air.
4. Inoculate blood specimens into the appropriate broth bottles according to individual institutional policy (5). *F. tularensis* grows in commercial blood culture systems in 2 to 5 days.

ANALYTICAL CONSIDERATIONS**IV. ORGANISM IDENTIFICATION****A. Culture characteristics**

1. 24 h on BAP, CHOC, and Thayer-Martin
 - a. Gray-white, translucent colonies
 - b. Usually too small to be seen individually
2. 48 h
 - a. BAP: <1-mm diameter, gray-white, opaque, no hemolysis or a tiny alpha-hemolytic zone
 - b. Thayer-Martin, CHOC: 1- to 2-mm diameter gray-white, flat, entire, smooth, shiny (4)
 - c. No growth on MAC
 - d. Oxidase negative
 - e. Catalase weakly positive or negative
 - f. Beta lactamase (Cefinase) positive (1)
 - g. Satelliting test negative using *Staphylococcus aureus* ATCC 25923 (1)
3. Broth growth characteristics (4) (*see* section 3 of this handbook)
Broth tubes may require 10 days of incubation due to slow growth of the organism.
 - a. Thioglycollate broth: growth is seen first as a dense band near the top that diffuses throughout the medium as the culture grows.
 - b. Isovitalax-supplemented broth: slight turbidity throughout the medium
 - c. Blood culture bottles: hold bottles for 7 to 10 days. If growth is detected, a sample should be removed for subculture on appropriate agar and for Gram staining (2).

B. Staining characteristics

The organisms are tiny, pleomorphic, faintly staining gram-negative coccobacilli that are hard to visualize even at $\times 1,000$ magnification. The use of basic fuchsin as a counterstain may aid in visualization.

C. Confirmatory identification (Fig. 16.8–1) (1)

If the organism appears to be *F. tularensis* based on Gram stain morphology, blood isolates that grow slowly on CHOC but poorly or not at all on BAP, faint growth in thioglycollate but not in unsupplemented broths (3), oxidase negative, Catalase weak positive or negative, cefinase positive, and Satellite test negative, refer the isolate to a level B laboratory for confirmatory identification.

■ Do not attempt identification using commercial identification systems due to the probability of misidentification.

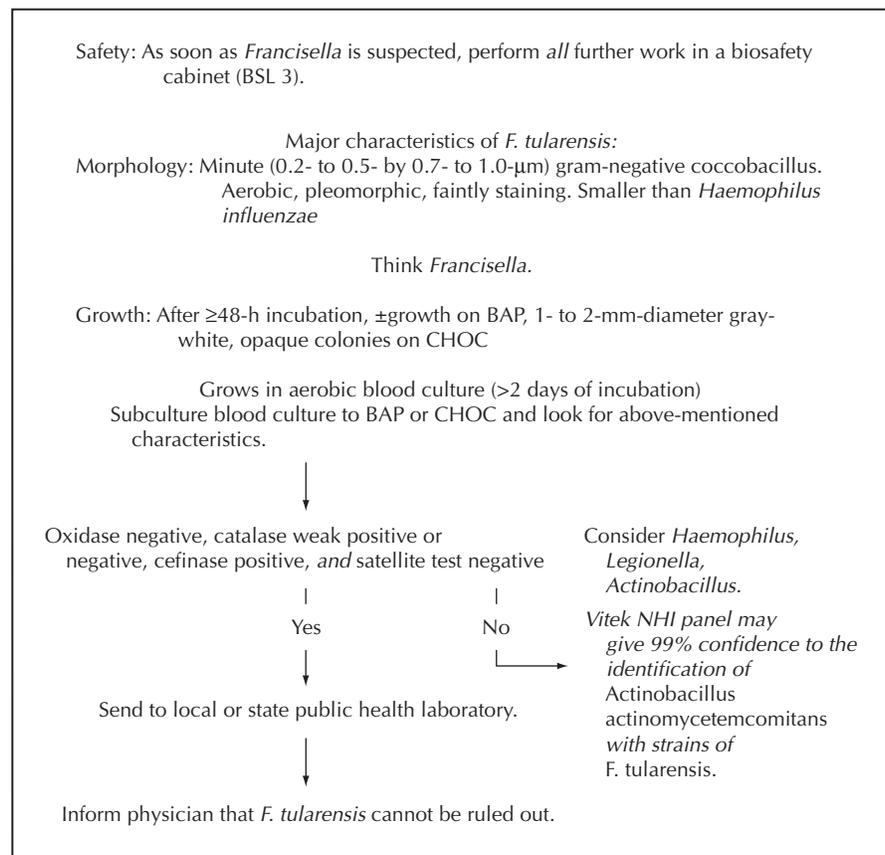

Figure 16.8–1 *Francisella* flowchart: level A laboratory of laboratory response network.

PREANALYTICAL CONSIDERATIONS

I. PRINCIPLE

Variola virus, the etiologic agent of smallpox, is considered among the highly virulent microorganisms likely to be used in bioterrorism activities. If a community exposure to variola virus occurs, the challenge for the clinical microbiology laboratory will be threefold: (i) management of clinical specimens and/or viral isolates safely and appropriately, (ii) recognition of the agent within the limitations of routine testing, and (iii) rapid notification of a potential outbreak to the proper authorities.

Variola virus is transmitted directly from person to person via inhalation of infective aerosols or by direct contact with contaminated materials. Transmission occurs at the onset of viral lesions and continues for 7 to 10 days. Infectivity diminishes with the onset of scab formation. Symptoms develop 12 to 14 days after a primary exposure. A period of approximately 2 weeks may ensue before detection of visible symptoms and confirmation

of the diagnosis. The symptoms are typical of many viral infections and include fever and severely aching muscles. Virus titers are concentrated in saliva during the first week of illness due to the initial presentation of vesicles in the oropharynx within 72 h of the advent of symptoms. Lesions then spread first to the face and then to the arms, hands, and feet during the next 7 to 14 days and are more abundant on the face, forearms, and lower legs and sparser on the trunk. Death may occur within 5 to 7 days in rapidly progressing infection or within 10 to 14 days in the more classical presentation of the infection.

The early appearance of the rash is identical to chickenpox; however, unlike chickenpox lesions, in which vesicles and older crusted lesions may occur together (crops), smallpox lesions are uniform in appearance during each stage of development. The rash is initially represented by erythematous papules (small round bumps), which progress to form vesicles,

then pustules, and finally scabs. Two severe variations of smallpox can also occur which may confuse the initial recognition of infected individuals. Hemorrhagic smallpox is characterized by a shorter incubation period followed by more severe prodromal symptoms and formation of petechiae and hemorrhages into the skin and mucous membranes. Death often occurs within 5 to 6 days of the onset of the petechial rash. Malignant smallpox is characterized not only by an abrupt onset of severe prodromal symptoms but also by the development of a vesicular rash that coalesces into soft, flattened, sometime hemorrhagic lesions which have the appearance of crepe rubber. The rash does not progress to the formation of pustules or scabs. The documentation of a carefully obtained clinical history will provide invaluable information that will help both the physician and the laboratory to recognize a smallpox infection (Table 16.9–1).

ANALYTICAL CONSIDERATIONS

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

Observe standard precautions.

A. Specimen collection

1. Smallpox may remain unrecognized in a patient at the time of initial specimen collection, and medical personnel may attempt to obtain samples from the skin lesions, as well as blood or other specimen sources, to verify the agent of infection. *Adherence to standard (universal) precautions is mandatory during the specimen collection and transport process. Medical and laboratory personnel must consider every specimen as a potential source of a highly infective agent.*
2. If smallpox is suspected, do not attempt to collect specimens for diagnostic testing. Immediately inform the appropriate personnel designated by the hospital's bioterrorism readiness protocol so that they may contact the local or

Table 16.9–1 Clinical conditions with symptoms compatible with smallpox

Preexanthem	Early exanthem	Late exanthem
Influenza	Measles, rubella	Chickenpox
Sepsis	Miscellaneous viral exanthem ^a	Erythema multiforme
Central nervous system infection	Drug eruptions	Stevens-Johnson syndrome
Appendicitis	Syphilis	Scabies
Pneumonia	Erythema multiforme	Impetigo
Leukemia	Insect bites	Drug eruptions
Enteric fever		Pemphigus
		Miscellaneous viral exanthem

^a A miscellaneous viral exanthem (skin rash) would include infections caused by herpes simplex virus, varicella-zoster virus, enteroviruses, or other poxviruses, such as the agents of vaccinia or molluscum contagiosum or poxviruses that can be passed from animals to humans. A careful clinical history, including travel and animal exposure, along with the appropriate diagnostic tests will aid in differentiation of the zoonotic poxvirus infections, which include monkeypox, cowpox, buffalopox, camelpox, orf, bovine papular stomatitis, sealpox, yabapox, and tanapox.

II. SPECIMEN COLLECTION, TRANSPORT, AND HANDLING

(continued)

state health department for further instructions. If no protocol exists, medical personnel should initiate direct communication with the local or state department of health.

- Individuals must be vaccinated before engaging in specimen collection from patients with suspected or confirmed cases of smallpox. Standard precautions, including gloves and mask, are mandatory.

B. Specimen transport and storage

- Store specimens from patients with suspected smallpox in a tightly sealed protective container under refrigeration prior to receiving transport instructions. Retain frozen specimens in the freezer, preferably at -70°C . Retain tissue culture tubes suspected of containing the virus at 35°C .
- Package each patient's specimen separately to avoid cross-contamination.

C. Transport

Clinical material collected for confirmation of a suspected case of smallpox must be transported to the CDC for analysis.

III. PROCEDURES

It is imperative that these cultures be handled in a biosafety hood.

A. Biosafety

A class II biological safety hood which meets BSL 2 specifications is adequate protection for processing of any specimens not initially recognized as harboring smallpox virus. As soon as preliminary information is received concerning the nature of the infection, any remaining specimens and/or culture isolates must be transported to a BSL 4 facility for further evaluation.

B. Methods of identification

Although a routine (level A) clinical laboratory should not attempt diagnostic testing for smallpox virus, the following methods are valuable for confirmation of infection.

- Electron microscopy using negative staining is the most rapid and sensitive method of detection for variola virus from lesions or scabs. Although all orthopoxviruses will look similar when viewed by electron microscopy, a presumptive identification can be made based on the patient's clinical history.
- Definitive identification requires growth of the virus in cell culture or on chorioallantoic egg membrane or by characterization of strains by newer molecular techniques, including PCR and measurement of restriction fragment length polymorphisms.

III. PROCEDURES *(continued)*

Observe standard precautions.

3. PCR has been described for identification of vaccinia virus and other types of poxviruses. Discrimination of different orthopoxvirus species by PCR is possible using primers directed against the gene sequences encoding the hemagglutinin protein. Electrophoretic analysis of viral proteins or viral DNA endonuclease cleavage profiles, restriction maps, and nucleotide sequences are definitive methods for differentiation of poxvirus genera and species.
4. Assays for measurement of the antibody response are only valuable for seroepidemiologic surveys and not for diagnosis of acute infection.

C. Recognition of smallpox in the routine clinical laboratory

1. Specimens sent for routine viral or bacterial culture, electron microscopy, or histopathology may harbor virus from a clinically unrecognized case of smallpox. Laboratorians are advised against initiating diagnostic testing for smallpox without the express consent of public health officials; however, differentiation of smallpox virus from other infectious agents in clinical specimens that may be discovered during routine testing procedures is mandatory for protection of the employee and rapid detection of an infection.
2. Refer to Table 16.9–2 for differential characteristics.

D. Reporting

In the event of an occurrence of smallpox, laboratories may be limited in their ability to confirm the presence of the virus in clinical samples without assistance from government reference laboratory facilities. Immediate communication with local, state, and federal health officials in the event of a suspected infection is mandatory in order to expedite the identification of smallpox virus and the initiation of outbreak protocols.

E. Interpretation of results

The documentation of a carefully obtained clinical history will provide invaluable information that will help both the physician and the laboratory in determining the etiologic agent of an orthopoxvirus infection. Acquisition of infection by members of the genus other than variola virus requires animal exposure. Additionally, the travel history of the patient is important in determining the source of zoonosis. This information, in conjunction with the sequence of prodromal symptoms and the location of vesicles, will allow rapid presumptive differentiation of these infections.

Table 16.9–2 Differentiation of smallpox virus from other agents of infection

Diagnostic test	Smallpox virus result	Differentiation
Electron microscopy	Brick-shaped particle 140–230 by 210–390 nm with rows of surface tubules arranged as parallel surface ridges	Large particle size limits identification to <i>Poxviridae</i> . Further distinction between viruses within <i>Poxviridae</i> is based on shape and surface morphology. Electron microscopy cannot differentiate variola virus from other members of the orthopoxviruses, such as whitepox, cowpox, tanapox, and molluscum contagiosum viruses, but can aid in differentiation of variola virus from members of other viral families, such as varicella-zoster virus.
Light microscopy	Visible as featureless unstained particles	Differentiation from bacteria and fungi based on size, morphology, and staining characteristics
	Hematoxylin-eosin-stained histological section or direct smear; round-oval basophilic or acidophilic intracytoplasmic bodies spreading from the vicinity of the nucleus (Guarnieri's bodies; B-type inclusions)	Histopathology of other causes of viral exanthems ^b
Tissue culture ^a	Growth in HEL, IHF, CEF, and MK cell lines at 35°C; CPE, 1–3 mm-diameter multinucleated plaques; cytoplasmic bridging; growth rate is variable; promotion of CPE may require several passages.	CPE caused by other agents of viral exanthems. ^b Initiate bioterrorism protocols if the identity of the viral agent is not confirmed using antigen detection or electron microscopy. Findings must be correlated with clinical symptoms.

^a Tissue cultures that will support the growth of smallpox include human embryonic lung (HEL) cells, infant human fibroblasts (IHF) or other human fibroblast cell lines, chicken embryonic fibroblasts (CEF), and various types of monkey kidney cell lines (MK). CPE, cytopathic effect.

^b See the footnote to Table 16.9–1.

rabbit plasma method, 3.17.14.1–3.17.14.3
colony morphology, 3.3.2.2, 3.3.2.5
CSF culture, 3.7.1–3.7.7
culture
initial examination of primary plates, 3.3.2.2–3.3.2.4
interpretation, 3.3.2.13
interpretation and rapid identification of bacteria on primary culture media, 3.3.2.1–3.3.2.14
limitations, 3.3.2.13
preliminary testing, 3.3.2.4–3.3.2.10
primary, 3.3.2.1–3.3.2.14
principles, 3.3.2.1
reporting results, 3.3.2.11–3.3.2.12
specimen, 3.3.1.1–3.3.1.9, 3.3.2.1
culture media, 3.3.1.2–3.3.1.3
cystic fibrosis culture, 3.11.3.1–3.11.3.9
decarboxylase-dihydrolase tests, 3.17.15.1–3.17.15.4
DNase test-rapid thermonuclease test, 3.17.16.1–3.17.16.3
esculin test, 3.17.5.1–3.17.5.3
fecal culture, 3.8.2.1–3.8.2.19
gelatin liquefaction test, 3.17.18.1–3.17.18.3
genital culture, 3.9.1.1–3.9.1.14
glucan production test, 3.17.19.1–3.17.19.2
Gram reaction enzymatic test, 3.17.20.1–3.17.20.2
Gram stain, 3.2.1.1–3.2.1.22
gram-negative bacteria, 3.18.2.1–3.18.2.21
gram-positive bacteria, 3.18.1.1–3.18.1.15
hippurate hydrolysis rapid test, 3.17.21.1–3.17.21.3
hydrogen sulfide production test, 3.17.22.1–3.17.22.3
identification, 3.16.1
indole test, 3.17.23.1–3.17.23.4
indoxyl acetate disk test, 3.17.24.1–3.17.24.2
Kligler's iron agar test, 3.17.25.1–3.17.25.3
lecithinase test, 3.17.27.1–3.17.27.3
leucine aminopeptidase test, 3.17.26.1–3.17.26.2
lipase test, 3.17.27.1–3.17.27.3
lower respiratory tract culture, 3.11.2.1–3.11.2.15
malonate test, 3.17.29.1–3.17.29.2
- methyl red-Voges-Proskauer test, 3.17.33.1–3.17.33.4
MGP test, 3.17.30.1–3.17.30.3
motility test, 3.17.31.1–3.17.31.4
MRS broth test, 3.17.32.1–3.17.32.2
MUG test, 3.17.34.1–3.17.34.3
nasal sinus culture, 3.11.9.1–3.11.9.4
nitrate reduction test, 3.17.35.1–3.17.35.3
nitrite reduction test, 3.17.35.1–3.17.35.3
ocular culture, 3.10.1–3.10.8
odor of colonies, 3.3.2.4
ONPG test, 3.17.37.1–3.17.37.2
optochin susceptibility test, 3.17.38.1–3.17.38.3
otitis culture, 3.11.5.1–3.11.5.6
oxidase test, 3.17.39.1–3.17.39.3
pathogens of gastroenteritis, fecal culture, 3.8.1.1–3.8.1.20
phenylalanine deaminase test, 3.17.40.1–3.17.40.3
pigment production, 3.3.2.3
polysaccharide production test, 3.17.19.1–3.17.19.2
preliminary identification, 3.3.2.1–3.3.2.14
PYR test, 3.17.41.1–3.17.41.3
rapid identification, 3.3.2.1–3.3.2.14
salmonella-shigella agar test for growth, 3.17.46.1–3.17.46.2
salt and temperature tolerance test, 3.17.43.1–3.17.43.3
satellite test, 3.17.44.1–3.17.44.3
sodium polyanetholsulfonate test, 3.17.45.1–3.17.45.2
soft tissue culture, 3.13.1.1–3.13.1.16
specimen acceptability, 2.1.20
specimen collection, 3.3.1.1
specimen processing, 3.3.1.1–3.3.1.9
incubation of plates and broths, 3.3.1.7–3.3.1.8
inoculation technique, 3.3.1.6–3.3.1.7
materials, 3.3.1.2–3.3.1.3
medium choices, 3.3.1.5–3.3.1.6
order of tests, 3.3.1.4
principle, 3.3.1.1
procedures, 3.3.1.4–3.3.1.8
quality control, 3.3.1.3–3.3.1.4
reporting results, 3.3.1.8
specimen pretreatment, 3.3.1.4–3.3.1.5
timing, 3.3.1.4
specimen transport, 3.3.1.1
starch hydrolysis test, 3.17.47.1–3.17.47.2
suppliers of media and reagents, 3.1.2–3.1.3
triple sugar iron agar test, 3.17.25.1–3.17.25.3
urea test, 3.17.48.1–3.17.48.3
urine culture, 3.12.1–3.12.31
wet mount, 3.2.3.1–3.2.3.6
wound culture, 3.13.1.1–3.13.1.16
quantitative, 3.13.2.1–3.13.2.4
- Aerococcus*, 3.2.1.13, 3.3.2.8, 3.17.3.3, 3.17.26.1–3.17.26.2, 3.17.43.1, 3.18.1.1
- Aerococcus urinae*, 3.12.2, 3.12.13, 3.18.1.4, 3.18.1.10

Borrelia afzelii, 11.6.1
Borrelia burgdorferi, 3.4.1.16, 3.5.7, 11.6.1, 11.7.2.6, 13.13.1
 antibody detection, 11.6.1–11.6.10
 commercial tests, 11.6.3–11.6.4
 first-step antibody testing, 11.6.2, 11.6.4, 11.6.6–11.6.7
 immunoblot (second-step testing), 11.6.4, 11.6.6–11.6.8
 characteristics, 11.6.1
 culture, 11.6.1
 ELISA, 11.6.2–11.6.3, 11.6.6–11.6.7
 enzyme immunoassay, 11.6.2, 11.6.6–11.6.7
 IFA test, 11.6.2
 immunoblot, 11.6.2
 serological tests, 11.1.2.4, 11.7.2.6
 urinary antigen, 11.6.1
- Borrelia burgdorferi* IgG/IgM, 11.6.3
Borrelia burgdorferi IgG/IgM ELISA, 11.6.3
 Borrelia Dot G test, 11.6.3
 Borrelia Dot M test, 11.6.3
Borrelia garinii, 11.6.1
Borrelia vincentii, 3.11.1.2
- Botulinum toxin, bioterrorism, 16.5.1–16.5.3
- Botulism
 adult, 16.5.1
 bioterrorism, 16.5.1–16.5.3
 child, 16.5.1
 food-borne, 16.5.1
 incubation period, 16.1.2
 wound, 16.5.1
- Bovine albumin solution, 7.1.2.6
- Bowel culture, surveillance cultures from immunocompromised hosts, 13.11.1–13.11.4
- Brachiola*, 9.10.2.7, 9.10.2.10–9.10.2.12, 9.10.2.18
- Brain abscess, 2.1.8
- Brain heart infusion broth, 3.3.1.3
- Brain specimen, *see* Central nervous system specimen
- Breakpoint MIC panels, 5.2.14, 5.2.17
- Breakpoint MIC testing, 5.2.1
- Breast milk specimen, 2.1.11
- Brefeldin A, flow cytometry whole-blood intracellular cytokine assay, 11.15.1–11.15.4
- Brevibacterium*, 3.18.1.13
Brevundimonas diminuta, 3.18.2.20
Brevundimonas vesicularis, 3.18.2.9, 3.18.2.13, 3.18.2.16
- Brilliant green agar, 3.8.1.5, 3.8.1.7
- Bromocresol green agar, 14.2.16
- Bromocresol purple, 3.17.9.1
- Bromocresol purple agar, *see* BCP agar
- Bromo-chloro-indolyl butyrate, 3.17.7.1
- Bromthymol blue, 3.17.29.1
- Bronchial aspirate, *M. tuberculosis*, 12.2.3.19–12.2.3.22
- Bronchial brushings
 cystic fibrosis culture, 3.11.3.1–3.11.3.9
Legionella culture, 3.11.4.2
- Bronchial lavage specimen
 Gram stain, 3.2.1.12
M. tuberculosis, 12.2.3.19–12.2.3.22
- Bronchial specimen, *Legionella* culture, 3.11.4.1–3.11.4.14
- Bronchial washing
 actinomycetes, 6.1.3
F. tularensis, 16.8.1
 Gram stain, 3.2.1.9, 3.2.1.12
Legionella culture, 3.11.4.1–3.11.4.14
 mycobacteria, 7.5.1–7.5.3
 viruses, 10.4.3
- Bronchiolitis, 3.11.1.2
- Bronchitis, 2.1.4, 3.11.1.2
- Bronchoalveolar lavage specimen
 cystic fibrosis culture, 3.11.3.1–3.11.3.9
 Gram stain, 3.2.1.4
Legionella culture, 3.11.4.2
M. pneumoniae, 12.2.3.62–12.2.3.73
M. tuberculosis, 12.2.3.7–12.2.3.19
 quantitative culture, 3.11.2.12–3.11.2.15
 viruses, 10.4.3
- Bronchoscopy specimen
 collection, 3.11.2.2–3.11.2.3
 culture, 3.11.2.1–3.11.2.15
 parasites, 9.7.3.1–9.7.3.6
- Broth culture, specimen for Gram stain, 3.2.1.6
- Broth macrodilution method, synergism testing, 5.12.1–5.12.23
 calculations, 5.12.9
 dilution schematics, 5.12.18
 limitations, 5.12.12
 limited-series checkerboard format, 5.12.18
 materials, 5.12.6
 principle, 5.12.1
 procedures, 5.12.7–5.12.12
 quality control, 5.12.7
 reporting results, 5.12.9–5.12.10
 specimen, 5.12.1
- Broth microdilution checkerboard method, synergism testing, 5.12.1–5.12.23
 calculations, 5.12.5
 dilution schematic for two-agent checkerboard, 5.12.15
 format of panel, 5.12.14
 indifference and antagonism, 5.12.17
 limitations, 5.12.12
 materials, 5.12.1–5.12.2
 principle, 5.12.1
 procedures, 5.12.2–5.12.4, 5.12.10–5.12.12
 quality control, 5.12.2
 reporting results, 5.12.5–5.12.6
 specimen, 5.12.1
 synergism, partial synergism, and indifference, 5.12.16
- Broth microdilution MIC testing, 5.2.1–5.2.17
 anaerobes, 5.7.1–5.7.8
 media and reagents, 5.7.6–5.7.7
 suppliers, 5.7.7
 breakpoint MIC panels, 5.2.14, 5.2.17
 extended-spectrum beta-lactamase testing, 5.2.12–5.2.13
Haemophilus, 5.2.10
 limitations, 5.2.8
 materials, 5.2.1–5.2.2
 preparation of MIC tray, 5.15.1–5.15.18
 principle, 5.2.1
 procedures, 5.2.3–5.2.5, 5.2.7–5.2.8
 quality control, 5.2.2–5.2.3, 5.2.8, 5.2.16, 5.7.2, 5.7.8, 5.13.10–5.13.11
 quick reference list, 5.2.9
 reporting results, 5.2.6
S. pneumoniae, 5.2.11
 skipped wells, 5.2.8, 5.7.5
 specimen, 5.2.1
Streptococcus, 5.2.11
- Brucella*, 3.4.1.1, 3.4.1.7, 3.4.1.10, 3.4.1.16, 3.5.1, 3.5.6, 3.11.6.7, 3.13.1.9–3.13.1.11–3.13.1.13, 15.2.1.1, 15.3.3.1
 biochemical tests, 3.17.44.2, 3.17.48.1, 3.17.48.3
 bioterrorism, 16.6.1–16.6.5
 blood culture, 3.4.2.1–3.4.2.6
 bone marrow culture, 3.4.2.1
 catalase test, 16.6.4
 colony morphology, 16.6.2
 Gram stain, 16.6.2–16.6.3
 identification schemes, 3.18.2.4, 3.18.2.7, 3.18.2.14
 oxidase test, 16.6.2–16.6.3
 satellite test, 16.6.4
 similar gram-negative coccobacilli, 3.4.2.4
 specimen collection, 16.6.1
 specimen processing, 16.6.2
 staining, 3.2.1.1, 3.2.1.7, 3.2.1.14
 urea hydrolysis test, 16.6.3–16.6.4
- Brucella abortus*, 3.4.2.1, 16.3.3, 16.6.1, 16.6.4
Brucella agar, 4.2.5, 14.2.7
Brucella blood agar, 4.3.3, 4.3.5–4.3.6
Brucella broth, 3.3.1.3
 supplemented, 5.7.6
Brucella canis, 3.4.2.1, 16.6.1, 16.6.4
Brucella melitensis, 3.4.2.1, 16.3.3, 16.6.1, 16.6.4
Brucella suis, 3.4.2.1, 16.3.3, 16.6.1, 16.6.4
 Brucellosis, 3.4.2.1
 bioterrorism, 16.6.1–16.6.5
 incubation period, 16.1.2

primary, 3.3.2.1–3.3.2.14
quality control, 3.3.2.2, 3.8.1.7, 5.14.3.2–5.14.3.3, 5.14.3.10, 7.3.1–7.3.3, 8.4.4, 8.9.9–8.9.10, 10.2.10, 14.2.2–14.2.19, 14.2.33–14.2.34, 14.3.15
yeasts, 8.8.12–8.8.13
- Culture worksheet, 14.3.9
- Cunninghamella*, 8.9.3, 8.9.39
- Cunninghamella bertholletiae*, 8.9.8

- Cunninghamella elegans*, 8.9.8
 Current Procedural Terminology codes, *see* CPT codes
Curvularia, 8.2.2, 8.3.5, 8.9.5, 8.9.13, 8.9.39, 8.9.42
 Custom panel, 1.1.3
 Cutaneous leishmaniasis, 9.10.2.6
 Cycloheximide, chlamydial culture, 10.6.4, 10.6.11
 Cycloheximide resistance test, fungi, 8.7.5, 8.8.5, 8.9.10, 8.9.12–8.9.13
 Cycloserine, antimicrobial susceptibility testing of *M. tuberculosis*, 7.8.1.7
 Cycloserine-cefoxitin fructose agar (CCFA), 4.3.4
 Cycloserine-cefoxitin-egg yolk agar, 3.8.1.5, 3.8.1.7
Cyclospora, 9.4.5.2, 9.10.5.1, 9.10.8.1
Cyclospora cayetanensis, 9.2.1.4, 9.3.6.5, 9.10.2.3–9.10.2.5, 9.10.2.9–9.10.2.11, 9.10.2.18
 acid-fast stain, 9.2.1.4
 Kinyoun's acid-fast stain, modified, 9.4.1.1–9.4.1.4
 Ziehl-Neelsen acid-fast stain (hot), 9.4.2.1–9.4.2.4
Cylindrocarpum, 8.9.39
 Cyst(s)
 Acanthamoeba, calcofluor white stain, 9.3.8.1–9.3.8.5
 E. hartmanni, 9.10.3.5
 E. histolytica/E. dispar, 9.10.3.3, 9.10.3.5
 parasite, fecal specimen, 9.3.1.1–9.3.1.2
 protozoan, 9.3.2.3, 9.10.2.11
 fecal specimen, 9.3.3.2, 9.3.4.3, 9.3.5.1, 9.3.5.3, 9.3.6.1–9.3.6.6, 9.3.7.1–9.3.7.7, 9.3.8.1–9.3.8.5
 Cysteine protease peptone agar, 14.2.8
 Cysteine trypticase agar, 3.17.9.1–3.17.9.2, 3.17.9.4–3.17.9.5
 Cysteine-peptone-liver-maltose (CPLM) complete medium, 9.9.3.4–9.9.3.5
 Cystic fibrosis, 3.11.1.2
 respiratory culture, 3.11.3.1–3.11.3.9
 interpretation, 3.11.3.8
 limitations, 3.11.3.9
 materials, 3.11.3.3
 principle, 3.11.3.1
 procedures, 3.11.3.4–3.11.3.9
 quality control, 3.11.3.3–3.11.3.4
 reporting results, 3.11.3.8
 specimen collection, 3.11.3.2
 Cystine lactose electrolyte-deficiency agar, 14.2.8
 Cystitis, 3.12.3
 Cystoscopy, urine collection, 3.12.4
 Cystostomy, 3.12.3
 Cyto centrifugation, 15.4.3.1
 Cytochrome oxidase, 3.17.39.1
 Cytohistopathology, viruses, 10.7.8–10.7.10
 Cytokines
 ELISA, 11.14.1–11.14.6
 quantitation of IL-4, IL-6, and gamma interferon, 11.14.1–11.14.6
 standards, 11.14.5–11.14.6
 whole-blood intracellular-cytokine assay, flow cytometric, 11.15.1–11.15.4
 Cytomegalovirus (CMV)
 cell culture, 10.2.3, 10.5.28
 clinical manifestations of disease, 10.1.3
 cytopathic effect, 10.5.6, 10.5.8, 10.5.17
 Digene Hybrid Capture CMV DNA assay, 12.2.2.6–12.2.2.10
 direct specimen testing, 10.7.1
 DNA in white blood cells, 12.2.2.6–12.2.2.10
 hybridization antibody capture assay, 12.2.2.6–12.2.2.10
 identification, 10.5.8, 10.5.24
 immunofluorescence test, 10.7.2, 10.7.5
 inclusions, 10.7.8–10.7.10
 molecular methods, 12.1.1–12.1.2
 serologic diagnosis, 11.1.2.2, 11.1.2.4, 11.1.2.8
 shell vial culture, 10.5.1, 10.5.4, 10.5.8
 specimen collection and processing, 10.4.2–10.4.4, 10.4.6–10.4.7
 Cytopathic effect (CPE), virus, 10.5.1, 10.5.5–10.5.18, 10.5.29
 Czapek-Dox agar, 8.4.3, 8.7.4, 14.2.16
- ## D
- D'Antoni's iodine solution, 9.3.3.3, 9.3.7.5, 9.6.2.2, 9.6.2.4, 9.7.1.4
 modified, 9.6.6.4
 Dacryoadenitis, 2.1.8, 3.10.3–3.10.4, 3.10.8
 Dacryocystitis, 2.1.8, 3.10.2, 3.10.4, 3.10.8
Dactylaria, 8.9.39
 DAEA-dextran procedure, isolation of *Chlamydia*, 10.6.9, 10.6.11
 Dairy products, unpasteurized, 3.4.2.1
 Dangerous goods, 16.3.3
 Daptomycin, 5.1.6, 5.2.7, 5.8.6, 5.16.8
 Dark-field microscopy, *T. pallidum*, 3.2.3.5
Debaryomyces, 8.5.4
Debaryomyces hansenii, 8.8.2
 Decarboxylase broth, 14.2.8
 Decarboxylase-dihydrolase tests, 3.17.15.1–3.17.15.4
 Decomposition of substrates, actinomycetes, 6.2.4–6.2.9, 6.3.3.3
 Decontamination of cell culture, 10.5.28
 Decontamination of work environment, 15.2.3.1–15.2.3.5
 biohazard pail, 15.2.3.2
 cleanup of biohazardous spills, 15.2.4.1–15.2.4.3
 computer keyboard, 15.2.3.3
 equipment, 15.2.3.2
 germicides, 15.2.3.1–15.2.3.5
 quality control, 15.2.3.4
 work surfaces, 15.2.3.2
 worksheet, 15.2.3.5
 Decubitus ulcer specimen, 4.2.3
 Deionization, water purification, 14.4.3
 Delafield's hematoxylin stain, 9.8.8.1–9.8.8.4
 blood films, 9.8.1.8
 reagents, 9.8.8.3–9.8.8.4
Delftia, 3.18.2.9
Delftia acidovorans, 3.17.1.1, 3.17.23.2, 3.18.2.20
 Dendritic cell assays, 11.1.3.1–11.1.3.2
 Dengue virus, 10.1.6
 Deoxycholate, 14.2.21
 Deoxycholate agar, 14.2.9
 Department of Health and Human Services, U.S., select-agent rule, 16.3.1–16.3.3
 Department of Transportation, U.S.
 regulation of infectious waste transport, 15.7.1, 16.3.1
 shipping guidelines for infectious substances, 15.5.1, 15.5.5

- Endotracheal aspirate (*continued*)
 culture, 3.11.2.1–3.11.2.15
 cystic fibrosis culture, 3.11.3.1–3.11.3.9
 rejection criteria, 3.2.1.20–3.2.1.21
- Engineering controls, 15.3.5.1–15.3.5.2
- Engyodontium album*, 8.9.41
- Entamoeba coli*, 9.3.3.2–9.3.3.3, 9.3.4.4, 9.3.5.3, 9.6.2.3, 9.6.3.3, 9.10.2.3, 9.10.2.8, 9.10.3.1–9.10.3.5
- Entamoeba dispar*, 9.10.2.3, 9.10.2.8
- Entamoeba gingivalis*, 9.7.1.1
- Entamoeba hartmanni*, 9.10.2.3, 9.10.2.8, 9.10.3.5
- Entamoeba histolytica*, 9.2.1.3–9.2.1.4, 9.6.2.1, 9.6.2.4, 9.6.3.1–9.6.3.3, 9.7.1.1, 9.7.3.4, 9.7.4.2–9.7.4.4, 9.10.1.1, 9.10.2.3–9.10.2.8, 9.10.2.18, 9.10.3.2–9.10.3.5, 9.10.6.6, 9.10.8.3
 biopsy specimen, 9.7.4.4
 culture, 9.9.1.1–9.9.1.8
 axenic, 9.9.1.1–9.9.1.8
 xenic, 9.9.1.1–9.9.1.8
 expectorated sputum, 9.7.1.1–9.7.1.4
 sigmoidoscopy specimen, 9.6.2.1–9.6.2.4, 9.6.3.1–9.6.3.3
- Entamoeba histolytica/E. dispar*, 9.2.1.2–9.2.1.4, 9.3.3.3, 9.3.4.4, 9.3.5.3, 9.3.6.4, 9.3.7.4, 9.6.2.1–9.6.2.4, 9.6.3.1–9.6.3.3, 9.10.1.1–9.10.1.2, 9.10.2.8, 9.10.3.1–9.10.3.5, 9.10.6.6, 9.10.8.1–9.10.8.3
 immunoassay, 9.2.1.4
 sigmoidoscopy specimen, 9.6.2.1–9.6.2.4, 9.6.3.1–9.6.3.3
- Entamoeba moshkovskii*, 9.9.1.2
- Enteric fermentation broth, 3.17.9.2–3.17.9.3, 3.17.9.5
- Enterobacter*, 3.12.1, 3.13.1.2, 12.4.5.5
 antimicrobial susceptibility testing, 5.1.6, 5.2.8, 5.13.16, 5.15.3, 5.17.7–5.17.11
 biochemical tests, 3.17.12.1, 3.17.16.1, 3.17.33.3
 epidemiology and infection control, 13.5.2–13.5.3, 13.13.4
- Enterobacter aerogenes*, 5.13.12, 5.17.3, 14.1.11, 14.2.6, 14.2.9–14.2.12
- Enterobacter agglomerans*, 3.16.5, 5.13.12, 13.13.1
- Enterobacter amnigenus*, 3.16.5
- Enterobacter asburiae*, 3.16.5
- Enterobacter cancerogenus*, 3.16.5
- Enterobacter cloacae*, 3.8.1.5, 3.16.5, 3.17.15.2, 5.12.13, 5.13.12, 5.15.16, 5.16.5, 5.17.3, 13.13.1, 13.13.4, 14.1.11, 14.2.8, 14.2.21
- Enterobacter gergoviae*, 3.16.5
- Enterobacter hormaechei*, 3.16.5
- Enterobacter intermedius*, 3.16.5
- Enterobacter sakazakii*, 3.16.5
- Enterobacteriaceae*, 3.6.1, 3.8.1.11, 3.10.2, 3.11.3.4, 3.12.14, 3.13.1.1, 3.13.1.13–3.13.1.14, 3.16.2, 12.1.4–12.1.5
 antibiogram, 5.13.12
 antimicrobial resistance determination, 12.1.5
 antimicrobial susceptibility testing, 5.1.9, 5.2.4–5.2.6, 5.2.9, 5.2.13, 5.3.4, 5.8.7, 5.10.1.13, 5.10.2.7, 5.11.14, 5.12.13, 5.13.5–5.13.8, 5.13.15–5.13.16, 5.16.1–5.16.7, 5.17.4
 biochemical tests, 3.17.9.5, 3.17.12.1–3.17.12.2, 3.17.15.2–3.17.15.3, 3.17.16.1, 3.17.16.3, 3.17.18.2, 3.17.22.1, 3.17.23.2, 3.17.29.1–3.17.29.2, 3.17.31.1–3.17.31.3, 3.17.33.1, 3.17.33.3, 3.17.34.1, 3.17.35.1–3.17.35.2, 3.17.37.1, 3.17.39.2–3.17.39.3, 3.17.40.1–3.17.40.3, 3.17.48.1–3.17.48.3
 genital culture, 3.9.1.1–3.9.1.6, 3.9.1.9
 identification schemes, 3.18.2.4, 3.18.2.8
 staining, 3.2.1.11, 3.2.1.14
- Enterobius*, 9.10.8.3
- Enterobius vermicularis*, 9.1.5, 9.3.1.1–9.3.1.2, 9.6.1.1–9.6.1.3, 9.10.2.3, 9.10.2.13
- Enterococci
 antimicrobial resistance determination, 12.1.5
 identification, 3.18.1.9
 vancomycin-resistant
 fecal culture, 3.8.5.1–3.8.5.4
 MGP test, 3.17.30.1–3.17.30.3
 multiplex PCR, 12.5.2.1–12.5.2.4
 prospective, focused surveillance, 13.17.1–13.17.3
 surveillance cultures from immunocompromised hosts, 13.11.1–13.11.4
- Enterococcus*, 3.3.2.5, 3.3.2.8, 3.4.1.9–3.4.1.12, 3.8.5.3, 3.9.1.1–3.9.1.4, 3.11.2.9, 3.13.1.2, 4.10.5, 12.4.5.5, 13.5.2
 antimicrobial susceptibility testing, 5.1.6, 5.1.9, 5.2.5–5.2.6, 5.2.9, 5.8.7, 5.10.1.13, 5.10.2.7, 5.11.14, 5.13.15–5.13.16, 5.15.3, 5.16.1
 biochemical tests, 3.17.4.4, 3.17.5.2, 3.17.26.1–3.17.26.2, 3.17.41.2, 3.17.43.1–3.17.43.2
 high-level aminoglycoside resistance
 agar screen method, 5.5.1–5.5.5
 broth dilution method, 5.5.3
 disk diffusion method, 5.5.3
 screen tests, 5.5.1–5.5.5
 identification schemes, 3.18.1.3–3.18.1.5, 3.18.1.10–3.18.1.11
 molecular methods, 12.1.3
 staining, 3.2.1.10, 3.2.1.13
 urine culture, 3.12.1–3.12.2, 3.12.7, 3.12.13
 vancomycin resistance agar screen test, 5.6.1–5.6.4
- Enterococcus avium*, 3.16.10, 3.16.13, 3.17.15.3, 3.18.1.9
- Enterococcus casseliflavus*, 3.8.5.1–3.8.5.2, 3.16.10, 3.16.13, 3.17.30.1–3.17.30.2, 3.17.31.3, 3.18.1.9, 5.6.2–5.6.3, 12.5.2.2
- Enterococcus cecorum*, 3.16.13
- Enterococcus columbae*, 3.16.13
- Enterococcus dispar*, 3.18.1.9
- Enterococcus durans*, 3.16.10, 3.16.13, 3.18.1.9
- Enterococcus faecalis*, 3.4.1.12, 3.9.2.3–3.9.2.5, 3.12.6, 3.16.10, 3.16.13
 antimicrobial susceptibility testing, 5.1.2, 5.1.6, 5.2.2, 5.2.7, 5.3.5, 5.5.2, 5.6.1–5.6.2, 5.8.2–5.8.5, 5.12.13, 5.13.2, 5.13.9, 5.13.14–5.13.15, 5.14.3.2, 5.14.3.10, 5.15.8, 5.16.7–5.16.9
 biochemical tests, 3.17.5.2, 3.17.6.1, 3.17.9.5, 3.17.15.3, 3.17.19.1, 3.17.26.1, 3.17.30.2–3.17.30.3, 3.17.32.1, 3.17.38.2, 3.17.41.1, 3.17.43.2, 3.17.46.2, 3.17.47.1
 fecal culture, 3.8.1.7, 3.8.5.1–3.8.5.2
 identification schemes, 3.18.1.2, 3.18.1.5, 3.18.1.9
 molecular methods, 12.5.2.1–12.5.2.4
 quality assurance/quality control, 14.1.12, 14.2.8–14.2.14, 14.2.21
- Enterococcus faecium*, 3.4.1.12, 3.8.5.1, 3.16.10, 3.16.13, 3.18.1.2, 3.18.1.5, 3.18.1.9, 12.5.2.1–12.5.2.4, 14.1.12
- antimicrobial susceptibility testing, 5.5.3, 5.6.2, 5.12.13, 5.13.14–5.13.15, 5.16.5, 5.16.5, 5.16.9, 5.17.4
 biochemical tests, 3.17.9.5, 3.17.14.3, 3.17.30.1–3.17.30.2, 3.17.31.3, 3.18.1.9, 5.6.2–5.6.3, 12.5.2.2
Enterococcus hirae, 3.16.10, 3.16.13, 3.18.1.9
Enterococcus malodoratus, 3.16.10, 3.16.13
Enterococcus mundtii, 3.16.14, 3.18.1.9
Enterococcus raffinosus, 3.8.5.1, 3.16.10, 3.16.14, 3.18.1.5, 3.18.1.9
Enterococcus solitarius, 3.16.10, 3.16.14
Enterocytozoon, 9.10.2.7, 9.10.2.10–9.10.2.12, 9.10.2.18
Enterocytozoon bieneusi, 9.3.8.1, 9.4.3.1–9.4.3.3, 9.4.4.1–9.4.4.3, 9.4.5.3, 9.7.4.4
- Enterohemorrhagic *Escherichia coli* (EHEC), 11.8.1
- Entero-Test capsule, 9.6.4.1–9.6.4.4
- Enterotube II, 3.16.2
- Enterovirus
 cell culture, 10.2.2–10.2.3
 clinical manifestations of disease, 10.1.2
 cytopathic effect, 10.5.8
 hemagglutination characteristics, 10.5.41
 identification, 10.5.8
 molecular methods, 12.1.3
 specimen collection and processing, 10.4.2–10.4.3
- Environment analysis, health care, *see* Health care environment analysis
- Environmental sampling
B. anthracis, 16.4.3
 contraindications, 13.3.1
 guidance for, 13.3.1
 infection control, policies for, 13.3.1–13.3.3
- Environmental surfaces
 microbiological assay
 culture procedures, 13.10.3–13.10.7
 culture workup, 13.10.8
 interpretation, 13.10.8–13.10.9
 materials, 13.10.2–13.10.3
 monitoring plan, 13.10.1–13.10.2
 recommendations against routine assays, 13.10.1
 noncritical, 13.10.8–13.10.9
 sampling, 13.10.3–13.10.7
 rinse fluid, 13.10.3–13.10.6
 rinse method using containment, 13.10.3, 13.10.7
 rinse sampling method using direct immersion, 13.10.3, 13.10.7
 RODAC sampling-culture method, 13.10.3, 13.10.7
 sponge-rinse method, 13.10.3, 13.10.6–13.10.7
 swab-rinse method, 13.10.3, 13.10.6
 wipe-rinse method, 13.10.3, 13.10.6–13.10.7
- Enzyme immunoassay (EIA)
 antibody detection, 11.1.2.3–11.1.2.4
 antigen detection, 11.1.2.3–11.1.2.4
B. burgdorferi, 11.6.2, 11.6.6–11.6.7
Campylobacter, 3.8.2.7, 3.8.2.16–3.8.2.19
Legionella urinary antigen, 11.4.1–11.4.6
 rickettsial disease, 11.7.3.1–11.7.3.3
 Shiga toxin, 11.8.1–11.8.6
 syphilis, 11.5.1.3
 Eosin-methylene blue medium, 3.3.1.2, 3.3.2.6, 14.2.9

- Eperythrozoon*, 3.4.3.4
Epicoccum, 8.9.13
Epicoccum nigrum, 8.9.47
Epidemic typhus, 11.7.2.5
Epidemiologic concepts, 13.4.1–13.4.5
Epidemiologic typing
 chromosomal restriction fragment analysis by pulsed-field gel electrophoresis, 12.4.5.1–12.4.5.7
 costs, 13.5.5
 genomic fingerprinting with arbitrarily primed PCR, 12.4.6.1–12.4.6.3
 genotypic, 13.5.3–13.5.5
 INNO-LiPA HCV II, 12.4.7.1–12.4.7.5
 molecular methods, 12.1.2, 12.1.4, 12.4.1.1–12.4.7.5
 phenotypic, 13.5.1–13.5.2, 13.5.5, 13.16.1.1–13.16.5.1
 plasmid fingerprinting
 gram-negative organisms, 12.4.2.1–12.4.2.4
 staphylococci, 12.4.3.1–12.4.3.5
 research versus clinical tools, 13.5.4–13.5.5
 ribotyping using chemiluminescent probe, 12.4.4.1–12.4.4.5
Epidermophyton, 8.2.3, 8.3.5–8.3.6
Epidermophyton floccosum, 8.9.24, 8.9.32–8.9.37
Epididymal aspirate, *Chlamydia*, 10.6.3
Epididymis, specimen collection, 3.9.1.6, 3.9.3.2
Epididymitis, 2.1.6, 3.9.1.4
Epidural abscess, 2.1.9
 cranial, 2.1.3
Epiglottitis, 2.1.3, 3.11.1.2
Epstein-Barr virus
 cell culture, 10.2.3
 clinical manifestations of disease, 10.1.3
 molecular methods, 12.1.3
Equipment, reusable, decontamination, 15.2.3.1–15.2.3.5
Error tracking
 quality assurance, 14.1.6, 14.1.17–14.1.18, 14.1.24–14.1.26
 random reviews for errors, 14.1.24
 reported error description log, 14.1.25
 reporting, 14.1.4
Ertapenem, 5.16.5
Erysipelothrix, 3.2.1.13, 3.3.2.8, 3.4.1.12, 3.13.1.11–3.13.1.12, 3.17.20.1, 3.17.25.1, 5.16.8
Erysipelothrix rhusiopathiae, 3.2.1.9, 3.13.1.2, 3.17.22.2, 3.17.25.3, 3.18.1.4, 3.18.1.11, 5.6.3, 5.13.15–5.13.16
Erythema migrans, 2.1.6, 11.6.1
Erythrocytes
 citrate-treated human type O, 11.2.2.2
 suspension for anti-streptolysin O test, 11.2.2.2
Erythromycin, 5.1.6, 5.2.7, 5.4.2, 5.15.7–5.15.8, 5.16.8, 5.17.4, 6.2.6
ESBL, *see* Extended-spectrum beta-lactamase
Escherichia coli, 3.3.2.5–3.3.2.7, 3.7.1, 3.13.1.2, 3.13.1.13–3.13.1.14, 3.16.5, 4.3.3–4.3.4, 4.6.2.1, 4.6.3.2, 4.6.13.1, 7.2.2, 7.3.2–7.3.3, 7.5.2, 8.5.2, 9.3.8.2–9.3.8.3, 15.2.1.1
 antimicrobial susceptibility testing, 5.1.2–5.1.5, 5.1.8, 5.1.13–5.1.14, 5.2.2–5.2.3, 5.2.6, 5.2.10–5.2.13, 5.8.2–5.8.5, 5.10.1.10, 5.12.2, 5.12.7, 5.13.2–5.13.5, 5.13.9–5.13.16, 5.14.1.3, 5.14.3.10, 5.15.8, 5.15.16, 5.16.2–5.16.7, 5.17.4, 5.17.8–5.17.11
 biochemical tests, 3.17.1.1, 3.17.2.1–3.17.2.2, 3.17.4.2, 3.17.5.2–3.17.5.3, 3.17.11.1, 3.17.12.1–3.17.12.2, 3.17.17.2, 3.17.18.2, 3.17.20.1, 3.17.23.2, 3.17.25.2, 3.17.27.2, 3.17.29.1, 3.17.31.2, 3.17.33.2, 3.17.34.1–3.17.34.3, 3.17.35.2, 3.17.37.1, 3.17.39.2, 3.17.40.2, 3.17.41.1, 3.17.46.1, 3.17.48.2
 diarrheagenic infections, 2.1.5
 epidemiology and infection control, 13.5.2–13.5.3, 13.13.1
 extended-spectrum beta-lactamase testing, 5.1.13–5.1.14, 5.2.12–5.2.13
 fecal culture, 3.8.1.1, 3.8.1.7–3.8.1.8, 3.8.1.11, 3.8.1.14–3.8.1.17, 3.8.1.20, 3.8.2.7, 3.8.4.3, 3.8.5.2
 genital culture, 3.9.1.1–3.9.1.4, 3.9.1.10
 identification schemes, 3.18.2.1, 3.18.2.8
 molecular methods, 12.1.3, 12.4.2.2, 12.4.4.1, 12.4.5.5
 quality assurance/quality control, 14.1.11, 14.2.6–14.2.16, 14.2.20–14.2.21, 14.2.32
 staining, 3.2.1.1, 3.2.2.2, 3.2.3.1
 urine culture, 3.12.1, 3.12.6–3.12.7, 3.12.12
 verotoxin-producing (enterohemorrhagic), 3.8.1.1, 3.17.34.1, 11.8.1
 immunoassay, 11.8.1–11.8.8
Escherichia coli O157:H7, 3.8.1.1–3.8.1.20, 3.8.2.1, 3.17.34.3
 immunoassay for Shiga toxin, 11.8.1–11.8.8
 latex agglutination test, 3.8.1.20–3.8.1.21
Escherichia fergusonii, 3.16.5
Escherichia hermannii, 3.8.1.20, 3.16.5
Escherichia vulneris, 3.16.5
Esculin agar, 3.17.5.1
Esculin hydrolysis medium, 6.3.3.3
Esculin test
 actinomycetes, 6.2.4, 6.2.8
 aerobes, 3.17.5.1–3.17.5.3
 disk test, 3.17.5.2
 tube test, 3.17.5.2
Esculinase, 3.17.5.1
Esophagitis, 3.11.1.2
Espundia, 9.9.5.1
Etest, 5.8.1–5.8.8
 quick reference list, 5.8.7
Ethambutol
 molecular methods for determining resistance, 12.1.5
 susceptibility testing of *M. tuberculosis*, 7.7.1–7.7.4, 7.8.1.1–7.8.1.7, 7.8.5.1–7.8.5.5, 7.8.7.1–7.8.7.4
 susceptibility testing of slow-growing mycobacteria, 7.8.3.1–7.8.3.3
Ethanol plus iodine solution, 9.3.6.6
Ethanol solutions, 5.14.2.4, 9.4.1.4
 acidified, 9.3.6.6
Ethionamide, susceptibility testing of *M. tuberculosis*, 7.8.1.1–7.8.1.7
Ethyl acetate, 9.1.7
Eubacterium, 4.11.1–4.11.5, 4.11.9
Eubacterium lentum, 4.6.8.1–4.6.8.2, 4.11.3, 4.11.6, 4.11.8–4.11.9, 5.7.2, 5.9.2, 5.9.6, 5.9.11, 5.13.9
Eubacterium limosum, 3.13.1.2, 4.9.3.1, 4.11.3, 4.11.8
Eubacterium nodatum, 4.2.4
Eurotium, 8.9.5.1
Evan's modified Tobie's medium, 9.9.5.5
Everglades encephalitis virus, 10.1.6
Ewingella americana, 3.16.6
Exiguobacterium acetylicum, 3.18.1.12
Exoantigen test, fungi, 8.9.7, 8.9.19–8.9.21, 8.9.56
Exophiala, 8.3.6, 8.9.5–8.9.6, 8.9.13, 8.9.39, 8.9.51
Exophiala dermatitidis, 8.9.9, 8.9.47
Exophiala jeanselmei, 8.3.4, 8.9.9
Exophiala mesophila, 8.9.9
Exophiala moniliae, 8.9.9
Exophiala spinifera, 8.9.9
Expiration dating, culture media, 14.2.5–14.2.18
Exposure control plan, 15.3.2.1–15.3.2.3
Exserohilum, 8.3.5, 8.9.7, 8.9.13, 8.9.39, 8.9.42
Extended-spectrum beta-lactamase (ESBL), 5.8.5, 5.13.5
Extended-spectrum beta-lactamase (ESBL) testing, 5.1.13–5.1.14, 5.2.12–5.2.13
External ear, specimen collection, 3.11.5.1
External otitis, 2.1.17

F
F agar, 3.17.17.1
Facial sinus scraping, fungi, 8.9.42–8.9.43
Facklamia, 3.18.1.10
Fair market value, 1.1.3
Fallopian tube specimen
 Chlamydia, 10.6.3
 collection, 3.9.1.5
Fasciola hepatica, 9.10.1.3, 9.10.2.3, 9.10.2.14
Fasciolopsis buski, 9.10.2.14
Favic chandelier, 8.9.23
FDA, regulation of laboratory testing, 1.1.1
FE-2 workstation, 9.3.4.4–9.3.4.5
Fecal antigen test, *H. pylori*, 11.9.2, 11.9.4
Fecal culture
 aerobic pathogens of gastroenteritis, 3.8.1.1–3.8.1.20
 interpretation, 3.8.1.17
 limitations, 3.8.1.17
 materials, 3.8.1.4–3.8.1.6
 principle, 3.8.1.1
 procedures, 3.8.1.8–3.8.1.14
 quality control, 3.8.1.6–3.8.1.8
 reporting results, 3.8.1.14–3.8.1.17
 specimen, 3.8.1.2–3.8.1.4
ameba, 9.9.2.1–9.9.2.8
Campylobacter, 3.8.2.1–3.8.2.19
 interpretation, 3.8.2.15
 limitations, 3.8.2.15
 materials, 3.8.2.5–3.8.2.6
 principles, 3.8.2.1
 procedures, 3.8.2.7–3.8.2.13
 quality control, 3.8.2.7
 reporting results, 3.8.2.14
 specimen, 3.8.2.1–3.8.2.5
E. histolytica, 9.9.1.1–9.9.1.8
larval-stage nematodes
 agar plate culture, 9.5.4.1–9.5.4.4
 Baermann technique, 9.5.1.1–9.5.1.4
 Harada-Mori technique, 9.5.2.1–9.5.2.3
 petri dish-filter paper slant, 9.5.3.1–9.5.3.3
 vancomycin-resistant enterococci, 3.8.5.1–3.8.5.4
Fecal preservatives, 9.2.2.1–9.2.2.7
Fecal specimen
 age and physical description, 9.3.1.1–9.3.1.3
 artifacts, 9.3.1.2, 9.10.1.1–9.10.1.3
 C. botulinum, 16.5.2
 C. difficile toxin detection, 3.8.3.1–3.8.3.7
 calcofluor white stain, 9.3.8.1–9.3.8.5

- Fecal specimen (*continued*)
 collection, 2.1.14, 3.8.1.2–3.8.1.3, 3.8.2.1–3.8.2.5, 3.8.3.2, 9.2.1.1–9.2.1.4
 concentration
 automated workstations for analysis of concentrates, 9.3.4.4–9.3.4.5
 formalin-ethyl acetate sedimentation, 9.3.4.1–9.3.4.5
 zinc sulfate flotation, 9.3.5.1–9.3.5.4
 consistency, 9.3.1.1–9.3.1.2
Cryptosporidium, 9.4.5.1–9.4.5.5
 direct smear, 9.3.3.1–9.3.3.4
 Gram stain, 3.2.1.11
 human cells seen in, 3.8.1.8
 immunoassays, 9.2.1.4
 iron hematoxylin stain, 9.3.7.1–9.3.7.7
 with carbol fuchsin step, 9.3.7.6–9.3.7.7
 labeling, 3.8.1.3–3.8.1.4
 leukocytes, 3.2.3.1
 microsporidia, 9.4.3.1–9.4.3.4, 9.4.4.1–9.4.4.5, 9.4.5.1–9.4.5.5

- GPVA medium, 13.6.13
- Graham-293 cells, 10.2.2
- Gram reaction enzymatic test, 3.17.20.1–3.17.20.2
- Gram stain, 3.2.1.1–3.2.1.22
 actinomycetes, 6.1.2–6.1.4, 6.1.6
 aerobes, 3.2.1.1–3.2.1.22
 anaerobes, 4.2.6, 4.3.2, 4.4.1–4.4.2, 4.4.4–4.4.5, 4.10.2–4.10.3, 4.10.13, 4.11.2–4.11.4, 4.11.6–4.11.8, 4.12.2–4.12.4
B. anthracis, 16.4.4–16.4.5
 biopsy specimen, 9.7.4.4
Brucella, 16.6.2–16.6.3
 CSF specimen, 14.1.27
 Hucker's modification, 3.2.1.6–3.2.1.7, 3.2.1.18
 interpretation, 3.2.1.1, 3.2.1.14–3.2.1.15
 Kopeloff's modification, 3.2.1.7–3.2.1.8, 3.2.1.19–3.2.1.20
 limitations, 3.2.1.17
 materials, 3.2.1.2
 preparation, 6.3.3.1
 principles, 3.2.1.1
 procedures
 broth and plate smears, 3.2.1.12
 discarding stained smears, 3.2.1.12
 examination of direct smear, 3.2.1.8–3.2.1.10
 slide preparation, 3.2.1.4–3.2.1.6
 smear fixation, 3.2.1.6
 staining, 3.2.1.6–3.2.1.8
 quality control, 3.2.1.3, 14.2.20
 reagent preparation, 3.2.1.18–3.2.1.20
 reporting results, 3.2.1.16–3.2.1.17
 specimen collection, 3.2.1.1–3.2.1.2
 specimen rejection, 3.2.1.2
 sputum specimen, 3.11.2.1, 14.1.22
 turnaround time, 14.1.19–14.1.20
 vaginal discharge, 3.2.1.12, 3.2.1.22–3.2.1.23
 Gram's iodine, 3.2.1.18–3.2.1.19, 6.3.3.1
- Gram-negative bacilli
 anaerobic, 4.10.1–4.10.13
 hemodialysis fluid, 13.7.1
- Gram-negative bacteria, 3.2.1.1
 antibiogram, 5.13.15
 commercial kit systems, 3.18.2.1
 direct smears from clinical specimens, 3.2.1.11–3.2.1.12
 identification charts, 3.18.2.1–3.18.2.21
 MIC tray layout, 5.15.18
 plasmid fingerprinting, 12.4.2.1–12.4.2.4
 polymyxin B-resistant, 3.18.2.19
 surveillance cultures from immunocompromised hosts, 13.11.1–13.11.4
- Gram-negative broth, 3.8.1.2, 14.2.9
- Gram-negative cocci, 3.2.1.14
- Gram-negative coccobacilli, 3.2.1.14
 genital microbiota, 3.9.1.10
- Gram-negative diplococci, 3.18.2.5
 oxidase-positive, that grow on Thayer-Martin agar, 3.18.2.11
- Gram-negative rods, 3.2.1.14
 anaerobic, bile test, 4.6.7.1, 4.6.13.2, 4.10.2
 catalase-negative, that grow on BAP agar with poor growth on MAC agar, 3.18.2.13
 catalase-positive
 indole-negative, non-yellow-pigmented, 3.18.2.14
 nonmotile, yellow, nonfermenting, 3.18.2.15
 oxidase-negative, non-glucose-fermenting, 3.18.2.18
 gastroenteritis, 3.8.1.1
 indole-positive, that grow poorly on MacConkey medium, 3.18.2.12
 motile, yellow, non-glucose-fermenting, 3.18.2.16
 oxidase-positive
 glucose-fermenting, 3.18.2.17
 nonyellow, grow well on MacConkey agar, 3.18.2.20
 that grow on Thayer-Martin agar, 3.18.2.11
 that do not grow on BAP aerobically, 3.18.2.6
 that do not grow well on MacConkey agar, 3.18.2.7
 that grow on BAP and MacConkey medium, 3.18.2.8, 3.18.2.10
 that grow well on BAP and MacConkey medium, 3.18.2.9
- Gram-positive bacilli, anaerobic, 4.11.1–4.11.9
 nonsporeformers, 4.11.1, 4.11.4–4.11.6, 4.11.9
 sporeformers, 4.11.1, 4.11.9
- Gram-positive bacteria, 3.2.1.1
 antibiogram, 5.13.14
 direct smears from clinical specimens, 3.2.1.9–3.2.1.10
 identification charts, 3.18.1.1–3.18.1.15
 surveillance cultures from immunocompromised hosts, 13.11.1–13.11.4
- Gram-positive cocci, 3.2.1.13
 catalase-negative, 3.18.1.3
 not beta-hemolytic, 3.18.1.4
 PYR-negative, 3.18.1.10
 PYR-positive, 3.18.1.5, 3.18.1.10
 catalase-positive, 3.18.1.3
 large white to yellow colonies, 3.18.1.7
 identification charts, 3.18.1.1–3.18.1.15
 PYR-positive, 3.18.1.9
- Gram-positive coccobacilli, 3.2.1.13
- Gram-positive rods, 3.2.1.13, 3.18.1.6
 catalase-negative, that grow aerobically, 3.18.1.11
 catalase-positive
 spore producing and motile, 3.18.1.12
 urease-negative, 3.18.1.13
 yellow or pink-pigmented, 3.18.1.12
 identification charts, 3.18.1.1–3.18.1.15
- Gram-variable bacteria, 3.2.1.13
- Granulicatella*, 3.17.43.2, 3.18.1.4, 3.18.1.10
- Granulicatella adiacens*, 3.17.44.1
- Granulicatella balaenopterae*, 3.17.44.1
- Granulicatella elegans*, 3.17.44.1
- Granulomatous amebic encephalitis, 9.3.8.1, 9.9.2.1, 9.10.2.6
- Graphium*, 8.9.6
- Group A streptococci
 antibodies to extracellular products, 11.2.1.1–11.2.1.2
 anti-DNase B test, 11.2.1.1–11.2.1.2, 11.2.3.1–11.2.3.3
 antihyaluronidase test, 11.2.1.1
 antistreptokinase test, 11.2.1.1

- anti-streptolysin test, 11.2.1.1–11.2.1.2, 11.2.2.1–11.2.2.4
 culture, 3.11.8.1–3.11.8.7
 direct antigen detection, 3.11.8.1–3.11.8.7
 interpretation, 3.11.8.6
 limitations, 3.11.8.6
 materials, 3.11.8.2–3.11.8.3
 procedures, 3.11.8.4
 reporting results, 3.11.8.6
 specimen collection, 3.11.8.1–3.11.8.3
 molecular methods, 12.1.1
 serologic diagnosis, 11.1.2.4
 Streptozyme test, 11.2.1.2
 Group A streptococcus culture, 3.11.8.1–3.11.8.7
 interpretation, 3.11.8.6
 limitations, 3.11.8.6
 materials, 3.11.8.2–3.11.8.3
 principle, 3.11.8.1
 procedures, 3.11.8.4–3.11.8.6
 quality control, 3.11.8.3–3.11.8.4
 reporting results, 3.11.8.6
 specimen, 3.11.8.2
 Group B streptococci, serologic diagnosis, 11.1.2.2
 Group B streptococcus culture, 3.9.2.1–3.9.2.6
 Growth factor tests, dermatophytes, 8.9.23–8.9.31, 8.9.36–8.9.37, 8.9.56–8.9.57
 Growth rate
 dermatophytes, 8.9.24–8.9.30
 mycobacteria, 7.6.1.1–7.6.1.2, 7.6.1.4–7.6.1.8
 Guillain-Barré syndrome, 3.8.2.2, 3.8.2.5
Gymnascella hyalinospora, 8.9.15
- ## H
- H. pylori* IgG ELISA kit, 11.9.2–11.9.3
 H292 cells, 10.2.2
Haemobartonella, 3.4.3.4
Haemophilus, 3.3.1.2–3.3.1.3, 3.3.1.7, 3.3.2.5, 3.13.1.2, 3.13.1.5, 3.13.1.12–3.13.1.13
 antimicrobial susceptibility testing, 5.1.3–5.1.6, 5.1.9–5.1.10, 5.2.3, 5.2.6–5.2.10, 5.3.5, 5.8.7, 5.10.1.13, 5.10.2.7, 5.11.14, 5.16.1, 5.16.5
 biochemical reactions, 3.9.1.10
 biochemical tests, 3.17.3.1, 3.17.3.3, 3.17.9.1, 3.17.44.2, 3.17.45.1
 bioterrorism, 16.6.4
 blood culture, 3.4.1.9–3.4.1.10, 3.4.2.3–3.4.2.4
 broth microdilution MIC testing, 5.2.10
 disk diffusion susceptibility testing, 5.1.10
 genital culture, 3.9.1.9, 3.9.3.5
 hemin and NAD requirement, 3.17.44.1
 identification schemes, 3.18.2.4, 3.18.2.11
 respiratory tract culture, 3.11.2.1, 3.11.2.5–3.11.2.7, 3.11.3.3, 3.11.3.7, 3.11.4.6
 satellite test, 3.18.2.11
 staining, 3.2.1.11–3.2.1.14, 3.2.1.17, 3.2.1.20
Haemophilus aphrophilus, 3.4.2.3, 3.18.2.13
Haemophilus ducreyi, 3.9.1.1–3.9.1.2, 3.9.1.6–3.9.1.14, 3.17.3.2, 3.17.44.2, 3.17.45.1–3.17.45.2, 3.18.2.6
Haemophilus ducreyi culture, 3.9.4.1–3.9.4.5
Haemophilus haemolyticus, 3.3.2.7, 3.9.1.10, 3.17.3.3, 3.17.44.2, 3.18.2.6, 3.18.2.11
Haemophilus influenzae, 3.3.1.3, 3.3.1.7–3.3.1.8, 3.3.2.6–3.3.2.7, 3.4.1.6, 3.4.1.10, 3.7.1, 3.7.5, 3.10.2–3.10.3, 3.13.1.11, 13.5.1
 antimicrobial susceptibility testing, 5.1.1, 5.1.9–5.1.10, 5.2.1, 5.2.10, 5.3.1, 5.3.4, 5.8.2, 5.13.6, 5.13.9, 5.13.15–5.13.16, 5.14.3.10, 5.16.3–5.16.8
 biochemical tests, 3.17.3.2–3.17.3.3, 3.17.44.1
 bioterrorism, 16.6.3
 genital culture, 3.9.1.2–3.9.1.4, 3.9.1.10, 3.9.3.5
 identification schemes, 3.18.2.6, 3.18.2.11
 molecular methods, 12.1.3
 quality assurance/quality control, 14.2.7–14.2.8, 14.2.21
 respiratory tract culture, 3.11.1.1–3.11.1.2, 3.11.2.1, 3.11.2.5–3.11.2.10, 3.11.3.1–3.11.3.4, 3.11.3.7, 3.11.5.1–3.11.5.5, 3.11.9.1–3.11.9.3
 serologic diagnosis, 11.1.2.2
Haemophilus parahaemolyticus, 3.9.1.10, 3.17.3.2, 3.17.44.2, 3.18.2.11
Haemophilus parainfluenzae, 3.9.1.2–3.9.1.4, 3.9.1.10, 3.17.3.2, 3.18.2.11, 14.2.21
Haemophilus paraphrophilus, 3.9.1.10, 3.17.3.2, 3.18.2.11
Haemophilus test medium (agar), 5.14.3.3–5.14.3.4, 5.14.3.10
Haemophilus test medium (broth), 5.14.3.5, 5.14.3.10
Haemophilus-Neisseria panel, 6.2.5
Hafnia, 3.8.1.1, 3.8.1.12
Hafnia alvei, 3.16.6, 3.17.33.2–3.17.33.3
 Hair perforation test
 dermatophytes, 8.9.24–8.9.30, 8.9.33–8.9.34
 fungi, 8.9.11
 Hair specimen
 dermatophytes, 8.3.7
 fungi, 8.2.3, 8.3.1, 8.3.5, 8.4.5
 Hand washing, 15.2.2.2, 15.3.5.2
 Hanks' balanced salt solution, 10.2.1, 10.2.8–10.2.9, 10.3.2, 10.4.10
Hansenula, 8.5.4, 8.8.3
Hansenula anomala, 8.5.8, 8.8.2–8.8.4
Hansenula jadonii, 8.8.2
 Hantavirus, 10.1.7
 Harada-Mori technique, culture of larval-stage nematodes, 9.5.2.1–9.5.2.3
 Haverhill fever, 3.4.1.17
 Hazardous chemicals, 9.1.7
 Hazardous goods, 16.3.3
 Hazardous materials, 16.3.3, *see also* Biohazardous entries
 shipment, 15.5.1–15.5.6, 16.3.1–16.3.4
 commercial carriers, 16.3.3
 list of select agents, 16.3.3
 select-agent rule, 16.3.1–16.3.3

 Leucine aminopeptidase (LAP) test, 3.17.26.1–3.17.26.2
- Leuconostoc*, 3.3.2.8, 3.4.1.11, 3.8.5.3, 3.16.10, 3.16.14, 3.18.1.4, 3.18.1.10
 biochemical tests, 3.17.4.4, 3.17.9.2, 3.17.9.4, 3.17.15.3, 3.17.26.1–3.17.26.2, 3.17.32.1–3.17.32.2, 3.17.43.2
 antimicrobial susceptibility testing, 5.6.3, 5.13.15–5.13.16, 5.16.8
- Leuconostoc mesenteroides*, 3.17.32.1
- Leukocyte(s)
 fecal, 3.2.3.1
 recovery from anticoagulated blood, 10.4.8–10.4.9, 10.4.11
 urine, 3.2.3.1
 wet mount, 3.2.3.1–3.2.3.6
- Leukocyte adhesion deficiency (LAD), neutrophil function test, 11.17.1–11.17.4
 Leukocyte culture, 10.2.3
 LEUKO-TEST, 3.2.3.1–3.2.3.6
 Levans, 3.17.19.1
 Levaquin, see Levofloxacin
 Levofloxacin, 5.16.7
 Light green solutions, 9.7.2.8
 Limited-coverage tests, 1.2.3
Limulus ameocyte lysate assay, endotoxin, 13.7.4–13.7.5

- Lincopenptide, **5.16.8**
 Lincosamide, **5.16.7**
 Linen packs, autoclaving, **15.4.2.1**
 Linezolid, **5.16.8**
 Lipase test
 aerobes, **3.17.27.1–3.17.27.3**
 anaerobes, **4.4.4, 4.6.9.1, 4.6.13.3, 4.10.3–4.10.4, 4.10.7, 4.10.11, 4.11.2, 4.11.5–4.11.6**
 Lipid A, **13.7.4**
 Lipophilism test
 broth method, **3.17.28.2**
 Corynebacterium, **3.17.28.1–3.17.28.2**
 plate method, **3.17.28.1–3.17.28.2**
 Lipopolysaccharide, **13.7.4**
 Liquid Dental Transport, **4.2.7**
 Liquid nitrogen cryopreservation
 cell lines, **10.3.5–10.3.6**
 peripheral blood mononuclear cells, **11.11.1–11.11.2**
 specimens/microorganisms, **15.4.6.1–15.4.6.2**
 LIS electronic specimen worksheet, **14.3.2–14.3.3**
Listeria, **3.3.2.5, 3.4.1.1, 3.4.1.8–3.4.1.12, 3.7.4–3.7.5, 3.9.1.2, 3.9.2.5, 3.13.1.11–3.13.1.12, 3.16.1.2, 3.18.1.1**
 antimicrobial susceptibility testing, **5.2.9, 5.8.5–5.8.7, 5.16.2–5.16.3**
 biochemical tests, **3.17.5.1, 3.17.20.1, 3.17.31.1–3.17.31.3, 3.17.33.2–3.17.33.3**
 staining, **3.2.1.13, 3.2.1.17**
Listeria monocytogenes, **3.3.2.9, 3.4.1.12, 3.7.1, 3.9.1.2, 3.9.1.9–3.9.1.11, 3.9.2.5, 3.16.9, 3.18.1.4–3.18.1.6, 13.5.2**
 antimicrobial susceptibility testing, **5.13.14**
 biochemical tests, **3.17.5.2, 3.17.8.1, 3.17.8.3, 3.17.21.1–3.17.21.2**

 BACTEC 460TB system, **7.8.3.1–7.8.3.3**

- slow-growing, 7.8.3.1–7.8.3.3
 arylsulfatase test, 7.6.1.1–7.6.1.6
 BACTEC 460TB radiometric system, 7.4.1.1–7.4.1.7
 BACTEC MGIT 960 automated system, 7.4.2.1–7.4.2.4
 BACTEC NAP test, 7.6.3.1–7.6.3.3
 catalase test, 7.6.1.1–7.6.1.2, 7.6.1.4, 7.6.1.6–7.6.1.7
 chromogens, 7.6.1.4
 colony morphology, 7.3.1, 7.3.3, 7.6.1.4–7.6.1.5
 culture media, 14.2.14
 solid media, 7.3.1–7.3.4
 digestion-decontamination procedures, 7.1.2.1–7.1.2.9
 cetylpyridinium chloride-sodium chloride method, 7.1.2.1, 7.1.2.4–7.1.2.5, 7.1.2.8
 NALC-sodium hydroxide method, 7.1.2.1–7.1.2.3, 7.1.2.6
 oxalic acid method, 7.1.2.1, 7.1.2.4, 7.1.2.8
 reagents and solutions, 7.1.2.6–7.1.2.8
 sodium hydroxide method, 7.1.2.1, 7.1.2.3, 7.1.2.7
 Zephiran-trisodium phosphate method, 7.1.2.1, 7.1.2.3–7.1.2.4, 7.1.2.7–7.1.2.8
 growth rate, 7.6.1.1–7.6.1.2, 7.6.1.4–7.6.1.8
 iron uptake test, 7.6.1.1, 7.6.1.3–7.6.1.4, 7.6.1.6, 7.6.1.8–7.6.1.9
 isolation, 7.3.1–7.3.4
 levels of laboratory service, 7.1.1.1–7.1.1.2
 MacConkey agar without crystal violet test, 7.6.1.1–7.6.1.2, 7.6.1.4, 7.6.1.8, 14.2.15
 MB/BacT mycobacterial detection, 7.4.4.1–7.4.4.4
 niacin accumulation test, 7.6.1.1, 7.6.1.3–7.6.1.4, 7.6.1.9, 14.2.15
 nitrate reduction test, 7.6.1.1, 7.6.1.3–7.6.1.4, 7.6.1.6, 7.6.1.10, 14.2.15
 nonchromogens, 7.6.1.4
 pigment production, 7.6.1.1–7.6.1.2, 7.6.1.4–7.6.1.5, 7.6.1.7–7.6.1.8, 14.2.15
 pyrazinamide test, 7.6.1.1, 7.6.1.3–7.6.1.4, 7.6.1.10
 rapid growers, 7.6.1.4
 reporting test results, 7.1.4.1–7.1.4.2
 safety, 7.1.1.1–7.1.1.2, 15.3.2.2
 Septi-Chek AFB biphasic medium, 7.5.1–7.5.3
 slow growers, 7.6.1.4, 7.8.3.1–7.8.3.3
 sodium chloride tolerance test, 7.6.1.1, 7.6.1.3–7.6.1.4, 7.6.1.6, 7.6.1.9
 specimen acceptability, 2.1.21
 specimen collection, 7.1.2.1–7.1.2.2
 specimen storage, 7.1.2.1–7.1.2.2
 specimen transport, 7.1.2.1–7.1.2.2
 stock cultures, maintenance, 14.2.24
 TCH susceptibility test, 7.6.1.1–7.6.1.3, 7.6.1.6, 7.6.1.10–7.6.1.11, 14.2.15
 tellurite reduction test, 7.6.1.2–7.6.1.4, 7.6.1.6, 7.6.1.11, 14.2.15
 Tween 80 hydrolysis test, 7.6.1.2–7.6.1.4, 7.6.1.6, 7.6.1.11, 14.2.15
 urease test, 7.6.1.2–7.6.1.4, 7.6.1.6, 7.6.1.11–7.6.1.12, 14.2.15
 VersaTREK (ESP Culture System II), 7.4.3.1–7.4.3.7

 bone marrow aspirates, 9.7.3.1–9.7.3.6
 buffy coat, 9.8.9.3
 drug-resistant, 9.8.7.1–9.8.7.3
Plasmodium falciparum, 9.8.1.2, 9.8.3.3, 9.8.4.3, 9.8.5.3, 9.8.6.3, 9.8.7.1–9.8.7.3, 9.10.2.16, 9.10.3.6
Plasmodium malariae, 9.8.6.3, 9.10.2.16
Plasmodium ovale, 9.8.1.2, 9.8.2.2, 9.8.3.3, 9.8.4.3, 9.8.5.3, 9.8.6.3, 9.8.7.2, 9.10.2.16
Plasmodium vivax, 9.8.1.2, 9.8.2.2, 9.8.3.3, 9.8.4.3, 9.8.5.3, 9.8.6.3, 9.8.7.2–9.8.7.3, 9.10.2.16, 15.2.1.2
Pleistophora, 9.10.2.7, 9.10.2.10–9.10.2.12, 9.10.2.18
Plesiomonas, 3.8.1.9, 3.8.1.12, 3.8.1.17, 3.17.15.1, 3.17.15.3, 3.17.33.3, 3.17.36.1, 3.18.2.4, 3.18.2.17
Plesiomonas shigelloides, 3.8.1.1, 3.8.1.5, 3.8.1.10, 3.8.1.15, 3.17.16.1, 3.17.16.3, 3.17.36.3, 3.17.39.3
 Pleural effusion, 3.11.1.2
 Pleural fluid culture, 3.5.1–3.5.8
 Legionella, 3.11.4.2
 Pleural fluid specimen, 2.1.11, 3.11.1.2
 collection, 3.5.2
 fungi, 8.2.3
 Gram stain, 3.2.1.9
 mycobacteria, 7.5.1–7.5.3
 viruses, 10.4.3
 Pleuropulmonary infections, potential etiological agents, 2.1.3–2.1.4
 PMK cells, 10.2.2
 Pneumatic tube system
 materials, 15.4.5.1
 quality control, 15.4.5.2
 receiving carriers, 15.4.5.1–15.4.5.2
 sending specimens, 15.4.5.1

- Pneumocystis*, 3.11.2.14
Pneumocystis carinii, 3.2.1.12, 3.11.2.2, 5.16.7, 8.4.4, 9.3.8.4, 9.7.1.3, 9.7.4.2–9.7.4.6, 9.10.2.3–9.10.2.6, 9.10.2.11, 9.10.2.18, 9.10.6.6
 aspirates, 9.7.3.1–9.7.3.6
 biopsy specimen, 9.7.4.4
 bronchoscopy specimens, 9.7.3.1–9.7.3.8
 Giemsa stain, 9.7.2.1–9.7.2.8
 immunospecific stain, 9.7.2.1–9.7.2.8
 molecular methods, 9.7.2.6
 serologic diagnosis, 11.1.2.6
 silver stain, 9.7.2.1–9.7.2.8
 sputum specimen, 9.7.2.1–9.7.2.8
Pneumocystis jirovecii, 14.2.20
 Pneumocytosis, 9.10.2.6
 Pneumonia
 aspiration, 3.11.2.1
 bacterial, 3.11.1.2, 3.11.2.1
 community-acquired, 3.11.2.1
M. pneumoniae, 12.2.3.62
 mycoplasmal, 3.15.1
 nosocomial, 3.11.2.1
P. carinii, 9.7.2.1
 potential etiological agents, 2.1.3–2.1.4
 ventilator-associated, 3.11.2.1
 Pneumoslides, 3.17.42.3
 Point-of-care testing, *H. pylori*, 11.9.2
 Pokeweed mitogen, 11.12.1–11.12.5
 Polio vaccine, laboratory personnel, 15.6.7
 Poliovirus
 cell culture, 10.2.2–10.2.3
 clinical manifestations of disease, 10.1.2
 specimen collection and processing, 10.4.2
 Polished-rice medium, 8.9.11
 Polished-rice test, *Microsporium*, 8.9.33
 Pollen grain, 9.10.1.2–9.10.1.3, 9.10.3.7
 Polyacrylamide gel electrophoresis (PAGE), epidemiologic typing, 13.5.2
 Polymorphonuclear leukocytes, 9.10.3.3
 fecal specimens, 3.8.1.8
 Polymyxin B disk test, 3.17.4.1–3.17.4.5
 Polymyxin B resistance, 3.18.2.19
 Polyomavirus
 cell culture, 10.2.3
 clinical manifestations of disease, 10.1.5
 Polysaccharide production test, 3.17.19.1–3.17.19.2
 Polyvinyl alcohol (PVA), 2.1.19, 9.2.2.1, 9.2.2.3–9.2.2.4, 9.2.2.7
 modified (zinc base), 9.2.2.1, 9.2.2.4–9.2.2.5, 9.2.2.7
 modified (copper base), 9.2.2.1, 9.2.2.4, 9.2.2.7
 Poroconidia, 8.9.5
 Porphobilinogen, 3.17.3.1
 Porphobilinogen synthase, 3.17.3.1
 Porphyrin synthesis, ALA test, 3.17.3.1–3.17.3.3
Porphyromonas, 4.2.6, 4.3.3–4.3.5, 4.4.1–4.4.5, 4.7.3, 4.10.1–4.10.9, 4.10.11, 4.10.13, 4.11.6
 rapid disk tests and spot tests, 4.6.5.1, 4.6.8.1–4.6.8.2, 4.6.11.1, 4.6.13.1–4.6.13.3
Porphyromonas asaccharolytica, 3.13.1.2, 3.17.23.2, 4.6.8.1, 4.10.6–4.10.8, 14.2.22
Porphyromonas cangingivalis, 4.10.6–4.10.8
Porphyromonas catoninae, 4.10.6–4.10.8
Porphyromonas endodontalis, 4.6.8.1, 4.10.6–4.10.8
Porphyromonas gingivalis, 4.4.3, 4.6.8.1, 4.6.11.1, 4.8.2, 4.10.6–4.10.8
Porphyromonas levii, 4.3.3, 4.5.2, 4.10.6–4.10.8
 Port-A-Cul tube/vial, 4.2.3, 4.2.7
 Pos ID 2, 3.16.3
 Posaconazole, susceptibility testing, 8.10.4
 Positive test, 14.2.27
 Postal regulations, 9.2.3.1–9.2.3.2, 15.5.1–15.5.6
 Postexposure prophylaxis (PEP), 15.6.1
 hepatitis B virus, 15.6.2, 15.6.5
 hepatitis C virus, 15.6.2
 human immunodeficiency virus, 15.6.2, 15.6.5
 Postpartum period, group B streptococcal infections, 3.9.2.1
 Potassium hydroxide mount
 actinomycetes, 6.1.4, 6.1.7
 fungi, 8.3.2, 8.3.8
 Potassium hydroxide-calcofluor mount, fungi, 8.3.2–8.3.3
 Potassium hydroxide-DMSO mount, fungi, 8.3.2, 8.3.8
 Potassium tellurite cystine agar, 14.2.12
 Potato dextrose agar, 8.4.3, 8.7.4, 14.2.16
 Potato flake agar, 8.4.3, 8.9.7, 8.9.10, 8.9.53–8.9.54
 Potato glucose agar (PGA), 8.9.7, 8.9.9, 8.9.53
 Pouch-Anaero, 4.2.7
 Powassan virus, 10.1.6
 Poxvirus, 10.1.7
 cell culture, 10.2.2
 clinical manifestations of disease, 10.1.5
 specimen collection and processing, 10.4.2
 PPE, *see* Personal protective equipment
 Practice guidelines, 14.1.5
Pragia fontium, 3.16.6
 PRAS media, 4.2.5, 4.3.1
 Praziquantel therapy, 9.5.6.3
 Precyst, *E. histolytica*/*E. dispar*, 9.10.3.3
 Predictive value of test, 14.2.27–14.2.28
 negative test, 14.2.27–14.2.28
 positive test, 14.2.27–14.2.28
 Pregnancy, group B streptococcal infection, 3.9.2.1
 Premarital testing, syphilis, 11.5.1.1
 Premier EHEC, 11.8.6
 Premier Human Lyme, 11.6.3
 Premier IgG ELISA (*H. pylori*), 11.9.2
 Premier Platinum HpSA, 3.8.4.5–3.8.4.6
 Preseptal cellulitis, 3.10.2, 3.10.4, 3.10.8

 Pyrazinamide, susceptibility testing of *M. tuberculosis*, 7.8.1.1–7.8.1.7
 BACTEC 460TB system, 7.8.2.1–7.8.2.3
 BACTEC MGIT 960 PZA kit, 7.8.6.1–7.8.6.4
 VersaTREK, 7.8.8.1–7.8.8.3
 Pyrrolidonyl peptidase, 3.17.41.1
 L-Pyrrolidonyl- β -naphthylamide test, *see* PYR test
 Pyruvate broth, 14.2.12
Pythium insidiosum, 8.9.39
 Pyuria, 3.2.3.1, 3.12.1, 3.12.3
 detection, 3.12.9, 3.12.15
- ## Q
- Q fever, 11.7.1.1, 11.7.3.2
 QBC Capillary Blood Tube, 9.8.9.3
 Q-Probes, 14.1.9
 Qualicode *B. burgdorferi* IgG Western blot kit, 11.6.4
 Qualicode *B. burgdorferi* IgM Western blot kit, 11.6.4
 Quality assessment, *see* Quality assurance
 Quality assurance, *see also* Quality control
 antimicrobial susceptibility testing, 5.13.1–5.13.13, 14.1.8–14.1.12, 14.1.20–14.1.21, 14.1.28
 case review, 14.1.29
 culture, 14.1.28
 culture of hospital water for *Legionella*, 13.6.3–13.6.4
 culture of peritoneal fluid, 13.8.4
 culture of small-bowel contents, 13.15.3
 cumulative antimicrobial susceptibility reports, 14.1.9
 data analysis, 14.1.5
 data collection, 14.1.2–14.1.3
 data sources, 14.1.1
 definitions, principles, and objectives, 14.1.1
 DFA test for *Legionella*, 11.3.3–11.3.4
 documentation, 14.1.5
 dot blot, 11.7.3.2
 ELISA, 11.9.3
 enzyme immunoassays, 11.8.2–11.8.3
 error tracking, 14.1.6, 14.1.17–14.1.18, 14.1.24–14.1.26
 external programs, 14.1.9
 IFA tests, 11.7.2.2–11.7.2.3
 infection control, 14.1.8–14.1.12
 infectious waste management, 15.7.5
 latex agglutination tests, 11.7.4.2, 11.8.2–11.8.3
 materials and resources, 14.1.1–14.1.8
 microbiological assessment of orthopedic surgery site, 13.14.6
 parasitology laboratory, 9.1.8–9.1.9
 participants, 14.1.1–14.1.2
 plan, 14.1.1
 problem-solving skills, 14.1.2
 procedure development, 14.1.2–14.1.5
 record keeping, 14.3.4
 result reporting, 14.1.17–14.1.18
 specimen collection, 14.1.6, 14.1.15–14.1.16
 specimen transport, 14.1.6, 14.1.15–14.1.16
 sputum specimen, 14.1.6–14.1.7, 14.1.15–14.1.16, 14.1.22–14.1.23
 surveillance culture from immunocompromised hosts, 13.11.3
 test utilization, 14.1.7–14.1.8
 thresholds, 14.1.5
 turnaround time, 14.1.6–14.1.7, 14.1.19–14.1.20, 14.1.27
 urine specimen, 14.1.14–14.1.15
 Quality assurance committee, 14.1.2
 Quality control, *see also* Quality assurance
 AccuProbe system, 7.6.2.2, 12.3.2.2, 12.3.3.2
 acetamide utilization test, 3.17.1.1
 acetate utilization test, 3.17.2.1
 acid-fast trichrome stain, 9.4.5.1–9.4.5.2

- Quality control, *see also* Quality assurance
(*continued*)
 acridine orange stain, 3.2.2.2
 agar dilution MIC test for anaerobes, 5.9.2, 5.9.11
 air sampling, 13.9.4
 ALA test, 3.17.3.2
 L-alanyl-alanylaminopeptidase test, 4.9.4.1
 alkaline phosphatase test, 4.9.2.1
 Amplicor HCV Monitor test, 12.2.3.46
 Amplicor HCV test, 12.2.3.40
 Amplicor HIV-1 Monitor test, 12.2.3.25
 Amplicor HIV-1 Ultrasensitive test, 12.2.3.32
 antifungal susceptibility testing, 8.10.3–8.10.4
 antimicrobial disk tests for identification, 3.17.4.2
 antimicrobial stock solutions, 5.14.2.2, 5.14.2.7
 antimicrobial susceptibility testing, 3.15.15
 broth microdilution MIC testing, 5.13.10–5.13.11
 disk diffusion method, 5.13.11–5.13.12
 limitations, 5.13.4–5.13.5
 maintenance of quality control strains, 5.13.3–5.13.4
 microorganisms suggested for, 5.13.2, 5.13.4–5.13.5, 5.13.9
 modified agar proportion method for *M. tuberculosis*, 7.7.3
 principle, 5.13.1
 requirements of accrediting agencies, 5.13.1–5.13.2
 sources of control strains, 5.13.3
 special-potency disks, 4.6.5.2
 strains with “on-scale” endpoint, 5.13.10
 verification of results for bacteria from patient specimens, 5.13.5–5.13.6
 antisera, 14.2.3, 14.2.19
 arbitrarily primed PCR, 12.4.6.2
 aspirates, 9.7.3.2
 autoclave, 15.4.2.2
B. anthracis, 16.4.4
 BACTEC 460TB radiometric system, 7.4.1.2, 7.8.1.2, 7.8.1.6, 7.8.2.1, 7.8.3.1
 BACTEC MGIT 960 automated system, 7.4.2.2
 BACTEC MGIT 960 PZA kit, 7.8.6.1
 BACTEC MGIT 960 SIRE kit, 7.8.5.1
 BACTEC NAP test, 7.6.3.1
Bartonella culture, 3.4.3.2
 bile solubility test, 3.17.6.1
 bile test, 4.6.7.1
 bile-esculin test, 3.17.5.2
 biological safety cabinet, 15.3.4.2–15.3.4.4
 biopsy specimen, 9.7.4.2–9.7.4.3
 blood culture, 3.4.1.6–3.4.1.7
 body fluid culture, 3.5.4
Bordetella culture, 3.11.6.5
 bronchoscopy specimens, 9.7.3.2
 broth microdilution MIC testing, anaerobes, 5.7.2, 5.7.8
Brucella culture, 3.4.2.2
 buffy coat preparation, 9.8.9.2
 butyrate esterase test, 3.17.7.2
C. difficile toxin detection, 3.8.3.3–3.8.3.4
C. diphtheriae culture, 3.11.7.3
 calcofluor white stain, 9.3.8.3
 CAMP factor test, 3.17.8.2
 carbohydrate utilization tests, 3.17.9.3
 catalase test, 3.17.10.1, 4.6.4.1
 catheter tip culture, 3.6.2
 cell culture, 10.2.3–10.2.6, 10.3.3, 10.5.2–10.5.3, 10.6.6
 centrifuges, 15.4.3.2–15.4.3.4
 cetrimide test, 3.17.11.1
 citrate utilization test, 3.17.12.1
 coagulase test, 3.17.13.2, 3.17.14.2
 combination enzymatic tablets for anaerobes, 4.9.7.1
 commercial kits, 14.2.3, 14.2.19
 CSF culture, 3.7.3
 culture media, 3.3.2.2, 3.8.1.7, 5.14.3.2–5.14.3.3, 5.14.3.10, 8.4.4, 8.9.9–8.9.10, 10.2.10, 14.2.2–14.2.19, 14.2.33–14.2.34, 14.3.15
 mycobacterial, 7.3.1–7.3.3
 culture of hospital water for *Legionella*, 13.6.3–13.6.4
 culture of intravascular catheter, 13.12.4
 culture of larval-stage nematodes, 9.5.1.2, 9.5.2.1–9.5.2.2, 9.5.3.1–9.5.3.2, 9.5.4.2–9.5.4.3
 culture of small-bowel contents, 13.15.3
 cystic fibrosis culture, 3.11.3.3–3.11.3.4
 cytokine assays, 11.14.2
 decarboxylase-dihydrolase tests, 3.17.15.2
 decontamination of work environment, 15.2.3.4
 Delafield’s hematoxylin stain, 9.8.8.1–9.8.8.2
 DFA test for *B. pertussis*, 3.11.6.10–3.11.6.11
 DFA test for *Legionella*, 3.11.4.10–3.11.4.14
 Dienes typing for *Proteus*, 13.16.2.1
 Digene Hybrid Antibody CMV assay, 12.2.2.7
 Digene Hybrid Antibody HPV assay, 12.2.2.12
 digestion-decontamination procedures for mycobacteria, 7.1.2.2
 direct fluorescent-antibody test for *T. pallidum*, 11.5.2.1–11.5.2.2
 direct saline mount of urogenital specimen, 9.6.6.2
 direct smear of fecal specimen, 9.3.3.1–9.3.3.2
 direct wet smear, 9.6.2.2
 disk diffusion susceptibility testing, 5.1.2–5.1.3, 5.1.6, 5.1.15
 DNase test-rapid thermonuclease test, 3.17.16.2
 ELISA, 11.9.3
 enterococcal vancomycin resistance by multiplex PCR, 12.5.2.2
Enterococcus high-level aminoglycoside resistance screen, 5.5.2, 5.5.5
Enterococcus vancomycin agar screen test, 5.6.1, 5.6.4
 Entero-Test, 9.6.4.2
 esculin test, 3.17.5.2
 Etest, 5.8.2–5.8.3, 5.8.8
 fecal culture, 3.8.1.6–3.8.1.8, 3.8.2.7
 vancomycin-resistant enterococci, 3.8.5.2
 fecal specimen concentration, 9.3.4.2, 9.3.5.1–9.3.5.2
 flow cytometry, 11.15.2, 11.16.2–11.16.3, 11.17.2, 11.18.2
 fluorescence in anaerobes, 4.6.8.1
 fluorescent-pigment agars for *Pseudomonas*, 3.17.17.2
 fungal culture, 8.5.2
 fungal identification, 8.7.3, 8.9.9–8.9.11, 8.9.54
 gas cylinders, 15.4.4.2–15.4.4.3
 gelatin liquefaction test, 3.17.18.2
 general QC parameters, 14.2.1–14.2.4
 genital culture, 3.9.1.9
 Gen-Probe Amplified *Mycobacterium tuberculosis* Direct test, 12.2.3.13–12.2.3.19
 Gen-Probe PACE 2 system, 12.2.2.3
 Giemsa stain, 9.8.5.2
 glucan and polysaccharide production tests, 3.17.19.1
 glutamic acid decarboxylase test, 4.9.3.1
 Gram reaction enzymatic test, 3.17.20.1
 Gram stain, 3.2.1.3
 group A streptococcus culture, 3.11.8.2–3.11.8.4
 group B streptococcus culture, 3.9.2.3
H. ducreyi culture, 3.9.4.3
H. pylori culture, 3.8.4.2–3.8.4.3
 hemadsorption test for *M. pneumoniae*, 3.15.14
 hippurate hydrolysis test, 3.17.21.2
 hydrogen sulfide production test, 3.17.22.1–3.17.22.2
 immunofluorescence tests for viruses, 10.7.3
 indole test, 3.17.23.2, 4.6.2.1
 indoxyl acetate disk test, 3.17.24.1
 infectious waste management, 15.7.5
 INNO-LiPA HCV II, 12.4.7.2
 instrument and equipment performance, 14.2.2, 14.2.4
 iron hematoxylin stain, 9.3.7.2
 Kinyoun’s acid-fast stain, 9.4.1.1–9.4.1.2
 Kligler’s iron agar test, 3.17.25.2
 Knott concentration, 9.8.11.2
 laboratory water, 14.4.5–14.4.6
 beta-lactamase testing, 5.3.1, 5.3.6
 lecithinase test, 3.17.27.2, 4.6.10.1
Legionella culture, 3.11.4.3–3.11.4.4
Leptospira culture, 3.14.3
 lipase test, 3.17.27.2, 4.6.9.1
 lipophilism test for *Corynebacterium*, 3.17.28.1
 lower respiratory tract culture, 3.11.2.5, 3.11.2.13
 lymphocyte immunophenotyping, 11.16.2–11.16.3
 lymphocyte proliferation assay, 11.12.2
 malonate test, 3.17.29.1
 MB/BacT mycobacterial detection, 7.4.4.2
 MBC testing, 5.10.1.2–5.10.1.6, 5.10.1.16
 McFarland standards, 3.16.16, 5.14.1.1–5.14.1.3
 membrane filtration concentration of blood, 9.8.10.1–9.8.10.2
 methicillin resistance in staphylococci by PCR, 12.5.3.2
 methyl red-Voges-Proskauer test, 3.17.33.2
 4-methylumbelliferone derivative substrates, 4.9.6.1
 MGP test, 3.17.30.2
 MIC testing, 5.2.2–5.2.3, 5.10.1.16
 MIC tray, 5.15.2–5.15.3, 5.15.6, 5.15.8, 5.15.13–5.15.16
 microbiological systems for anaerobes, 4.7.2
 microbiological assessment of orthopedic surgery site, 13.14.6
 microbiological loop, 3.12.17–3.12.18
 microscope calibration, 9.3.2.1
 motility tests, 3.17.31.2
 MRS broth test, 3.17.32.1
 MUG test, 3.17.34.2
 mycoplasma culture, 3.15.5–3.15.6
N. gonorrhoeae culture, 3.9.3.5
 nasal sinus culture, 3.11.9.2
 natural killer cell assay, 11.13.2
 neutrophil function test, 11.17.2
 nitrate reduction test, 3.17.35.2, 4.6.3.2
 nitrite reduction test, 3.17.35.2

- O/129 disk susceptibility test, 3.17.36.2
ocular culture, 3.10.5
ONPG test, 3.17.37.1
optochin susceptibility test, 3.17.38.2
otitis culture, 3.11.5.2
oxacillin salt-agar screen test, 5.4.1, 5.4.4
oxidase test, 3.17.39.2
parasite culture, 9.9.1.2, 9.9.2.2–9.9.2.3, 9.9.3.2, 9.9.4.2, 9.9.5.2
parasitology laboratory, 9.1.8, 9.10.4.1–9.10.4.5
patient reports, 14.2.2, 14.2.4
PCR test for *B. pertussis*, 12.2.3.76–12.2.3.77
PCR test for herpes simplex virus, 12.2.3.55–12.2.3.56
PCR test for *M. pneumoniae*, 12.2.3.68
permanent stained smear, 9.3.6.2, 9.6.3.2, 9.6.7.2
personnel, 14.2.2–14.2.3
phenylalanine deaminase test, 3.17.40.2
pigment production by anaerobes, 4.6.11.1
pinworm examination, 9.6.1.1–9.6.1.2
plasmid fingerprinting, 12.4.2.2, 12.4.3.2
pneumatic tube system, 15.4.5.2
preservation of fecal specimens, 9.2.2.1
ProbeTecET system, 12.2.3.21
procedure manual, 14.2.1–14.2.2
proficiency testing, 14.2.2, 14.2.4, 14.2.26
L-proline-aminopeptidase test, 4.9.5.1
PYR test, 3.17.41.1
Quellung reaction, 3.17.42.1
rapid enzymatic systems for anaerobes, 4.8.2
rapid plasma reagin test, 11.5.3.2
reagents, 14.2.3, 14.2.19, 14.2.21–14.2.22

referral specimens, 14.2.2, 14.2.4
restriction fragment analysis, 12.4.5.2
ribotyping, 12.4.4.2
Roche Amplicor PCR kits, 12.2.3.3, 12.2.3.9
Ryan blue stain, 9.4.4.2
salmonella-shigella agar test for growth, 3.17.46.1
sample QC sheet, 4.6.13.5
satellite test, 3.17.44.2
schistosomal egg hatching, 9.5.5.1–9.5.5.2
scolices and proglottids of cestodes, 9.5.6.1
selection of test method, 14.2.26
Septi-Chek AFB biphasic medium, 7.5.2
serum bactericidal titer, 5.11.3, 5.11.6–5.11.7
serum inhibitory titer, 5.11.3, 5.11.6–5.11.7
slime test for staphylococci, 13.16.3.1
sodium polyanethol sulfonate test, 3.17.45.1, 4.6.6.1–4.6.6.2
soft tissue culture, 3.13.1.6
sources for guidelines, 14.2.1, 14.2.25
specific QC parameters, 14.2.4–14.2.19
specimen collection, 9.2.1.1, 14.2.1–14.2.2
specimen processing, 3.3.1.3–3.3.1.4
specimen transport, 14.2.1–14.2.2
sputum preparation, 9.7.1.2, 9.7.2.2
stains, 14.2.3, 14.2.19–14.2.20
starch hydrolysis test, 3.17.47.1
stock bacteriology cultures, 14.2.22–14.2.23
surveillance culture from immunocompromised hosts, 13.11.3
synergism testing, 5.12.2, 5.12.7
synergistic hemolysis, 13.16.4.1
thick blood film, 9.8.3.1, 9.8.4.1
thin blood film, 9.8.2.1, 9.8.4.1
time-kill assay, 5.10.2.2, 5.10.3.1
triple centrifugation concentration of blood, 9.8.12.1–9.8.12.2
triple sugar iron agar test, 3.17.25.2
urea test, 3.17.48.2
urease test, 4.6.12.1
urinary antigen test for *Legionella*, 3.11.4.9, 11.4.2–11.4.3
urine concentration, 9.6.8.2, 9.6.9.2
urine culture, 3.12.6–3.12.9
validation of test method, 14.2.27–14.2.29
VersaTREK, 7.4.3.2, 7.8.7.1–7.8.7.2, 7.8.8.2
viral acid lability assay, 10.5.38
virus neutralization assay, 10.5.34–10.5.35
Weber green stain, 9.4.3.2
wet mount, 3.2.3.2
wound culture, 3.13.1.6, 3.13.2.2
Wright's stain, 9.8.6.1–9.8.6.2
yeast identification, 8.6.2–8.6.3, 8.8.3–8.8.5
Ziehl-Neelsen acid-fast stain, 9.4.2.1
Quality improvement, *see* Quality assurance
Quality indicators, 14.1.3–14.1.4
Quasiautochthonous organisms, 2.1.1
Quaternary ammonium compounds, decontamination of work environment, 15.2.3.1–15.2.3.2
Quellung reaction, pneumococci, 3.17.42.1–3.17.42.3
Quick Spense dispenser, 5.15.1
Quickvue *H. pylori* test, 11.9.2
Quinolones, 5.1.6, 5.16.6
Quinsy, 2.1.3
Quinupristin-dalfopristin, 5.16.9

- Serratia fonticola*, 3.16.7, 3.17.16.1
- Serratia liquefaciens*, 3.16.7
- Serratia marcescens*, 3.8.1.5, 3.16.7, 3.17.16.2, 5.13.16, 5.16.5–5.16.8, 5.17.3, 12.4.2.3, 14.1.11, 14.2.6, 14.2.9, 14.2.12
- Serratia odorifera*, 3.16.7–3.16.8
- Serratia plymuthica*, 3.16.8
- Serratia rubidaea*, 3.16.8
- Serum bactericidal titer (SBT), 5.11.1–5.11.16
- calculated sensitivity and specificity, 5.11.15
 - limitations, 5.11.11
 - macrodilution procedure materials, 5.11.6
 - procedures, 5.11.7–5.11.11
 - quality control, 5.11.6–5.11.7
- microdilution procedure
- configuration of microdilution plate, 5.11.14
 - materials, 5.11.2
 - procedures, 5.11.3–5.11.6, 5.11.10–5.11.11
 - quality control, 5.11.3
 - principle, 5.11.1
 - rejection value, 5.11.15
 - results, 5.11.9
 - specimen, 5.11.1–5.11.2
 - test conditions and media for various bacteria, 5.11.14

- Serum bactericidal titer (SBT) (*continued*)
 use of pooled human serum as diluent, **5.11.12–5.11.13**
 use of ultrafiltrate of patient's serum as diluent, **5.11.13**
 worksheet, **5.11.16**
- Serum inhibitory titer (SIT), **5.11.1–5.11.16**
 calculated sensitivity and specificity, **5.11.15**
 limitations, **5.11.11**
 macrodilution procedure
 materials, **5.11.6**
 procedures, **5.11.7–5.11.11**
 quality control, **5.11.6–5.11.7**
 microdilution procedure
 configuration of microdilution plate, **5.11.14**
 materials, **5.11.2**
 procedures, **5.11.3–5.11.6, 5.11.10–5.11.11**
 quality control, **5.11.3**
 principle, **5.11.1**
 rejection value, **5.11.15**
 results, **5.11.9**
 specimen, **5.11.1–5.11.2**
 test conditions and media for various bacteria, **5.11.14**
 use of pooled human serum as diluent, **5.11.12–5.11.13**
 use of ultrafiltrate of patient's serum as diluent, **5.11.13**
 worksheet, **5.11.16**
- Serum specimen, *see* Blood specimen
- Setae (fungi), **8.9.6, 8.9.23**
- Settling plate, **13.9.2–13.9.4**
- Sexually transmitted diseases, **2.1.6**
- Sharps injury, **15.2.1.2**
- Sheep blood agar, **14.2.14**
- Shell vial culture, virus, **10.5.1, 10.5.6, 10.5.8–10.5.11, 10.5.26–10.5.27**
- Shewanella algae*, **3.17.22.2, 3.18.2.10, 3.18.2.20**
- Shewanella putrefaciens*, **3.17.22.2, 3.18.2.10, 3.18.2.20**
- Shiga toxin
 commercial EIA reagents, **11.8.6**
 enzyme immunoassay, **11.8.1–11.8.6**
 latex agglutination test, **11.8.1–11.8.5**
 reverse passive latex agglutination test, **11.8.2, 11.8.5, 11.8.7**
- Shiga toxin-producing *Escherichia coli*, immunoassay, **11.8.1–11.8.8**
- Shigella*, **3.2.3.1, 3.4.1.10, 3.8.1.1–3.8.1.19, 3.9.1.3, 3.9.1.9, 3.9.1.12, 3.13.1.11–3.13.1.13, 3.16.8, 3.18.2.8, 3.18.2.17, 16.7.4**
 antimicrobial susceptibility testing, **5.1.5, 5.2.6, 5.8.5, 5.13.12, 5.16.2**
 biochemical tests, **3.17.2.1–3.17.2.2, 3.17.12.1, 3.17.34.1, 3.17.34.3, 3.17.46.1–3.17.46.2**
 epidemiology and infection control, **13.5.1–13.5.2**
- Shigella boydii*, **3.8.1.11**
- Shigella dysenteriae*, **3.8.1.11–3.8.1.12, 15.2.1.1**
- Shigella flexneri*, **3.8.1.8, 3.8.1.11–3.8.1.12, 3.17.46.1, 14.2.6, 14.2.9–14.2.10, 14.2.13–14.2.14**
- Shigella sonnei*, **3.8.1.11, 14.2.9**
- Shipper's Declaration for Dangerous Goods (DGR) document, **15.5.1–15.5.3**
- Shipping guidelines, **15.5.1–15.5.6, 16.3.1–16.3.4**
 fecal specimens, **9.2.3.1–9.2.3.2**
 frozen specimens, **15.5.5**
 fungal specimens, **8.2.4**
 international label for packages, **15.5.2**
 labeling packages, **15.5.2–15.5.4, 16.3.1–16.3.4**
 materials, **15.5.1**
 procedures, **15.5.1–15.5.5**
 select-agent rule, **16.3.1–16.3.3**
 sources of information, **15.5.5**
 specimens, **15.5.1**
- Sieve impactor, **13.9.2, 13.9.6**
- Sigmoidoscopy specimen
 direct wet smear, **9.6.2.1–9.6.2.4**
 parasites, **9.10.2.1**
 permanent stained smear, **9.6.3.1–9.6.3.3**
- Silicate content, laboratory water, **14.4.1–14.4.2, 14.4.5, 14.4.9–14.4.10**
- Silver stain, *P. carinii*, **9.7.2.1–9.7.2.8**
- Simian B virus, **10.1.9**
 cell culture, **10.5.29**
- Simmons citrate agar, **14.2.13**
- Simonsiella muelleri*, **3.18.2.13**
- Sink testing, **1.1.3, 1.2.2**
- Sinus tract specimen, anaerobes, **4.2.4**
- Sinusitis, **2.1.3, 3.11.1.2**
- SIT, *see* Serum inhibitory titer
- Site registration number (SRN), **16.3.1**
- Skene's gland, specimen collection, **3.9.1.5**
- Skenitis, **3.9.1.3**
- Skin infections
 potential etiological agents, **2.1.6–2.1.7**
 transmission of laboratory-acquired infections, **15.2.1.2**
 viral, **10.1.2–10.1.5**
 zoonotic, **10.1.6–10.1.9**
- Skin specimen
 collection, **2.1.15**
 fungi, **8.2.3, 8.3.6, 8.4.5, 8.7.6**
 dermatophytes, *see* Dermatophyte(s)
 nondermatophytes, **8.9.43–8.9.44**
 Gram stain, **3.2.1.9, 3.2.1.12**
Leishmania, **9.9.5.1–9.9.5.6**
 mycobacteria, **7.5.1–7.5.3**
 parasites, **9.7.4.4, 9.10.2.1–9.10.2.3, 9.10.2.5**
 viruses, **10.4.2**
- Slide culture, fungi, **8.7.3–8.7.4**
- Slime test, staphylococci, **13.16.3.1–13.16.3.2**
- Slit impactor, **13.9.2, 13.9.6–13.9.7**
- Small bowel, bacterial overgrowth, **13.15.4**
- Small-bowel specimen
 anaerobes, **4.2.2**
 quantitative culture, **13.15.1–13.15.4**
- Smallpox, **16.9.1–16.9.5**
 clinical conditions with symptoms compatible with, **16.9.2**
 hemorrhagic, **16.9.1**
 malignant, **16.9.1**
- Smallpox vaccine, laboratory personnel, **15.6.7**
- Smallpox virus
 bioterrorism, **16.9.1–16.9.5**
 cell culture, **16.9.4**
 electron microscopy, **16.9.4**
 identification, **16.9.2–16.9.3**
 light microscopy, **16.9.4**
 reporting, **16.9.3**
 safety, **16.9.2**
 specimen collection and transport, **16.9.1–16.9.2**
- Social Security Act, **1.1.1**
- Sodium acetate agar, **3.17.2.1**
- Sodium acetate-acetic acid-formalin (SAF), **2.1.19, 9.2.2.1, 9.2.2.5, 9.2.2.7, 9.10.5.2**
- Sodium bicarbonate stock solutions, **5.9.8, 5.14.2.5**
- Sodium bisulfite solution, **9.7.2.8**
- Sodium borate solution, **9.7.2.8**
- Sodium chloride solutions, **9.3.3.3, 9.6.2.4, 9.6.6.3, 9.6.7.4, 9.6.8.4, 9.6.9.4**
- Sodium chloride tolerance test, mycobacteria, **7.6.1.1, 7.6.1.3–7.6.1.4, 7.6.1.6, 7.6.1.9**
- Sodium hydroxide method, digestion-decontamination procedure for mycobacteria, **7.1.2.1, 7.1.2.3, 7.1.2.7**
- Sodium hydroxide stock solutions, **5.14.2.4, 5.14.3.8, 7.1.2.7**
- Sodium hydroxide:sodium citrate stock solution, **7.1.2.6**
- Sodium polyanetholsulfonate (SPS), **3.4.1.1**
- Sodium polyanetholsulfonate (SPS) disk, **4.4.2**
- Sodium polyanetholsulfonate (SPS) test
 aerobes, **3.17.45.1–3.17.45.2**
 anaerobes, **4.6.6.1–4.6.6.2, 4.6.13.2, 4.12.2–4.12.3**
- Sodium thiosulfate solution, **9.7.2.8**
- Soft tissue culture, **3.13.1.1–3.13.1.16**
 interpretation, **3.13.1.15**
 limitations, **3.13.1.15–3.13.1.16**
 materials, **3.13.1.5–3.13.1.8**
 principle, **3.13.1.1**
 procedures, **3.13.1.7–3.13.1.13**
 quality control, **3.13.1.6**
 reporting results, **3.13.1.14–3.13.1.15**
- Soft tissue infections, **3.13.1.1**
 potential etiological agents, **2.1.6–2.1.7**
- Soft tissue specimen
 anaerobes, **4.2.2**
 collection, **3.13.1.2–3.13.1.4**
 labeling, **3.13.1.4**
 rejection criteria, **3.13.1.4**
- Soil sample
 actinomycetes, **6.1.6**
 amoeba, culture from, **9.9.2.1–9.9.2.8**
- Solution hybridization antibody capture assay
 cytomegalovirus DNA in white blood cells, **12.2.2.6–12.2.2.10**
 human papillomavirus in cervical specimens, **12.2.2.11–12.2.2.15**
- Somatic O antigen serogroups, detection, **3.8.1.19**
- Sonication method, catheter tip culture, **3.6.5**
- South American trypanosomiasis, *see* Chagas' disease
- Southern blotting, epidemiologic typing, **13.5.3**
- 2-SP medium, **10.4.11**
- SP-4 broth/agar, **3.15.13–3.15.14**
- Special-potency disks, antimicrobial susceptibility testing of anaerobes, **4.6.5.1–4.6.5.2, 4.6.13.1, 4.10.1–4.10.2, 4.10.9, 4.11.2, 4.12.4**
- Specificity of test, **14.2.27–14.2.28**
- Specimen acceptability
 aerobes, **2.1.20**
 anaerobes, **2.1.20, 4.2.2**
 fungi, **2.1.21**
 mycobacteria, **2.1.21**
 parasites, **2.1.21**
 viruses, **2.1.21**
- Specimen collection
 aerobes, **3.3.1.1**
 air sampling, **13.9.1–13.9.3**
 anaerobes, **2.1.10, 4.2.1–4.2.7**
 bacteria, **2.1.10–2.1.16**
 blood specimen, **2.1.10, 3.4.1.1–3.4.1.4, 9.8.1.2–9.8.1.3**
 body fluids, **2.1.11, 3.5.1–3.5.3**
Brucella, **16.6.1**

- C. botulinum*, 16.5.2–16.5.3
Chlamydia, 10.6.1–10.6.3
 procedure for pretesting swabs, 10.6.5, 10.6.11
 CSF specimen, 2.1.12, 3.7.2
F. tularensis, 16.8.1–16.8.2
 fecal specimen, 2.1.14, 3.8.1.2–3.8.1.3, 3.8.2.1–3.8.2.5, 3.8.3.2, 9.2.1.1–9.2.1.4
 fungi, 2.1.17, 8.2.1–8.2.5
 genital specimen, 3.9.2.1–3.9.2.2, 3.9.3.1–3.9.3.3, 3.9.4.1–3.9.4.2
 Gram stain, 3.2.1.1–3.2.1.2
 hemodialysis fluid, 13.7.1–13.7.2
 hospital water, 13.6.2–13.6.3
 from intravascular catheter, 13.12.1–13.12.3
Leptospira culture, 3.14.1–3.14.2
 mycobacteria, 7.1.2.1–7.1.2.2
 mycoplasma, 3.15.1–3.15.17
 nasal sinus specimen, 3.11.9.1–3.11.9.2
 nasopharyngeal specimen, 3.11.6.1–3.11.6.4, 3.11.7.1–3.11.7.2
 ocular specimen, 2.1.12, 3.10.1–3.10.4
 orthopedic surgery sites, 13.14.1–13.14.2
 otitis culture, 3.11.5.1–3.11.5.2
 parasites, 2.1.18, 9.1.5
 peritoneal dialysis fluid, 13.8.1–13.8.2
 quality assurance, 14.1.15–14.1.16
 quality control, 14.2.1–14.2.2
 respiratory tract specimen, 2.1.14–2.1.15, 3.11.2.2–3.11.2.4, 3.11.3.2, 3.11.4.1–3.11.4.3
 skin specimen, 2.1.15
 small-bowel aspirate, 13.15.1
 smallpox virus, 16.9.1–16.9.2
 soft tissue, 3.13.1.2–3.13.1.4
 urine specimen, 3.12.1–3.12.4
 urogenital tract specimen, 2.1.12–2.1.14, 3.9.1.4–3.9.1.8
 viruses, 10.4.1–10.4.11

 Staphylococci, 3.2.1.10, 3.2.1.13, 3.3.1.2, 3.4.1.9, 3.6.4, 3.8.1.8, 3.11.7.6, 3.12.2, 3.13.1.9, 3.13.1.12, 3.17.3.3, 12.4.5.5, 13.8.3
 antimicrobial resistance determination, 12.1.5
 antimicrobial susceptibility testing, 5.1.6, 5.1.9, 5.2.6, 5.2.9, 5.3.4–5.3.5, 5.8.5–5.8.7, 5.10.1.13, 5.10.2.7, 5.11.14, 5.13.14, 5.16.1, 5.16.4
 coagulase-negative, 3.17.4.1–3.17.4.5
 beta-lactamase testing, 5.3.4–5.3.5
 methicillin (oxacillin)-resistant, 5.1.5–5.1.6, 5.2.6–5.2.7, 5.8.5
 PCR test, 12.5.3.1–12.5.3.3
 surveillance cultures from immunocompromised hosts, 13.11.1–13.11.4
 plasmid fingerprinting, 12.4.3.1–12.4.3.5
 slime test, 13.16.3.1–13.16.3.2
 synergistic hemolysis test, 13.16.4.1–13.16.4.2
Staphylococcus arlettae, 3.16.9, 3.16.12
Staphylococcus aureus, 3.3.2.5, 3.3.2.8, 3.5.1, 3.5.6, 3.6.1, 3.6.4, 3.7.5, 3.10.2–3.10.3, 3.13.1.1–3.13.1.2, 3.13.1.11–3.13.1.15, 3.15.15, 3.16.9, 3.16.12, 4.6.4.1, 4.6.13.2, 6.1.2, 7.5.2

- Staphylococcus aureus* (continued)
 antimicrobial susceptibility testing, 5.1.2, 5.1.5–5.1.6, 5.1.8–5.1.9, 5.2.2, 5.2.7, 5.3.1, 5.6.3, 5.8.2–5.8.5, 5.10.1.9–5.10.1.11, 5.10.2.2–5.10.2.5, 5.10.2.11, 5.13.5–5.13.9, 5.13.14–5.13.15, 5.14.3.10, 5.15.3, 5.15.8, 5.15.16, 5.16.4, 5.16.9, 5.17.4, 5.17.8–5.17.10
 biochemical tests, 3.17.4.1–3.17.4.4, 3.17.8.1–3.17.8.2, 3.17.10.1, 3.17.13.1–3.17.13.3, 3.17.14.1–3.17.14.3, 3.17.15.2, 3.17.16.1–3.17.16.3, 3.17.20.1, 3.17.27.2, 3.17.44.1
 biohazards and safety, 15.2.1.2
 bioterrorism, 16.6.4
 blood culture, 3.4.1.8–3.4.1.9, 3.4.2.3
 chromosomal restriction fragment analysis, 12.4.5.6
 epidemiology and infection control, 13.4.1–13.4.3, 13.5.1–13.5.3, 13.8.3, 13.12.5, 13.13.1, 13.13.4
 fecal culture, 3.8.1.1, 3.8.1.7, 3.8.1.10, 3.8.1.14
 genital culture, 3.9.1.1–3.9.1.4, 3.9.1.10, 3.9.2.2
 identification schemes, 3.18.1.3–3.18.1.4, 3.18.1.7
 methicillin-resistant, 3.17.13.1–3.17.13.3, 3.17.14.3
 oxacillin salt-agar screen test, 5.4.1–5.4.4
 PCR test, 12.5.3.1–12.5.3.3
 prospective, focused surveillance, 13.17.1–13.17.3
 molecular methods, 12.1.3–12.1.4, 12.4.3.2–12.4.3.4, 12.4.4.1–12.4.4.5, 12.4.5.2, 12.4.5.6, 12.5.3.1–12.5.3.3
 plasmid fingerprinting, 12.4.3.4
 quality assurance/quality control, 14.1.12, 14.2.4, 14.2.7–14.2.14, 14.2.20, 14.2.32
 respiratory tract culture, 3.11.1.1–3.11.1.2, 3.11.2.5–3.11.2.10, 3.11.3.1–3.11.3.9, 3.11.4.4, 3.11.5.1–3.11.5.5, 3.11.6.5, 3.11.7.3, 3.11.9.1–3.11.9.3
 cystic fibrosis, 3.11.3.1–3.11.3.9
 ribotyping, 12.4.4.1–12.4.4.5
 staining, 3.2.1.1, 3.2.1.10
 urine culture, 3.12.2, 3.12.7, 3.12.13
 vancomycin-intermediate, 5.6.3
Staphylococcus auricularis, 3.16.9, 3.16.12
Staphylococcus capitis, 3.16.9, 3.16.12, 3.17.13.3, 12.5.3.3
Staphylococcus caprae, 3.16.9, 3.16.12, 3.18.1.7, 12.5.3.3
Staphylococcus carnosus, 3.16.9, 3.16.12
Staphylococcus caseolyticus, 3.16.9, 3.16.12
Staphylococcus chromogenes, 3.16.9, 3.16.12
Staphylococcus cohnii, 3.16.9, 3.16.12, 3.17.4.4
Staphylococcus delphini, 3.17.14.1, 3.18.1.7
Staphylococcus epidermidis, 3.9.1.3, 3.9.3.5, 3.11.2.5, 3.16.9, 3.16.12, 3.18.1.7, 12.5.3.3, 14.2.7–14.2.12
 biochemical tests, 3.17.4.1, 3.17.4.4, 3.17.13.2, 3.17.14.2, 3.17.44.1
 epidemiology and infection control, 13.13.1, 13.13.4, 13.16.3.1, 13.16.4.1
Staphylococcus equorum, 3.16.9, 3.16.12
Staphylococcus fallinarum, 3.16.9, 3.16.12
Staphylococcus felis, 3.16.9, 3.16.12
Staphylococcus haemolyticus, 3.16.9, 3.16.12, 3.17.4.1, 3.18.1.7, 12.5.3.3, 13.16.3.1
Staphylococcus hominis, 3.16.9, 3.16.12, 12.5.3.3
Staphylococcus hyicus, 3.16.9, 3.16.12, 3.17.13.3, 3.17.14.1, 3.17.14.3, 3.18.1.7
Staphylococcus intermedius, 3.16.9, 3.16.13, 3.17.4.1, 3.17.4.4, 3.17.8.1, 3.17.13.3, 3.17.14.1, 3.17.14.3, 3.18.1.3, 3.18.1.7, 13.16.4.1
Staphylococcus kloosii, 3.16.9, 3.16.13, 3.17.4.4
Staphylococcus lentus, 3.16.9, 3.16.13
Staphylococcus lugdunensis, 3.3.2.8, 3.4.1.10–3.4.1.11, 3.16.10, 3.16.13, 3.17.4.1, 3.17.4.4, 3.17.13.1, 3.17.13.3, 3.17.14.1–3.17.14.3, 3.17.15.2–3.17.15.3, 3.17.41.1–3.17.41.2, 3.18.1.3, 3.18.1.7
Staphylococcus lutrae, 13.17.14.1
Staphylococcus maltophilia, restriction fragment length polymorphisms, 12.4.5.7
Staphylococcus muscae, 3.16.13
Staphylococcus pasteurii, 3.16.10, 3.16.13
Staphylococcus saccharolyticus, 3.16.10, 3.16.13, 3.17.13.1
Staphylococcus saprophyticus, 3.3.2.8, 3.12.2, 3.12.13, 3.16.10, 3.16.13, 3.17.4.1–3.17.4.4, 3.17.13.3, 3.18.1.3, 3.18.1.7, 12.5.3.3
Staphylococcus schleiferi, 3.16.10, 3.16.13, 3.17.13.1, 3.17.13.3, 3.17.14.1, 3.17.14.3, 3.17.16.3, 3.18.1.7
Staphylococcus sciuri, 3.16.10, 3.16.13, 12.5.3.3
Staphylococcus simulans, 3.16.10, 3.16.13
Staphylococcus vitulinus, 3.16.10, 3.16.13
Staphylococcus warneri, 3.16.10, 3.16.13, 3.17.13.3
Staphylococcus xylosum, 3.16.10, 3.16.13, 3.17.4.4
 Staphylokinase, 3.17.14.1
 Starch hydrolysis medium, 14.2.13
 Starch hydrolysis test, 3.17.47.1–3.17.47.2
 Steam sterilizer, *see* Autoclave
 Steers replicator, 5.9.10
Stenotrophomonas, 3.11.2.9, 3.13.1.11, 3.17.9.5, 3.17.15.1, 3.18.2.9, 5.13.13, 12.4.5.5, 13.5.2
Stenotrophomonas maltophilia, 3.11.2.7, 3.11.3.1–3.11.3.7, 3.13.1.2, 3.13.1.13, 3.18.2.3, 3.18.2.9, 3.18.2.16–3.18.2.18, 14.1.10–14.1.11, 14.2.6–14.2.7, 14.2.11
 antimicrobial susceptibility testing, 5.2.6, 5.8.7, 5.13.13–5.13.16, 5.16.5
 biochemical tests, 3.17.15.3, 3.17.16.1, 3.17.16.3
 molecular methods, 12.4.2.3, 12.4.5.6–12.4.5.7
Stephanoascus ciferrii, 8.8.2
 Stereoscopic microscope, 9.1.1
 Sterilants, 15.2.3.1–15.2.3.5
 Sterile-scalpel method, tissue homogenization, 3.13.1.5
 Sterility documentation, 13.2.2
 Sterility testing, 13.2.2
 Sterilization, autoclave, *see* Autoclave
 Stock culture
 bacteria
 long-term storage, 14.2.22–14.2.23
 short-term storage, 14.2.23
 Chlamydia, 14.2.24
 Chlamydomydia, 14.2.24
 fungi
 long-term storage, 14.2.23–14.2.24
 short-term storage, 14.2.24
 mycobacteria, 14.2.24
 virus, 14.2.24
 Stolon, 8.7.2
 Stomach specimen, *see* Gastric specimen
 Stomacher method, tissue homogenization, 3.13.1.6
Stomatococcus mucilaginosus, *see* *Rothia mucilaginosus*
 Stool specimen, *see* Fecal specimen
 Straight catheter urine, 3.12.3
 Strand displacement amplification, 12.2.3.19
 Streak plate, 3.3.1.6
 Streptavidin-HRP solution, 11.14.5
Streptobacillus, 3.18.2.6
Streptobacillus moniliformis, 3.4.1.1, 3.4.1.17, 3.13.1.2, 3.13.1.11, 3.18.2.13
 Streptococci
 group A, *see* Group A streptococci
 group B, *see* Group B streptococci
 nutritionally variant, 3.17.44.1
 viridans group, 3.18.1.8
Streptococcus, 3.3.1.2, 3.3.2.5, 3.4.1.9, 3.10.2, 3.11.2.7, 3.12.2, 3.13.1.2, 3.18.1.1–3.18.1.3, 3.18.1.10, 4.12.5, 6.2.5
 alpha-hemolytic, 3.17.6.1
 antimicrobial susceptibility testing, 5.1.1–5.1.6, 5.1.12, 5.2.1–5.2.3, 5.2.6–5.2.11, 5.8.7, 5.10.1.13, 5.10.2.7, 5.11.14, 5.13.14–5.13.16, 5.16.1, 5.17.4
 biochemical tests, 3.17.6.1, 3.17.20.2, 3.17.26.1–3.17.26.2
 broth microdilution MIC testing, 5.2.11
 disk diffusion susceptibility testing, 5.1.12
 staining, 3.2.1.10, 3.2.1.13
Streptococcus acidominimus, 3.16.10, 3.16.14
Streptococcus agalactiae, 3.3.2.8, 3.4.1.11, 3.7.1, 3.7.5, 3.12.7, 3.12.12, 3.13.1.12, 3.16.10, 3.16.14, 3.18.1.3
 biochemical tests, 3.17.8.1–3.17.8.3, 3.17.21.1–3.17.21.3, 3.17.43.2
 genital culture, 3.9.1.1–3.9.1.3, 3.9.1.9, 3.9.2.1–3.9.2.5
 molecular methods, 12.1.3
 quality assurance/quality control, 14.1.12, 14.2.10, 14.2.13, 14.2.21
Streptococcus anginosus, 3.11.8.5–3.11.8.6, 3.13.1.2, 3.16.10, 3.16.14, 3.17.15.3, 3.18.1.8, 14.1.12
Streptococcus aureus, 14.2.21
Streptococcus bovis, 3.16.10, 3.16.14, 3.17.5.1, 3.17.5.3, 3.17.19.1–3.17.19.2, 3.17.43.2, 3.17.47.1–3.17.47.2, 3.18.1.4, 3.18.1.8, 14.2.8–14.2.9, 14.2.13
Streptococcus constellatus, 3.16.10, 3.18.1.8
Streptococcus cremoris, 3.16.11
Streptococcus criceti, 3.16.11, 3.16.14
Streptococcus crista, 3.16.11, 3.16.14
Streptococcus cristatus, 3.18.1.8
Streptococcus diacetylactis, 3.16.11
Streptococcus dysgalactiae, 3.16.11, 3.16.14
Streptococcus epidermidis, 14.2.21
Streptococcus equi, 3.16.11, 3.16.14
Streptococcus equisimilis, 3.16.11, 3.16.14
Streptococcus gallolyticus, *see* *Streptococcus bovis*
Streptococcus gordonii, 3.16.11, 3.16.14, 3.18.1.8
Streptococcus group B selective broth, 14.2.13
Streptococcus infantarius, *see* *Streptococcus bovis*
Streptococcus intermedius, 3.16.11, 3.16.14, 3.18.1.8
Streptococcus lactis, 3.16.11
Streptococcus milleri, 3.16.11, 3.16.14, 3.18.1.8

- Streptococcus mitis*, 3.16.11, 3.16.14, 3.17.19.2, 3.17.33.3, 3.18.1.8
- Streptococcus mutans*, 3.16.11, 3.16.14, 3.16.19.1, 3.17.19.2, 3.17.47.2, 3.18.1.8
- Streptococcus oralis*, 3.16.11, 3.16.14, 3.18.1.8
- Streptococcus parasanguis*, 3.16.11, 3.16.14, 3.18.1.8
- Streptococcus pasteurianus*, *see Streptococcus bovis*
- Streptococcus pneumoniae*, 3.3.1.8, 3.3.2.8, 3.7.1, 3.7.4–3.7.5, 3.9.1.10, 3.10.2–3.10.3, 3.13.1.9, 3.16.11, 7.5.2
- antimicrobial resistance determination, 12.1.5
- antimicrobial susceptibility testing, 5.1.1–5.1.6, 5.1.9, 5.1.12, 5.2.1–5.2.3, 5.2.6–5.2.11, 5.8.2–5.8.7, 5.10.1.13, 5.10.2.7, 5.11.14, 5.13.4–5.13.9, 5.13.14–5.13.16, 5.14.3.10, 5.16.1, 5.16.7–5.16.8, 5.17.4
- biochemical tests, 3.17.6.1–3.17.6.3, 3.17.38.1–3.17.38.3, 3.17.42.1–3.17.42.3
- blood culture, 3.4.1.6, 3.4.1.9–3.4.1.11
- broth microdilution MIC testing, 5.2.11
- disk diffusion susceptibility testing, 5.1.12
- epidemiology and infection control, 13.5.2
- identification schemes, 3.18.1.4
- molecular methods, 12.1.3, 12.1.5, 12.3.2.2
- quality assurance/quality control, 14.1.12, 14.2.7–14.2.9, 14.2.12–14.2.14, 14.2.21, 14.2.32
- Quellung reaction, 3.17.42.1–3.17.42.3
- respiratory tract culture, 3.11.1.1–3.11.1.2, 3.11.2.1, 3.11.2.4–3.11.2.10, 3.11.3.1, 3.11.3.4, 3.11.3.7, 3.11.5.1, 3.11.5.4–3.11.5.5, 3.11.9.1–3.11.9.3
- serologic diagnosis, 11.1.2.2
- staining, 3.2.1.10, 3.2.1.13, 3.2.1.17
- Streptococcus porcinus*, 3.16.11, 3.16.14
- Streptococcus pyogenes*, 3.3.2.8, 3.3.2.12–3.3.2.13, 3.4.1.11, 3.5.1, 3.10.2–3.10.3, 3.13.1.12–3.13.1.14, 3.16.11, 3.16.15, 4.6.4.1, 4.6.13.2, 14.1.12, 14.2.7–14.2.14, 14.2.21, 14.2.32, 15.2.1.2
- biochemical tests, 3.17.4.1–3.17.4.2, 3.17.5.2, 3.17.8.2–3.17.8.3, 3.17.10.1, 3.17.21.2, 3.17.41.1–3.17.41.2
- genital culture, 3.9.1.2–3.9.1.3, 3.9.1.9, 3.9.1.12, 3.9.2.3–3.9.2.4
- identification schemes, 3.18.1.3
- molecular methods, 12.1.3
- respiratory tract culture, 3.11.1.1–3.11.1.2, 3.11.2.7, 3.11.5.1–3.11.5.4, 3.11.7.3–3.11.7.6, 3.11.8.3–3.11.8.6, 3.11.9.1–3.11.9.3
- Streptococcus rattii*, 3.18.1.8
- Streptococcus salivarius*, 3.16.11, 3.16.15, 3.17.19.2, 3.17.47.2, 3.18.1.8
- Streptococcus sanguinis*, 3.16.11, 3.16.15, 3.17.19.2
- Streptococcus sanguis*, 3.9.1.11, 3.16.11, 3.17.10.2, 3.17.15.3, 3.17.45.1, 3.18.1.8
- Streptococcus* selective medium, 14.2.3
- Streptococcus sobrinus*, 3.16.11, 3.16.15, 3.18.1.8
- Streptococcus thermophilus*, 3.16.11
- Streptococcus uberis*, 3.16.11, 3.16.15
- Streptococcus vestibularis*, 3.16.11, 3.16.15, 3.17.33.3, 3.18.1.8
- Streptococcus viridans*, 3.16.15
- Streptokinase, 9.7.3.6
- Streptolysin O, *see* Anti-streptolysin O test
- Streptolysin O reagent, 11.2.2.2
- Streptomyces*, 3.2.1.13, 6.1.1–6.1.7, 6.2.2–6.2.4, 6.3.4.1, 8.3.6, 14.2.20
- Streptomyces somaliensis*, 6.3.1.1
- Streptomycin, 5.5.1–5.5.5, 5.15.5, 5.16.6
- drug synergisms and antagonisms, 5.12.13
- molecular methods for determining resistance, 12.1.5
- susceptibility testing of *M. tuberculosis*, 7.7.1–7.7.4, 7.8.1.1–7.8.1.7, 7.8.5.1–7.8.5.5, 7.8.7.1–7.8.7.4
- Streptomycin-vancomycin stock solution, 10.6.5
- Streptonase-B, 11.2.1.1, 11.2.3.1–11.2.3.3
- Streptozyme test, 11.2.1.2
- String test, duodenal contents, 9.6.4.1–9.6.4.4
- Strongyloides*, 9.2.1.4, 9.5.1.2, 9.5.2.2, 9.5.3.2, 9.5.4.3, 9.6.4.1–9.6.4.3, 9.6.5.3, 9.10.2.7, 9.10.8.1
- fecal culture of larvae, 9.5.1.1–9.5.1.4, 9.5.2.1–9.5.2.3, 9.5.3.1–9.5.3.3
- larvae
- duodenal aspirate, 9.6.5.1–9.6.5.4
- Enterotest, 9.6.4.1–9.6.4.4
- Strongyloides stercoralis*, 9.1.5, 9.2.1.4, 9.3.1.2, 9.3.3.2, 9.3.4.4, 9.5.1.1–9.5.1.3, 9.5.2.2, 9.5.3.1–9.5.3.2, 9.5.4.1–9.5.4.3, 9.6.4.4, 9.6.5.1–9.6.5.3, 9.7.1.1, 9.7.3.1, 9.10.2.3–9.10.2.5, 9.10.2.13, 9.10.2.19, 9.10.3.6
- agar plate culture, 9.2.1.4
- agar plate culture of larvae, 9.5.4.1–9.5.4.4
- duodenal aspirates, 9.7.3.1–9.7.3.6
- expectorated sputum, 9.7.1.1–9.7.1.4
- hyperinfection, human T-cell leukemia virus and, 9.5.4.1

 harvesting and subpassing inoculated cultures, 10.5.28
 incubation, 10.5.2–10.5.5
 inoculation, 10.5.3–10.5.4
 materials, 10.5.1–10.5.2
 observation of inoculated monolayers, 10.5.5–10.5.7
 principle, 10.5.1
 procedures, 10.5.3–10.5.29
 quality control, 10.5.2–10.5.3
 refeeding inoculated cultures, 10.5.28
 results, 10.5.29
 rubella interference assay, 10.5.7, 10.5.39–10.5.40
 specimens, 10.5.1
 tissue culture infective dose, 10.5.31
 tube culture, 10.5.1
 viral titration, 10.5.31–10.5.32
 virus detection and identification, 10.5.5–10.5.11
 contamination of cell cultures, 10.2.6, 10.3.3
 CSF specimen, 10.4.2
 culture characteristics, 10.5.8–10.5.11
 cytopathology, 10.7.8–10.7.10
 cytopathic effect, 10.5.1, 10.5.5–10.5.18, 10.5.29
 direct detection, 10.7.1–10.7.10
 electron microscopy, 10.7.8
 evaluation of specimen, 10.4.5–10.4.6
 fecal specimen, 10.4.2, 10.4.9
 hazardous materials, 16.3.3
 hemadsorption test, 10.5.1, 10.5.5–10.5.6, 10.5.19–10.5.20, 10.5.29
 hemagglutination test, 10.5.40–10.5.41
 immunofluorescence test, 10.5.5–10.5.7, 10.5.22–10.5.25, 10.7.2–10.7.8
 cell spot preparation, 10.7.3
 observation of viral antigens, 10.7.3
 quality control, 10.7.3
 staining, 10.5.22, 10.7.3
 supplies, reagents, and equipment, 10.7.2
 troubleshooting, 10.7.6
 inclusions, 10.7.8–10.7.10
 intestinal tract specimen, 10.4.2
 isolation and identification, 10.5.21–10.5.22
 laboratory diagnosis of infections, 10.1.1–10.1.10
 molecular detection assays, 10.7.1
 neutralization assay, 10.5.33–10.5.36
 noncultivable, 10.2.3
 ocular specimen, 10.4.3
 patient information, 10.4.5
 pericardial fluid specimen, 10.4.3
 pleural fluid specimen, 10.4.3
 respiratory tract specimen, 10.4.3–10.4.4
 safety, 10.4.6, 15.3.2.2–15.3.2.3
 saliva, 10.4.4
 semen specimen, 10.4.8
 shell vial culture, 10.5.1, 10.5.6, 10.5.8–10.5.11, 10.5.26–10.5.27
 skin specimen, 10.4.2
 specimen acceptability, 2.1.21
 specimen collection, 10.4.1–10.4.11
 specimen processing, 10.4.1–10.4.11
 specimen storage, 10.4.6
 specimen transport, 10.4.1, 10.4.4–10.4.6
 stock cultures, maintenance, 14.2.24
 test ordering, 10.4.5
 tissue specimen, 10.4.4, 10.4.8–10.4.9
 urogenital specimen, 10.4.2

 Yeast extract phosphate medium, **8.4.3**
 Yeast fermentation broth, **8.8.13**
 Yeast-inhibiting blood agar, **8.9.58–8.9.59**
 Yellow fever virus, **10.1.6**
 Yellow IRIS, **3.12.15**
Yersinia, **3.2.3.1, 3.13.1.11–3.13.1.13, 3.18.2.8,**
 13.13.1
 biochemical tests, **3.17.12.1, 3.17.31.3,**
 3.17.33.2, 3.17.34.1, 3.17.34.3, 3.17.48.1
 fecal culture, **3.8.1.4–3.8.1.5, 3.8.1.9,**
 3.8.1.12–3.8.1.14, 3.8.1.17
 Yersinia enterocolitica, **3.8.1.1, 3.8.1.5–3.8.1.8,**
 3.8.1.13–3.8.1.15, 3.16.8, 3.17.25.3,
 3.17.31.3, 3.18.2.17, 13.13.1, 13.13.4,
 14.2.13–14.2.14
 Yersinia frederiksenii, **3.16.8**
 Yersinia intermedia, **3.16.8**
 Yersinia kristensenii, **3.16.8**
 Yersinia pestis, **3.11.1.2, 3.11.2.7–3.11.2.8,**
 3.16.8, 3.18.2.17, 15.2.1.1
 bioterrorism, **16.1.1, 16.2.3, 16.3.3, 16.7.1–**
 16.7.5
 culture, **16.7.2–16.7.4**
 differentiation from similar bacteria, **3.18.2.17**
 identification, **16.7.2–16.7.4**
 serology, **16.7.2–16.7.4**
 specimen collection and transport, **16.7.1**
 staining, **16.7.2–16.7.4**
 Yersinia pseudotuberculosis, **3.8.1.13, 3.16.8,**
 3.18.2.17, 16.7.4
 Yersinia regensburgei, **3.16.8**
 Yersinia selectiva agar, **14.2.14**
 YT MicroPlate, **8.8.5**
- Z**
 Z value, distilled water, **3.12.24**
 Zefazone, *see* Cefmetazole
 Zephiran-trisodium phosphate method, digestion-
 decontamination procedure for mycobac-
 teria, **7.1.2.1, 7.1.2.3–7.1.2.4, 7.1.2.7–**
 7.1.2.8
 Zero tolerance, **1.1.3**
 Ziehl-Neelsen acid-fast stain, hot
 C. cayetanensis, **9.4.2.1–9.4.2.4**
 coccidia, **9.4.2.1–9.4.2.4**
 Ziehl-Neelsen stain, **7.2.2–7.2.4**
 quality control, **14.2.20**
 Zinacef, *see* Cefuroxime-sodium
 Zinc sulfate flotation, concentration of fecal
 specimen, **9.3.5.1–9.3.5.4**
 Zinc sulfate solution, **9.3.5.4**
 Zithromax, *see* Azithromycin
 Zolicef, *see* Cefazolin
 Zoonoses, viral, **10.1.6–10.1.9**
 Zosyn, *see* Piperacillin-tazobactam
 Zygomycosis, **2.1.17**
 Zygomycota, **8.9.1**
 cycloheximide resistance, **8.9.13**
 micromorphology, **8.9.2–8.9.3**
 thermotolerance, **8.9.8**
 Zygosporangium, **8.9.3**
 Zyvox, *see* Lineolid
